Effect of the Supporting Strata on Design of Windmill Tower

K.S. Rahane¹, M.R. Wakchaure²

1(PG student, Civil Engineering Department, Amrutvahini College of Engineering, Maharashtra, India)

2(Faculty, Civil Engineering Department, Amrutvahini College of Engineering, Maharashtra, India)

Abstract : Windmill, machine that converts wind into useful energy. This energy is derived from the force of wind acting on oblique blades or sails that radiate from a shaft. The turning shaft may be connected to machinery used to generate electricity. The present paper makes an attempt to show the effect of wind and earthquake load on tubular type windmill and its foundation considering hard, medium and soft soil strata. The modeling of windmill tower was done in computer software by finite element modeling technique. In that windmill tower was subjected to wind and earthquake forces and check bending stresses, mode Shape, base shear comparison, stability, safety of windmill for hard, medium and soft strata. Also check stability, safety of windmill foundation and design of reinforcement required in the foundation for hard, medium and soft strata. Based on the analytical investigation and design it has been concluded that the effect of wind on windmill is significant as compare to earthquake, hence stability of windmill is thoroughly check for this load. Soil strata also play a major role in deciding its safety and stability. The normalized base shear, seismic moments, natural time period, bending stresses in tower and sizes and reinforcement of foundation increases from hard strata to soft strata.

Keywords - Wind load, Earthquake load, stability of tower and foundation, soil strata.

I. Introduction

The world of wind power is growing at a very faster rate. This projection put the average growth of the industry at 24% for the next five years. Theoretically wind could produce enough energy to meet global demand. Growth will be driven by rapidly developing countries, such as India, Brazil, and China. Improving efficiency and falling cost of turbine production and installation will make wind power more price competitive. The amount of wind energy generated depends mostly on the size, height, type and location of a wind turbine. Windmill although are structurally simple, their behavior under the operating condition is quit complex due to the static and dynamic effect of wind. Due to the operation of the windmill during high wind makes the behavior still more complex. If these windmills are founded on relatively soft foundation soil, structural stability during dynamic loads can be one more matter of concern.

The main components of windmill are windmill tower, nacelle, hub, and blade. The windmill basically divided into Horizontal axis machines and Vertical axis machines, based on their axis of rotation. For more electric energy generation Vertical axis Windmill i.e. tubular type windmill and lattice type of tower windmill is mostly used. Foundations for windmill are rectangular, square, and circular of a similar configuration. Very high requirements

are imposed on windmill foundation with respect to durability and strength. This uneven loading also has effects on the strength of the reinforcement structure provided in the concrete main part. With the windmill foundation, the reinforcement structure generally consists of the known reinforcing bar or reinforcing steel mesh.

For the analysis we have taken the 74 meter height tubular type windmill with three blade of each 32 meter length. The total weight of windmill was 184 ton. The power generation capacity of this windmill was 1250 KW. This windmill were analyzed in computer software for different load such as dead load, wind and earthquake loads. The main objectives of this paper was to determine the most vulnerable combination of windmill structure and foundation under the action of dynamic load for different soil strata such as hard, medium, soft strata. So that suitable remedial measures can be taken during the design. According to that design of circular foundation was done in order to achieve economy, stability, safety of foundation, so that windmill is withstand safely.

II. Methodology

Windmill structures are relatively flexible and have a longer fundamental period. If such structures are founded on rigid foundation such as rock or hard soil, seismic force may not govern the design as wind force become more critical, but many times due to non availability of hard rock it may be necessary to construct such structures on soft soil. This is especially true near the sea shore, where most of the area consists of reclaimed soil and mostly windmills are constructed at the sea shore as wind is much effective in this area and availability of land is easily accessible. As a result of this soft layer of soil the earthquake ground motion gets modified and have relatively longer predominant period. Due to this it is essential to analyze and design of windmill for soft, medium, and hard soil strata.

2.1 Wind Analysis

Wind speed in the atmospheric boundary layer increases with height from zero at ground level to a maximum height called the gradient height. As the windmill is of greater height and normally situated in open terrain category the wind load is major affecting factor. This effect of wind on structure as a whole was determined by the combined action of external and internal pressure acting on it. The Wind analysis was done by using IS-875(Part-3) code. As per code wind speed considered for proposed site was 39 m/s. Due to the high rise of the structure the wind speeds also increasing. So the greater effect produced on the Windmill. Therefore wind load (F) on windmill structure acting in a direction normal to the individual structural element was calculated by:

$$F = C_f A P_z \quad (1)$$

Where, C_f = Force coefficient; A = surface area of structural or cladding unit; P_z = design wind pressure.

The windmill experiences both compression and a bending moment about its footing. The compression is due to the weight of the nacelle and rotor whilst the bending moment is induced by the thrust caused by drag forces on the blade of windmill. The tower itself also experiences an unevenly distributed force due to the drag forces created by the oncoming wind. This drag force or thrust due to wind was calculated as per IS-875 Part-3 as below:

$$F = C_f A P_z \quad (2)$$

2.2 Earthquake Analysis

The dynamic response of a structure against an earthquake vibration is an important structural aspect which directly affects structural resistance and consequently the hazard level. For analysis for earthquake loads, it is necessary to find out characteristics of structure as well as earthquake. Characteristics of the windmill were determined by Response Spectrum method analysis. In Response Spectrum method analysis the fundamental time period and mode shapes of the structure can be found out. The main objective of this analysis was to understand the overall behavior of windmill structures founded on soil strata. Response Spectrum method analysis of the different windmill towers was carried out by considering tower as a continuous system. By considering tower as cantilever beam fixed at one end and free at the other, natural time period can be computed from the Equation:

$$W_n = C_n \sqrt{EI/ml^4} \text{ \& } C_n = a_n L^2 \quad (3)$$

Where, W_n = Natural frequency of the system in n^{th} mode; C_n = Constant for boundary conditions; $a_n = 4\sqrt{m/w^2/EI}$; E = Modulus of elasticity; I = Moment of inertia of the given system; m = Mass per unit length of the system; L = Total length of the system

III. Performance Analysis

Selection of windmill is depending upon the availability of wind speed, power generation capacity. Windmill can be best analyzed as tall cylindrical tower of uniform cross section because they produce minimal lift as they display no surfaces that with an angle of attack that can produce a significant pressure difference.

3.1 Modeling of Windmill Tower

The modeling of windmill tower was done by using Finite element modeling technique. Tower of the windmill was modeled with 4-noded tetrahedral elements in computer software which is shown in Figure 1. All elements were connected to each other with proper boundary condition. The support condition considered for this structure was pinned because of load transfer from tower to foundation is through anchor bolt.

Total number of 4-noded tetrahedral elements = 2700

Figure1. Modeling of windmill Tower

3.2 Loading

The windmill is mainly subjected to Dead load, Wind load and Earthquake load. In that Wind load is the major governing factor for changing behavior of windmill.

3.2.1 Dead load

The nacelle, hub and blades were mounted on windmill tower. So weights of these components were taken to be considered for the analysis. And also considered self weight of tower.

Dead load of nacelle = 52 Ton = 510 KN

Dead load of hub = 12 Ton = 120 KN

Dead load of 3 blade = 130 KN

3.2.2 Live load

In this case there was not any type of Live load acting on windmill tower; so live load considered should be zero.

3.2.3 Wind load

Windmills are cylindrical and high rise structure, so the wind analysis of this structure is important and shall be done by using IS-875 (Part-3) method.

i) Design wind Pressure (P_z)

The wind pressure on plates of windmill tower was given by:

$$P_z = 0.6 V_z^2 \quad (4)$$

Where, $V_z = k_1 k_2 k_3 V_b$; $k_1 = 0.92$; $k_2 = 0.93$ for 10 m height; $k_2 = 0.97$ m for 15 m height; $k_2 = 1.0$ m for 20 m height; $k_2 = 1.04$ m for 30 m height; $k_2 = 1.10$ m for 50 m height; $k_2 = 1.17$ m for 100 m height; $k_3 = 1$; $V_b = 39$ m/s

Table 1 Design wind pressure (P_z)

Height of tower (M)	V_z (m/s)	P_z (KN/m ²)
10	33.37	0.67
15	34.80	0.73
20	35.88	0.77
25	36.60	0.81
30	37.32	0.84
35	37.86	0.86
40	38.40	0.89
45	38.93	0.91
50	39.47	0.93
55	39.72	0.94
60	39.97	0.96
65	40.22	0.97
70	40.47	0.98
75	40.73	1.00

ii) Wind forces on windmill tower

The wind load, F acting as a pressure load on the individual plate element was given by;

$$F = C_f A P_z \quad (5)$$

Where, $C_f = 1$ for H/B ratio = 18.50 & Circular shaped element... (Table No.23, Page No.40); A = surface area of four noded rectangular plate; P_z = design wind pressure.

Table 2 Wind force (F)

Height of tower (m)	$F = C_f A P_z$ (KN/m ²)
---------------------	--------------------------------------

10	0.67
15	0.73
20	0.77
25	0.81
30	0.84
35	0.86
40	0.89
45	0.91
50	0.93
55	0.94
60	0.96
65	0.97
70	0.98
75	1.00

This wind load are applied on plate of windmill tower as a pressure load along positive X-direction(WLX+), negative X-direction(WLX-), positive Z-direction(WLZ+), negative Z-directive (WLZ-) in computer software which is shown in Fig.2

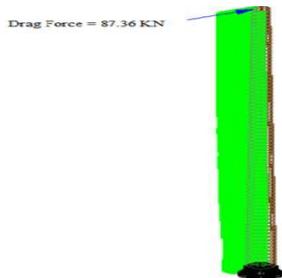

Figure 2.Wind load on windmill tower

iii) Drag force on blade of windmill due to wind pressure
 The tower itself also experiences an unevenly distributed force due to the drag forces created by the oncoming wind on blades .This drag force or thrust due to wind was calculated as per IS-875 Part-3 as below;

$$F = C_f A P_z \tag{6}$$

Where, $C_f = 0.6$...for ellipse shape element..... (Table No.23, Page No.40); $A =$ Average area of one blade = $32 * ((2.75+1.5+0.3)/3) = 48.53 \text{ m}^2$; $P_z = 1 \text{ KN/m}^2$
 Therefore, $F = 0.6 * 1 * 48.53 * 3 = 87.36 \text{ KN}$

This drag force applied at top of tower horizontally which is as shown in Fig.3

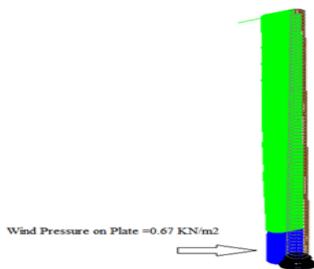

Figure 3. Drag force on windmill

3.2.4 Earthquake load

In computer software the earthquake analysis of windmill was done by using response spectrum method. The analysis gives result such as seismic base shear, seismic

moment at C.G.of tower due to seismic forces, seismic moment at bottom of tower due to seismic shear, deflection of tower, bending stresses in plate due to seismic forces.

The total design lateral force or design seismic base shear (V_B) along any principal direction shall be determined by the following expression;

$$V_B = A_h W \tag{7}$$

Where, $A_h = Z/2 * I/R * S_a/g$; $W =$ seismic weight of structure

The basic parameters required for the analysis of earthquake as per code IS-1893-2002 are:

- Zone factor (Z) = 0.16 for Pune (India) region
- Importance factor = 1
- Response reduction factor = 5
- Damping factor = 0.02
- Frequency (ZPA) = 33

$S_a/g =$ Average response acceleration coefficient and depend on natural period of vibration and damping of the structure.

The seismic load applied in X, Y & Z direction as shown in Fig.4

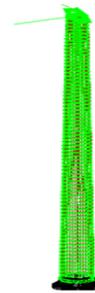

Figure 4.Earthquake load on windmill

3.3 Load Combinations

The load combinations for Design of RCC foundation and analysis and design of steel structure shall be taken as per IS-456-2002, IS-800-1984, and IS-1893-2002.

Load combinations for Foundation design:

1. (DL+LL)
2. DL+LL± (WLX+)
3. DL+LL± (WLZ+)
4. DL±EQX
5. DL±EQZ
6. DL±EQY
7. DL± (WLX+)
8. DL± (WLZ+)

Load combinations for Windmill tower:

1. DL+LL
2. 0.75[DL+0.5LL±EQX]
3. 0.75[DL+0.5LL±EQZ]
4. 0.75[DL+0.5LL±EQY]

10. 0.75[DL± (WLX+)]
11. 0.75[DL± (WLZ+)]
12. 0.75[0.9DL±EQX]
13. 0.75[0.9DL±EQZ]
14. 0.75[0.9DL±EQY]
15. 0.75[0.9DL± (WLX+)]
16. 0.75[0.9DL± (WLZ+)]

IV. Design of Circular Foundation

The function of foundation is to transmit the load from the structure to underlying soil. If these loads are to be properly transmitted, footing must be designed to limit the total settlement of the structure to a tolerably small amount and to eliminate as nearly as possible the differential settlement or rotation of the various part of the structure and to provide adequate safety against overturning and sliding. The choice of suitable type of footing for a structure depends on the depth at which the bearing strata lies, the soil condition and the type of superstructure.

For this structure we used circular type foundation with pedestal. The general dimensions of the circular foundation are shown in Figure 5. The size of foundation is depending upon the total load from tower to foundation and bearing capacity of soil. The foundation was checked for one way shear, two way shears. The foundation was design for soft, medium and hard strata. The net safe bearing capacity of hard, medium and soft strata soil was considered as 350.00 KN/m², 200.00 KN/m², and 115.00 KN/m² respectively. The design of pedestal and footing for different soil strata are listed in Table 3

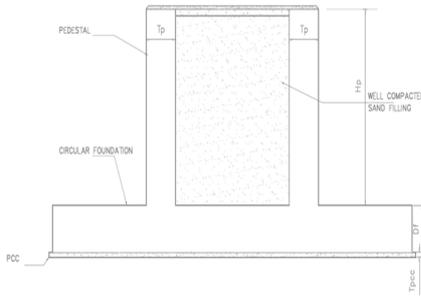

Figure 5. Circular Foundation

Table 3 Design of Foundation for hard, medium and soft strata

Sr. No.	Item	Hard strata	Medium strata	Soft strata

V. Result and Discussion

5.1 Deflection of tower

It was observed that the deflection is maximum for wind load as compare to seismic load for different soil strata. So in this case the windmill tower is more critical for wind load as compare to seismic load. The deflection of tower increasing from hard strata to soft strata. The deflection of tower for different soil strata are presented in Table 4, 5&6.

Table 4 Maximum deflection of windmill tower for hard strata

3558	0.75[DL+0.5LL+EQX]	14.895	0	EQ Lo ad
3564	0.75[DL+0.5LL+EQZ]	3.746	10.845	

5.2 Stability of windmill tower

It was observed from the analysis that bending stresses are maximum at the bottom level plates of the tower. There was tensile and bending stresses are developed in the tower of windmill. The bending stresses developed in the bottom plate of windmill tower were maximum for wind load as compared to seismic load for different strata.

The permissible bending stress in tension and compression = $\sigma_{bt} = 0.66 * f_y$, where, f_y = yield stress of steel. For steel of yield strength 250 N/mm², $\sigma_{bt} = 0.66 * 250 = 165$ N/mm². From Table 7 it is observed that no bending stresses are exceeding the value of permissible stresses hence windmill tower structure is safe for the bending.

Table 7 Bending stress in tower

Sr.No.	Soil Strata	Bending Stress(Kn/m2)	Loading
1	Hard strata	151	Wind Load
		15.8	Earthquake load
2	Medium strata	151	Wind Load
		17.2	Earthquake load
3	Soft strata	151	Wind Load
		18.8	Earthquake load

5.3 Base shears comparison

It was observed from the seismic analysis that absolute base shear for soft soil strata are maximum as compared to hard soil strata. It is obvious when soil becomes softer, stiffness of soil goes on decrease and as result of this there is maximum vibration in the structure. The absolute base shear for different soil strata is listed in Table 8

Table 8 Base Shear

Earthquake Load	Base Shear (KN)
-----------------	-----------------

	Hard Strata	Medium Strata	Soft Strata
EQX	40.96	44.32	47.36
EQZ	40.91	44.39	47.55
EQY	27.18	27.18	27.18

5.4 Safety of foundation

It was observed that the actual bearing pressure on the soil for design size of footing is less than the permissible safe bearing capacity for hard, medium and soft strata which is shown in Table 9, 10&11. So foundation is Safe.

Table 9 Pressure intensities for hard strata

Load combination	Net pressure intensities (KN/m2)		Gross pressure intensities (KN/m2)		Allowable SBC for hard strata(KN/m2)
	Max	Min	Max	Min	
DL of foundation +VW of windmill	35.92	35.92	75.47	75.47	
DL of foundation +Vertical weight +Wind	69.49	2.34	142.63	8.31	350.00

DL of foundation+ Vertical weight +Seismic	34.9 7	31.8 3	76.11	69.8 3	

5.5 Stability of foundation

For stability of foundation the soil must be capable of carrying the loads from any engineered structure placed upon it without a shear failure and with resulting settlements being tolerable for that structure. Excessive settlements can result in structural damage to a building frame, and excessive wear or settlements. So it is necessary to check windmill for sliding and overturning. From Table 12, 13&14 it is observed that the windmill for different soil strata is safe for sliding and overturning. The factor of safety against sliding and overturning is greater than 1.5

Table 12 Check for stability of foundation for hard strata

5.6 Reinforcement details of foundation

The reinforcement for foundation was increases from hard strata to soft strata which are presented in Table 15. So the cost of foundation is increases with respect to increasing reinforcement in foundation.

VI. Conclusion

In this work attempt was made to critically study the behavior of windmill tower and foundation system subjected to wind load and earthquake load for different supporting condition such as hard, medium and soft strata.

Based on this analysis and design following conclusion were made:

1. The effect of wind is significant as compared to earthquake and has to be considered in the analysis of windmill.
2. When effects of wind are considered the stability of windmill has to be thoroughly checked.
3. Soil strata play a major role in safety and stability of windmill.
4. The effect of wind on blade i.e. drag force is more critical in the analysis of windmill and its make more drastic changed in the structure.
5. In earthquake analysis, the normalized base shear, moment due to shear is increasing with respective to hard, medium and soft soil strata.

6. The foundation sizes, concrete material, reinforcement material shall be increasing with respect to hard, medium and soft Strata. So cost of structure also increased.

²(PG student, dept: Eee Rgm cet, Nandyal, A. P)

Abstract: This paper investigates a Closed loop Control of high-efficiency clamped voltage dc–dc converter with reduced reverse-recovery current and switch-voltage stress. In the circuit topology, it is designed by way of the combination of inductor and transformer to increase the corresponding voltage gain. Moreover, one additional inductor provides the reverse-current path of the transformer to enhance the utility rate of magnetic core. In addition, the voltage-clamped technology is used to reduce the switch-voltage stress so that it can select the Schottky diode in the output terminal for alleviating the reverse-recovery current and decreasing the switching and conduction losses. Furthermore, the closed-loop control methodology is utilized in the proposed scheme to overcome the voltage-drift problem of power source under the variation of loads. Thus, the proposed converter topology has a favourable voltage-clamped effect and superior conversion efficiency.

Index Terms: Converter, Schottky diode, closed loop, reverse recovery, voltage clamped.

I. Introduction

IN RECENT years, dc–dc converters with steep voltage ratio are usually required in many industrial applications, e.g., the front-end stage for clean energy sources, the dc backup energy system for an uninterruptible power supply (UPS), high intensity discharge (HID) lamps for automobile headlamps, and the telecommunication industry [1]–[3]. The conventional boost converters cannot provide such a high dc-voltage ratio due to the losses associated with the inductor, filter capacitor, main switch, and output diode. Even for an extreme duty cycle, it will result in serious reverse-recovery problems and increase the

rating of the output diode. As a result, the conversion efficiency is degraded, and the electromagnetic interference (EMI) problem is severe under this situation to increase the conversion efficiency and voltage gain, many modified boost-converter topologies have been investigated in the past decade [5]–[10]. Although voltage-clamped techniques are manipulated in the converter design to overcome the severe reverse-recovery problem of the output diode in high-level voltage applications, there still exist overlarge switch-voltage stresses, and the voltage gain is limited by the turn-ON time of the auxiliary switch [5], [6] presented a boost soft-single-switch converter, which has only one single active switch. It is able to operate with soft switching in a pulse width modulation (PWM) way without high voltage and current stresses. Unfortunately, the voltage gain is limited below four in order to achieve the function of soft switching. In [8] and [9], coupled inductors were employed to provide a high step-up ratio and to reduce the switch-voltage stress substantially, and the reverse-recovery problem of the output diode was also alleviated efficiently. In this case, the leakage energy of the coupled inductor is another

problem as the main switch was turned OFF. It will result in a high-voltage ripple across the main switch due to the resonant phenomenon induced by the leakage current. In order to protect the switch devices, either a high-voltage-rated device with higher $R_{DS(ON)}$ or a snubber circuit is usually adopted to deplete The leakage energy. Consequently, the power-conversion efficiency will be degraded. Zhao and Lee [10] introduced a family of high-efficiency high-step-up dc–dc converters by only adding one addition diode and a small capacitor. However, a snubber circuit is energy losses.

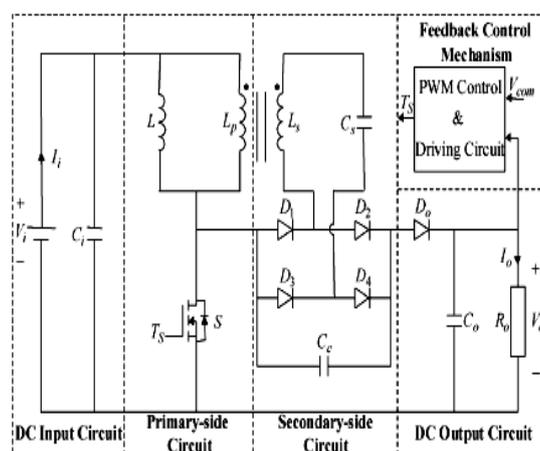

Fig. 1. System configuration of a high-efficiency voltage-clamped dc–dc converter.

II. Converter Design And Analyses

A newly designed converter topology is depicted in Fig. 1, where it contains five parts including a dc-input circuit, a primary-side circuit, a secondary-side circuit, a dc-output circuit, and a feedback-control mechanism. The major symbol representations are summarized as follows. V_i and I_i denote the dc-input voltage and current, and C_i is the input filter capacitor in the dc-input circuit. L_p represents the primary inductor of the transformer; L is the additional inductor in

the primary-side circuit; and S is the main switch. L_s denotes the secondary inductor of the transformer; C_s and C_c are the balanced capacitor and clamped capacitor in the secondary-side circuit; and $D_1, D_2, D_3,$ and D_4 are the rectifier diodes. V_o and I_o describe the output voltage and current; R_o is the output load; $D_o,$ and C_o are the output diode and filter capacitor in the output circuit. V_{com} and

T_S are the output-voltage command and switch-driving signal in the feedback-control mechanism, respectively.

The equivalent circuit and state definition of the newly designed converter is depicted in Fig. 2, where the transformer is modelled as an ideal transformer with a secondary leakage

Inductor (L_k). The turns ratio of this ideal transformer is defined as

$$n = \frac{N_2}{N_1} \tag{1}$$

Where N_1 and N_2 are the primary and secondary winding turns. The additional inductor (L) is located in parallel with the

primary side of the transformer. Moreover, the rectifier diodes ($D_1, D_2, D_3,$ and D_4) are connected between the primary and

Secondary sides of the transformer. The voltages across the additional inductor, the main switch, the ideal transformer primary

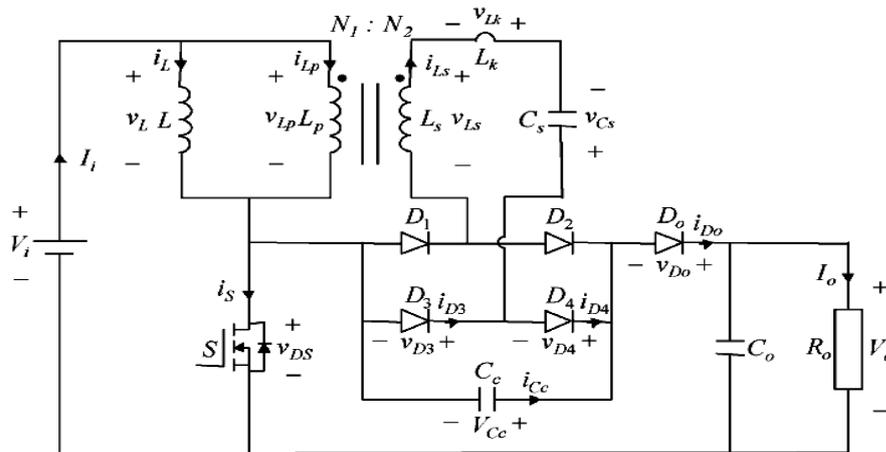

Fig. 2. Equivalent circuit.

and secondary winding, the secondary leakage inductor, the balanced capacitor, and the output diode are $v_L, v_{DS}, v_{Lp}, v_{Ls}, v_{Lk}, v_{Cs},$ and v_{Do} , respectively. The clamped capacitor C_c is assumed to be large enough to be viewed as a constant voltage source, V_{C_c} . The conductive voltage drops of the main switch (S) and all diodes ($D_1, D_2, D_3, D_4,$ and D_o) are neglected to simplify the circuit analyses. The characteristic waveforms of the proposed high-efficiency converter are depicted in Fig. 3. In addition, Fig. 4 illustrates the operational modes in one switching cycle, and the detailed operation stages are described as follows.

A. Mode 1 ($t_0 - t_1$) [Fig. 4(a)]

At time $t = t_0$, the main switch (S) is turned ON. At the same time, the diodes (D_1 and D_4) become conducted, and other diodes ($D_2, D_3,$ and D_o) are reverse biased. The additional inductor (L) and clamped capacitor (C_c) are linearly charged by the input-voltage source (V_i) through the transformer. Applying Kirchhoff's law [4], the voltages of $v_L, v_{Lp}, v_{Ls},$ and v_{Lk} during this period can be expressed as

$$v_L = v_{Lp} = V_i \tag{2}$$

$$v_{L_s} = nV_i \tag{3}$$

$$v_{L_k} = V_{C_c} - nV_i - v_{C_s}. \tag{4}$$

According to (2)–(4), the rate of change of the additional inductor current (i_L), the primary-side current (i_{Lp}), and the N secondary-side current (i_{Ls}) of the transformer can be represented as

$$\frac{di_L}{dt} = \frac{V_i}{L} \tag{5}$$

$$\frac{di_{Lp}}{dt} = \frac{V_{C_c} - nV_i - v_{C_s}}{L_k} + \frac{V_i}{L_p} \tag{6}$$

$$\frac{di_{Ls}}{dt} = \frac{V_{C_c} - nV_i - v_{C_s}}{L_k}. \tag{7}$$

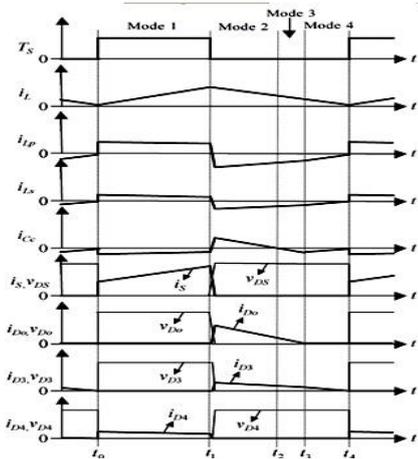

Fig. 3. Characteristic waveforms.

B. Mode 2 (t1 – t2) [Fig. 4(b)]

At time $t = t_1$, the main switch (S) is turned OFF. At this time, the diodes (D2, D3, and Do) become forward biased to start conducting, and other diodes (D1 and D4) are reverse biased. The stored energy of the additional inductor (L) and

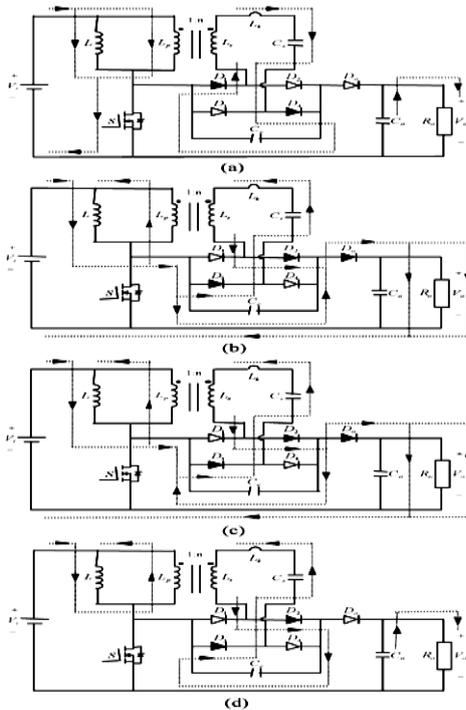

Fig. 4. Operational modes: (a) mode 1 [t0 – t1]; (b) mode 2 [t1 – t2]; (c) mode 3 [t2 – t3]; (d) mode 4 [t3 – t4].

clamped capacitor (Cc) in Mode 1 is released to output loads. Moreover, the transformer can be operated at four quadrants to enhance the utility rate of the magnetic core and to keep the clamped voltage (Vcs), since the additional inductor (L) supplies energy to the output terminal by way of the transformer. Applying Kirchhoff’s law [4], the voltage and current relations of each element during this mode can be described by

$$v_L = v_{Lp} = V_i + V_{C_c} - V_o \tag{8}$$

$$v_{L_s} = n(V_i + V_{C_c} - V_o) \tag{9}$$

$$v_{L_k} = -V_{C_c} - v_{C_s} - n(V_i + V_{C_c} - V_o) \tag{10}$$

$$v_{DS} = V_i - V_L = V_o - V_{C_c} < V_o \tag{11}$$

$$i_{D_o} = i_L + i_{L_p} = i_{C_c} - i_{L_s} \tag{12}$$

Where i_{Do} is the current of the output diode D_o ; i_{Cc} is the current of the clamped capacitor C_c . According to (11), the cutoff voltage of the main switch (S) is clamped at $V_o - V_{Cc}$. Moreover, the main switch (S) with low-voltage-rated capacity can be selected since the switch-voltage stress (v_{DS}) is smaller than the output voltage (V_o). The selection of a low-voltage rated device with lower $R_{DS(ON)}$ is useful for improving the conversion efficiency. Referring to (8)–(10), the rate of change of i_L , i_{Lp} and i_{Ls} is given by

$$\frac{di_L}{dt} = \frac{V_i + V_{C_c} - V_o}{L} \tag{13}$$

$$\frac{di_{L_p}}{dt} = \frac{-V_{C_c} - v_{C_s} - n(V_i + V_{C_c} - V_o)}{L_k} + \frac{V_i + V_{C_c} - V_o}{L_p} \tag{14}$$

$$\frac{di_{L_s}}{dt} = \frac{-V_{C_c} - v_{C_s} - n(V_i + V_{C_c} - V_o)}{L_k} \tag{15}$$

C. Mode 3 (t2 – t3) [Fig. 4(c)]

At time $t = t_2$, the residual energy of the clamped capacitor (C_c) is discharged entirely, i.e., $i_{Cc}(t_2) = 0$. Immediately, the clamped capacitor (C_c) is charged by the energy of the additional inductor (L) through the transformer, and the rate of change of the clamped-capacitor current (i_{Cc}) can be denoted as

$$\frac{di_{C_c}}{dt} = \frac{V_i + V_{C_c} - V_o}{L} + \frac{V_i + V_{C_c} - V_o}{L_p} + 2 \left[\frac{-V_{C_c} - v_{C_s} - n(V_i + V_{C_c} - V_o)}{L_k} \right] \tag{16}$$

Moreover, the stored energy of the additional inductor (L) is released continuously to the output terminal by way of the transformer. The rate of charge of i_{Do} is given by

$$\frac{di_{D_o}}{dt} = \frac{V_i + V_{C_c} - V_o}{L} + \frac{V_i + V_{C_c} - V_o}{L_p} + \frac{-V_{C_c} - v_{C_s} - n(V_i + V_{C_c} - V_o)}{L_k} \quad (17)$$

D. Mode 4 (t3 – t4) [Fig. 4(d)]

At time $t = t3$, the clamped-capacitor current (i_{C_c}) equals to the secondary-side current (i_{L_s}) of the transformer, and the output diode current (i_{D_o}) decays to 0, i.e., $i_{D_o}(t3) = 0$. During this period, the voltage of the output diode (v_{D_o}) maintains the zero status until the main switch (S) is turned ON. Moreover, the magnitude of the additional inductor current (i_L) is equal to the one of the primary-side current (i_{L_p}). According to (13) and (14), the rate of change of i_{L_p} and i_{L_s} can be represented as

$$\frac{di_{L_p}}{dt} = -\frac{di_L}{dt} = -\frac{V_i + V_{C_c} - V_o}{L} \quad (18)$$

$$\frac{di_{L_s}}{dt} = -\frac{V_i + V_{C_c} - V_o}{L} - \frac{V_i + V_{C_c} - V_o}{L_p} \quad (19)$$

Since the secondary leakage inductor (L_k) and the change rate of i_{L_s} in the transformer are very small, the voltage of the secondary leakage inductor (v_{L_k}) can be neglected. According to the concept of the zero average voltage across the inductor over one period [4], the voltages of v_{C_s} , V_{C_c} , and V_o for steady-state operation can be described via (2), (4), (8), and (10) as

$$v_{C_s} = \frac{nV_i(2d - 1)}{2(1 - d)} \quad (20)$$

$$V_{C_c} = \frac{nV_i}{2(1 - d)} \quad (21)$$

$$V_o = \frac{2 + n}{2(1 - d)} V_i \quad (22)$$

where ϵ is the switch (S). Continuously, the main switch (S) is turned ON at time $t = t4$ to begin the next switching cycle.

Since the voltage difference may be caused by the secondary inductor of the transformer, as $d \neq 0.5$, the major function of the balanced capacitor (C_c) is used for keeping the cutoff voltages of the rectifier diodes ($D1$, $D2$, $D3$, and $D4$) balanced. Moreover, it also can avoid the overlarge current that passed through the rectifier diodes. According to (22), the voltage gain can be tuned by regulating the turns ratio (n) in the transformer to overcome the boost-ratio limitation of the conventional

converter. In addition, the switch-voltage stress (v_{DS}) can be calculated via (11), (21), and (22) as

$$v_{DS} = \frac{V_i}{(1 - d)} \quad (23)$$

According to (22) and (23), one can obtain

$$v_{DS} = \frac{2V_o}{(2 + n)} \quad (24)$$

By analyzing (24), the switch-voltage stress (v_{DS}) is not related to the dc-input voltage (V_i) and duty cycle (d) if the values of the output voltage (V_o) and the turns ratio (n) are fixed. Thus, it can ensure that the sustainable voltage of the main switch (S) is constant. As long as the dc-input voltage is not higher than the

rated voltage of the main switch, the high-efficiency voltage clamped dc–dc converter can be applied well to the low-voltage power sources even with large voltage variations, e.g., fuel cell, solar cell, etc.

Fuel-cell generation systems have been receiving more attention in the last years due to the advantages of high-conversion efficiency, low aggression to the environment, no moving parts, and superior reliability and durability. Owing to the electrochemical reaction, fuel cell has the power quality of low voltage and high current. However, the fuel-cell stack with high output voltage is difficult to fabricate and it may be failure when any single cell is inactive. Besides, the output voltage is varied easily with respect to the load variations. In order to satisfy the requirement of high-voltage demand, a stable boost converter with high voltage gain and superior conversion efficiency is necessary to utilize the fuel-cell energy more efficiently. The validity of the proposed converter is verified by the following experimental results via an example of a PEMFC power source.

III. Experimental Results

In experimentation, the high-efficiency voltage-clamped dc–dc converter is designed to operate from the fuel-cell variability dc input, $V_i = 27\text{--}37.5$ V, to deliver a constant dc output, $V_o = 200$ V, with the maximal capability of output power, $P_{o,max} = 330$ W. If the maximal value of main switch voltage (v_{DS}) is arranged for clamping at 50 V, the turns ratio can be determined as $n = (2V_o/v_{DS(max)}) - 2 = 6$ according to (24). As can be seen from Figs. 3 and 4, the voltage stress of the output diode (v_{D_o}) is the same as the switch-voltage stress. In addition, the voltage stresses of rectifier diodes (v_{D1} , v_{D2} , v_{D3} , and v_{D4}) can be calculated via (21) and (23) as $n v_{DS} / 2 = 150$ V. For conservative consideration, the main switch (FQI90N08, 80 V), the output diode (Schottky diode SR20100, 100 V), and the rectifier diodes (Schottky diode SR20200, 200 V) are adopted in the experimental converter. In order to solve the problem of the fuel-cell output voltage varied with the variations of loads, the proposed converter with dc-voltage feedback

control is utilized to ensure the system stability, and a PWM control IC TL494 is adopted to achieve this goal of feedback control. The prototype with the following specifications is designed in this section to illustrate the design procedure given in Section II:

- switching frequency $f_s = 100 \text{ kHz};$
- turns ratio $n = 6;$
- Additional inductor $L = 5.9 \mu\text{H};$
- primary inductor of transformer $L_p = 213.6 \mu\text{H};$
- secondary inductor of transformer $L_s = 7689.6 \mu\text{H};$
- secondary leakage inductor $L_k = 0.6 \mu\text{H};$
- balanced capacitor $C_s = 4 \times 6.8 \mu\text{F};$
- clamped capacitor $C_c = 6 \times 4.7 \mu\text{F};$
- input filter capacitor $C_i = 3300 \mu\text{F};$
- output filter capacitor $C_o = 3 \times 4.7 \mu\text{F};$
- main switch $S:$ FQI90N08 (80 V, DS (ON) = 16 mΩ);
- Output diode $D_o:$ Schottky diode SR20100 (100 V, 20 A);
- Rectifier diodes $D_1, D_2, D_3, D_4:$ Schottky diode SR20200 (200 V, 20 A).

Fig. 5 depicts the results voltage and current curves of the main switch (S) at 310-W output power. As can be seen from this figure, the shaken switch voltage at the beginning is caused by the line inductor when the switch is turned OFF. Fortunately, the steady state of this switch-voltage stress is about 50 V due to the utilization of voltage-clamped technique, and it is much smaller than the output voltage, $V_o = 200 \text{ V}$. It has the merit of selecting a low-voltage-rated device in order to reduce the conduction loss of the switch. The simulated current waveforms of the additional inductor (L), in parallel with the transformer, primary inductor of transformer (L_p), and secondary inductor of transformer (L_s) at 310-W output power, are depicted in Fig. 6, the balanced capacitor (C_s) can be used for balancing the current and cutoff voltage of the diodes (D_3 and D_4) when the condition of $d \neq 0.5$, holds.

For verifying the voltage-clamped property, the experimental voltage responses of the output voltage (V_o), clamped capacitor (C_c), and main switch (S) at 310-W output power are depicted. As can be seen from this figure, the output voltage, $V_o = 200 \text{ V}$, is strode mainly across the clamped capacitor in the secondary-side circuit (i.e., $V_{C_c} = 150 \text{ V}$). Thus, the switch-voltage stress and the cutoff voltage of the output diode are clamped at about 50 V. In order to examine the robust performance of the proposed converter scheme, the experimental results of the converter output voltage (V_o), and the PEMFC output current (I_i) under the step load variation between no load (0 W) and full load (310 W) are depicted. the converter output voltage, $V_o = 200 \text{ V}$, is insensitive to the variation of loads due to the closed-loop control, and the output current ripple is also slightly extreme as a result of the high switching frequency.

IV. CONCLUSION

This project has developed a voltage-clamped dc–dc converter with reduced reverse recovery current and switch-voltage stress, with a power quality of low voltage and high current. The newly designed converter circuit has the following improvements compared to the previous work.

- 1) Proposed converter can select the main switch with lower sustainable voltage for alleviating the switch conduction loss due to the utilization of voltage-clamped technique.
- 2) All diodes in this circuit topology are Schottky diodes with the reduction of switching and conduction losses.
- 3) The additional inductor is used for providing the reverse current path of the transformer to raise the utility rate of the magnetic core.
- 4) Additional snubber circuits for absorbing the voltage spikes in the diodes are not required to further cut down the manufacture cost.
- 5) There is no circulating current to overcome the problem of degenerate efficiency under slight loads.
- 6) The voltage-drift problem of power source under the variation of loads can be solved by the closed-loop control methodology.

Design and Implementation of an Integrated Rf Antenna-Filter Co-Design For Uwb Applications

J.Ramprasad^a, Mrs. T.J.Jeyaprabha^b,

^{1,2} Department of Electronics and Communication, Sri Venkateswara college of Engineering/Anna University,
Sriperumbudur, 602105, India

Abstract: In the co-design approach, the patch antenna and hairpin filter is sandwiched with ground plane. The impedance at the interfaces is optimized to improve the performance of the antenna-filter, without restricting it to 50Ω. Impedance optimization is done using via hole. The simulation of S_{11} parameter for patch antenna has operating center frequency of 6.5GHz. The low pass hairpin filter is designed at 6.5GHz and simulated to show S_{11} parameter. Then design of co-design approach is done and simulation of S_{11} parameter for the antenna-filter co-designed approach provides operating frequency range of 6.5 – 6.9GHz which has increased bandwidth capacity, reduction in size and high gain.

Keywords - Antenna, co-design, filter, patch, hairpin.

I. Introduction

Miniaturization and low cost are the two most fundamental demands for RF receiver front-ends. One way to miniaturize an RF front-end is to embed its passive circuitries and interconnects into a package, which is called system-in package (SIP) [2], [3]. Another way is to integrate required multiple functional circuitries into one device without the 50Ω (or 75Ω) constraints, referred to as co-design [4]–[11]. The co-design method can change the structure of the circuit, improve the performance of the circuits, and simplify the connections between different components. For example, the noise figure of a RF antenna-filter-LNA system has been significantly improved with the co-design strategy [4]. In [5] and [6], antennas were co-designed with an amplifier and transceiver to attain higher integration degree. Similarly, an RF device was implemented by integrating three-dimensional (3-D) cavity filters/ duplexers and antennas [7]. In [8], the resonator of an antenna also acted as an element of filter. In [9] and [10], a coplanar antenna-filter was co-designed. In [11], a two-pole filter was realized by integrating a filter and an antenna. In this letter, a co-designed antenna-filter is presented. A microstrip patch antenna is layered on the top of a hairpin filter, and they share the same ground plane. A via hole is implemented to connect the antenna and the filter.

The impedance at the interfaces is optimized to improve the performance of the antenna-filter, without restricting it to 50Ω. The proposed antenna-filter operates in the frequency band 6.5–6.9 GHz, and the bandwidth for $|S_{11}| \leq -10\text{dB}$ is increased when compared with traditional cascade connection of antenna-filter. The simulated results indicate that the proposed co-design approach can be used to reduce the size, improve the bandwidth, and increase the gain.

II. CO-DESIGN OF ANTENNA AND FILTER

The configurations of the traditional and the co-designed antenna-filters are shown in Fig. 1. Unlike the traditional antenna-filter in which the components are cascaded with 50Ω interfaces [Fig. 1(b)], co-designed antenna-filter is assembled vertically and connected using a metalized via hole, as shown in Fig. 1(a). Also, the ground plane is sandwiched in the middle and shared by both the antenna and the filter. With this configuration, the size of the whole device can be significantly reduced. In order to avoid the electromagnetic (EM) interference between the antenna and the filter, they are arranged to have the parallel current. Furthermore, the impedance at the interfaces is optimized by adjusting the location and dimension of the via hole to attain better performance.

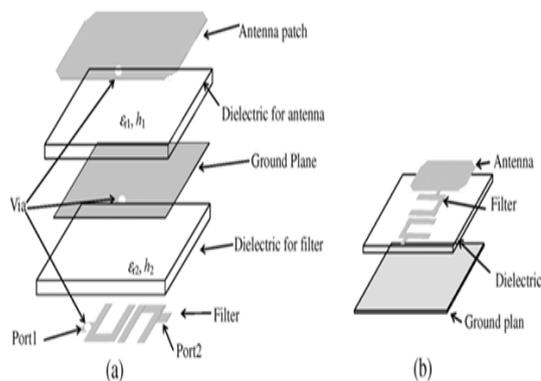

Fig. 1 Antenna-filter with (a) co-design version, (b) traditional version.

III. FILTER DESIGN

Fig. 2 shows the configuration of hairpin filter. The filter is designed to have a fractional bandwidth (FBW) of 6% at 6.5 GHz. We choose a two-pole butterworth low-pass filter prototype. The low-pass prototype parameters include $g_0=1$, $g_1=1.4142$, $g_2=1.4142$, and $g_3=1$ [11]. Based on the low-pass parameters, the design parameters of the band-pass can be calculated by

$$Q_{e1} = \frac{g_0 g_1}{FBW}; Q_{en} = \frac{g_n g_{n+1}}{FBW}$$

$$M_{i,i+1} = \frac{FBW}{\sqrt{g_i g_{i+1}}} \text{ for } i = 0 \text{ to } n - 1$$

where Q_{e1} and Q_{e2} are the external quality factors of the resonators at the input and output port, and $M_{i,i+1}$ are the coupling coefficients between the i th and $(i+1)$ th

resonators. For this design, we have $Q_{e1}=23.57$, $Q_{e2}=23.57$, and $M_{1,2}=0.042$.

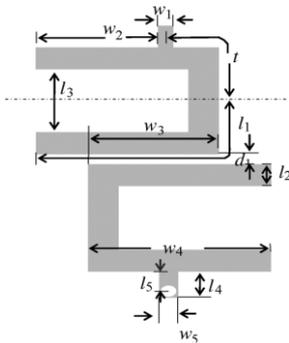

Fig. 2. The configuration of the hairpin filter.

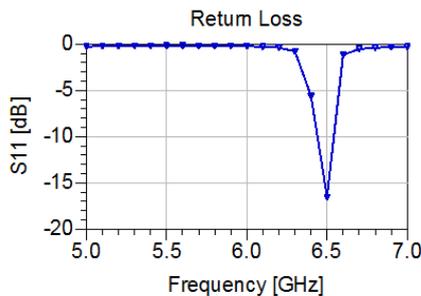

Fig. 3. S11 parameters for the filter.

IV. Antenna Design

The structure of the microstrip rectangular patch antenna with four sharp cuts is shown in Fig. 4. The antenna is designed to operate at the center frequency of 6.5 GHz, and the sharp cuts are used to improve the bandwidth. The optimized design parameters for the antenna with 50Ω interface impedance are used accordingly to provide better bandwidth. The simulated results are shown in Fig. 5.

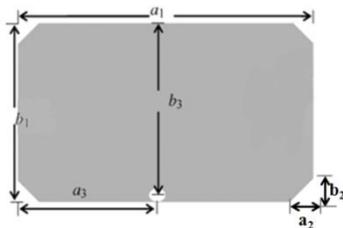

Fig. 4. The configuration of the microstrip patch antenna with four sharp cuts.

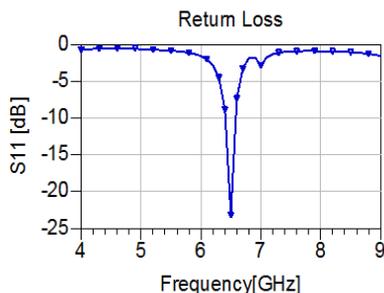

Fig. 5. S11 parameters for the antenna.

V. Simulated Results For Co-Design Antenna-Filter

With the designs of antenna and filter, the co-designed antenna-filter [shown in Fig. 1(a)] is implemented. We also optimize the location and dimension of the via hole, the coupling between via and ground plane, and the impedance at the interface of the antenna and the filter. Design of co-design approach is done and simulation of S_{11} parameter for the antenna-filter co-designed approach provides operating frequency range of 6.5 – 6.9GHz. Fig. 6 shows the simulated parameters for the co-designed antenna-filters. Obviously, due to the better coupling between the antenna and the filter, as well as via hole and ground plane, two resonant frequencies appear that show the co-designed version has a broader bandwidth, which increases bandwidth capacity.

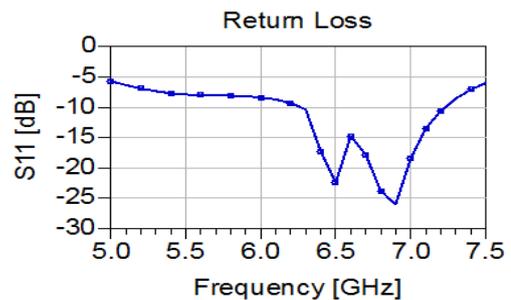

Fig.6 Simulated S11 parameter for the co-design approach.

VI. Conclusion

A co-designed antenna-filter is presented. The simulated results demonstrate the co-design can be used to improve the bandwidth, the gain of the antenna and also it can reduce the size of device. Since co-designed antenna-filter design provides broader bandwidth, more number of users can use channel for wireless communications.

Abstract: This paper is devoted for designing high speed arithmetic logic unit. All of us know that ALU is a module which can perform arithmetic and logic operations. The reason behind choosing this topic as a research work is that, ALU is the key element of digital processors like as microprocessors, microcontrollers, central processing unit etc. Every digital domain based technology depends upon the operations performed by ALU either partially or whole. That's why it highly required designing high speed ALU, which can enhance the efficiency of those modules which lies upon the operations performed by ALU. The speed of ALU greatly depends upon the speed of multiplier. There are so many multiplication algorithms exist now-a-days at algorithmic and structural level. Our work proved that Vedic multiplication technique is the best algorithm in terms of speed. Further we have seen that the conventional Vedic multiplication hard wares have some limitations. So to overcome those limitations a novel approach has been proposed to design the Vedic multiplier with the use of unique addition tree structure, which is used to add partially generated products. For designing the two bit Vedic multiplier conventional hardware of Vedic multiplier has been used. For designing the four and eight bit level Vedic multiplier divide and conquer approach has been used. After designing the proposed Vedic multiplier, it has been integrated into an eight bit module of arithmetic logic unit along with the conventional adder, subtractor, and basic logic gates. The proposed ALU is able to perform three different arithmetic and eight different logical operations at high speed. All of these operational sub-modules (adder, subtractor, multiplier and logical gates) have been designed as the combinatorial circuit. And for the synchronization of these operational sub-modules, the multiplexers which have been used to integrate these sub-modules in a single unit have been triggered by positive edge clock To design proposed arithmetic logic unit verilog hardware description language (HDL) has been used. For designing operational sub-modules data flow modeling and for integration purpose behavioral modeling style has been used. For this design the target FPGA which we have taken belongs to Virtex-2P (family), XC2VP2 (device), FG256 (package) with speed grade of -7. For synthesis purpose Xilinx synthesis tool (XST) of Xilinx ISE-9.2i has been used. The behavioral simulation purpose ISE simulator has been used.

The maximum combinational path delay of proposed multiplier is 11.886 ns. And the ALU that has been designed can operate at the maximum frequency of 741.455 MHz.

Keywords: - Vedic Urdhva Triyambakam multiplication algorithm, Arithmetic Unit, Arithmetic Logic Unit, Addition tree structure.

I. Introduction

As all of us know that the Computation unit is main unit of any technology, which performs different arithmetic operations like as addition, subtraction and multiplication etc. also in some places it performs logical operations also like as and, or, invert, x-or etc. which is dominant feature in the digital domain based applications. ALU is the execution unit which does not only performs Arithmetic operations but also Logical operations. And that's why ALU is called as the heart of Microprocessor, Microcontrollers, and CPUs. No technology can exist, without those operations which are performed by ALU. Every technology uses works upon those operations either fully or partially which are performed by ALU. The block diagram of ALU is given below, where ALU has been implemented on FPGA tool

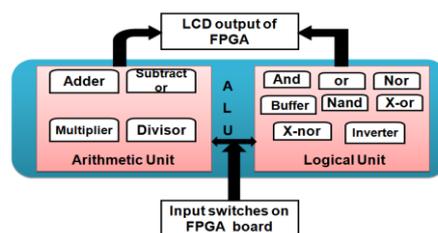

Figure 1.1 Block Diagram of ALU

Here the input interface to access ALU module is input switches on FPGA board, and after processing on the data the result can be seen from LCD output of FPGA. For multiplication purpose vedic Urdhva Triyambakam multiplication scheme has been used. Urdhva Triyambakam Sutra is a general multiplication formula applicable to all cases of multiplication. It literally means "Vertically and Crosswise". To illustrate this multiplication scheme, let us consider the multiplication of two decimal numbers (32×44). The conventional methods already know to us will require 16 multiplications and 15 additions. An alternative method of multiplication using Urdhva Triyambakam Sutra is shown in following figure. The Vedic multiplication algorithm for 2 digit decimal numbers is shown below:-

32 X 44 = 1,408

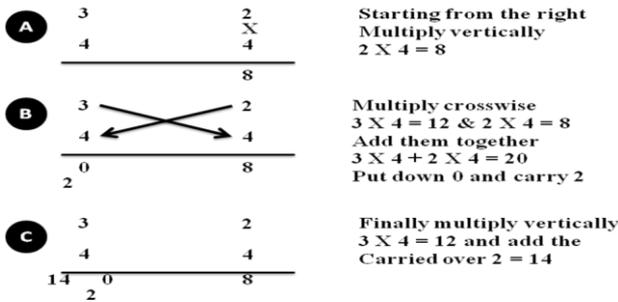

Figure 1.2 Vedic Multiplication Technique

On the basis of this the conventional Vedic Multiplier hardware has been designed which is shown below for 4x4 Bit, Using the same approach N-Bit Multiplier can be introduced[10]:-

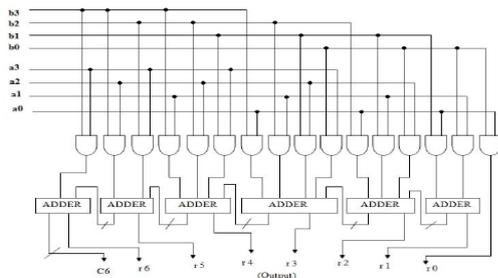

Figure 1.3 Conventional Four Bit Vedic Multiplier

But it has large carry propagation path delay which limits the speed of it. So to overcome this problem many methodologies have been introduced in which the latest and popular technique is to replace the conventional addition structure with carry save addition (CSA) structure. But we have seen that its speed is also limited because of intermediate processes followed by the CSA to convert three operands into two operands addition. Diagram of this is given following for 4-Bit level Multiplication [4]:

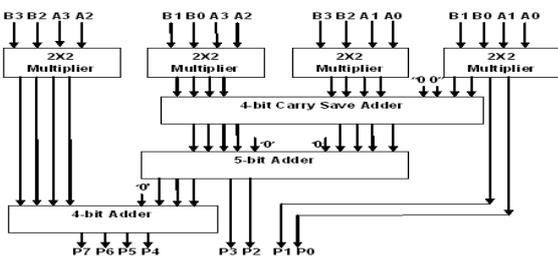

Figure 1.4 Four Bit Vedic Multiplier with CSA

II. Proposed ALU Module

Our Proposed 8x8 bit Arithmetic Unit is shown in the following:-

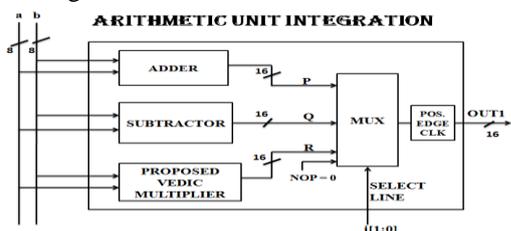

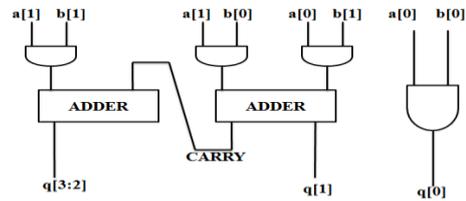

Figure 2.1 Proposed Arithmetic Unit Integration

Here a and b are the two 8 bit inputs of our Arithmetic Unit. And other sections of the design are self-explanatory.

For 2-Bit multiplication Conventional Vedic multiplication Hardware has been used. As at 2 bit level multiplication we have not to worry about the carry propagation path.

Here inputs are a [1:0] and b[1:0], and output is q[3:0].

Figure 2.2 Two Bit Conventional Vedic Multiplier

Diagram for Unique addition tree structure for partial product addition for 4 bit is given in the following:-

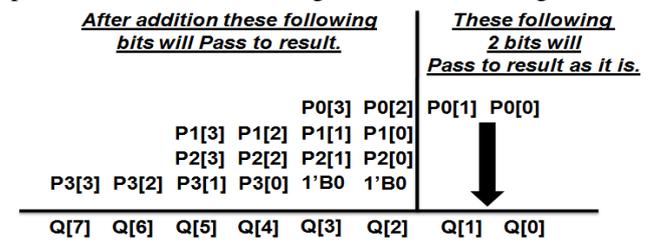

Figure 2.3 Proposed Addition Tree Structure of 4-Bit Multiplier

Diagram for Unique addition tree structure for partial product addition for 8 bit is given in the following:-

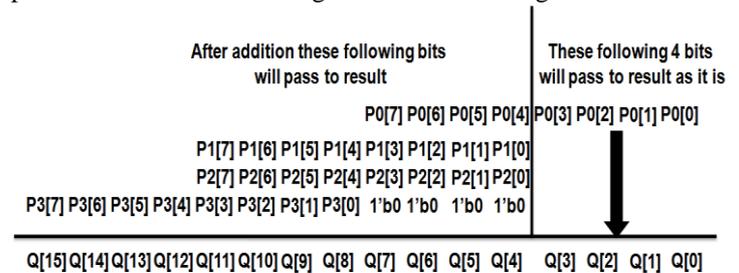

Figure 2.4 Proposed Addition Tree Structure of 8-Bit Multiplier

Here the assignment of partial products P0, P1, P2, P3 has given from right to left at output of Vedic N/2-Bit Vedic multiplier, where N shows the no. of bits in one input of multiplier. And also which addition tree structure we have designed is very simple to understand, design and implement. Here for the addition purpose the unique addition tree structure. The block diagram for 4 bit level multiplication shown below.

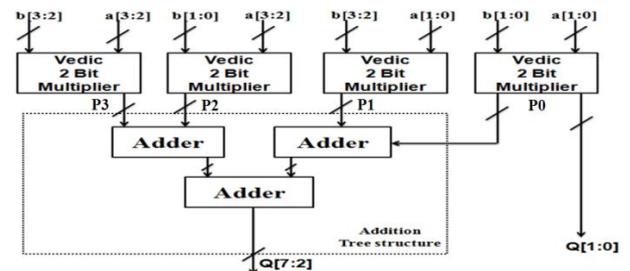

Figure 2.5 Block Diagram of Proposed 4-Bit Vedic Multiplier

Block diagram of 8-Bit Vedic Multiplier is shown below:-

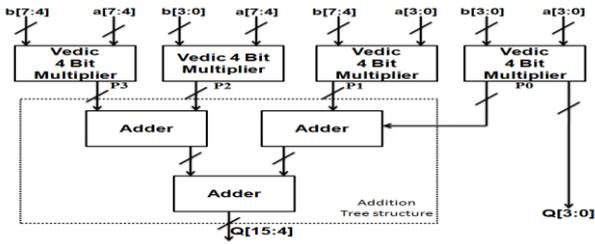

Figure 2.6 Block Diagram of Proposed 8-Bit Vedic Multiplier

After designing the Arithmetic Unit, it has been incorporated into the ALU module. The block diagram of proposed ALU is given following, which is self explanatory in itself:-

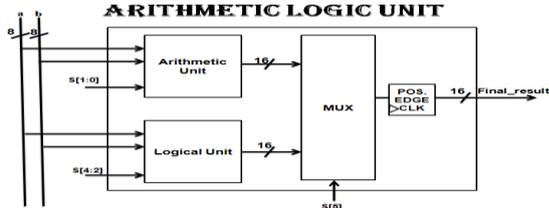

Figure 2.7 Proposed ALU

For designing the Logical unit we have used the simple conventional logic gates and multiplexer has been used for integration purpose. It can be easily built by referring any standard book of digital electronics so it has not been discussed here. Control word for the proposed ALU is:-

CONTROL WORD OF ALU

S[5]	S[4]	S[3]	S[2]	S[1]	S[0]	OPERATIONS PERFORMED
0	x	x	x	0	0	ADDITION (a,b)
0	x	x	x	0	1	SUBTRACTION (a,b)
0	x	x	x	1	0	MULTIPLICATION (a,b)
0	x	x	x	1	1	NOP = 0
1	0	0	0	x	x	AND (a,b)
1	0	0	1	x	x	OR (a,b)
1	0	1	0	x	x	NOR (a,b)
1	0	1	1	x	x	DATA BUFFER (a)
1	1	0	0	x	x	NAND (a,b)
1	1	0	1	x	x	X-OR (a,b)
1	1	1	0	x	x	X-NOR (a,b)
1	1	1	1	x	x	NOT (a)

Figure 2.8 Control Word

III. QUANTITATIVE RESULTS

Following table shows the area and timing constraints of proposed Vedic multiplier at different bit levels.

N Bit multiplier	Number of LUT used as logic	Number of occupied Slices	Total eq. gate count for design	Additional JTAG gate count for design	Maximum combinational path delay (ns)
2-Bit	4	2	24	384	4.626ns
4-Bit	31	16	230	768	8.387ns
8-Bit	139	70	1073	1536	11.886ns

Table 3.1 Device Utilization Summary of N-Bit Multiplier

IV. COMPARATIVE RESULTS

To show the efficiency of proposed Vedic multiplier at eight bit level, it has been compared with some other popular multiplier structures based on different multiplication algorithms at the eight bit level. For the comparison purpose some standard papers have been used.

For true and reliable comparison, proposed multiplier has been implemented on the same platform of target FPGA, which has been used by the reference papers. Comparative tables are shown below:-

(a) In the following given table the target FPGA used belongs to Virtex 2P (family), XC2VP2 (device), FG 256 (Package), -7 (speed grade).

Karatsuba [10]	Vedic Karatsuba [10]	Modified Booth Wallace [4]	Vedic with Partitioning [4]	Conventional Vedic [10]	Vedic with CSA [4]	Proposed
31.039	18.695	15.815	15.685	15.418	13.07	11.886

Table 4.1 Comparative Table 1 for Different Multipliers at 8-Bit Level

(b) In the following given table the target FPGA used belongs to Spartan 3 (family), XC3S50 (device), PQ 208 (Package), -4 (speed grade).

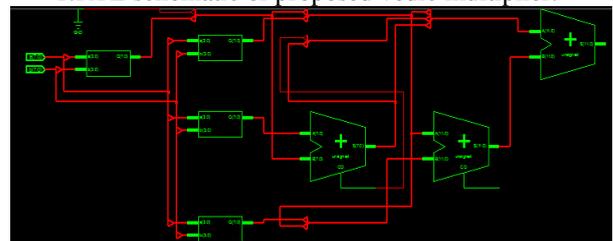

Array [2]	Booth [2]	Conventional Vedic [2]	Proposed
32.01	29.549	21.679	19.467

Table 4.2 Comparative Table 2 for Different Multipliers at 8-Bit Level

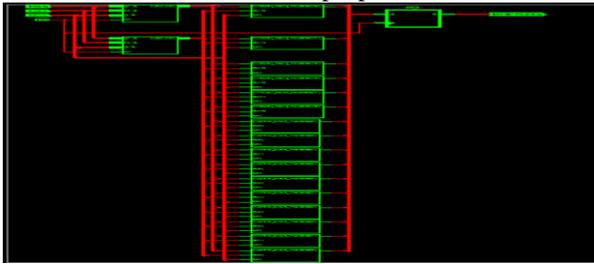

By designing the proposed Vedic multiplier for the same reconfigurable hardware as shown in [4] and [2], make the comparison platform (hardware) independent, algorithmic, technique and approach based comparison. So by comparing with different multipliers at the same platform it can be concluded that the algorithm and approaches which has been proposed to design Vedic multiplier, in this thesis work, is better in comparison to the other popular algorithms and approaches shown in [4] and [2]. In [10] M. Ramalatha et.al. Have not shown that which target FPGA they have used to design their modules so we have compared our proposed multiplier design with our conventional target FPGA, which we have used to make the overall design of ALU. So by this it can be concluded that our proposed algorithm, approach and platform are better than [10].

V. Synthesis And Simulation

1. RTL schematic of proposed vedic multiplier:-

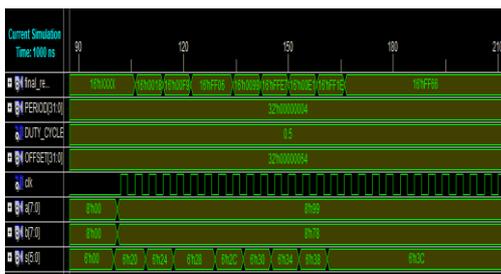

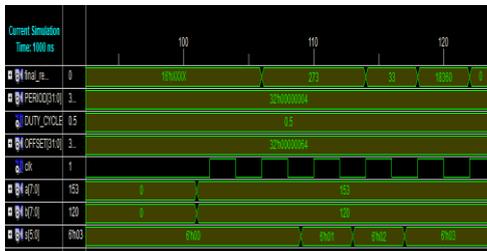

2.RTL schematic of proposed ALU:-

3.Device utilization summary of proposed ALU:-

Device Utilization Summary				
Logic Utilization	Used	Available	Utilization	Note(s)
Number of Slice Flip Flops	25	2,816	1%	
Number of 4 input LUTs	216	2,816	7%	
Logic Distribution				
Number of occupied Slices	116	1,408	8%	
Number of Slices containing only related logic	116	116	100%	
Number of Slices containing unrelated logic	0	116	0%	
Total Number of 4 input LUTs	227	2,816	8%	
Number used as logic	216			
Number used as a route thru	11			
Number of bonded IOBs	39	140	27%	
IOB Flip Flops	16			
Number of FPC405s	0	0	0%	
Number of GCLKs	1	16	6%	
Number of GT1s	0	4	0%	
Number of GT10s	0	0	0%	
Total equivalent gate count for design	2,133			
Additional JTAG gate count for IOBs	1,872			

4. Simulation results of proposed ALU as per control word of ALU:-

VI. Conclusion

We have proposed a new technique to design Vedic multiplier using unique addition tree structure, which gives better response in terms of speed in comparison to the conventional vedic multiplier hardware, Vedic multiplier with partitioning, Vedic multiplier with carry save adder, Modified Booth Wallace, Karatsuba, Vedic Karatsuba, Array, Booth, Wallace multiplier. And then this multiplier module has been put in the ALU along with conventional modules.

Concurrent Engineering: Impact on New Product Design and Development in Indian Two Wheeler Auto Industry

¹V. Venkata Ramana,

¹ Head, Mechanical Department, Intell Engineering College, ANANTAPUR- 515 003, A.P, INDIA

Abstract: Concurrent Engineering (CE) has a great deal of importance in design and development of new products in automobile industry and is posing a big challenge to Indian firms in the wake of globalization. Success of CE demands that major areas of product design and development of an organization need to be under constant focus. Most of the companies adopt CE procedures to reduce the time of launching the new product in the market, especially firms of western countries and Middle East. This paper analyzes the influence of concurrent engineering practices followed by some selected Indian two wheeler automobile manufacturers in the area of new product development as they seek to improve their competitive position in global markets. The research survey presents its evaluation based on analysis by application of statistical tools on the primary data which was collected through a pre-tested questionnaire. The findings reveal that the selected two wheeler manufacturing companies in India are realizing maximum benefits with the implementation of the concurrent engineering in new product design and development.

Keywords: Concurrent Engineering, New Product Development, Product and Process development, Optimization.

I. Introduction:

In the present global business world market needs are volatile, the firms must be able to act and react quickly and responsively. Moreover, they must be able to significantly reduce their product introduction time to market and adapt to the changing business environments, because of shorter life period of the product's. Therefore, concurrent engineering (CE) has emerged as a way for rapid solutions in design and development process.

Concurrent engineering is no doubt the mark of future for new product introduction and development for all companies regardless of their size, sophistication. In order to be competitive, firms must revise their product and process development cycle to be able to complete diverse tasks concurrently. This process will benefit the company, although it requires a great deal of refinement in its implementation, as concurrent engineering is a process that must be reviewed and regulated for continuous improvements of both engineering and business processes.

According to Pennell and Winner, (1988)¹, "Concurrent Engineering is a systematic approach to the integrated, concurrent design of products and their related processes, including, manufacturing and support. This approach is intended to cause the developers from the very outset to consider all elements of the product life cycle, from conception to disposal, including cost, schedule, quality and user requirements". This strategy focuses on the optimization and distribution of a firm's resources in the design and development process to ensure effective and efficient product development process also enhances productivity and leads to high-class designs.

II. Literature Survey:

Shina S.G. in his paper "Concurrent engineering: new rules for world-class companies"(1991)² discussed how concurrent engineering technique is best suitable for manufacturing of high quality products by companies highlighting the benefits such as shorter time for product introduction, improved design quality, reduced design iterations, and shorter production time. Also enlightened the effects of multifunctional teaming which include design for manufacturing (DFM) continuous process improvement (CPI), total quality management (TQM), and quality function deployment (QFD) i.e., product development with concurrent engineering involves all parts of organization.

Rob Kinna, in his paper "Team working and Concurrent Engineering – A Success Story" (1995)³ has discussed the experiences and success of adopting Concurrent engineering highlighting the criticality of team selection, building and empowerment. He is of the opinion that the concurrent engineering team must include both internal group and external group such as customers, suppliers.

David Bradley in his paper, "Concurrent Engineering for bespoke products" (1995)⁴, discussed the disadvantages of traditional design techniques and shown how concurrent engineering benefits the organization. He says that concurrent engineering will advocate building teams working together from initial phase and in close contact with the customer. He has also discussed the benefits of developing computer modelling for further development including virtual reality.

III. Purpose of the Study:

The objective of the research study is to explore and establish the impact of concurrent engineering on product design and development on selected Indian two wheeler automobile industries.

IV. Methodology:

The evaluation of the study is based on a data analysis of the primary data using Cumulative Weighted Average statistical analysis technique. The primary data was collected through a well-structure questionnaire from a sample size of 234 respondents of design, production and marketing groups of selected two wheeler manufacturing companies in India. The questionnaire was sent to all respondents of 3 automobile companies and the usable response rate was 66% (see the Table 1)

Table 1: Response Rating of the Survey

	Number of Organizations		Response Ratio (in percentage)
	Questionnaire Sent to	Response Received	
Two Wheeler Industry Automobile manufacturers	03	03	100%
No. of Respondents	234	155	66%

V. Data Analysis and Interpretation:

The data pertaining to the outcomes of concurrent engineering in new product design and development in two wheeler manufacturing companies are presented in the Table 2 and the same is depicted in the Figure 1

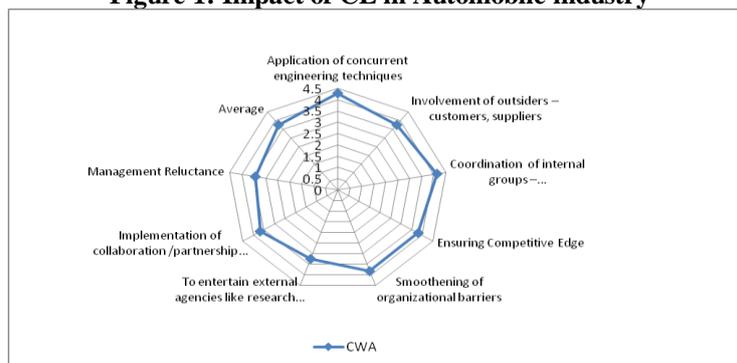

Table 2: Impact of Concurrent Engineering

Variables	Cumulative Weighted Average
Application of concurrent engineering techniques	4.28
Involvement of outsiders – customers, suppliers	3.76
Coordination of internal groups – design, Manufacturing	4.12
Ensuring Competitive Edge	3.8
Smoothing of organizational barriers	3.82
To entertain external agencies like research organizations	3.24
Implementation of collaboration /partnership of managements	3.66
Management Reluctance	3.42
Average	3.7625

Source: Field Survey

CWA: Cumulative Weighted Average

Figure 1: Impact of CE in Automobile industry

VI. Interpretation:

The data presented in the Table 2, clearly establishes that the influence of concurrent engineering in new product design and development of two wheeler companies is considerably high in India. In specific, the variables with CWA score of greater than 3.75 on a 5-point scale: Application of concurrent engineering techniques, Involvement of outsiders – customers, suppliers, Coordination of internal groups – design, manufacturing, Ensuring competitive edge, Smoothing of organizational barriers, are identified as key areas that realized most of the benefits.

VII. Results and Discussion:

Concurrent engineering has shown a very positive impact on design, development and introduction of new product in two wheeler automobile companies. Though companies are implementing concurrent engineering and realizing maximum benefits, they need to focus their attention in identifying the appropriate revolutionary technologies for proto-typing and thus increase cost savings and reduce time to market ultimately satisfying the customer needs.

Modeling and Control of a Variable Speed Wind Turbine Equipped With Permanent Magnet Synchronous Generator

B.Ratheen Kumar Reddy 1, Dr.M.Padma Lalitha 2, Mr.P.B.Chennaiah 3

*M.Tech, Annamacharya Institute Of Technology And sciences,Rajampet,
Professor & H.O.D.Annamacharya Institute of Technology and Sciences,
Assistant Professor, Annamacharya Institute of Technology and Sciences,*

Abstract: *The energy demand around the world increases; the need for a renewable energy source that will not harm the environment has been increased i. e. Wind power is one of them. There are many loads (such as remote villages, islands, ships etc) that are away from the main grid. They require stand-alone generator system (which can provide constant nominal voltage and frequency) to provide for their local electrification. Wind power can be used in off-grid systems, also called stand-alone systems, not connected to an electric distribution system or grid. The power conversion unit features a wind-turbine-driven PMSG, a diode rectifier, a buck-boost dc/dc converter, a battery bank, and a dc/ac inverter. In this paper, a distributed generation based on standalone wind energy conversion system (WECS) using a variable speed permanent magnet synchronous generator (PMSG) is proposed with PWM rectifier and a battery for storing the extra wind energy. The topology for the same has been demonstrated using MATLAB Simulink based simulations.*

Keywords-*BESS, DC/DC Converter, Isolated load, PMSG and WECS*

I. Introduction

Renewable energy sources including wind power offer a feasible solution to distributed power generation for isolated communities where utility grids are not available. In such cases, stand-alone wind energy systems (i.e., systems not connected to the utility grid) can be considered as an effective way to provide continuous power to electrical loads. One of the most promising applications of renewable energy generation lies in the development of power supply systems for remote communities that lack an economically feasible means of connecting to the main electrical grid. For isolated settlements located far from a utility grid, one practical approach to self-sufficient power generation involves using a wind turbine with battery storage to create a stand-alone system.

If wind conditions are favorable, these stand-alone wind energy systems usually can provide communities with electricity at the lowest cost. Stand-alone wind energy systems often include batteries, because the available wind does not always produce the required quantities of power. If wind power exceeds the load demand, the surplus can be stored in the batteries.

The function of an electrical generator is providing a mean for energy conversion between the mechanical torque from the wind rotor turbine, as the prime mover, and the local load or the electric grid. Different types of generators are being used with wind turbines. Small wind turbines are equipped

with DC generators of up to a few kilowatts in capacity. Modern wind turbine systems use three phase AC generators.

The common types of AC generator that are possible candidates in modern wind turbine systems are as follows:

- Squirrel-Cage rotor Induction Generator (SCIG),
- Wound-Rotor Induction Generator (WRIG),
- Doubly-Fed Induction Generator (DFIG),
- Synchronous Generator (With external field excitation),
- Permanent Magnet Synchronous Generator (PMSG). For assessing the type of generator in WECS, criteria such

As operational characteristics, weight of active materials, price, maintenance aspects and the appropriate type of power electronic converter are used.

Historically induction generator (IG) has been extensively used in commercial wind turbine units. Asynchronous operation of induction generators is considered an advantage for application in wind turbine systems, because it provides some degree of flexibility when the wind speed is fluctuating. There are two main types of induction machines: squirrel cage and wound rotor.

The induction generator based on Squirrel-Cage rotor (SCIG) is a very popular machine because of its low price, mechanical simplicity, robust structure, and resistance against disturbance and vibration. The wound-rotor is suitable for speed control purposes. By changing the rotor resistance, the output of the generator can be controlled and also speed control of the generator is possible. Although wound rotor induction generator has the advantage described above, it is more expensive than a squirrel-cage rotor.

The induction generator based on wound rotor is the doubly fed induction generator (DFIG), which is a kind of induction machine in which both the stator windings and the rotor windings are connected to the source. The rotating winding is connected to the stationary supply circuits via power electronic converter. The advantage of connecting the converter to the rotor is that variable-speed operation of the turbine is possible with a much smaller and therefore much cheaper converter. The power rating of the converter is often about 1/3 the generator rating. Another type of generator that has been proposed for wind turbines in several research articles is synchronous generator. This type of generator has the

capability of direct connection (direct-drive) to wind turbines, with no gearbox. This advantage is favorable with respect to lifetime and maintenance. Synchronous machines can use either electrically excited or permanent magnet (PM) rotor.

The PM and electrically-excited synchronous generators differ from the induction generator in that the magnetization is provided by a Permanent Magnet pole system or a dc supply on the rotor, featuring providing self-excitation property. Self-excitation allows operation at high power factors and high efficiencies for the PM synchronous generators.

The PM and electrically-excited synchronous generators differ from the induction generator in that the magnetization is provided by a Permanent Magnet pole system or a dc supply on the rotor, featuring providing self-excitation property. Self-excitation allows operation at high power factors and high efficiencies for the PM synchronous generators. It is worth mentioning that induction generators are the most common type of generator use in modern wind turbine systems.

A comparison between the variable speed wind turbine and the constant speed wind turbine shows that variable speed reduce mechanical stresses: gusts of wind can be absorbed, dynamically compensate for torque and power pulsations caused by back pressure of the tower. This backpressure causes noticeable torque pulsations at a rate equal to the turbine rotor speed times the number of rotor blades.

II. Permanent Magnet Generator

Figure 1 shows the cross-section of a typical Permanent Magnet Generator (PMG). The PMG differs from the Induction Generator in that the magnetization is provided by a Permanent Magnet Pole System on the rotor, instead of taking excitation current from the armature winding terminals, as it is the case with the Induction Generator. This means that the mode of operation is synchronous, as opposed to asynchronous. That is to say, in the PMG, the output frequency bears a fixed relationship to the shaft speed, whereas in the mains connected IG, the frequency is closely related to the network frequency, being related by the slip. These differences will be discussed at length. However, it must be recognized at the outset that the differences have a significant effect on the operating characteristics and performance of the two generator types.

Permanent magnet machines may be set in several categories, those with surface mounted magnets, those with buried magnets, those with damper windings, etc., etc. All categories where data was found were considered, as each has some special features to offer [3]. The advantages of PM machines over electrically excited machines can be summarized as follows according to literatures:

- Higher efficiency and energy yield,
- No additional power supply for the magnet field Excitation,
- Improvement in the thermal characteristics of the PM machine due to the absence of the field losses,
- Higher reliability due to the absence of Mechanical components such as slip rings,
- Lighter and therefore higher power to weight Ratio.

However, PM machines have some disadvantages, which can be summarized as follows:

- High cost of PM material,
- Difficulties to handle in manufacture,
- Demagnetization of PM at high temperature.

In recent years, the use of PMs is more attractive than before, because the performance of PMs is improving and the cost of PM is decreasing. The trends make PM machines with a full-scale power converter more attractive for direct-drive wind turbines. Considering the performance of PMs is improving and the cost of PM is decreasing in recent years, in addition to that the cost of power electronics is decreasing, variable speed direct-drive PM machines with a full-scale power converter become more attractive for offshore wind powers. On the other hand, variable speed concepts with a full-scale power converter and a single- or multiple-stage gearbox drive train may be interesting solutions not only in respect to the annual energy yield per cost but also in respect to the total weight. For example, the market interest of PMSG system with a multiple-stage gearbox or a single-stage gearbox is increasing.

III. Topologies For Isolated Operation Of Variable Speed Wind Driven Pmsg

Variable speed use is good for extracting more prime mover power as in wind turbine or for providing optimum efficiency for the prime mover by increasing its speed with power. Variable speed also allows for a more flexible generator system. For wind turbines, a battery may be added to store the extra wind energy that is not momentarily needed for the existing loads or local power grids. At variable speed, the DC link voltage is maintained constant by exchanging power with battery as shown in Fig. 1

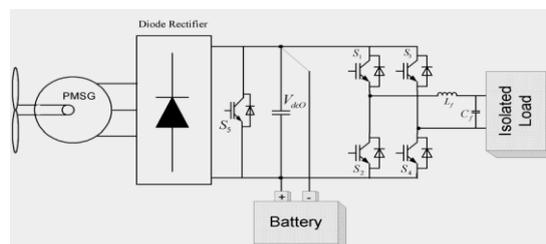

Fig.1 PMSG with PWM rectifier with battery for storing the extra wind energy

IV. Matlab Simulation Of The Proposed Topology

The MATLAB Simulation of proposed topology has been Shown in the Fig.2. The mat lab simulink tool box simpower Has been used for getting the required results.

V. Modeling Of Proposed System

A. Modeling of System

This section includes modeling of supply system (PMSG), load, controller etc. The relevant mathematical analysis is illustrated as follows.

B. Modeling of Supply system

The supply system consists of three-phase (PMSG) system, diesel engine and governor blocks. The model of permanent magnetsynchronousgenerator(PMSG)isrealized by consideringfixedexcitation of an alternator. The mathematical representation of all these are given below.

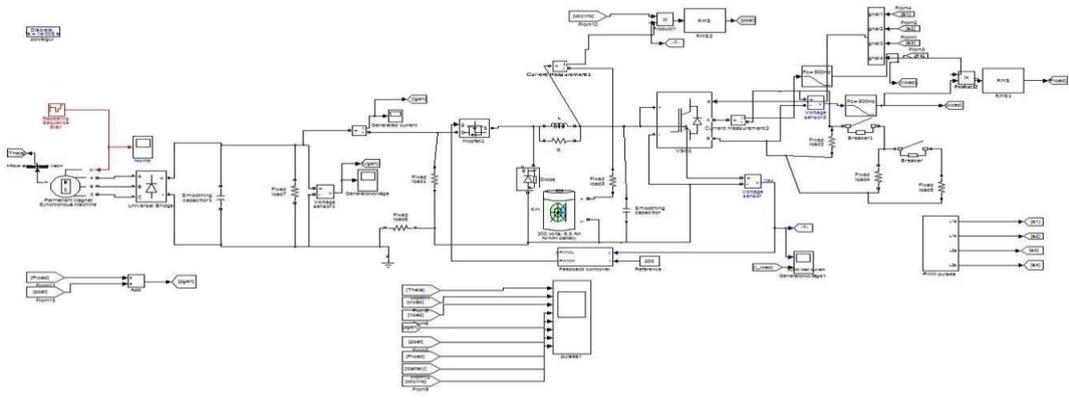

Fig.2. MATLAB Simulated model of PMSG connected to local Load

C. Modeling of Permanent Magnet Synchronous Machine

The permanent magnet synchronous machine block operates in generating or motoring modes. The operating mode is dictated by the sign of the mechanical power (positive for generating, negative for motoring). The electrical part of the machine is represented by a sixth-order state-space model. The model takes into account the dynamics of the stator and damper windings. The equivalent

frame (d-q frame). The following equations are used to express the model of the PMSG as:

$$V_d = R_s i_d + p \psi_d - \omega_r \psi_q \dots\dots\dots (1)$$

$$V_q = R_s i_q + p \psi_q + \omega_r \psi_d \dots\dots\dots (2)$$

$$V'_{fd} = R'_{fd} i'_{fd} + p \psi'_{fd} \dots\dots\dots (3)$$

$$V'_{kd} = R'_{kd} i'_{kd} + p \psi'_{kd} \dots\dots\dots (4)$$

$$V'_{kq1} = R'_{kq1} i'_{kq1} + p \psi'_{kq1} \dots\dots\dots (5)$$

$$V'_{kq2} = R'_{kq2} i'_{kq2} + p \psi'_{kq2} \dots\dots\dots (6)$$

Where

$$\psi_d = L_d i_d + L_{md} (i'_{fd} + i'_{kd}) \dots\dots\dots (7)$$

$$\psi_q = L_q i_q + L_{mq} i'_{kq} \dots\dots\dots (8)$$

$$\psi'_{fd} = L'_{fd} i'_{fd} + L_{md} (i_d + i'_{fd}) \dots\dots\dots (9)$$

$$\psi'_{kd} = L'_{kd} i'_{kd} + L_{md} (i_d + i'_{fd}) \dots\dots\dots (10)$$

$$\psi'_{kq2} = L'_{kq2} i'_{kq2} + L_{mq} i_q \dots\dots\dots (11)$$

Where the subscripts used are defined as: d, q: d and q axis quantity, r, s: Rotor and stator quantity, l, m: Leakage and magnetizing inductance, f, k: Field and damper winding quantity. R_s represents stator resistance, L_{ls} stator leakage inductance, L_{md} and

L_{mq} represent d-axis and q-axis magnetizing inductances. R'_f denotes field resistance and L_{lfd} leakage inductance both referred to the stator. Damper d-axis resistance R_{kd} and leakage inductance L_{lkd} , Damper q-axis resistance R_{kq1} and leakage inductance L_{lkq1} and the q-axis resistance R_{kq2} and leakage inductance L_{lkq2} . All these values are referred to the stator. All rotor parameters and electrical quantities are viewed from the stator and are identified by primed variables. The simplified synchronous machine block implements the mechanical system described by:

$$\Delta\omega(t) = \int (T_m - T_e) dt / (2H) - K_d \Delta\omega(t) \dots\dots\dots (12)$$

$$\omega(t) = \Delta\omega(t) + \omega_0 \dots\dots\dots (13)$$

D. Excitation System

The excitation system block is a Simulink system implementing an IEEE Type I synchronous machine voltage regulator combined to an exciter. The basic elements that form the excitation system block are the voltage regulator and the exciter. The exciter is represented by the following transfer function between the exciter voltage V_{fd} and the regulator's output E_f .

$$V_{fd}/E_f = 1/(K_e + sT_e) \dots\dots\dots (14)$$

where K_e represents exciter gain, T_e exciter time constant. The block uses actual terminal voltage, desired value of terminal voltage and outputs appropriate field voltage to be applied to synchronous alternator. For simulation of PMSG, the excitation is kept constant at 1.0 pu. in this model of synchronous generator.

E. Wind Turbine Modeling

This block implements a wind energy conversion system. The inputs are actual and desired speed and the output of the block is mechanical power (P_{ω}).

The amount of power harnessed from the wind of velocity is as follows.

$$P = 1/2 \rho A C_v^3 \quad (15)$$

Where

P_{ω} = wind power in watts

ρ = air density in kg/m^3

A = swept area in m^2

C_p = power coefficient of wind turbine

v = wind speed in m/s

VI. Simulation Results

The Fig.3 show the Variation of load voltages, load currents, generator power, battery power, , load power battery current & d c voltage. The rating of the PMSG is given in the Appendix.

VII. CONCLUSION

This paper discuss a distributed generation based stand alone wind energy conversion system (WECS) using a variable speed permanent magnet synchronous generator (PMSG) with PWM rectifier and a battery for storing the extra wind energy. According to the proposed topology, Battery energy storage system provides power balance between the generated power and the load. The power mismatch is absorbed by the BESS

Rehab Assistance for Hansen Diseased Patients

A. N. Nithyaa, R. Prem Kumar

(Dept. of Biomedical Engineering, Rajalakshmi Engineering College,
Thandalam, CHENNAI – 602105).

Abstract: Hansen disease is a chronic disease caused by a bacillus, *Mycobacterium leprae*. According to World Health Organization's latest estimate, among 35% of leprosy cases in India, 48,000 are women. The side effects are permanent disability of hands, feet or eyes. Hansen disease can damage the peripheral nerves and nerves in the skin. This damage can lead to loss of sweat and oil gland function which causes dry and cracked skin on the hands and feet, loss of the ability to feel light touch or, with more severe damage, loss of protective sensation, weakness of the eyelids, preventing proper closure of the lid which protects the eye, loss of strength in the hands and feet. Therefore our main objective is to design a glove for Hansen diseased patients. It is a smart glove with an inbuilt sensor network and data acquisition system for storing the information for the Hansen diseased patients. The main purpose of the system is to provide alertness to the Hansen diseased patients with an assistive device that can improve their confidence and daily independence. Therefore this proposal may prove to be a breakthrough in the medical field and a step towards the enhancement of life and safety of human race.

Key Words: Hansen Disease, Leprosy, SMART GLOVE, ASSISTIVE DEVICE

I. Introduction

Hansen disease is also called Leprosy. Hansen disease is caused by the organism *Mycobacterium leprae*. It is defined as a chronic bacterial disease affecting mainly skin and nerves. If untreated, there can be progressive and permanent damage to the skin, nerves, limbs and eyes. It is a major public health problem in most of the developing world and is often found in conditions connected with poverty, overcrowding, poor sanitation and insufficient nutrition. According to current World Health Organization's data, the current global prevalence rate is around 1.4 cases per 10,000 people. Around 5, 00,000 new cases of leprosy are registered each year. India alone has about 5, 00,000 infected people, which represents 63% of the global occurrences.

Leprosy, a chronic infectious disease that, if left untreated, can cause debilitating deformities and slowly progress throughout one's life. It is characterized by peripheral nerve damage, cutaneous lesions and a wide range of clinical manifestations. The major side effects are permanent disability of hands, feet or eyes. Hansen disease can damage the peripheral nerves and nerves in the skin. This damage can lead to loss of sweat and oil gland function which causes dry and cracked skin on the hands and feet, loss of the ability to feel light touch or, with more severe damage, loss of protective sensation, weakness of the eyelids, preventing proper closure of the lid which protects the eye, loss of strength in the hands

and feet. In order to contract the disease, one has to live in close contact with an infected individual for a prolonged amount of time. These physical effects paired with the social stigma of being infected with this dreaded disease, often lead to those affected being afraid to come forward to seek treatment in the early stages of the disease. Hence there arises a need for rehabilitation.

II. A step towards rehabilitation

The basic concepts behind rehabilitation are that the persons affected with Hansen disease should be restored back to normal social life or as near as possible. Rehabilitation means restoration of economic productivity leading to economic independence. In India economic independence outweigh many other considerations. Rehabilitation in the field of Hansen disease requires greater efforts than the rehabilitation in other types of disabled persons because the question of social acceptance does not arise in non-Hansen disease disabled persons. In the case of a orthopedically handicapped or a blind or deaf person their stay with the family is not prejudiced as in the case of Hansen disease patients. This is due to the stigma attached to the disease. Therefore our paper is a step towards restoring their normal live. Being known the virulence of this disease, most of the research is based on its cure. Some of the existing treatments include drug therapy and chemotherapy. Also steps are being taken to eradicate and to a larger extend control its spread. A step towards rehabilitation is yet to catch up its pace. The main objective of this paper is to design a glove for Hansen diseased patients in order to alert them in case of any physical parameter extremity such as pressure or temperature using an inbuilt sensor network and a data acquisition system for storing the information acquired from the sensor for further analysis.

Fig 1. Picture of a person with Hansen disease(Hansen's disease)

III. General Block Diagram

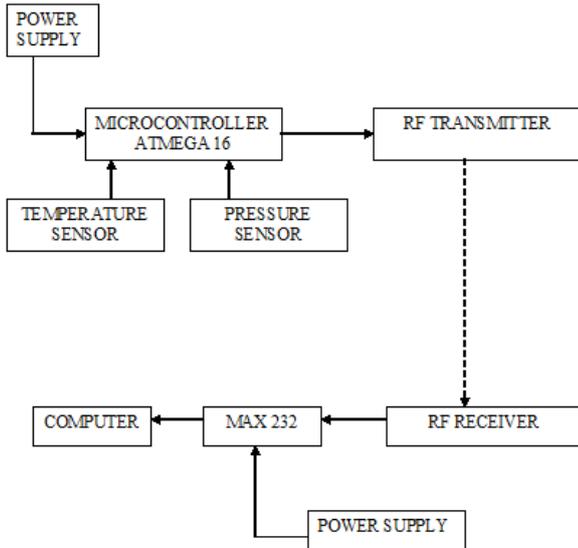

Fig 2. General Block Diagram

3.1 Description of Block Diagram

The block diagram represents the overall working of the glove. In the transmitter part, a temperature and a pressure sensor is used. The temperature sensor used here is LM35 and pressure sensor is FLEXIFORCE. The microcontroller ATMEGA 16 a low-power CMOS 8-bit microcontroller, which acquires the input from the sensors. To drive the microcontroller a power supply is given. These sensors give input to the controller in terms of voltage. The controller is programmed to send the analog voltage to the RF transmitter. At the other end a RF receiver module is placed which obtains the signal from the transmitter. MAX 232 is a level shifter which converts CMOS input levels into RS232 levels. RS-232 (Recommended Standard 232) is a standard for serial binary single-ended data and control signals connecting between a DTE (Data Terminal Equipment) and a DCE (Data Circuit-terminating Equipment). Now the digital values thus obtained is processed in SMART SOFTWARE supported by .NET. It is programmed in such a way that when the temperature and pressure reaches its extremities, indication is shown to the patient through alarm and LED glow respectively.

3.1.1.1 Transmitter Module

Transmitter module has the following components:

- LM35 sensor
- Flexi force sensor
- ATMEGA 16
- Power supply

LM35 sensor

Temperature measurement is very important in all spheres of life. Taking a temperature essentially requires the transmission of a small portion of an object's thermal energy to the sensor, whose function is to convert that energy into an electrical signal. When a contact sensor (probe) is placed inside or on the object, heat conduction takes place through the interface between the object and the probe. Contact temperature sensors measure their own temperature. One infers the temperature of the object to

which the sensor is in contact by assuming or knowing that the two are in thermal equilibrium, that is, there is no heat flow between them. Non Contact Sensors - Most commercial and scientific non contact temperature sensors measure the thermal radiant power of the Infrared or Optical radiation that they receive from a known or calculated area on its surface, or a known or calculated volume within it (in those cases where the object is semitransparent within the measuring wavelength pass band of the sensor). One then infers the temperature of an object from which the radiant power is assumed to be emitted (some may be reflected rather than emitted).

The LM35 series are precision integrated-circuit temperature sensors, whose output voltage is linearly proportional to the Celsius (Centigrade) temperature. The LM35 thus has an advantage over linear temperature sensors calibrated in ° Kelvin, as the user is not required to subtract a large constant voltage from its output to obtain convenient Centigrade scaling. The LM35 does not require any external calibration or trimming to provide typical accuracies of $\pm 1/4^{\circ}\text{C}$ at room temperature and $\pm 3/4^{\circ}\text{C}$ over a full -55 to $+150^{\circ}\text{C}$ temperature range. Low cost is assured by trimming and calibration at the water level. The LM35's low output impedance, linear output, and precise inherent calibration make interfacing to readout or control circuitry especially easy. It can be used with single power supplies, or with plus and minus supplies. As it draws only 60 μA from its supply, it has very low self-heating, less than 0.1°C in still air. The LM35 is rated to operate over a -55° to $+150^{\circ}\text{C}$ temperature range.

Flexi force Sensor

Pressure is defined as the normal force per unit area exerted by a fluid (liquid or gas) on any surface. It should be noted that pressure is not defined as a vector quantity and is therefore non directional.

Flexi force pressure sensors can measure force between almost any two surfaces and is durable enough to stand up to most environments. Flexi force has better sensor properties, linearity, hysteric, drift and temperature sensitivity than any other thin film force sensor. Its single element sensor acts as a resistor in an electrical circuit. When the sensor is unloaded, its resistance is very high. When a force is applied to the sensor, this resistance decreases. The resistance can be read by connecting an ohm meter to the outer two pins of the sensor connector and applying a force to the sensing area. There are many ways to integrate the sensor into an application. One way is to incorporate it into a force-to-voltage circuit. A means of calibration must be established to convert the output into the appropriate engineering units. Depending on the setup, an adjustment could then be done to increase or decrease the sensitivity of the sensor.

The Flexi Force sensor is an ultra-thin and flexible printed circuit, which can be easily integrated into most applications. With its paper-thin construction, flexibility and force measurement ability, the Flexi Force sensor can measure force between almost any two surfaces and is durable enough to stand up to most environments. Flexi Force has better force sensing properties, linearity, hysteric, drift, and temperature sensitivity than any other thin-film force sensors. The "active sensing area" is a $0.375''$ diameter circle at the end of the sensor. The sensors are constructed of two layers of substrate. This

substrate is composed of polyester film (or Polyimide in the case of the High-Temperature Sensors). On each layer, a conductive material (silver) is applied, followed by a layer of pressure-sensitive ink. Adhesive is then used to laminate the two layers of substrate together to form the sensor. The silver circle on top of the pressure-sensitive ink defines the “active sensing area.” Silver extends from the sensing area to the connectors at the other end of the sensor, forming the conductive leads. Flexi Force sensors are terminated with a solder able male square pin connector, which allows them to be incorporated into a circuit. The two outer pins of the connector are active and the center pin is inactive. The length of the sensors can be trimmed by Tekscan to predefined lengths of 2”, 4” and 6” or can be trimmed by the customer. If the customer trims the sensor, a new connector must be attached. This can be accomplished by purchasing staked pin connectors and crimping tool. A conductive epoxy can also be used to adhere small wires to each conductor. The sensor acts as a variable resistor in an electrical circuit. When the sensor is unloaded, its resistance is very high (greater than 5 Meg-ohm); when a force is applied to the sensor, the resistance decreases. Connecting an ohmmeter to the outer two pins of the sensor connector and applying a force to the sensing area can read the change in resistance. Sensors should be stored at temperatures in the range of 15°F (-9°C) to 165°F (74°C).

Fig 3. Flexi force Sensor

ATmega16

The ATmega16 is a low-power CMOS 8-bit microcontroller based on the AVR enhanced RISC architecture. By executing powerful instructions in a single clock cycle, the ATmega16 achieves throughputs approaching 1 MIPS per MHz allowing the system designer to optimize power consumption versus processing speed. The ATmega16 provides the following features: 16 Kbytes of In-System Programmable Flash Program memory with Read-While-Write capabilities, 512 bytes EEPROM, 1 Kbytes SRAM, 32 general purpose I/O lines, 32 general purpose working registers, a JTAG interface for Boundary scan, On-chip Debugging support and programming, three flexible Timer/Counters with compare modes, Internal and External Interrupts, a serial programmable USART, a byte oriented Two-wire Serial Interface, an 8-channel, 10-bit ADC with optional differential input stage with programmable gain (TQFP package only), a programmable Watchdog Timer with Internal Oscillator, an SPI serial port, and six software selectable power saving modes. The Idle mode stops the

CPU while allowing the USART, Two-wire interface, A/D Converter, SRAM, Timer/Counters, SPI port, and interrupt system to continue functioning. The Power-down mode saves the register contents but freezes the Oscillator, disabling all other chip functions until the next External Interrupter Hardware Reset. In Power-save mode, the Asynchronous Timer continues to run, allowing the user to maintain a timer base while the rest of the device is sleeping. The ADC Noise Reduction mode stops the CPU and all I/O modules except Asynchronous Timer and ADC, to minimize switching noise during ADC conversions. In Standby mode, the crystal/resonator Oscillator is running while the rest of the device is sleeping. This allows very fast start-up combined with low-power consumption. In Extended Standby mode, both the main Oscillator and the Asynchronous Timer continue to run. The device is manufactured using Atmel’s high density nonvolatile memory technology. The On chip ISP Flash allows the program memory to be reprogrammed in-system through an SPI serial interface, by a conventional nonvolatile memory programmer, or by an On-chip Boot program running on the AVR core. The boot program can use any interface to download the application Program in the Application Flash memory. Software in the Boot Flash section will continue to run while the Application Flash section is updated, providing true Read-While-Write operation. By combining an 8-bit RISC CPU with In-System Self-Programmable Flash on a monolithic chip, the Atmel ATmega16 is a powerful microcontroller that provides a highly-flexible and cost-effective solution to many embedded control applications.

Power Supply

Using the circuit shown in Figure 13, the following voltages at a current limited to one ampere are obtained (3V, 4.5V). The AC main is stepped down by transformer X1 to deliver the secondary output of 18V AC at a maximum current of 1A dependent on the load. The transformer output is rectified by the bridge rectifier comprising diodes D1 through D4, filtered by capacitor C1 and to regulator IC LM317, which is a 3 terminal positive regulator capable of providing 1.2V to 37V at 1.5A current to the load Resistor R3 and R2 are used to produce 3 V at the output, Similarly Resistor R5 and R4 are used to produce 4.5 V at the output.

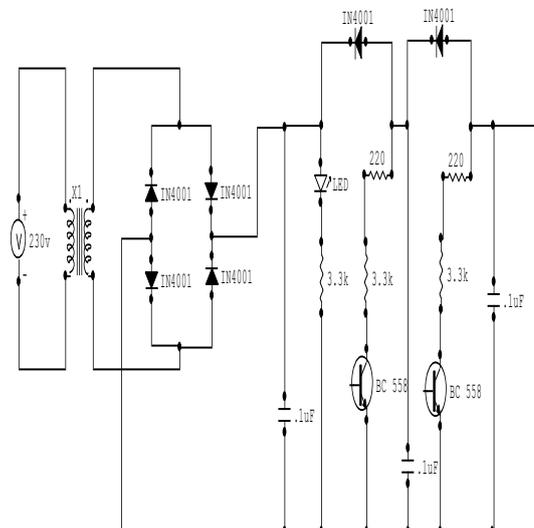

Fig 4. Power Supply

Capacitors. C2 and C3 bypass any ripple in the output. Diodes D5 and D6 are used as the protection diode. Heat sink is used for IC LM 317 to dissipate the heat from it. The LM386 is a power amplifier designed for use in low voltage consumer applications. The gain is internally set to 20 to keep the external part count low, but the addition of an external resistor and capacitor between pins 1 and 8 will increase the gain to any value from 20 to 200. The inputs are ground referenced while the output automatically biases to one-half the supply voltage. The quiescent power drain is only 24 mill watts when operating from a 6-volt supply, making LM386 ideal for battery operation

3.1.1.2 Receiver Module

The receiver module has the following components:

- Level Shifter
- MAX 232
- RF Module

MAX 232

The MAX232 is a dual driver/receiver that includes a capacitive voltage generator. Each receiver has a typical threshold of 1.3 V and a typical hysteresis of 0.5 V, and can accept ± 30 -V inputs. Each driver converts CMOS input levels into RS232 levels.

RF Module

RS-232 (Recommended Standard 232) is a standard for serial binary single-ended data and control signals connecting between a DTE (Data Terminal Equipment) and a DCE (Data Circuit-terminating Equipment). It is commonly used in computer serial ports. The signal levels for RS-232 represent a digital 1 bit as a voltage in the range of 5 to 12 V on the wire, and a digital 0 bit as a voltage of negative 5 to 12 V on the wire. RS-232 is typically implemented in a full duplex fashion, since each station can transmit to the other simultaneously using separate wires. RS-232 can be made to operate at a variety of bit rates, but typically is used at bit rates from 300 bit/s up to 115,200 bit/s.

IV. Conclusions

An Alarm is used and if there is any abnormal condition, it will initiate the buzzer. This alarm will alert the patient. Once the abnormality is rectified, the buzzer is terminated. Light emitting diodes are simply LEDs function in converting the voltage and exhibiting it in the form of light. They are used as indicators. These like alarms, are used to indicate abnormal conditions. They glow when the ideal conditions are disturbed. This is used to indicate pressure abnormality. In our paper the transmitter and receiver module is miniaturized. Also a data acquisition system is used to transfer the data. Thus smart glove is highly reliable and low cost. The main aim of this paper is to assist the Hansen diseased patients in order to alert them in case of any physical extremities.

ABSTRACT: This paper introduces a new reversible and blind scheme based on the analysis of Multi-band Dual Tree Wavelet domain in medical image watermarking domain. Different from many other watermarking schemes with wavelet transform are used on one side in which the studies have dealt only in the dyadic case, in the other hand, in multi-band only on the classical discrete wavelet (DWT), for this suggested approach: security issues for medical information and technical solution to protect these data in medical information are examined. A solution is proposed, which consist in watermarking image areas that are not relevant for the diagnosis, considering advantages of multi-bands wavelet analysis. Applications of the method were examined for MRI images watermarking, inserting data in different sub-bands with private key provides high security for the embedded data using discrete wavelet and complex wavelet (CWT) domain. Experimental results obtained from several watermarked medical images indicate imperceptibility, in each case; the CWT provides higher capacity than the real DWT and DWT domain, by increasing the number of bands. The system is transparent to the user and allows image integrity control; in addition it provides information on the location of potential alterations and evaluation of image modifications which is of major importance in medico-legal frame-work. The proposed method generalizes the findings of previous works.

Keywords: Dual-tree wavelets, medical image, watermarking, multi-band wavelets, watermarking.

I. INTRODUCTION

Medical image protection and authenticity are becoming increasingly important in an e-health era where images are readily distributed over electronic networks. Research has shown that medical image watermarking is a relevant process for enhancing data security, content verification and image fidelity. At the same time, it is necessary to preserve as much original information in the image data as possible, to avoid causing performance loss for human viewers. Most medical image watermarking research focuses on developing watermarking systems that preserve image fidelity and/or robustness, under typical non-medical image degradation processes.

The Digital Imaging and Communications in Medicine (DICOM) standard is the standard to exchange medical data. The DICOM medical image files are attached with header containing patient information which may be lost, attacked or disordered with other header file. However, the watermarking method of medical images using patient information overcomes these problems [1]. However, there is a challenge that interleaving data in a medical image

must not affect the image quality as this may result in wrong diagnosis.

The most promising Dual-Tree wavelet Transform (DTT) proposed by N. Kingsbury, used two classical wavelet trees developed in parallel, looking into the benefits, such as good directional selectivity, shift invariance and perfect signal reconstruction (PR) [2]

The implementation of DT-CWT use couple of filters $\{h_0(n), h_1(n)\}$ to implement one separable wavelet transform and uses another filters couple $\{g_0(n), g_1(n)\}$ to implement [3]. Applying both separable transformations to the some 2D data gives a total of six sub bands: two HL, two LH and two HH subbands.

Being motivated by several applications and advantages of the complex wavelet decomposition in the images processing, we focus our approach by working to put the multi-band extension case to its best directional selectivity and the choice of analysis. This new transform found several applications in image processing, especially that we will exploit in watermarking images [4, 5].

Caroline Chaux proposed the construction of 2D dual-tree M-band wavelet decomposition and suggested that this analysis is the best way in the context of de-noising or higher dimension signal processing [4].

In this paper we presented an extension to M-DT-CWT and, the previously works of Xiangui Kang in [6] and Ning Bi [7] where only the standard DWT have been used.

Taking into account of limitations of DWT, we want to exploit the benefits of DT-CWT by incorporating the principal component analysis (PCA).

Previous work

This paragraph presents, an overview of the important existing watermarking schemes based on wavelet transform in medical domain and other research areas.

We will present them into two cases, dyadic and multi-band cases.

In dyadic case a lots of watermarking schemes are presented in the literature, only with the standard DWT.

Giakoumaki.A and al (2004) proposed a wavelet-based multiple watermarking scheme, which addresses the problems of medical confidentiality protection and both origin and data authentication, this scheme embeds multiple watermarks serving different purposes; a robust watermark for authentication a fragile watermark for the purpose of data integrity control, the scheme added-value tool offers alternatives for different issues associated with medical data management and distribution [8].

Salwa.A. and al(2010) proposed a new method for protecting the patient information in which the information

is embedded as a watermark in the discrete wavelet packet transform (DWPT) of the medical image using the hospital logo as a reference image. The patient information is coded by an error correcting code (ECC), BCH code, to enhance the robustness of the proposed method [9].

Golpina.H andDanyali.H (2009) have proposed a blind reversible watermarking approach for medical images based on histogram shifting in wavelet domain. An integer wavelet transform is applied to map the integer host image components to integer wavelet coefficients. Enabling lossless reconstruction of both watermark and host image, besides providing the high quality for the watermarked image [10].

Cheng-RI and al (2008) proposed a new fragile watermarking algorithm for medical images that makes it possible to resolve the security and forgery problem of the medical images with the discrete wavelet transform, an integer wavelet transform is used to utilize hash function. The watermark associated with the hash values is inserted into the LSBs of the integer wavelet transform coefficients, it can be confirmed that the proposed algorithm detects a forged area of the image very well [11].

ChokriChemak and al(2007) suggested to use the watermarking scheme which preserved the security of medical images for the pocketNeuro project,for reason that image watermarking allows doctors and personnel to hide invisible and robust medical information about a patient [12].

R. Mavudila and al present an algorithm based on dual-tree transform wavelet domain for medical image watermarking, a method that presents a good compromise between robustness and integrity [13]. However only few watermarking methods have been developed willingly the rich properties of dual tree transform wavelet.

With M-band wavelet transform approaches we can observe the works of Ning and al in [7] proposed a blind watermarking scheme based in the multi-band wavelet domain and Empirical mode decomposition.

Xiangui Kang and al, present a new multi-band wavelet scheme by incorporating the principal component analysis (PCA), a blind watermarking technique which achieved higher perceptual transparency and stronger robustness only with the classical Discrete Wavelet Transform (DWT) [6].

We take this latter watermarking embedding strategy in our proposed scheme; particularly we embed watermark bits indirectly in the m-band Dual tree wavelets domain with $M \geq 2$.

II. M-BAND DUAL TREE ANALYSIS (M-DTT)

Given the earlier works of watermarking images based on wavelet transform, we will apply our watermarking by using multi-band ($M \geq 2$ band) in DWT and complex wavelet (CWT) cases, in order to draw good result for a better comparative study.

2.1.Dual-tree Complex Transform (DT-CWT)

The Dual Tree Wavelet Transform initially proposed by N. Kingsburg and further investigated by I. Selesnick, analyses the signal by two DWT trees different with the filters chosen so that at the end of process it returns to approximately the decomposition by analytic wavelet.

The algorithm uses two different sets of filters: h_1 and g_1 , high-pass filters of first and second tree and h_0 and g_0 low-pass first and the second tree. The first tree produces the coefficients of the real part $dr(j, k)$ and the second tree those of the imaginary part $di(j, k)$, we then construct complex coefficients:

$$dcomplex(j, k) = dr(j, k) + i di(j, k). \quad (1)$$

The DT-CWT presents the advantages over simple Hilbert transform of the signal [14].

This implementation uses consists in analyzing the signal by two different DWT trees, with filters chosen so that at the end, the signal returns with the approximate decomposition by an analytical wavelet.

The dual-tree structure has an extension of conjugate filtering in 2-D case.

This structure needs four trees for analysis as well as for synthesis. The pairs of conjugate filters are applied to two dimensions (0 and 1), which can be expressed as:

$$\begin{aligned} (h_0 + jg_0)(h_1 + jg_1) \\ = (h_0h_1 - g_0g_1) + j(h_0g_1 + g_0h_1) \end{aligned} \quad (2)$$

The synthesis of filters suitable for this structure was performed by several people.

The wavelet corresponding to the tree's "imaginary part" is very close to the Hilbert transform of the wavelet corresponding to the trees "real part" [15].

For J level decomposition, the corresponding details sub bands at leven η are denoted: $HL\eta$ real, $HL\eta im$, $LH\eta real$, $LH\eta im$, $HH\eta real$ and $HH\eta im$, where $\eta = 1, 2, \dots, J$.

2.2.M-band Discrete Wavelet Transform (M-DWT).

As reminder that one dimensional dyadic case ($M=2$), is a scaling function $\Phi(x) \in L^2(\mathbb{R})$ and M-1 wavelet function $\{\varphi_l(x), 1 \leq l \leq M-1, M > 2\}$ [16,17] in M-band analysis, these functions satisfy the following equations respectively

$$\Phi(x) = \sum_{k \in \mathbb{Z}} h_1(k) \Phi(Mx - k) \quad (3)$$

$$\varphi_l(x) = \sum_{k \in \mathbb{Z}} h_l(k) \Phi(Mx - k) \quad (4)$$

$$1 \leq l \leq M - 1$$

Where \mathbb{Z} is the integer set and sequence $\{h_l(k), 0 \leq l \leq M-1\}$ has finite length.

The one dimensional Mallat decomposition and reconstruction formulas of orthogonal M-band wavelet are expressed in (5) and (6) respectively [16]

$$C_{j+1} = \sqrt{M} \sum_{k' \in \mathbb{Z}} C_j(k') h_0(k' - Mk) \quad (5)$$

$$d_{j+1} = \sqrt{M} \sum_{k' \in \mathbb{Z}} d_j(k') h_1(k' - Mk)$$

$$1 \leq l \leq M - 1$$

$$C_j(k) = \sqrt{M^{-1}} \sum_{k' \in Z} C_{j+1}(k') h_0(k' - Mk) + \sqrt{M^{-1}} \sum_{l=1}^{M-1} \sum_{k' \in Z} d_{j+1}^l(k) h_1(k' - Mk)$$

$$1 \leq l \leq M - 1 \tag{6}$$

Where $\{C_{j+1}(k), j = 1, 2, \dots, \}$ is the approximation coefficients of the j+1 level M-band wavelet decomposition of 1D signal $C_0(k)$ and $\{d_{j+1}^l(k); j = 0, 1, 2, \dots, \}$ is the detail coefficient of the J+1 level band wavelets decomposition.

For the image, the 1D M-band discrete wavelet transform is easy to extend to 2D M-band wavelet transform, by applying 1D MDWT

2.3. M-band Dual-Tree (M-DTT)

This implementation uses consisting of analyzing the signal by two different MDWT trees, primal and who gives the real and imaginary coefficients respectively.

The M-band -DT-CWT employs two real M-band DWT.

The first M-DWT gives the real part of the transform while the second MDWT gives the imaginary part.

Let $h_0(n), h_1(n)$ denote the low-pass/high-pass filter and $g_0(n), g_1(n)$ denote the low-pass/high-pass for upper and lower filter banc respectively.

For the scaling function $\Phi^H(x) \in L2(R)$ and M-1 wavelet functions $\{\varphi_l^H(x), 1 \leq l \leq M - 1, M > 2\}$

The equations (3, 4, 5 and 6) precedents can be used at the primal tree (real part).

In parallel the decomposition applying at dual tree (imaginary part) gives:

$$\Phi^H(x) = \sum_{k \in Z} h_1(k) \Phi^H(Mx - k) \tag{7}$$

$$\varphi_l^H(x) = \sum_{k \in Z} h_1(k) \Phi^H(Mx - k) \tag{8}$$

$$1 \leq l \leq M - 1$$

$$C_{j+1}^H(k) = \sqrt{M} \sum_{k' \in Z} C^H(l) g_0(k' - Mk) \tag{9}$$

$$d_{j+1}^H(k) = \sqrt{M} \sum_{k' \in Z} d_{j+1}^H(k') g_1(k' - Mk)$$

and

$$C_j^H(k) = \sqrt{M^{-1}} \sum_{k' \in Z} C_{j+1}^H(k') g_0(k' - Mk) + \sqrt{M^{-1}} \sum_{l=1}^{M-1} \sum_{k' \in Z} d_{j+1}^H(k) g_1(k' - Mk) \tag{10}$$

Where $\{C_{j+1}^H(k), j = 1, 2, \dots, \}$ are approximation coefficients of the j+1 level M-band wavelet decomposition of 1D signal $C^H(k)$ and $\{d_{j+1}^H(k); j = 0, 1, 2\}$ are the detail coefficients of the J + 1 level band wavelets decomposition.

For the image, the one dimensional DT-CWT M-band can be extended to using the procedure described in section 2 above.

III. WATERMARK EMBEDDING METHOD

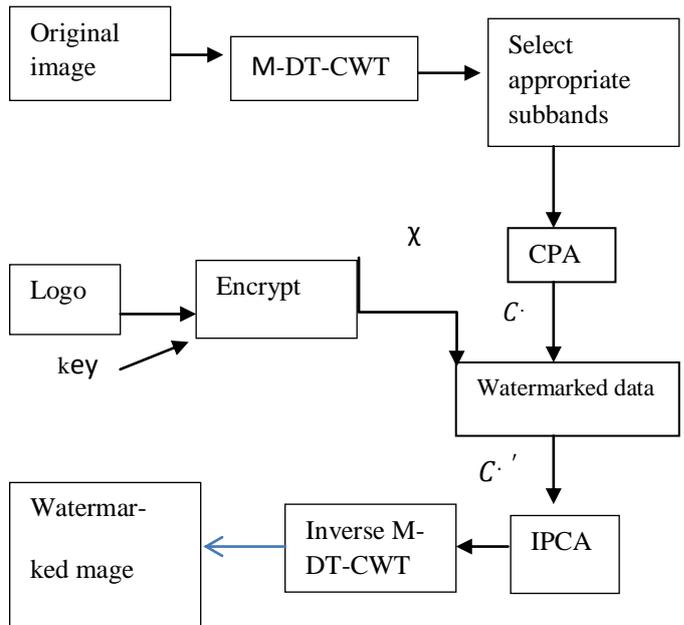

Fig.1. Diagram of embedding watermark

We extend the approach developed in [6], in DT-CWT analyzed an image with DT-CWT equivalent to use two DWT in each tree respectively, in real part and imaginary part.

In this study we will have two components, Primal (real coefficients) and dual (imaginary coefficients).

We consider the watermark logo image Figure 2. encrypted using a 2D pseudo-random sequence with the same size of the logo.

1. The 2D pseudo-random binary (0 and 1) sequence is generated by a key. The binary image logo is XOR operated with the 2D pseudo-random sequence and is raster scanned to obtain a 1D watermark sequence = $\{xi\}, (1 < i < N)$, which is composed of -1 and 1. The occurrence probability of -1 or 1 in X is close to 0.5 because the above encrypting binary sequence is pseudo random sequence (PN).
2. One one level, forward M-band Dual-tree wavelet decomposition is applied to the host medical image I(x,y) we obtain one approximation subband and fifteen detail subbands in each tree (primal and dual) [4,17].
3. Then the coefficients corresponding to the same spatial location in all detail subbands form a one dimensional data array:

$$g_i^1 = (g_i^1.1, g_i^1.2, g_i^1.3, \dots, g_i^1.16) \text{ (Primal tree)}$$

$$g_i^2 = (g_i^2.1, g_i^2.2, g_i^2.3, \dots, g_i^2.16) \text{ (Dual tree)}$$

$1 < i < N$, e.g., a vector of a total of fifteen coefficients, one per subband.

4. The principal component analysis (PCA) is used to transform a coefficient corresponding to the same spatial location in all detail subband [6], it is applied to the obtained ones dimensional matrices are calculated in the tree as follows:

$$V^1 = E(g_i^1 \times g_i^1 T) \\ V^2 = E(g_i^2 \times g_i^2 T)$$

where the g_i is the i -th one dimensional data array, E denotes expectation operation and T denotes the matrix transpose operation.

-The eigenvectors Φ (basis function) corresponding to eigenvalue ζ of the covariance matrix respectively:

$$V^1 \cdot V^1 \zeta \Phi^1 \text{ and } V^2 \cdot V^2 \zeta \Phi^2$$

Where eigenvectors Φ are sorted in descending order:

$$\Phi^1 = (\varphi_1^1, \varphi_2^1, \varphi_3^1, \dots, \varphi_{16}^1)$$

$$\Phi^2 = (\varphi_1^2, \varphi_2^2, \varphi_3^2, \dots, \varphi_{16}^2)$$

-Then calculate the PCA components;

$$p^1 i = \Phi^1 T g^1 i = (p^1 i.1, p^1 i.2, p^1 i.3, \dots, p^1 i.16)$$

(Primal tree)

$$p^2 i = \Phi^2 T g^2 i = (p^2 i.1, p^2 i.2, p^2 i.3, \dots, p^2 i.16) \text{ (Dual tree).}$$

In the following, we can write the data with $(.)$ to indicate 1 or 2 for defined the real and imaginary parts respectively (e.g. $C \cdot$ instead of C^1 or C^2).

4. All the obtained first principle components $p \cdot i.1$ ($1 < i < N$) from a 1-D array $\{C \cdot \{C \cdot (i)\} | C \cdot (i) = \{p \cdot i.1, 1 < i < N\}$ in the same raster scanning fashion as in step:

1. Finally, watermark X is embedded in the principle components $C \cdot$ using quantization-based method [18,19,20] equation (11) to obtain $C \cdot'$, where $C \cdot (i)$ and $C \cdot' (i)$ denote the i -th element in $C \cdot$ and $C \cdot'$, respectively. The quantizer $q(\cdot)$ is a uniform, scalar quantization function of step size S , and $q(x) = kS + 0.5S$,

$$k = x \left\lfloor \frac{x}{S} \right\rfloor \quad (k \in Z)$$

Where $\lfloor \cdot \rfloor$ denotes the floor operation.

The embedding strength S can be chosen so as, to achieve a good compromise between the contending requirements of imperceptibility and robustness. Note that the difference between $C \cdot (i)$ and $C \cdot' (i)$ is between $-0.5S$ and $+0.5S$.

If $x = -1$, $C \cdot (i) \bmod S = 0.25S$. If $x_i = +1$, $C \cdot (i) \bmod S = 0.75S$.

Where \bmod denotes the signed remainder after division.

5. Apply inverse PCA on the modified PCA components to obtain the modified one dimensional wavelet coefficients array.

6. Performing inverse M-band DT-CWT on the modified image coefficients, we obtain a watermarked image $\Gamma'(x, y)$.

$$\begin{cases} C \cdot' (i) = g \left(C \cdot (i) - \frac{1}{4S} \right) + \frac{1}{4S}, & \text{if } x_i = 1 \\ C \cdot' (i) = g \left(C \cdot (i) + \frac{1}{4S} \right) - \frac{1}{4S}, & \text{if } x_i = -1 \end{cases} \quad (11)$$

$$x_i^* = \begin{cases} +1, & r = C \cdot^*(i) \bmod S > S/2 \\ -1, & \text{otherwise} \end{cases} \quad (12)$$

Watermark detection

The watermark extraction is the inverse process of watermark embedding. The test image is M DT-CWT decomposed, then PCA is applied, and the first principle components are obtained to form a 1-D array $C \cdot^* \{C \cdot^* (i), (1 < i < N)\}$. $C \cdot^* (i)$ is the extracted principle component. According to equation (12), we can extract the hidden binary data $X^* \{x \cdot^* (i), (1 < i < N)\}$.

Equation (12) indicates that if $r (r = C \cdot^*(i) \bmod S)$ is in the interval $(0, 0.5S)$, then the decision is made in favor of " $x_i^* = -1$ ". Otherwise, " $x_i^* = 1$ ". Then following correlation coefficient is used to decide if the watermark exists in the test image

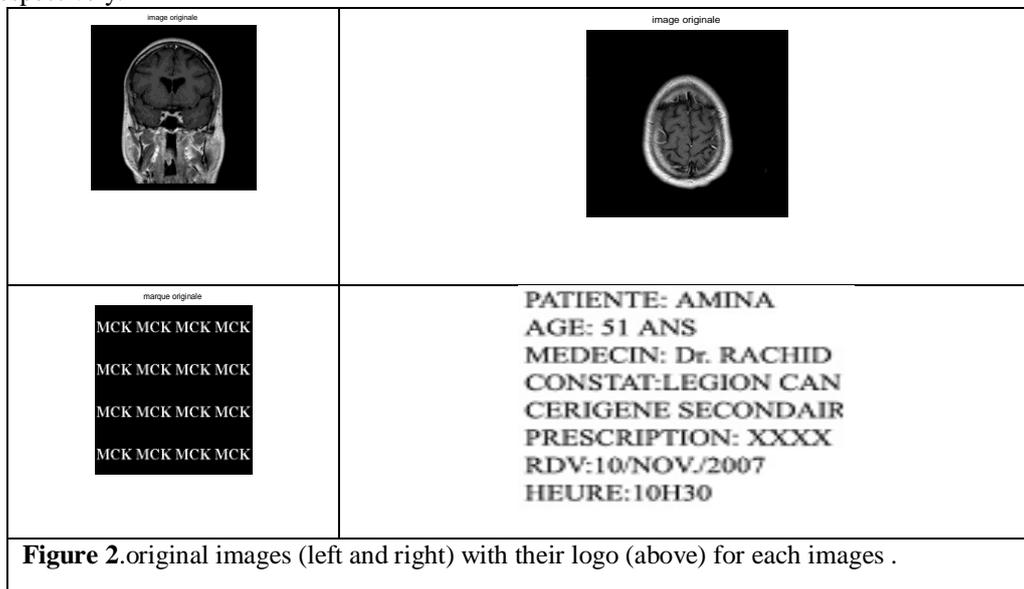

$$p_{x, x^*} = \frac{x \cdot x^*}{\|x\|} \quad (14)$$

where $\|x\|$ is the size of the watermark X (that is N in this paper) and $x \cdot x^*$ is the inner product of X and the extracted sequence X^* .

If the correlation coefficient between the embedded sequence X and the extracted sequence X^* from a test image is larger than a threshold (δ), i.e. $p_{x, x^*} \geq \delta$, we can determine that watermark exists and we write "1", or "0" if no [21].

IV. Results and Discussion

The proposed approach has been tested for two MRI images of the size 250x250 shown in 'Fig.2', with their logo images (watermark) respectively.

The data obtained, shows that 3-band leads to visually better results and the details are well explained in ‘Fig.3 and 4’, compared to the case of 2-band.

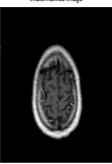

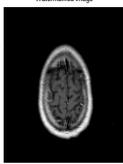

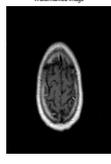

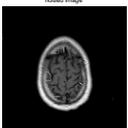

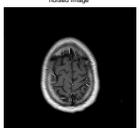

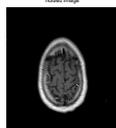

If we exploit only a process for dyadic case the best results are for CWT following real DWT see the benefits of DT-CWT and advantages of M-band in statically characteristic processing in noise study, mentioned previously [4]. For each transformed DWT or DT-CWT, the result is improving as and when we increase the number of bands.

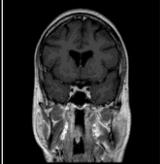

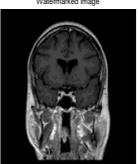

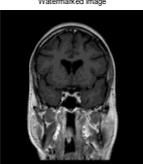

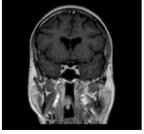

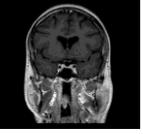

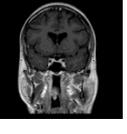

‘Fig.3 and 4’, shows the results after applying DWT and DT-CWT in 2-band and 3-band to the MRI images respectively, we only used the one- resolution level.

Analysis of the results shows that the proposed scheme has high degree of robustness to each attack in $M > 2$ bands. For Gaussian noise attack, the presence of watermark is ‘0’ with the variance > 0.005 in axial images in both cases.

We have tested the proposed algorithm on many attacks. The watermark is robust to JPEG compression with quality factor as low as 15% (JPEG 15) and to common image processing such as median filtering Gaussian filtering. The watermark could be detected when the marked image has been cropped by 50%. We compare the proposed algorithm M-DT-CWT watermarking with DWT dyadic case, for fair comparison, in DWT.

I. FIGURES AND TABLES

M	DWT	realDWT	CWT

Figure 3 : a , d. watermarked images without attack (DWT left), b , e. (real DWT middle) and c , f (CWT right)			

M	DWT	realDWT	CWT
2			
	PSNR:39.01	PSNR:40.12	PSNR:41.19
3			
	PSNR:40.15	PSNR:41.15	PSNR:42.48
Figure 4: a, d. watermarked images without attack (DWT left), b,e (real DWT middle) and c,f (CWT. left)			

The performance and robustness have been tested with the attacks of image processing the presence the watermark in the attacked images shown in “Table2”above. PSNRs results (in dB) of the watermarked image after attacks are shown in table 1, we find the performances for M=3 band in comparison with M=2 band, also those of CWT to DWT for each case.

Table 1: PSNR VALUE BETWEEN ORIGINAL IMAGES AND WATERMARKED IMAGES

Band number	PSNR (Coronal image)		PSNR (Axial image)		
	DWT	CWT	DWT	CWT	Attacks
M = 2	30.23	35.33	30.12	35.10	JPEG 15%
M = 3	33.62	36.10	33.29	36.01	
M = 2	30.12	32.53	30.01	32.10	Rotation 10°
M = 3	31.45	32.98	30.25	33.29	
M = 2	30.43	32.25	29.45	30.05	Median filter (3x3)
M = 3	32.44	33.55	30.45	33.55	
M = 2	26.95	28.67	25.51	29.07	Cropping 50%
M = 3	30.11	32.20	30.10	31.45	
M=2	29.21	30.23	28.45	29.74	Sharpen attack
M=3	30.12	31.10	30.25	32.19	

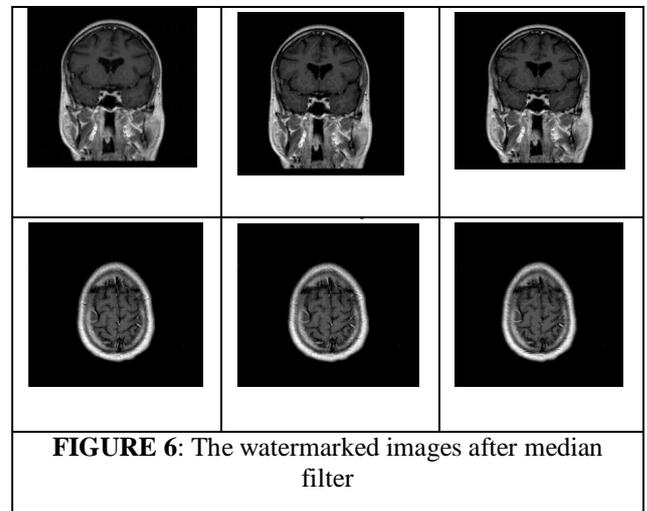

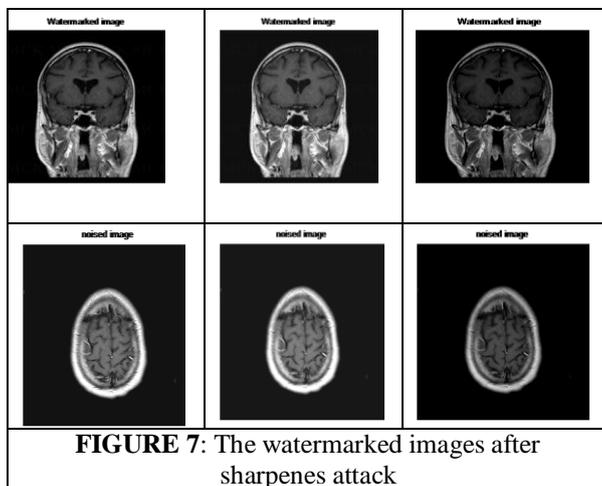

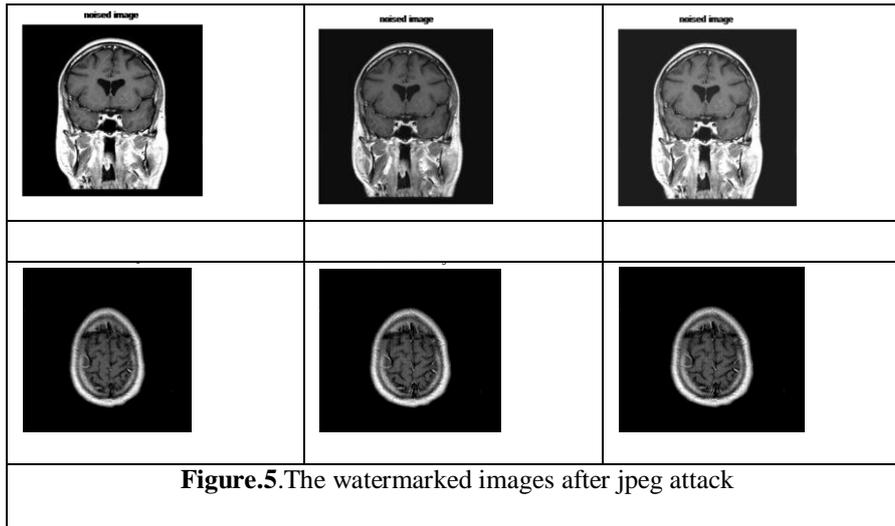

“Table2”, show the robustness of our approach to the attacks, the results are visually impressive, better for the case M = 3 bands, and also for the M-band analysis. The watermarked images obtained are shown in “Fig. 2.”

Table 2: THE PRESENCE OF WATERMARK IN THE STEP OF DETECTION.

Band	presence in Coronal image		presence in Axial image		
	DWT	CWT	DWT	CWT	Attacks
2	0	1	0	1	JPEG 15%
3	1	1	1	1	
2	0	1	0	1	Rotation 10°
3	1	1	1	1	
2	0	1	0	1	Median filter(3x3)
3	0	1	1	1	
2	0	1	0	0	Cropping 50%
3	1	1	1	1	
2	0	1	0	1	Sharpen attack
3	1	1	1	1	

The obtained PSNR values with M-DWT for M=2 bands and M=3 bands are presented” in Table 1”, respectively; while the marked image in M-DT-CWT domain, with 3-band has excellent perceptual quality without any artifacts.

‘‘In Fig.5,6 and 7’’, are shown the result of the watermarked images after common attacks onlyfor M =3 case.

Robustness of the scheme is so proved against JPEG, with different quality factors (QF<60%) for the two images in DT-CWT and $M > 2$ band, the presence of watermark.is successfully recovered.

In Axial cropped image by 50° , the presence of watermark is no found in each wavelet analysis case.

The medical images have some diversity and their treatment may differ from case to case. Clinical information then locates areas that define and separate Regions of Interest (ROI) we seek to highlight the anatomical and pathological structures that detected by physicians sought after diagnosis.

By ttaking into account the specificity of these images, we manage these ROI, for the watermarking. Therresults made object of blind test of more than technicians and doctors of the hospitals who affirmed that for images shown in ‘Fig.3and 4’’, had a good perceptually visibility after watermarking.

In addition for the test result, it shows the following observation; All images were considered acceptable for diagnosis by all observers for all Multi-band of DT-CWT and suggested that the images DWT are degraded to be retable with the geometric attack in dyadic case. Finally overall test result support the previous confirmations in all cases

V. CONCLUSION

The performances of the complex wavelet transform for watermarking image in dyadic cases are already demonstrated in the literature. In our work, efforts are to generalize their conclusions by demonstrating the efficiency of the complex multi-band wavelet transform, in consideration of its qualities. It can be concluded that the implementation of M-band complex wavelet can be treated as the best for watermarking images by considering the results of watermarked image summarized in the figures. The additional privilege of the suggested algorithm is its compatibility with human visual characteristics to embed the watermark for a high number of bands. In this way higher capacity of M-band wavelet domain is applied to embed the watermark information along with preserving the quality and clinical information of medical images and integrity of watermarked image which is of major importance in medico-legal frame work.

In future we open the way for researchers for the detection step which shows how to extract the watermark in integrality.

Acknowledgements

The authors are grateful to physicians and medical technique staff in a medical images service centre at CheikZaid hospital (Morocco) for their entire assistance and suggestions during data collection in test step. The special thanks to Caroline Chaux, Xiangui Kang and al for their contributions in Multi-band wavelets domain, source of inspirations in this work.

Anna University, Chennai-600025, India

ABSTRACT: This paper reports the effect of thrust force during drilling of 10mm diameter holes in 20mm thick Carbon Fibre Reinforced Plastic composite laminate using HSS, Solid Carbide (K20) and Poly Crystalline Diamond insert drills. Experiments are conducted on a vertical machining centre using Taguchi design of experiments. A model is developed to correlate the drilling parameters with thrust force using Response surface Methodology (RSM). The results indicate that the developed model is suitable for prediction of thrust forces in drilling of CFRP composites. The influence of different parameters on thrust force of CFRP composites have been analyzed through contour graphs and 3D plots. The investigation has revealed that the type of drill geometry affects the thrust force significantly followed by the feed rate and the speed.

Keywords: Drilling, CFRP, response surface methodology, Thrust Force

I. INTRODUCTION

CARBON FIBER REINFORCED PLASTIC (CFRP) composite materials are continuously replacing conventional metals and alloys in many applications such as automotives, aircraft etc. The combination of superior mechanical properties such as high specific strength, stiffness and fatigue strength, enable the structural design more reliable than conventional metals [1]. They can be easily fabricated to near net shapes by processes such as hand lay-up, filament winding, pultrusion; etc. Machining is required in places where composites are assembled by joining processes. Machining of composites has been recognized as a process different from that of conventional materials. A proper selection of cutting parameters facilitates good machinability since the coexistence of hard abrasive fibres and a soft matrix behave differently during machining [2].

Drilling is a frequently employed in industries owing to the need for component assembly in mechanical structures. Many researchers [3-5] reported that the quality of the drilled surfaces depend strongly on the tool geometry, drilling parameters and tool material. An inappropriate selection of these parameters can lead to material degradations, such as fiber pull-out, matrix cratering, thermal damage and delamination [3].

Tsao [6] reported that the feed rate and the drill diameter are recognized as the most significant factors affecting the thrust force. The radial basis function network is demonstrated more effective than multi-variable regression analysis for the evaluation of drilling-

induced thrust force and surface roughness in drilling of composite material. Latha and Senthilkumar [10] used fuzzy logic technique to predict thrust force in drilling of composite materials. Davim [11] presented a study for selecting the cutting parameters for damage-free drilling in carbon fiber reinforced epoxy composite material which was based on a combination of Taguchi's techniques and on the analysis of variance (ANOVA).

Karnik et al., [12] carried out drilling as per full factorial design using cemented carbide (grade K20) twist drills that serve as input-output patterns for ANN training and reported that the developed ANN model shows a good correlation both for training and testing data sets, thus validating the model. Two-factor interaction effects were also analyzed by generating 3D surface plots. The interaction effects analysis demonstrates the advantages of employing a high spindle speed for drilling CFRP composite material which reduces the delamination at the entrance of the holes.

This paper investigates the effect of different drilling parameters on Thrust force in drilling CFRP composites. The experiments were conducted on a Vertical machining centre using HSS, Carbide (K20) and PCD drills of diameter 10mm. Response surface model is developed to correlate the thrust force with respect to different drilling parameters. The machining parameters considered for the experiments are spindle speed, feed rate, and type of drills. The results proved that the developed model can be effectively used for the prediction of Thrust forces in machining of CFRP laminates.

II. EXPERIMENTAL

2.1 Materials and Methods

The CFRP laminates were fabricated using the hand lay-up technique. Carbon fibre (Zoltek, PANEX® 35) was used as a reinforcement in the Epoxy matrix (Huntsman, Warm curing epoxy system based on Araldite® LY 1564 SP/Hardener XB3486 formulated amine hardener) and was cured at 220 deg Celsius for 90 minutes. This composite laminate was produced with a fiber orientation of 0/90 degrees with 20 layers of the fabric and resin used successively. The properties of the fibre are listed in Table 1. The different types of drill used in this study are shown in Fig 1.

Figure 1.a) HSS Ball Nose, b) Carbide Ball Nose, c) PCD Ball Nose

Table 1. Properties Carbon Fibre

TYPE OF FIBRE	TENSILE STRENGTH (MPa)	TENSILE MODULUS (GPa)	ELECTRICAL RESISTIVITY (Ω-cm)	% CARBON CONTENT	DENSITY (g/cc)	FIBRE DIAMETER (microns)
Stitch Bonded Unidirectional	3800	228	0.00155	95	1.81	7.2

2.2 Experimental Procedure:

The experimental setup is shown in Fig.2 Arix VMC 100 CNC drilling machining centre was used for making drills in the CFRP composites using different drill bits such as HSS, Solid Carbide and PCD. The experiments were conducted as per the L₂₇ orthogonal array. The computer controlled data acquisition system was used to collect and record the data during experiments. The Kistler dynamometer was used to record the cutting forces.

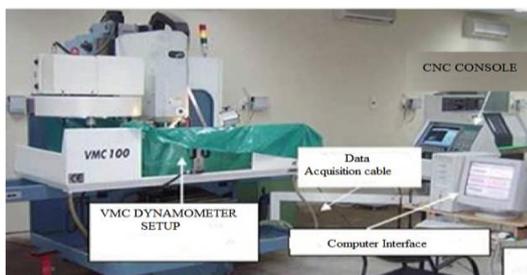

Figure 2. Experiment setup with dynamometer arrangement

2.3 Response Surface Modelling

Response surface methodology (RSM) is a collection of mathematical and statistical techniques that are useful for the modelling and analysis of problems in which a response of interest is influenced by several variables and the objective is to minimize this response [10].

The process parameters, their notations, and their ranges are given in Table 2. The experiments for the present work have been carried out using full factorial taguchi design of experiments. In the current investigation the number of variables considered for the response surface modelling is three and the numbers of experiments conducted are 27. The independently controllable process parameters identified for the experimentation are: Spindle speed (V) rpm, feed rate (f) in mm/min, and type of drills (d) used. The steps involved in the RSM technique [3] are as follows: (i) designing of a set of experiments for adequate and reliable measurement of the true mean response of interest, (ii) determination of mathematical model which best fits; (iii) finding the optimum set of experimental factors that produces maximum or minimum value of response; and (iv) representing the direct and interactive effects of process variables on the best parameters through two-dimensional and three-dimensional graphs.

Table 2. Process Parameters used for modelling

Control Parameters	Unit	Symbols	Levels		
			-1	0	1
Cutting Speed	rpm	v	250	3000	3500
Feed Rate	mm/min	f	50	75	100
Drill Type	-	d	HSS	CARBIDE	PCD

In most RSM problems, the form of relationship between the response and the independent variable are unknown. When the experimenter is close to optimum, a model that incorporates curvature is usually required to approximate the response. Usually a second order model is utilized in response surface methodology.

$$y = \beta_0 + \sum_{i=1}^k \beta_i x_i + \sum_{i=1}^k \beta_{ii} x_i^2 + \sum_{i<j} \beta_{ij} x_i x_j + \epsilon$$

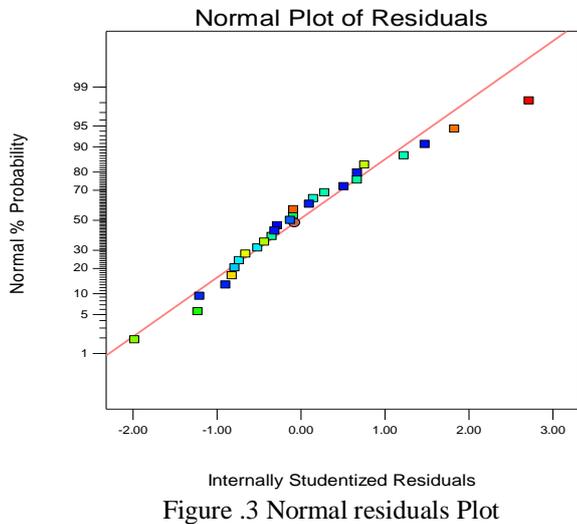

Least square method is used to determine the β coefficients, in the model. Values of the controllable parameters that results in optimization of response or discover what values for the 'x' values will result in a product (process) satisfying several requirements or specifications can be determined by using RSM [8]. A second-order model is normally used when the response function is not known or nonlinear. In the present study a second-order model has been utilized. The thrust force F is given by

$$\text{Thrust Force} = 81.56 - 25.56 * V + 55.22 * f + 202.5 * d + 12.67 * V * f - 54.58 * V * d + 9.58 * f * d - 5.33 * V^2 + 20 * f^2 + 442.83 * d^2 \text{ - equation (2)}$$

R² is called coefficient of determination, is used to judge the capability of regression model developed, 0 ≤ R² ≤ 1. The R² value is the variability in the data accounted by the model in percentage [8]. After estimating the sum of squares (SS) and mean squares

(MS), R^2 value can be used to check the adequacy of the model developed
 $R^2 = 1 - \text{SSerror} / \text{SS Total}$

There is good concurrence between the experimental and predicted values since the coefficient of determination calculated is 95.10%. The diagnostic checking of developed model can be checked by residual analysis. The normal probabilities of residuals are shown in Fig.3. The normal probability plot is used to verify the normality assumption.

From the Fig.3 it is clear that the data are spread roughly along the straight line. Hence, it can be concluded that the data are normally distributed. Fig.4 shows predicted results against the actual results. It is understood that predicted results are very close to the experimental results so response surface models are suitable for predicting Thrust force of CFRP composites.

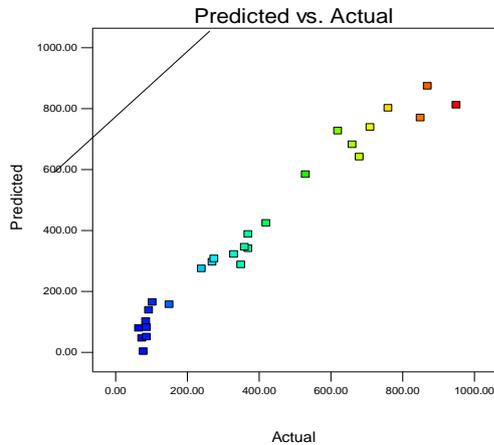

Figure.4 Graph showing variation of Experimental Values with predicted values

III. RESULTS AND DISCUSSION

It can be seen that effect of cutting speed on the cutting forces differs with various tool geometry and material. As expected, the type of drill used has a greater influence on thrust force. From Fig.5 it is observed that thrust force is high as feed rate increases due to the change in the shear area. There is tremendous increase in thrust force values

for PCD because the amount of margin left after providing the flute is more. This reveals that drill geometry has significant effect on the thrust force. The thrust force generally increases as the speed increases but decreases further in the case of Carbide and PCD tool. On contrary to carbide, the cutting force observed during drilling using PCD is quite different. The value of cutting force is high as compared with the carbide. The analysis of response variable thrust force can be explained through contour and surface plots. The typical three-dimensional (3D) surface plots and two-dimensional (2D) contour plots for Thrust force in terms of the process variable are shown in Figures.6-11

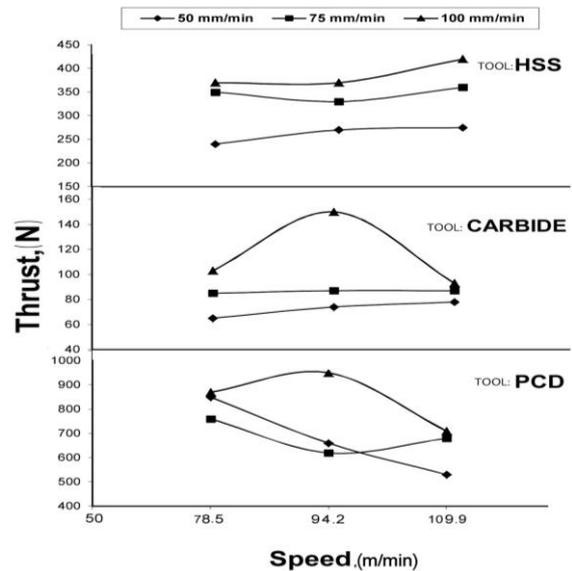

Figure 5. Measured thrust force at different speeds

Equation (2) is plotted in Fig.6-8 as contours for each of the response surfaces. These response contours can be used to predict of thrust force at any point of the experimental domain.

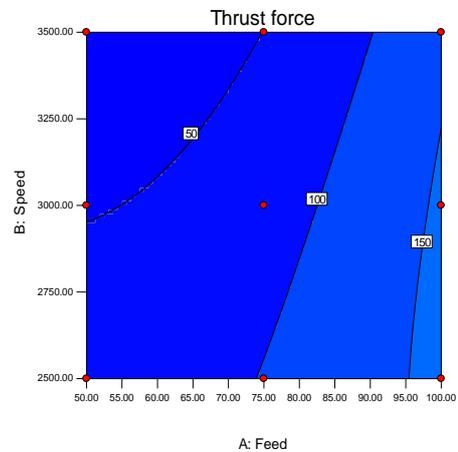

Figure.6 Estimated contour plots for Thrust force (Drill)

Fig.9 illustrates the surface plot for thrust force by varying the two variables Spindle speed and type of drill by keeping the feed as constant. It is found that the thrust force is high at lower speeds and found to decrease as speed increases.

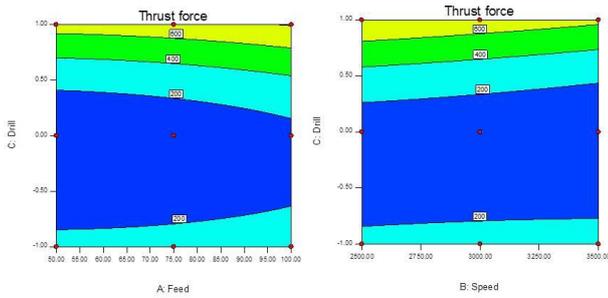

Figure.7 Estimated contour plots for Thrust force (Speed=3000rpm), Figure.8 (Feed=75mm/min)

PCD drill results in producing high forces. Thrust force increases as feed rate increases in the case of PCD. This effect is different in the case of Carbide drill. Fig.10 shows the 3D response surface plot for Thrust force with constant speed. Effect of keeping the type of drills constant can be witnessed from Fig.11. It can be seen that as feed increases and speed decreases the thrust force is found to increase.

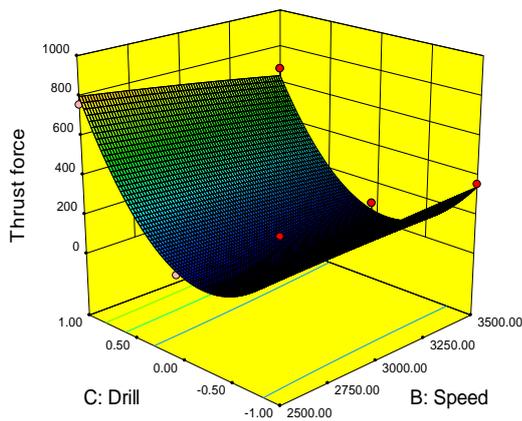

Figure .9 Estimated 3D response surface plot for Thrust force (Force vs. V and d).

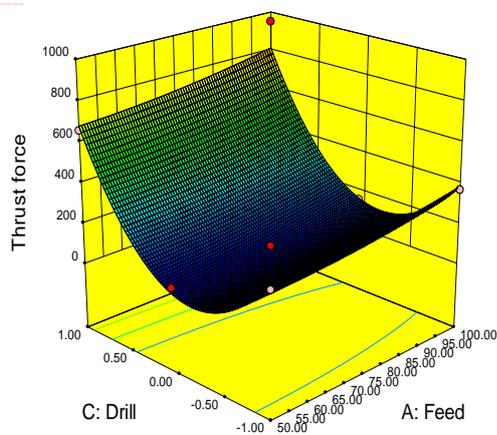

Figure .10 Estimated 3D response surface plot for Thrust force (Force vs. d)

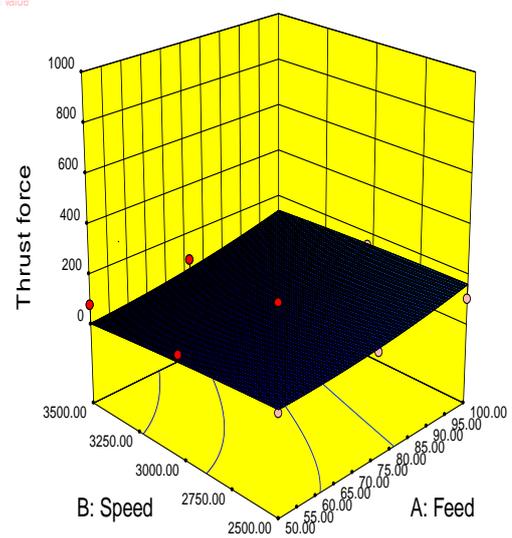

Figure.11 Estimated 3D response surface plot for Thrust force (Force vs. V and f).

IV. CONCLUSIONS

The following are the conclusions drawn from the experimental work

- For correlating the drilling parameters with respect to thrust force a second order response surface model has been developed. The developed model is significant at 95% confidence level, which shows that the developed model can be effectively used for drilling of CFRP composites within the range of the process parameters.
- Analysis of variance for the developed model revealed that the type of drill and the feed rate are the dominant factors that influence the thrust force. Thrust force recorded for HSS drill was high when compared to Carbide. Since the hardness of HSS tool is less than the Carbide drill.
- Medium cutting speed and feed rate provided optimum thrust forces irrespective of the drills used. Significant reduction in cost and timing can be achieved by using this response surface model

ACKNOWLEDGEMENTS

The authors would like to thank the Central Workshop Division of Mechanical Engineering Department, Anna University for providing facilities to carry out the work. The support of Mr.Samy, and Foreman Mr.Srinivasan is well acknowledged

Review of the Latest Developments in Grain Refinement

Lakhwinder Singh¹, Geetesh Goga², Rupinderpreet Singh³
Mechanical, K.C.College of Engg. & I.T./ PTU, India^{1,2,3}

ABSTRACT: There have been a number of studies in recent years relating to the mechanisms of grain refinement of Al-Ti-B refiners. Grain refinement of Aluminium and its alloys is a common industrial practice. The field has been investigated by many workers over past 60 years, not only to develop efficient grain refiners for different aluminium alloys, but also to achieve an understanding of the mechanism of grain refinement. There have also been studies on the interaction of refiners in the cast house environment. More recently there have been several new grain refining products introduced, which have been the subject of their own studies. These new refiners have a number of specific beneficial attributes, which distinguish them from the traditional Al-Ti-B refiners. The characteristics of the expanding family of refiners are reviewed, and their benefits explored in terms of these characteristics. The paper also aims to give an overview of the grain refiners available and guidance on their choice in different alloy systems and processing applications.

Keywords: Aluminum, Boron, Grain refinement, refiners, Titanium

I. INTRODUCTION

It is well known that metals and alloys usually solidify with coarse columnar grain structure under normal casting conditions unless the mode of solidification is carefully controlled. It is possible to develop fine equiaxed grains in the as cast structure either by increasing the number of nucleation sites or by grain multiplication. McCartney has defined grain refinement as deliberate suppression of columnar grain growth in ingots and castings and formation of fine equiaxed solidification structure throughout the material. It is known that the grain size is inversely related to the degree of undercooling due to an increased nucleation rate. In other words, fine grains can be achieved by fast cooling that ensures a high degree of undercooling. Chemical grain refiners based on Al-Ti-B are widely used in aluminium casthouses and foundries worldwide. They are a key part in improving casthouse productivity, allowing faster DC ingot casting speeds, resistance to hot-cracking, as well as improving surface finish and mechanical properties. The pioneering work of Cibula on grain refining started in the early 1950's. This led to the first industrially used grain refiners based on the formation of TiB₂ particles in situ in the melt via the addition of KBF₄ and K₂TiF₆ salts. However, this method suffered from rapid fade of the refining effect due to particle settling. The master alloy approach gave benefits in terms of providing 'readymade' TiB₂ particles of a more controlled and optimised size. A major breakthrough in the development of the use of refiners came with the availability of the alloy in rod form, first used in the mid 1960's. This allowed grain refiner additions to be made outside the furnaces, thus

further reducing the fading effect of furnace additions and also the effects of 'poisoning' in certain alloy systems; this allowed much lower addition levels to be made and a more consistent grain refining performance to be achieved. Adding rod outside the furnace put a greater emphasis on the need to develop refiners with clean microstructures; the major features to be addressed were to reduce boride agglomerations, oxide films and residual fluoride salts. Rod is nowadays the most commonly used form of grain refiners, accounting for over 80% of grain refiner usage.

For many years the range of grain refiners available was mostly limited to three compositions all based on the Al-Ti-B system; namely Al-5%Ti-1%B, Al-3%Ti-1%B and Al-5%Ti-0.2%B. The Al-5%Ti-1%B was, and remains, the most popular composition due to its high refining potency. The lower Ti content Al-3%Ti-1%B refiner was developed to meet the requirements to have a potent refiner, but not to exceed melt Ti specifications, which could be exceeded especially in plants with a high level of recycle. The lower B content refiners are used more specifically for production of surface critical products, to help reduce or eliminate the number of boride defects in the end product (simply by introducing fewer boride particles). The quality of Al-Ti-B grain refiners available in the market steadily improved in terms of cleanliness, grain refining effectiveness and especially consistency, during the 1980's and 90's.

With the ever-increasing demands on the quality of surface critical applications, an intense period of development in the mid 1990's resulted in the introduction of Al-3%Ti-0.15% C grain refiner. The Al-Ti-B quality development took place over a 40 year period – this was effectively matched by a concentrated development period of just a few years for the Al-Ti-C system. Whilst this refiner has penetrated a relatively small proportion of the market, it has proved to give benefits in terms of reduced particle agglomeration behaviour, resistance to poisoning by Zr (for 7xxx alloys), and better surface finish in 5xxx series alloys.

II. REFINER PARTICLE CHEMISTRIES AND TYPES

The nominal chemistry and particle types of the main refiners used in the aluminium industry are summarised in Table I.

Refiners	% Ti	% B	% C	% Sr	Borides	Aluminides
Al-5%Ti-1%B	5.0	1.0	0	0	TiB ₂	TiAl ₃
Al-3%Ti-	3.0	1.0	0	0	TiB ₂	TiAl ₃

1%B						
Al-5%Ti - 0.2% B	5.0	0.2	0	0	TiB ₂	TiAl ₃
Al-3%Ti - 0.2% B	3.0	0.2	0	0	TiB ₂	TiAl ₃
Al-3%Ti - 0.15% C	3.0	0.0	0.1	0	TiC	TiAl ₃
TiB ₁ oy	1.6	1.4	0	0	(Al,Ti)B ₂	-
Strobloy	1.6	1.4	0	Up to 10	TiB ₂ , SrB ₆	SrAl ₄

Note: International standards deliberately allow a higher Ti (up to 3.4%) and lower B (down to 0.7%) content than indicated. This is to encourage a superior boride microstructure.

Table I: Summary of Refiner Particle Chemistries and Types

III. TiBAI ROD ADDITIONS IN A TYPICAL DC CASTING SITUATION

On addition of the rod to the melt, the Al matrix of the Al-Ti-B refiner melts releasing the TiB₂ and TiAl₃ particles into the flowing metal.

3.1 Degassing:

If chlorine is used the conditions are conducive to agglomeration of TiB₂ particles. Apart from the role of chlorine, the input metal is relatively rich in oxide films compared to the output metal. In addition, the metal turbulence inside the degasser encourages particle collisions. Many individual casthouses have been able to demonstrate these effects using LiMCA technology. All of these issues would tend to suggest it is preferable to add grain refiner after a degasser rather than before it, particularly if chlorine gas is being used. This is dependent on the casthouse layout, however, as the addition point needs to also take account of the cleanliness of the grain refiner, and the time required for dissolution of TiAl₃ particles. It is suggested that provided there is sufficient time for TiAl₃ dissolution before the next in line melt treatment (e.g. a filter) or casting (in the case of no filter), then rod addition after the degasser should provide benefits. Even if no chlorine is used in the degasser, there is still likely to be both some particle loss in the dross and some particle agglomeration.

3.2 Filtration:

An extensive programme on ceramic foam filter performance has been carried out in Europe [1]. If the incoming metal cleanliness is high then there is minimal impact of the grain refiner on the performance of the filter. However, if there is an artificially high inclusion loading from the metal (achieved by deliberately vigorously stirring the metal in the furnace), then the introduction of the grain refiner leads to a reduction in filtration efficiency. If grain refiner rod is added before a filter, then the time required for TiAl₃ particles to dissolve needs to be considered. It is known from practical experience that if the rod is added too close to the filter, the filter can become rapidly blocked (or "Blinded") by undissolved TiAl₃ particles. Studies [2] on the effects of long time exposure to liquid aluminium of grain refiner particles, by examining used tube filters, which had been in extended production use found that the thermal cycles and/or the extended quiescent periods during the lifetime of a tube filter can be critical. Under these circumstances, it was observed that there was a transformation of the trapped TiB₂ particles into (Ti,V)B₂. Subsequent growth of such particles can then lead to the formation of more complex agglomerates and bridging within the filter, and so impair filtration efficiency and filter life.

3.3 Addition point:

Due to concerns over the cleanliness of grain refiners, they have traditionally been added before filters. However filters remove some of the required nucleant particles from the metal stream, so addition of grain refiner after the filter might allow lower addition rates. In the normal situation, metal (including oxide films, and if recycled material is used also borides) flows along the launder and rod is injected before the filter. The rod adds aluminides, which dissolve within one minute, borides, which do not dissolve, and some oxide films. The oxide films from the furnace (and the grain refiner) and borides pass to the filter, where the oxide films are trapped (with some borides). The loss of borides in a filter system is considered to be mostly by adherence to oxide films, which the filter has trapped. The remaining borides pass through the filter along with the Ti in solution. There has been ample evidence in the industry of showers of borides being released from a filtration system, caused by changes in the metal head and hence pressure, or by vibrations or accidental tapping of the filtration assembly. A shower of oxide films decorated by TiB₂ particles is a potentially damaging defect, and is the likely cause of many of the defects found in surface critical products. If the quality of grain refiners is sufficiently high such that they can be added after the filter, then these showers of defects can be eliminated. In addition the loss of borides in the filter system would not occur, so less grain refiner would need to be added.

In the foundry situation there are many types of operation done in many different ways [such as melting, degassing, ladling and pouring]. The addition point of the grain refiner can be considered in the same terms as in DC casting. Whereas fade is not really an issue for launder additions in the casthouse, it is of relevance in the foundry, where additions are typically made to a ladle which may be left for several hours prior to use.

IV. Overview of the use of Different Refiners

A summary of the use of grain refiners in the wrought sector is presented here:

4.1 Twin roll casters:

Low boron refiners are often used (the dense TiB₂ particles tending to settle particularly at the relatively slow metal flow rates encountered in this process). End applications can often be surface critical and low boron refiners can also be of benefit compared to the 1%B containing refiners. The Al-Ti-C system may also provide benefits in this process in terms of less particle agglomeration, reduced chemical segregation, as well as finer grain sizes at the higher casting speeds.

4.2 Electrical conductor applications:

Al-5%Ti-1%B and Al-3%Ti-1%B are used. If too much boron is added at boron treatment, it can be almost impossible to grain refine. The Al-Ti-C system seems to suffer less from this issue and is finding increasing usage, as significant reductions in addition rate as well as improvements to product quality can be achievable.

4.3 Extrusion billets (mostly 6xxx alloys):

For the DC casting process Al-5%Ti-1%B is mainly used as the principle requirement is refiner potency. Some Al-3%Ti-1%B is also used. In terms of avoiding the formation of columnar crystals, Al-5%Ti-1%B provides the best robustness in terms of temperature sensitivity [3]. A feature of the Al-Ti-C system is consistency of grain size across the billet section [4], and possibly an improved surface finish on extrusion (the refiner particles being one potential cause of die lines, or streaking on anodising).

4.4 Rolling slabs:

Subsequent to DC casting these are processed to a variety of end applications, which can affect the refiner chosen, as discussed in the following:

4.4.1 1xxx slab:

The refiner used is dependent on the end application, as highlighted in the previous sections, but a number of 1xxx alloys fall into the category of surface critical.

4.4.2 2xxx slab:

The main refiners used are Al-5%Ti-1%B and Al-3%Ti-1%B.

4.4.3 3xxx slab:

The main refiners used are Al-5%Ti-1%B and Al-3%Ti-1%B. The Al-Ti-C refiners are generally not used as there is thought to be a mild poisoning effect with Mn.

4.4.4 4xxx slab:

The main refiners used are Al-5%Ti-1%B and Al-3%Ti-1%B.

4.4.5 5xxx slab:

The Al-Ti-B system dominates, but there is increasing usage of Al-Ti-C due to no negative effects on Mg oxide build up [5]. The Al-Ti-C system also has benefits in terms of less chemical segregation.

4.4.6 6xxx slab:

The main refiners used are Al-5%Ti-1%B and Al-3%Ti-1%B (see also comments above on extrusion billets).

4.4.7 7xxx slab:

The Al-Ti-C system is finding most of its use in these alloys, particularly the Zr containing ones due to the poisoning effect with the Al-Ti-B refiners.

4.4.8 8xxx slab:

The refiner used is dependent on the end application, as highlighted in the previous sections.

4.5 Foundry sector:

This sector is dominated by Al-5%Ti-1%B, however, growth is seen with substoichiometric refiners (such as TiBloy) particularly in wheel foundries, where reduced levels of rejects are being experienced. The foundry sector consists of foundry ingot producers (who are generally in the wrought sector), large foundries (where master alloy grain refiners dominate) and very many small foundries (where both master alloy refiners and salts/tablets refiners are used). Combined modifier (Sr) and grain refiner (Ti, B) master alloys (such as Strobloy) are also used.

V. SUMMARY AND CONCLUSIONS.

Grain refinement of aluminium and its alloys has become common industrial practice. The immense technological importance of this field has led to extensive investigations by many industrial and academic researchers during the past 60 years. A great majority of the past investigations were primarily focused on the search for grain refiners that act quickly and provide the grain refining effects without fading even on prolonged holding of the molten alloy. Among a number of grain refiners developed, Al-5Ti-1B master alloys are more popular due to their high grain refining efficiency with respect to many aluminium alloys. Al-Ti-C master alloys are also becoming popular as grain refiners for many aluminium alloys, particularly when boron is not desirable in the aluminium alloy.

The grain refining behaviour of the master alloy appears to be sensitive to its microstructure, particularly the morphology and size distribution of TiAl₃ particles, which are in turn influenced by the processing parameters used in the preparation of the master alloy, such as reaction temperature, reaction time, and thermo mechanical treatment

Much work has been focused on attempts to understand the mechanisms of grain refinement and several theories have been proposed. However, none of these theories can explain all the observations made in the grain refining experiments. Perhaps more than one mechanism operates depending on the grain refiner used, the alloy being cast, and the casting process involved. Further work is necessary in this direction to develop a unified description of grain refinement, poisoning, and fading.

Temperature Controlled Voltage Oscillation in Neural Circuit Undergoing Homoclinic Bifurcation

** Frankfurt Institute for Advanced Studies (FIAS), Goethe University Frankfurt, Germany

ABSTRACT: We analyze a frequency decrease as well as a frequency transition with a temperature increase in the Hodgkin-Huxley (HH) oscillator undergoing saddle homoclinic bifurcations. A gradient of frequency for temperature is derived by perturbation analysis of the stable HH oscillators, in combination with the other gradient of frequency for input current and a so-called phase response curve (PRC) multiplied by its related voltage-gated channel currents. We then show that the PRC is clearly classified by the gradient of frequency for temperature. More interestingly, different bifurcation mechanisms of the Andronov-Hopf and the saddle-node are commonly categorized.

Keywords: Hodgkin-Huxley oscillator, frequency decrease, oscillatory transition, saddle homoclinic orbit bifurcation, phase response curve

I. INTRODUCTION

Temperature is one of important physical variables, which significantly affects autonomous oscillations generated in the nervous system. Gamma oscillations evoked on rat hippocampal slices are dependent of temperature [1]. In simulations on models of the nervous system, temperature alters nonlinear phenomena of desynchronization or chaos synchronization in the voltage activities [2][3]. It is thus interesting to understand mechanisms on emergences of the oscillation, which are subject to temperature variation, or to study temperature effects on cooperative behavior in the neural network.

Mathematical analysis on voltage oscillations in a single neuron is fundamental for understanding collective behavior in the assemblies. The Hodgkin-Huxley (HH) model is the first mathematical description on such voltage dynamics. The HH model can describes how membrane potentials in neurons are initiated and propagated [4]. It is modified for simulating peripheral cold receptors discharges that exhibit different firing patterns [5]. One firing pattern is an abrupt increase of the interspike intervals in a certain temperature region. This is originated from a homoclinic bifurcation of a saddle-node (SN) equilibrium embedded in the chaotic attractors [6]. However, why the homoclinic bifurcation appears is still unclear. The modified HH model seems to be different from the original. We will have to study again stability analysis on equilibriums in both the original and modified HH models.

It is also necessary for us to find another measurement for characterizing firing properties or dynamical mechanisms in their models. The good measurement is the frequency-current ($f-I$) curve [7], which has already been examined in electrophysiological experiments [8][9]. The $f-I$ curve generally categorizes oscillations into the two classes: For the class I, emergence of the oscillation with zero frequency is characterized by saddle-node (SN) or saddle-node on invariant circle (SNIC) bifurcations with an increase of the I . The SNIC, which is also called the SN on a limit cycle (SNLC), means that the SN bifurcation occurs on the LC. In the class II, emergence of the oscillation with a finite frequency is characterized by the Andronov-Hopf (AH) bifurcation.

In recent analysis, one unexpected oscillatory phenomenon has been highlighted that the class I Morris-Lecar (ML) model decreases firing frequency with temperature increase [10]. This seems to be very similar to frequency discharge of cold fibers, which also shows the paradoxical frequency discharge at high temperature [11][12] (In what follows, let us call it the frequency transition). In 1999, Adair simulated the frequency discharge of cold fibers by Boltzmann description of voltage-gated Na^+ and Ca^{2+} channels [13]. Presumably, this Boltzmann model is not functionally different from the original HH model. However, using the original HH model, how the paradoxical frequency discharge occurs is still unclear. It should thus be clarified by analyzing stabilities as well as bifurcation mechanisms in the original HH model.

In this paper, we show that temperature (μ) modulated frequency are characterized with current I and so-called phase response curves (PRCs) derived by making phase descriptions for small μ perturbation. $f-\mu$ formulations give us mathematical conditions for a frequency decrease and a frequency transition with an increase in temperature, dependent of different bifurcation mechanisms on oscillation generation. Frequency gradients in terms of μ classify PRC into two types, regardless of conventional classification. We demonstrate heuristically firing frequency transition for larger μ in the HH model undergoing a SNIC bifurcation mechanism. Also, a frequency increase with a μ decrease is determined by appropriate proportion of frequency gradient for I to the product of the PRC and its current dynamics. In addition, the frequency gradient in terms of μ shows the critical μ -value for the frequency transition of a normal saddle-node homoclinic orbit to its separatrix loop. Finally, discussion and conclusion will be given.

II. BIFURCATIONS IN SPIKING MODEL

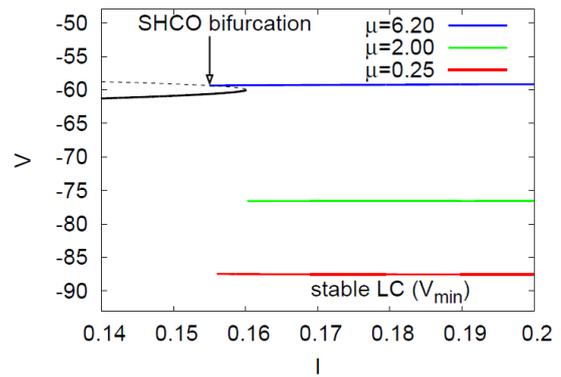

We shall begin by studying bifurcation analysis on the Hodgkin-Huxley (HH) model parameterized as a class I. The HH model, which is employed to simulate frequency-current ($f-I$) and frequency-temperature ($f-\mu$) relations, is given by

$$C_m \frac{dV}{dt} = Q(V, m, h, n) + I = -g_{Na} m^3 h (V - E_{Na}) - g_K n^4 (V - E_K) - g_L (V - E_L) + I, \quad (1)$$

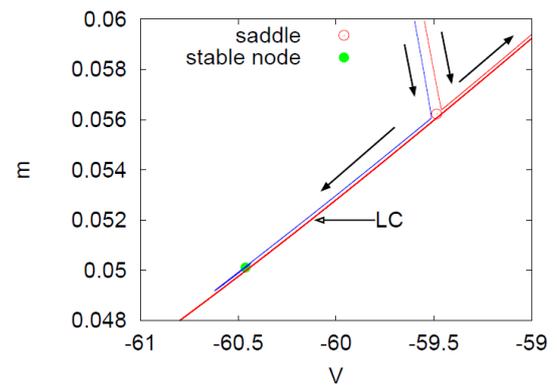

$$\frac{dy}{dt} = \mu P_y(V, y) = \mu (Y_\infty(V) - y) / \tau_y(V). \quad (2)$$

$C_m (= 1\mu F/cm^2)$ is the membrane capacity. $y \in \{m, n, h\}$ is the non-dimensional gating variable. The parameters E_{Na} , E_K , and E_L are the reversal potentials of Na^+ , K^+ and leak currents respectively, while g_{Na} , g_K , and g_L are the conductances. $Y_\infty(V) = \alpha_y(V) / (\alpha_y(V) + \beta_y(V))$, $\tau_y(V) = 1 / (\alpha_y(V) + \beta_y(V))$ where $\alpha_m(V) = -0.1(V + V_1) / (\exp(-0.1(V + V_1)) - 1)$, $\beta_m(V) = 4 \exp(-(V + V_2) / 18)$, $\alpha_h(V) = 0.07 \exp(-(V + V_3) / 20)$, $\beta_h(V) = 1 / (\exp(-0.1(V + V_4)) + 1)$, $\alpha_n(V) = 0.01(V + V_5) / (\exp(-0.1(V + V_5)) - 1)$ and $\beta_n(V) = 0.125 \exp(-(V + V_6) / 18)$. The class I dynamics are parameterized with $g_{Na} = 35 \text{ mS/cm}^2$, $E_{Na} = 55 \text{ mV}$, $g_K = 9 \text{ mS/cm}^2$, $E_K = -90 \text{ mV}$, $g_L = 0.1 \text{ mS/cm}^2$, $E_L = -65 \text{ mV}$, $V_1 = 35$, $V_2 = 60$, $V_3 = 58$, $V_4 = 28$, $V_5 = 34$ and $V_6 = 44$ (see [2]) so that the HH model represents an oscillatory system exhibiting repetitive firings via a saddle homoclinic orbit (SHCO) bifurcation with the current increase (see Fig. 1). The detailed bifurcation mechanism will be examined below. As shown in Fig. 1, firing frequency of oscillation decreases and then increases again, and its amplitude of oscillation monotonically decreases when μ increases.

We study dynamical mechanisms underlying changes of firing frequency with a temperature increase by analyzing stabilities of stationary solutions of the HH model. The result is shown in Fig. 2(a). For any μ , a saddle, stable and unstable nodes coexist for $I < I_{SN}$ ($=0.16$). Their stabilities are numerically calculated as referred in [14][15]. I_{SN} is saddle-node (SN) equilibrium. Trajectories, which diverge from the unstable node and the saddle, converge to the stable node (not shown here). When I exceeds 0.152 for $\mu=0.25$, a stable LC attractor appears through a SHCO bifurcation so that the attractor exists together with the stable node. Since trajectories on the LC attractor pass outside the saddle and stable node on the $V-m$ phase plane,

(a)

(b)

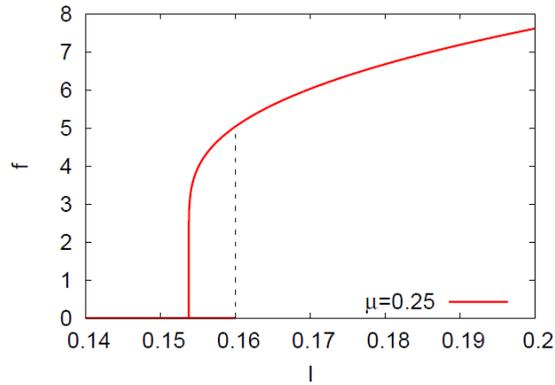

Fig. 2. (a) Bifurcation diagram for the class I HH model. There are two stationary voltages in the I range of 0.14 to 0.2. One is a saddle (the broken line) while the other is a stable node (the black line). The oscillations occur via a SNIC bifurcation that the limit cycle (LC) involves the saddle and node. Colored lines present the minimum voltages (V_{min}) of the oscillations. (b) A trajectory of the LC on the $V-m$ phase plane. The trajectory outside of the saddle and node points is the one of a "big" saddle homoclinic orbit. Stable manifold (separatrix) of the saddle (empty circle) between the red and blue lines separates resting (green circle) and oscillatory states.

the LC can be called as the big homoclinic orbit (Fig. 2(b)). The LC attractor still remains even if $I > I_{SN}$.

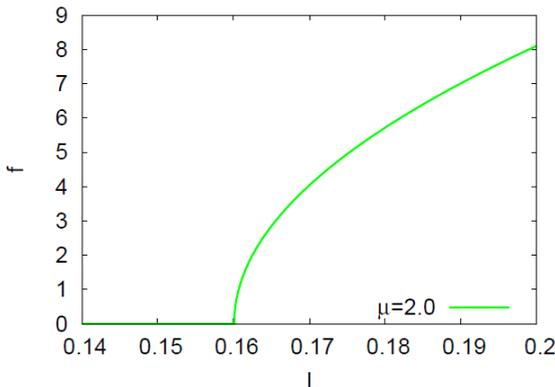

This indicates emergences of the oscillation via two different bifurcation mechanisms: The first oscillation with 0-frequency occurs via the SHCO bifurcation. The second oscillation with a finite frequency occurs via the SN bifurcation [Fig. 3(a)]. We notice that the second oscillation emergence is slightly different from the typical one via the SN bifurcation.

Next we show that for $\mu=2$, the HH model begins oscillations with 0-frequency through the SN bifurcation as shown in Figs. 2(a) and 3(b). We cannot find any bi-stability state of the node and the LC attractor as shown in Fig. 3(a). To be more precise, such a SN bifurcation is called the SN on invariant cycle (SNIC) as referred to [7]. This means SN equilibrium occurs on a LC attractor. Here notices that a size of the LC is apparently reduced as in the increased V_{min} of Fig. 2(a).

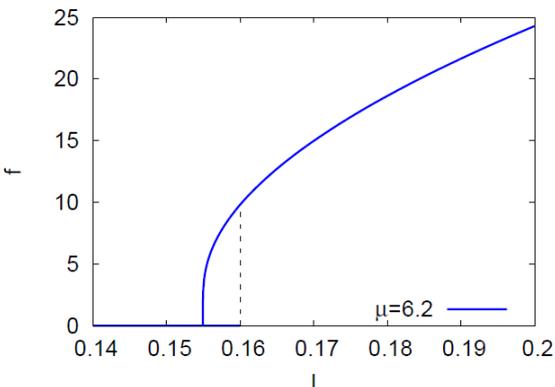

Finally, we can see again a SHCO bifurcation when $\mu=6.2$ [Fig. 2(a)]. This is a slightly different from the case for $\mu=0.25$, in terms of whether or not the SN equilibrium is

(a)

(b)

(c)

Fig. 3. f - I curves for $\mu = 0.25, 2$ and 6.2 . The HH model ((a) $\mu = 0.25$ and (c) $\mu = 6.2$) begins class II oscillations via the SN bifurcation while terminating the oscillations in the class I. (b) The HH model ($\mu = 2$) shows simultaneous excitabilities and oscillations of the class I.

outside of the homoclinic orbit. We show again the f - I curve with the bi-stability (see Fig. 3(c)). Because the trajectory is attracted into the HCO, the amplitude as well as the frequency of the oscillation is respectively small and high as shown in Fig. 1.

In summary, we find f - μ relation at each current level as shown in Fig. 4. Before a SN bifurcation, the frequency is in small peak for $\mu < 0.5$ while its frequency slope for $\mu > 6.0$ is extremely sharp. Immediately after the SN bifurcation, a constant low frequency level appears in the middle range of μ . It gradually increases as I increases from I_{SN} . The f - μ curve then becomes a monotonic increasing curve for temperature. This indicates that a

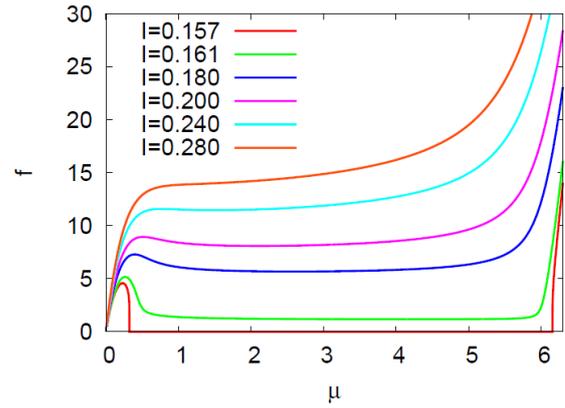

Fig. 4. Frequency f versus temperature μ on simulation with the class I HH neuron model. When $I=0.161$, the frequency passed through a minimum for $\mu=6$ and then extremely increased at the higher temperature. The low frequency level gradually rises so that the frequency is a monotonically increasing function of temperature.

frequency decrease and a frequency transition with a temperature increase are based on two SHCO bifurcation mechanisms for $\mu < 0.5$ and $\mu > 6.0$ around the SN equilibrium.

III. PERTURBATION APPROACHES

Next, in order to deepen more understandings of the frequency decrease and frequency transition, we employ a phase reduction method [10][16][17][18]. In the phase reduction method, reducing n -dimensional oscillatory dynamics, subject to small perturbations of temperature and current ($\Delta\mu$ and ΔI), to the one-dimensional phase equation, the perturbations are even phase-described. Then, we find that frequency gradient for temperature ($[\partial f / \partial \mu]$) is related to another oscillatory property such as PRCs and f - I curves.

The HH oscillator perturbed with small temperature and small current is written in the general form:

$$\frac{dx}{d\tau} = \mathbf{F}(\mathbf{x}) + \mathbf{G}(\mathbf{x}), \quad (3)$$

where $\mathbf{x}=(V, \mathbf{y}) \in \mathbb{R}^4$. V is the potential variable while \mathbf{y} is a vector consisting of 3 recovery variables. $\mathbf{F}(\mathbf{x})$ is a vector field ($Q(\mathbf{x}) + I_0, \mu_0 \mathbf{P}(\mathbf{x})$) where Q is the membrane potential dynamics for V . $\mathbf{P}(\mathbf{x})$ is the recovery dynamics for \mathbf{y} . The perturbation term $\mathbf{G}(\mathbf{x}) = (\Delta I, \mathbf{P}(\mathbf{x}) \Delta\mu)$.

Let $\mathbf{x}_p(\tau)$ denote the unique phase asymptotically stable T_p -periodic function to

$$\frac{d\mathbf{x}_p}{d\tau} = \mathbf{F}(\mathbf{x}_p). \quad (4)$$

where $\mathbf{x}_p(\tau + T_p) = \mathbf{x}_p(\tau)$. Then a stable solution for Eq. (3) is approximated as

$$\mathbf{x}(\tau) = \mathbf{x}_p(\tau + \eta(\tau)) + \mathbf{u}(\tau + \eta(\tau)), \quad (5)$$

where $\eta(\tau)$ means a small perturbation in the phase direction on the periodic orbit. $\mathbf{u}(\tau + \eta(\tau))$ denotes the orbital deviation to the periodic orbit $\mathbf{x}_p(\tau)$. Substituting Eq. (5) into Eq. (3) and expanding the both-hand sides into a Taylor series leads

$$\left[\dot{\eta}(\tau) \frac{dx_p(q)}{dq} + \frac{d}{dq} \mathbf{u}(q) \right]_{q=\tau+\eta(\tau)} = \frac{\partial \mathbf{F}(x_p(\tau+\eta(\tau)))}{\partial \mathbf{x}} \mathbf{u}(\tau) + \eta\tau + \mathbf{G} \mathbf{x}_p \tau + \eta\tau. \tag{6}$$

In the perturbed oscillator, the orbital deviation vector $\mathbf{u}(\tau) = \mathbf{x}(\tau) - \mathbf{x}_p(\tau)$ evolves as $[d\mathbf{u}(\tau)/d\tau] = [\partial \mathbf{F}(x_p(\tau))/\partial \mathbf{x}] \mathbf{u}(\tau)$. The vector $\mathbf{Z}(\tau)$ tangent to the periodic orbit $\mathbf{x}_p(\tau)$, which is the unique solution to

$$\frac{d\mathbf{Z}}{d\tau} = - \left[\frac{\partial \mathbf{F}(x_p)}{\partial \mathbf{x}} \right]^t \mathbf{Z}, \tag{7}$$

where t is transpose and the normalization condition

$$\mathbf{Z} \cdot \frac{d\mathbf{x}_p}{d\tau} = 1 \tag{8}$$

is satisfied for every τ . $\mathbf{Z}(\tau)$ is the adjoint solution to the linearization around the limit cycle. The first element of the adjoint solution, $Z_V(\tau)$, is the PRC widely used in computational neuroscience. Eq. (3) is then reduced to the evolution equation for η :

$$\dot{\eta}(\tau) = \mathbf{Z}(\tau + \eta(\tau))^t \cdot \mathbf{G}(\mathbf{x}_p(\tau + \eta(\tau))). \tag{9}$$

Introducing phase variables defined by $\theta = (\tau + \eta) / T_p$ ($\in [0, 1)$), Eq. (9) is rewritten as

$$\frac{d\theta}{d\tau} = \frac{1}{T_p} + \frac{1}{T_p} \int_0^1 \mathbf{Z}(\theta')^t \cdot \mathbf{G}(\mathbf{x}_p(\theta')) d\theta' = f + f \langle Z_V \rangle_\theta \Delta I + f \langle \mathbf{Z}_y \cdot \mathbf{P} \rangle_\theta \Delta \mu, \tag{10}$$

where $f = f(I_0, T_0) = [1 / T_p]$ and $\langle \cdot \rangle_\theta = \int_0^1 d\theta'$.

Next, $f(I_0, T_0)$ can straightforwardly be expanded in $(\Delta I, \Delta \mu)$. The quadratic Taylor series is obtained:

$$f(I_0 + \Delta I, \mu_0 + \Delta \mu) = f(I_0, \mu_0) + \frac{\partial f(I_0, \mu_0)}{\partial I} \Delta I + \frac{\partial f(I_0, \mu_0)}{\partial \mu} \Delta \mu + O(\Delta I^2 + \Delta \mu^2). \tag{11}$$

Eqs. (10) and (11) gives us following relational expressions:

$$\frac{\partial f}{\partial I} = f \langle Z_V \rangle_\theta, \tag{12}$$

$$\frac{\partial f}{\partial \mu} = f \langle \mathbf{Z}_y \cdot \mathbf{P} \rangle_\theta. \tag{13}$$

Using Eq. (8),

$$\begin{aligned} \frac{\partial f}{\partial \mu} &= f - f \langle Z_V(Q + I_0) \rangle_\theta \left(\equiv f \left(1 - \langle Z_V \frac{dV}{d\tau} \rangle_\theta \right) \right) = \\ &= f - f \langle Z_V Q \rangle_\theta - f \langle Z_V \rangle_\theta I_0 = f \left(1 - \langle Z_V Q \rangle_\theta - \frac{1}{f} \left(\frac{\partial f}{\partial I} \right) I_0 \right). \end{aligned} \tag{14}$$

$[\partial f / \partial \mu] < 0$ is thus satisfied with

$$\langle Z_V Q \rangle_\theta > 1 - \frac{1}{f} \left(\frac{\partial f}{\partial I} \right) I_0.$$

Eq. (14) means that the value of $[\partial f / \partial \mu]$ is determined by values of $\langle Z_V Q \rangle_\theta$ and $[1 - (\partial f / \partial I)(I_0 / f)]$. It also gives us a condition for frequency transition that $[\partial^2 f / \partial \mu^2]$ changes from the positive to the negative as μ gradually increases via $\mu = \mu_c$. μ_c represents that $[\partial f / \partial \mu]$ takes the maximum.

IV. SIMULATION RESULT

Using Eq. (14), we systematically investigate frequency characteristics (the frequency decrease and oscillatory transition) of the HH oscillator undergoing a SHCO bifurcation, in terms of I and μ , referring to dynamical mechanisms of a SNIC bifurcation shown in [7].

Firstly, let us explain reasons why frequency decreases, in terms of firing properties in the HH oscillator. Fig.5 shows regions for $[\partial f / \partial \mu] < 0$ and $[\partial f / \partial \mu] > 0$ on the $I-\mu$ phase diagram, being associated with Fig. 4. In Fig. 5, $(I_{SN}, \mu_{SN}) = (0.16, 0.45)$ classifies a SN bifurcation into two categories: One is the SNIC bifurcation when $\mu > 0.45$ while the other is the SN bifurcation when $\mu < 0.45$. Immediately after SN or SHCO bifurcations, $[\partial f / \partial \mu] < 0$ is widely occupied in the μ range. The range is however rapidly diminished as I increases. When $I > 0.26$, we cannot find any range for $[\partial f / \partial \mu] < 0$. This is in a good agreement with changes of the $f-\mu$ curve in Fig. 4.

Fig. 6(a) shows whether or not $\langle Z_V Q \rangle_\theta$ is larger than $[1 - (\partial f / \partial I)(I_0 / f)]$ in Eq. (12) for $\mu = 1$, to determine the positive or negative value of $[\partial f / \partial \mu]$. $[\partial f / \partial \mu] < 0$ if $\langle Z_V Q \rangle_\theta > [1 - (\partial f / \partial I)(I_0 / f)]$. In contrast, $[\partial f / \partial \mu] < 0$ if $\langle Z_V Q \rangle_\theta < [1 - (\partial f / \partial I)(I_0 / f)]$. Fig. 6(b) represents another evaluation of $[\partial f / \partial \mu]$ in Eq. (12). $[\partial f / \partial \mu] > 0$ if $\langle Z_V \cdot [dV / d\tau] \rangle_\theta < 1$. To be more precise, $Z_V \cdot [dV / d\tau]$ for almost all θ is greater than 1 at $I=0.161$. This can easily expect $\langle Z_V \cdot [dV / d\tau] \rangle_\theta < 1$ so that $[\partial f / \partial \mu] < 0$. However as I increases from 0.161, the θ region that $Z_V \cdot [dV / d\tau]$ takes greater than 1 is reduced. Thereby, $\langle Z_V \cdot [dV / d\tau] \rangle_\theta$ is less than 1 so that $[\partial f / \partial \mu] > 0$.

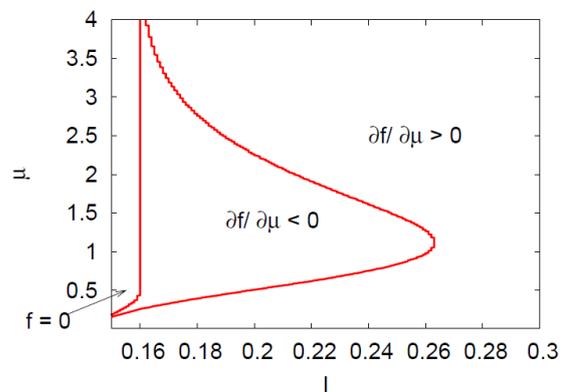

Fig. 5. $I-\mu$ phase diagram for the class I HH model. The left region show the stationary state of $f = 0$ while the middle (or right) region shows $[\partial f / \partial \mu] < 0$ (or $[\partial f / \partial \mu] > 0$). In the diagram, the regions of $\mu > 0.45$ and $\mu < 0.45$ are respectively SN and SNIC bifurcations.

Secondly, we confirm a frequency transition of the low to the high level for $\mu > 6$ and $I=0.161$ in Fig. 4. For this, we numerically calculate $[\partial f/\partial \mu]$ as a function of I . In Fig. 7(a), the $[\partial f/\partial \mu]$ - I curve has the sharper positive slope, $[(\partial/\partial I)(\partial f/\partial \mu)] > 0$, around onsets of oscillations for $\mu = 5.8$. However, the curve monotonically decays when $\mu > 6$. This implies that the phase transition of the frequency happens. In fact, when μ increases at $I=0.161$, $[\partial^2 f/\partial \mu^2]$ switches from the positive to the negative at $\mu = \mu_c$ exhibiting $[\partial^2 f/\partial \mu^2] = 0$. The peak of the $[\partial f/\partial \mu]$ - μ curve is diminished and then disappears for larger I (Fig. 7(b)). When I approaches to the bifurcation point (I_{SN}), we obtain the following condition for a frequency transition:

$$\lim_{\mu \rightarrow \mu_c^+} \frac{\partial f}{\partial \mu} = +\infty, \quad \lim_{\mu \rightarrow \mu_c^-} \frac{\partial f}{\partial \mu} = +\infty.$$

From bifurcation analysis of Fig. 2(a), let μ be μ_c when $V_{SN} = V_{min}(\mu_c)$. Periodic motions of a trajectory on the LC around $\mu = \mu_c$ can be described as followings: Membrane potential dynamics immediately before depolarization is extraordinary slow for $\mu < \mu_c$, because a trajectory is converge to the LC through the SN equilibrium, thereby leading to a significant phase delay. However when $\mu > \mu_c$, a trajectory passes on the LC via the saddle to increase $[dV/d\tau]$.

We notice $[\partial f/\partial \mu] > 0$ after a frequency transition. This is the same result as the HH oscillator undergoing the AH bifurcation [19]. Therefore, we have found that, for any I in the oscillation range,

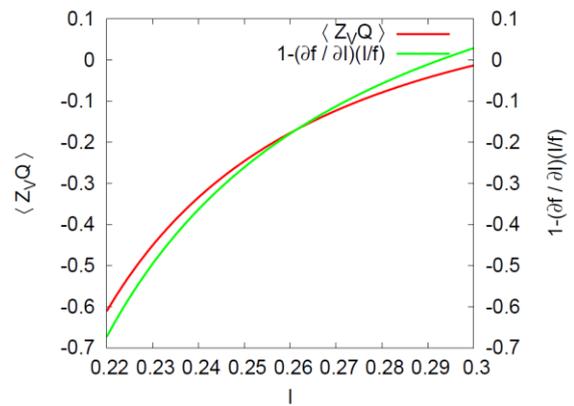

- Class I oscillation: $[\partial f/\partial \mu]$ takes both the positive and negative values if $\mu < \mu_c$, and has the positive value if $\mu > \mu_c$.
- Class II oscillation: $[\partial f/\partial \mu]$ takes the positive value for any μ .

V. DISCUSSION

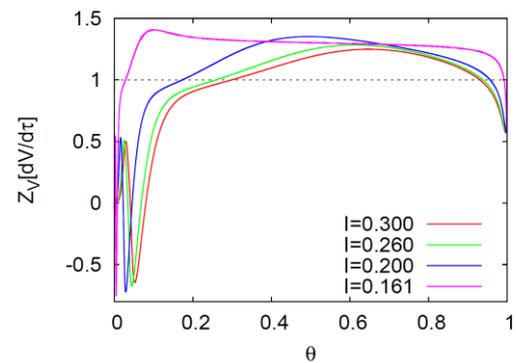

Calculations of $[\partial f/\partial \mu]$ have ruled out the ambiguity in the conventional classification with different PRC forms, to give clearer classification regardless of the PRC forms. The PRC was traditionally classified into two types: Type I takes almost all positive values for any phase while type II has the obvious negative values as well [20][21]. However, the type I PRC even takes the negative value for extreme narrow phase range and its shape continuously changes to the type II with an increase in I (as shown in red lines of Fig. 8). There was an open question about definition of the PRC classification.

In comparison with the $[\partial f/\partial \mu]$ results for the class I, the typical class II f - I curve has been analyzed by using the original HH neuron that starts oscillations with a finite frequency through the AH bifurcation. The result is only $[\partial f/\partial \mu] > 0$ for any I in the oscillation range. We may conclude that, in the class I for the SHCO bifurcation, the $[\partial f/\partial \mu]$ takes both the positive and negative values, meanwhile $[\partial f/\partial \mu] > 0$ in the class II for the AH bifurcation.

We have thus shown that computing $[\partial f/\partial \mu]$ is significantly potential for oscillation classification. One may criticize that the analysis studied here only supports the

(a)

(b)

Fig. 6. (a) $\langle Z_V Q \rangle_\theta$ (red line) and $[1 - (\partial f/\partial I)(I_0/f)]$ (green line) represent as functions of I when $\mu=1$. (b) $Z_V \cdot [dV/d\tau]$ is a function of θ ($\in [0, 1)$) at each level of $I = 0.161, 0.2, 0.26$ and 0.3 .

conventional classification with different bifurcation mechanisms of the SN (or SNIC) and AH.

In order to evade such criticism, the two-dimensional Hindmarsh-Rose (2DHR) model, which retains the analytic tractability of the FitzHugh-Nagumo model [22][23], is employed [24]. All bifurcations requested, those being, the AH, the SNIC and the SN are computed in the 2DHR model with appropriate parameter sets. The $[\partial f/\partial \mu]$ - I curve for each bifurcation is then computed. As the result, the AH, SNIC and SN bifurcations have been categorized into two types:

- Category I ($[\partial f/\partial \mu] > 0$ and $[\partial f/\partial \mu] < 0$): The SNIC bifurcation.
- Category II ($[\partial f/\partial \mu] > 0$): The AH and SN bifurcations.

As far as we know, the AH and SN bifurcations were not categorized into the same. On the contrary, the SN has so far been regarded to belong to the category for the SNIC bifurcation. In fact, the condition that only $[\partial f/\partial \mu] > 0$ is showed even if the Terman-Wang (TW) model [25][26] is used [19]. The TW model is one of the analytic tractable neuron models, which generates oscillations via the SN bifurcation.

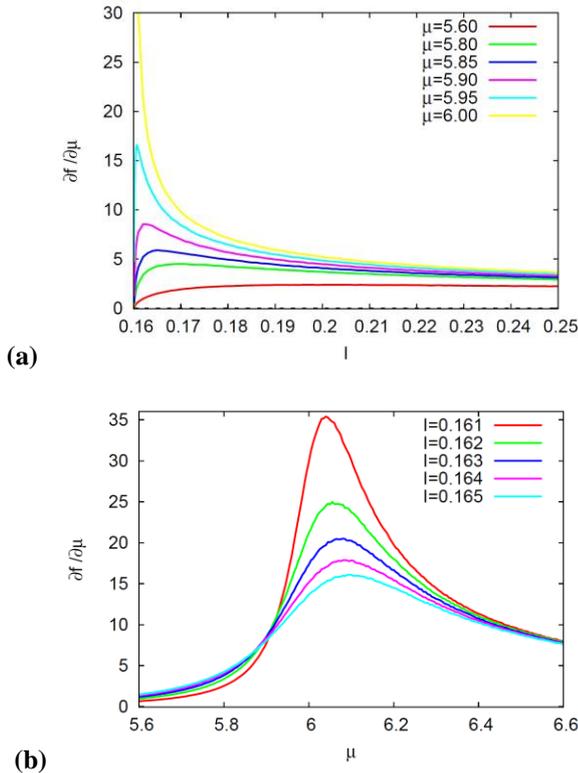

Fig. 7. Results of the Frequency transition when $\mu > 6$. (a) $[\partial f / \partial \mu]$ - I curves when $\mu=5.6, 5.8, 5.85, 5.9, 5.95$ and 6.0 . (b) $[\partial f / \partial \mu]$ - μ curves for $I = 0.161, 0.162, 0.163, 0.164$ and 0.165 .

These $[\partial f / \partial \mu]$ results are supposed to give us important indications about conventional classifications with different bifurcation mechanisms, or different PRC forms. The SN bifurcation that occurs on the LC is crucial for the aforementioned categorization. To be more precise, the necessary condition for $[\partial f / \partial \mu] < 0$ is that the bi-stability of stable equilibrium and a LC attractor exists. Such a bi-stability cannot be found in the TW model and the 2DHR model exhibiting only stable equilibrium.

Furthermore, the categorization suggested in this work does not address that the PRCs are intensively related to the emergence of oscillations via bifurcation mechanisms. The previous work for class and type classifications [27] indicated that type I PRC has the class I oscillations. This was however no more than an indication at that moment. In Fig. 3(b), the f - I curve for $\mu = 0.25$ is the logarithmic class I. Nevertheless, type II PRCs are calculated in any frequency range. As referred to [28] and described in Eq. (5), more precisely, the average of the PRC equals to the slope of the f - I curves. Therefore, the categorization suggested above is more comprehensive and more sophisticated than the conventional classifications.

The potential task in the near future is to discover some still-unknown oscillatory property of the neuronal circuit undergoing the corresponding bifurcation. Finding novel oscillatory properties allows us to predict bifurcation mechanisms hidden in complex behavior of the neuronal circuit. Since $[\partial f / \partial \mu]$ is intensively related to f - I relations as well as PRCs, at least, it can expect to identify bifurcation mechanisms with the more accuracy, compared to only observation of the f - I relations or PRCs. In the f - I relations,

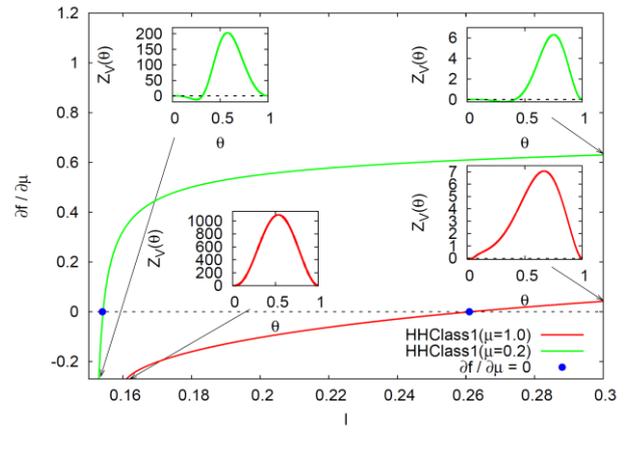

Fig. 8. $[\partial f / \partial \mu]$ - I curve for $\mu=1$ (red line) shifts to the one for $\mu=0.2$ (green line). Correspondingly, the cross point of $[\partial f / \partial \mu] = 0$ (blue circles) moves so that the I range for $[\partial f / \partial \mu] < 0$ is reduced. The PRCs are drawn respectively for $I = 0.161$ and $I = 0.3$ when $\mu=1.0$, and for $I = 0.153$ and $I = 0.3$ when $\mu=0.2$.

it is difficult to record at the same time the zero and nonzero frequencies. The PRCs are observed under the environmental noise [29] so that we can difficultly specify bifurcation mechanisms.

Finally, we discuss the temperature scaling factor μ . In general, time courses of the ion-channel activations are rescaled with $\mu = Q_{10}^{(T-T_e)/10}$ with temperature T °C, $Q_{10} \sim 3$ and environmental temperature T_e . In physiological experiments, the temperature is usually fixed around either room temperature or body temperature so that there is not so much temperature variation [5][30]. We may thus have to take care of the temperature parameter to observe stable oscillatory properties of individual neuron corresponding to the recording temperature. Recent model studies are not significantly careful for handling with the temperature parameter [31][32]. In this work, the experimental temperature variation was ignored, because it was crucial and interesting for us to systematically investigate oscillatory properties of the HH model.

VI. CONCLUSION

We studied a frequency decrease and a frequency transition with a temperature increase in the HH model undergoing SHCO bifurcations. In this study, $[\partial f / \partial \mu]$ was derived by perturbation analysis of the stable HH oscillators, in combination with $[\partial f / \partial I]$ and $\langle Z_V Q \rangle_\theta$. We showed that the PRC was clearly classified by $[\partial f / \partial \mu]$. More interestingly, different bifurcation mechanisms of the AH and the SN were commonly categorized.

Abstract: Rapid demand on system-on-chip (SoCs) and communication increases with the help of very-large-scale integration (VLSI) circuits, even though prime factor is to reduce the Power consumption and the thermal wall have become the major factors limiting the speed of while interconnect is becoming a primary power consumer. High bandwidth is desired to enhance parallelism for better performance, and the power efficiency on this bandwidth is critical to the overall SoC power consumption. Current bus architectures such as AMBA, Core connect, and Avalon are convenient for designers but not efficient on power. This paper proposes a physical synthesis scheme for on-chip buses and bus matrices to minimize the power consumption, without changing the interface or arbitration protocols. By using a bus gating technique, data transactions can take shortest paths on chip, reducing the power consumption of bus wires to minimal. Routing resource and bandwidth capacity are also optimized by the construction of a shortest-path Steiner graph, wire sharing among multiple data transactions, and wire reduction heuristics on the Steiner graph. Experiments indicate that the gated bus from our synthesis flow can save more than 90% dynamic power on average data transactions in current AMBA bus systems, which is about 5–10% of total SoC power consumption, based on comparable amount of chip area and routing resources.

Index Terms: Algorithm, communication graph, data throughput, physical synthesis, power efficiency, Steiner graph.

I. Introduction

As the feature size of process technology scales down, system-on-chips (SoCs) are capable of integrating more components and gaining higher complexity. Since clock frequency on single components is reaching a limit due to power and thermal limitations, better performance will be mostly exploited through parallelism [1], [3]. As a result, two factors determine that on-chip communication architectures are becoming a critical aspect in future systems. First, the communication latency and bandwidth among system components may become a bottleneck of performance. Second, the percentage of power consumed on inter-component communications in the whole system power has scaled up to a significant level [9], [13], [15]. Industrial on-chip bus standards include AMBA [29], [31], CoreConnect [30], Avalon [32], and so on. These existing standards can provide an interface for IP developers and a communication solution for system designers. Compared to the network-on-chip [10] type of communications, buses are small on silicon footprint, fast in terms of latency, and easy to implement. Moreover, the implementations can be

reconfigured according to specific applications, enabling designers to apply various optimizations for best performance on available resources. The advantages of simplicity make buses popular in industrial SoC designs. However, current bus architectures are not power efficient on transferring data through bus lines. And since this part of power is scaling up as technology advances [13], it becomes a necessity to introduce physical level optimization on bus synthesis to minimize the power consumed by inter-component communication on bus lines. When high bandwidth is required on these buses, wire efficiency may also become low, which ultimately limits the system bandwidth capacity and performance. We propose a physical synthesis scheme for on-chip buses to eliminate the disadvantages in existing bus architectures, but not to change the existing protocols and component interfaces. Based on shortest-path Steiner graphs, efficiency on bus lines is maximized without the need to redesign system components and IP modules. Routing resource is also reduced without compromising low power. The cost on our new scheme is the additional silicon resource consumed by distributed controls and switches, which is scaling down by Moore's law. Under technology trends, this physical synthesis scheme is capable of bringing a large improvement on power and performance based on current state-of-the-art on-chip buses and bus matrices.

A. Related Work

An elaborate power analysis on AMBA on-chip bus is performed in [15]-[18] where the detailed decomposition of power consumed by system components is obtained by simulation on NEC's gate-level power estimator. Power saving techniques have been explored and applied extensively to break through the "power wall" of VLSI circuit performance. Clock gating [5] is nowadays widely used to reduce dynamic power, and power gating [20] is used to avoid unnecessary static power. In bus communications, a large part of the power is consumed on the wires of bus lines [15], which is relatively scaling up with technology and applications [9], [13]. Techniques of clock gating can be used on bus lines to achieve a similar goal, which is to mask off signals wherever they are not needed. Bus segmentation in [6] has such effect to help reduce dynamic power, but the effect is largely limited by tree structures topologies. Also in [18], a power performance tradeoff is analyzed on bus matrices, where a bus matrix is composed of a set of tree structured buses. We extend the structures from trees to graphs, using Steiner graph connections for a thorough optimization of "bus gating" to minimize the communication power. Topologies have been mostly discussed in bus optimizations, while the physical/geometrical information is not being emphasized.

B. Paper Overview

In this paper, to obtain the bus getting architecture and optimize bus communications, and get minimal tradeoff power maximal bandwidth, and minimal total wire length. the protocols are of AMBA AHB [29] and AXI [31], since they are most popular in industrial designs. And apply optimizations which is biased toward minimal power, but also favors bandwidth and routing resource. To construct a minimal shortest-path Steiner graph, and to reduce its scale with a minimal increment on path lengths. The overall optimization flow can be viewed as three major steps:

- Step 1: generating the shortest-path Steiner graph H (for minimal power);
- Step 2: deciding edge weights on H

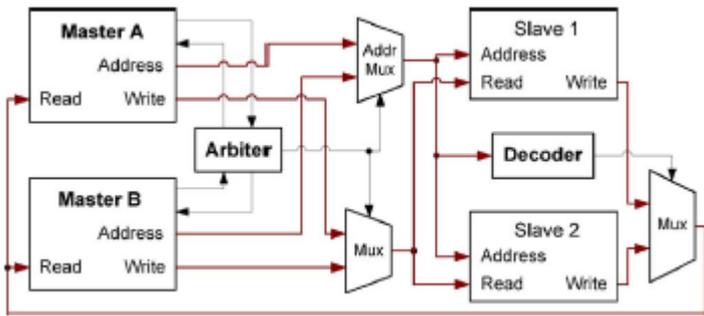

Fig 1 AMBA AHB bus

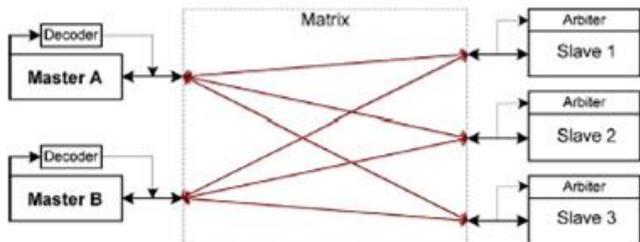

Fig 2 AMBA AXI full bus matrix (drawn)

Step 3: applying incremental modifications on H (for minimal wire length).

The rest of this paper is organized as follows. Section II introduces some background information on bus architecture and bus gating. Section III shows the heuristics for minimizing power and Section IV for minimizing wire length. Experiments are illustrated in Section V. Finally, Section VI gives our conclusions on bus matrix, with comparisons to network-on-chips and analogies to city traffic planning.

II. Bus Architectures and Bus Gating Background

Standard on-chip buses like AMBA were designed to enable fast and convenient integration of system components into the SoC, where simplicity is one of the major objectives. When the bus power consumption comes to a significant level that we cannot afford to ignore [15], power optimization will be desirable. We introduce a “bus gating” technique [23] to minimize the power on bus lines with a small compromise on design simplicity.

A. AMBA On-Chip Bus and Bus Matrix Architectures

The AMBA AHB on-chip bus [29] and bus matrix [31] are drawn in Figs. 1 and 2. The components connected by these buses can be classified into masters and slaves. Masters are typically microprocessors, each can start a transaction with one slave device at a time, where the slave is selected by giving an address to the decoder. Slave devices respond to masters passively. When conflicting requests come from multiple masters, arbiters will decide the order of services. The main difference between the bus and bus matrix is on multiple access from masters. The basic bus allows one master access at a time, while the bus matrix may allow multiple accesses. In a full bus matrix like Fig. 2, the masters and slaves are connected like a bi-clique, and each slave has an arbiter. Full bus matrices have largest bandwidth capacity, typically applied for maximum performance.

B. Power and Wire Efficiency of Gated Bus Using Steiner Graphs

The power efficiency of a bus architecture like Fig. 1 is low because the bus lines from masters to slaves are connecting all the slave devices by a single large wire net. The same is on slave-to-master connections. While the communication is one-to-one, the signals are sent to all the receivers regardless of whether they are needed, which results in wasted dynamic power on bus wires and component interfaces. Moreover, this low power efficiency is still being worsened by the technical scaling of global wires [13] and the increasing number of components integrated into SoCs. Gated bus is a solution to save the wasted dynamic power. The simplest way is to add a de-multiplexer after each multiplexer in Fig. 1, and add a de-multiplexer after each master device in Fig. 2, so that the signals only propagate to where they are needed. This method works in a similar way as clock gating [5], [11], and can be even more effective because the signal receivers here have much less complex behaviors than in a clock tree. For tree structured buses, distributing the multiplexer and de-multiplexer into the wire net [Fig. 3(a)] helps to save both power and wires. For wire length, while the single multiplexer needs independent lines from every sender, the lines can be shared with distributed multiplexers and form a Steiner arborescence [7], [21], [22]. An arborescence is a directed tree such that every root-to-leaf path is shortest. On the receivers’ side with distributed de-multiplexers, the bus lines change from a rectilinear Steiner arborescence to a minimum rectilinear Steiner arborescence (MRSA). By the research in [2], this change increases the wire length by only 2–4% on average. So the total bus wire length can be reduced by the distributing the multiplexer/de-multiplexers, while the dynamic power can also be reduced at the same time. There is a small control overhead for sending the signals over the arborescence, but compared to the bus width and data throughput, this dynamic power overhead is negligible. Based on the same tree topology, effective bus gating can be applied by distributing the control over the entire tree (arborescence). On bus matrices, however, simply adding de-multiplexers may increase the total wire length, because when the number of master-to-slave paths becomes large, each path will need its own bus wires [as in Fig. 3(b)]. To reduce wire length in the bus matrix, also to further reduce power on the basic bus, we adopt the structures of Steiner

graphs. A Steiner graph is a generalization of Steiner trees, without the limitation of tree structure that there is only one root placed at a certain point, which cannot be on the shortest path of every connection. By removing the constraint of tree topologies, we gain higher freedom to choose shortest paths for reduced power on data

Else if
 If there is T_j at V_i then $Q \leftarrow Q \cup V_i$
 $X \leftarrow Q \cap \{V_j : \forall P(s-p(v_j)) = |P(s) - P(V_i)| + |P(V_i) - P(V_j)|\}$
 If $(|X| > 2)$ then merge the nodes in X rooted at V_i
 $Q \leftarrow (Q \cap X) \cup \{V_j\}$ return the arborescence at s'

Our shortest-path Steiner graph is constructed by multiple iterations of a revised MRSA construction.

A. k-IDeA/G Heuristic for MRSA

The RSA/G heuristic for the MRSA problem was first introduced in [21], and is proved to be 2-approximate. Given a single source and n terminals, the basic flow is to start with n subtrees and iteratively merge a pair of subtree roots v and v' such that the merging point is as far from the source as possible, so that the wires can be shared as much as possible. It terminates when only one subtree remains. For efficient implementation, the RSA/G first sorts all the nodes on the Hanan grid [26]

In each iteration, it removes up to k nodes from v_1, \dots, v_n some nodes are skipped it will reduce the memory and utilize the same location as address when running the RSA/G algorithm. By removing the nodes, some SMO merges are skipped, which in some cases can result in a better overall solution. All the combinations of the k or fewer skipped nodes are tried in an iteration, and the best set of skipped nodes are marked as permanently deleted. The iterations are repeated until no further improvement occurs.

B. Shortest-Path Steiner Graph by Multiple MRSA

For a shortest-path Steiner graph with multiple sources s_1, \dots, s_m , the idea behind single source MRSA is still valid. In fact, our algorithm constructs the Steiner graph H just by iteratively constructing the MRSA rooted at every source. While a single arborescence can be optimized by the k -IDeA heuristic, the m arborescences are individually optimized with the same idea, plus that these arborescences also need to share as much wire as possible to optimize the final Steiner graph. For this purpose, we add additional heuristics based on the RSA/G to construct multiple MRSA one by one. First, starting from the second MRSA construction, we can reduce terminals by using existing wires. For each MRSA with source s_i , the terminals that need connection from the source can be moved along existing edges of H toward s_i . As the example shown in Fig. 5, with the wires of previous aborescences, we only need to connect eight nodes instead of the original 16 terminals to form the MRSA rooted at s_2 , because all the other terminals can be reached from one of these eight nodes by a shortest path from s_2 . This set of nodes (denoted as T') can be obtained by checking each terminal t_j , move from t_j toward s_i as much as possible along existing paths until reaching a vertex (can be a terminal or a Steiner node) in H where no vertex closer to s_i can be reached, and add this vertex to T' . When there are multiple paths in the graph, we pick the final vertex closest to s_i , so the rest part of the path is short and likely to need less wires. Details are in the routine "Necessitate(v)" Second, we construct the MRSA based on the set of nodes T' using as much existing wires as possible. Compared to the RSA/G heuristic, the TMO condition is changed to v_i' , $\Delta T'$ the SMO condition is changed, also for the purpose of wire reusing, from $|X| \geq 2$ to $|X| \geq 2$ or $(|X| = 1$ and $v_i \Delta H)$. Because when v_i is already

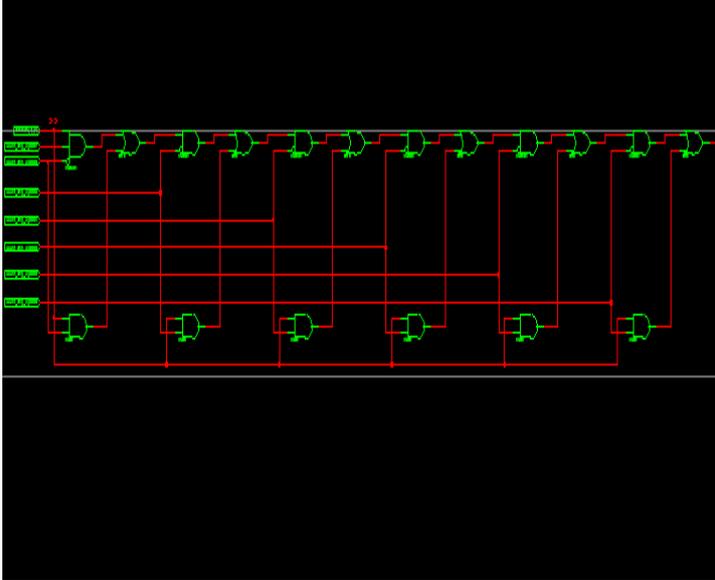

Fig 3 Bus gating using distributed mux and de-mux. (a) On single bus. (b) On bus matrix.

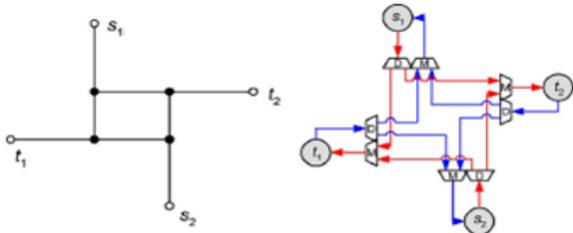

Fig 4 Shortest-path Steiner graph G_n and its bus implementation.

transactions, and to let the paths share wires for reduced. Shortest-path Steiner graphs have advantage on power efficiency as shown above. Naturally, graph structures also have advantage on communication bandwidth over trees. Our objective of bus gating and bus matrix synthesis is to perform a balanced optimization on power and bandwidth even when available routing resource is limited.

III. Bus Matrix Graph Construction

The flow we use is to first construct a shortest-path Steiner graph based on the given placement of $\forall s \cup V_t$ and communication graph G_c and then decide the weight $\omega(e)$ on each edge. The single-source case is the MRSA problem, which is well studied in previous work such as [7] and [21]. Although it is proved to be NP-complete in [22], heuristic algorithms can provide close-to-optimal solutions of Steiner arborescences.

RSA algo

Given a source s and n terminals t_1, \dots, t_n ,
 v_1, \dots, v_N are the Hanan grid nodes of $\{s, t_1, \dots, t_n\}$ sorted by decreasing distance to s

$Q \leftarrow \emptyset$

For $I = 1$ to N do

in the graph, it was added into previous MRSAs and can share wires with the node in X like the case in RSA/G when $|X| \geq 2$. As the example in

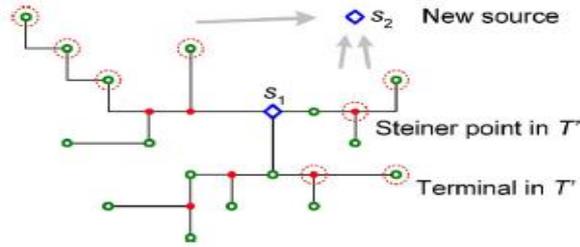

Fig 5 Nodes requiring connections (in dotted circles).

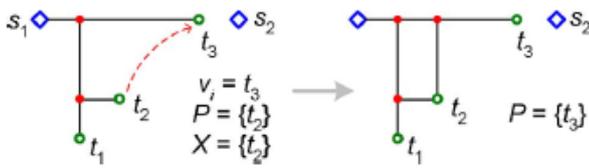

Fig. 6 Connecting a node into the Steiner graph.

shows, when X contains only one node $\{t_2\}$, it should be connected into H when v_i comes to t_3 , and half of the connection length can be saved using the existing horizontal wire. where the routine “connect(u, v)” uses existing wires if applicable on shortest connections. The k -IDeA iterations remain unchanged here. And after the shortest-path Steiner graph is constructed by applying k -IDeA on the m sources, there are possibly some redundant edges that can be removed. So the final step is to check each edge $(v_i, v_j) \Delta H$, if H still contains all the source-to-terminal shortest paths without (v_i, v_j) , then remove it from H .

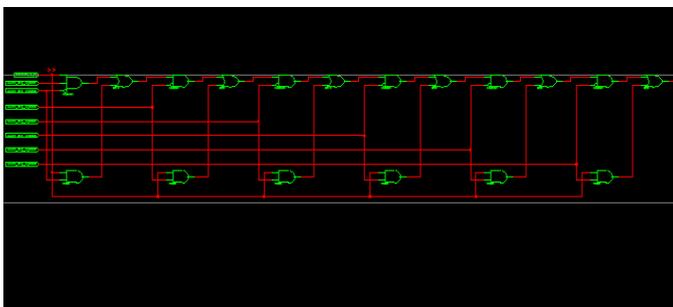

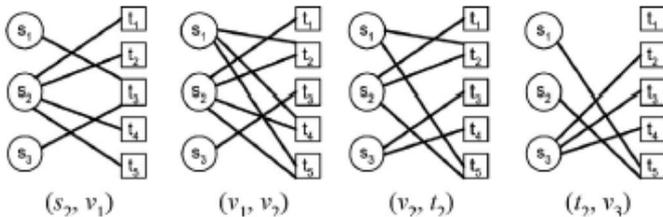

Fig7 Bipartite graphs of four edges in the bus matrix

i.e., all the $|Vs| \times |Vt| = 15$ arcs are present. The resulting bus matrix graph contains five Steiner nodes and 13 edges. Every arc from a master s_i to a slave t_j has a connection of minimal length, and the 15 shortest paths shown in Fig. 7 are fixed. To assign a weight on each edge, we take $e = (s_2, v_1)$ as example. Six of the 15 paths go through e , so $G'(e)$ consists of the six corresponding arcs $(s_1, t_3), (s_2, t_1), (s_2,$

$t_2), (s_2, t_4), (s_2, t_5),$ and (s_3, t_3) . The maximum matching has two edges, because t_3 can only connect to one of s_1 and s_3 . Therefore, $\omega(e) = 2$ is adequate to support all communication patterns. Fig.7 shows the bipartite graphs of four edges on the central horizontal line. Despite the number of connections, most of the edges are weighted 1. Yet this bus matrix graph is adequate for maximum bandwidth capacity, i.e., wires will not be the bottleneck of multiple simultaneous connections. The total weighted wire length in this bus matrix is 108. Compared to the total path length 266 if implemented as a full bus matrix in Fig. 2, the Steiner graph approach saves more than half of the routing resources.

IV. Tradeoffs on Power, Wire, and Bandwidth

A. Steiner Graph Reduction

Since high bandwidth bus matrices will need significantly more wires to support parallel communications across the chip, routing resource may become another limitation as more components are integrated into SoCs and interactions increase. Especially when the components are placed in irregular placement instead of cell arrays, the shortest-path Steiner graph generated by the algorithm in which bring additional wire length. We look for changes in the graph structure which can significantly reduce the wires, while preserving the short paths at the same time.

Fig. 8 Searching for mergeable parallel segments (in vertical direction).

when the double edges are geometrically very close to each other, combining them into one edge only slightly increases the length of some connections, while possibly saving much more wire length. Fig. 8 shows the effect of merging parallel segments in narrow rectangles. The total edge length is greatly reduced, while the increment on average path length is relatively small. Although fewer edges will generally result in larger edge weight, the total weighted edge length (wire length) can still be reduced by this merging operation due to improved wire sharing among paths. Thus, if we relax the requirement on the path length in definition 4, from the exact Manhattan distance $\|P(u)-P(v)\|$ to within $(1 + \epsilon)\|P(u) - P(v)\|$, we can merge the double parallel edges to save wires. Assume we have a vertical narrow rectangle with dimensions $h \times w$, and we merge the two vertical edges to a single edge placed in middle. The total edge length may be reduced by h , while the lengths of some connection paths increase by $w/2 + w/2 = w$. So if the h/w ratio is high, this operation can be very helpful on relieving routing congestion, while preserving the low power consumption of a bus matrix. In the wire length reduction algorithm, we

repeatedly search for pairs of parallel double lines in the bus matrix graph, and for each pair, calculate its potential reduction Δl on edge length and possible increment Δp on path lengths. The pair with highest $\Delta l/\Delta p$ ration is merged, and the modified graph will have a new set of connection paths and edge weights. If the added total wire length is really reduced, we keep the merging operation and continue to the next iteration, otherwise discard the operation. Eventually, there will be no positive wire length reduction in the graph, and we have a series of bus matrix graphs with decreasing wire length and increasing path lengths, where a comprise can be chosen. The process of searching for vertical mergeable parallel segments is illustrated in Fig. 8. (Horizontal lines are processed in the same way with x - y coordinates switched.) First, the vertical line segments in the Steiner graphs are sorted by their x coordinates, denoted as u_1, u_2, \dots, u_k . Then for each pair of segments u_i, u_j ($i < j$) with a common y interval $[y_1, y_2]$, if between i and j there is no other vertical segment on $[y_1, y_2]$, u_i and u_j are a pair of mergeable segments. On the parallel segments u_i and u_j , let cl denote the count of horizontal lines connected to the left, cr denote the count of lines connected to the right, and cm the count of lines connecting u_i and u_j in the middle. Assume $cl < cr$, so the combined vertical segment may not be at the middle but have an offset δ to the right of the midpoint. The reduction on total edge length Δl is by combining the vertical segments of length h and changing the lengths of related horizontal connections. The two vertical segments are reduced to one, which reduces edge length by h . The central cm edges of length w are totally removed. However, the lengths of cl connections on the left are increased by $\omega/2 + \delta$ and the lengths of cr connections on the right are increased by $\omega/2 - \delta$. To sum up $\Delta l = h + Cm\omega - Cl(\omega/2 + \delta) - Cr(\omega/2 - \delta)$. On the possible increment on path lengths, since the left vertical segment is pushed rightward by $w/2 + \delta$, a path may need to detour and add $\Delta p = w + 2\delta$ of distance. So the ratio is

$$\Delta l/\Delta p = \frac{h + Cm\omega - Cl(\omega/2 + \delta) - Cr(\omega/2 - \delta)}{w + 2\delta} = \frac{Cr - Cl}{2} + \frac{h - (Cr - Cm)\omega}{w + 2\delta}$$

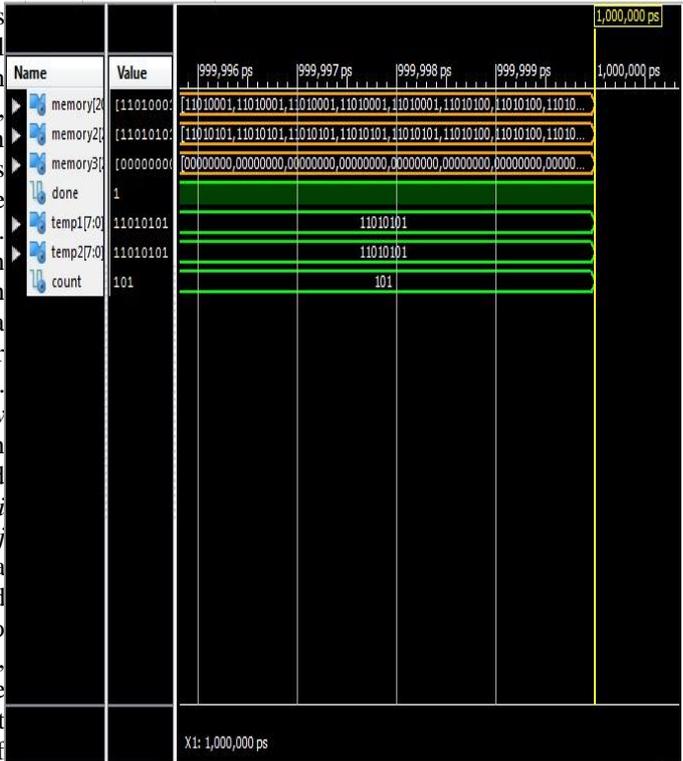

Fig 9 Merging stages of iterations

In Fig. 9, the stages of the merging iterations applied on a Steiner graph. First, the long and narrow rectangles are removed, followed by wider rectangles. still can achieve a significant reduction on total wire length in average cases. Notice that the segment merging operation also helps to merge Steiner nodes which are generated very close to each other. In practice, locally congested Steiner nodes can be hard to implement, because each node needs the area for a switch box and its control unit. Our operation does not guarantee to resolve all closely placed nodes, since it prioritizes longer segments, and may leave small square-shaped sub graphs unchanged. Nevertheless, this situation can be easily resolved by a post-processing algorithm, which scans each Steiner node (denoted as v_i), look at v_i 's close neighbors within a small $d \times d$ box and compute the density of Steiner nodes in the area. For a box with too many nodes, we can shrink all the nodes in that box into one, and implement it by a single switch. The changes on the bus matrix graph by this operation are limited in the small box areas.

V. Bus Matrix Control Units and Wires

Apart from path lengths and data wire lengths, the control overhead needs to be considered for a complete optimization. Although the data lines consume the major amount of routing resource because they are usually at least 64 bit (32 bit \times 2-way) wide, control overhead is increased compared to traditional bus architectures by adopting Steiner graphs. We need a lot of switches at Steiner nodes to guide the on-chip traffic, and each switch needs a certain number of control signals depending on its node degree and edge weights. Each slave device has an arbiter which handles the requests from masters and decides the connection. The result is sent to the central switch control unit, where all the connection paths are stored. Depending on the set of active paths, the central switch control sends

control signals to all the switches on each path, which together instantly create the master-to-slave connection requested by the master device.

VI. Experimental Results

In our experiments, we implement all the related algorithms, including the shortest-path Steiner graph generation, Steiner graph reduction by parallel line merging, and the edge weight maximum matching. The programs are tested on Windows Vista platform with a 2.2 GHz Intel Core2 processor. The running time is short on all the test cases, because the algorithms are time/space efficient, and also because most SoC bus matrices will not need to connect too many components (under 32 in our cases). The test cases we use are mostly artificial, hand made ($T0$ and $T1$), or randomly generated ($T2\Delta12$). They are the same cases used in [23] and [24]. In each test case, the master and slave devices are distributed over a $10\text{mm} \times 10\text{mm}$ square. The power consumption is estimated by the driven capacitance

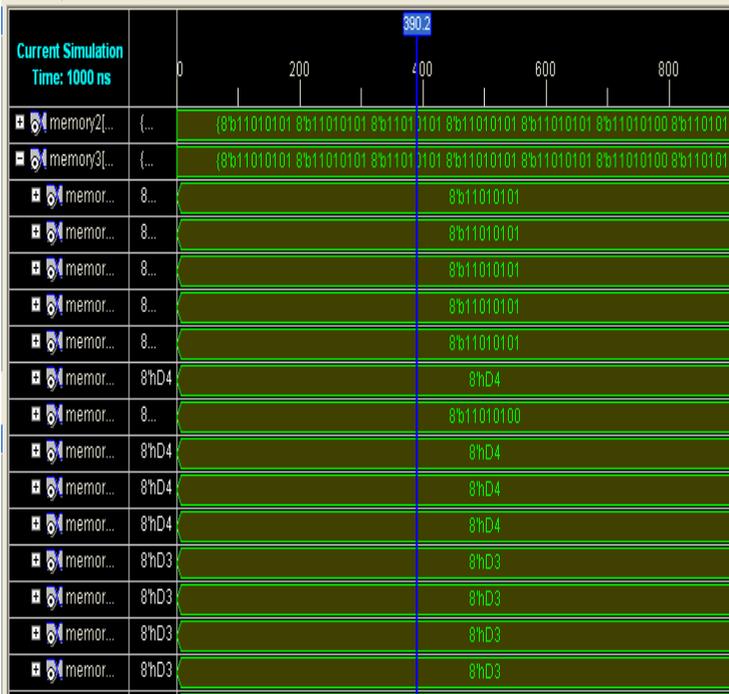

Fig 10 the effect of merging parallel segments with address location

of data transactions, and can be calculated as a linear combination of path length and switches along the path. Path lengths are minimized by the bus matrix graph construction, since wires are the major power consumer. For the purpose of data completeness, we add the power overhead from the switches on Steiner nodes. According to [27] and [28], we estimate that under 90 nm technology, each mux or demux in crossbar switches has about the same capacitance as $25\ \mu\text{m}$ of wires. The total wire length on data wires and control overhead are added straightforwardly. Data wire length is the sum of weighted edge length in the bus matrix graph.

The objective can be minimum power (i.e., average path length), minimum wire length, or a combination of the two. At the top of each column:

1) $\sum L_{vs,vt}$ is the sum of Manhattan distances on all the master-slave pairs;

2) L_{tree} is the average induced path length (major dynamic power) of master-slave connections in tree structured AMBA AHB buses or bus matrices;

3) L_{path} is the average path length (major dynamic power) of master-slave connections in the bus matrix graph;

4) P_{switch} is the added percentage of power overhead in data transactions by the switches on Steiner nodes;

5) $\sum L_{wire}$ is the total data wire length;

6) $\sum W_{ctrl}$ is the added percentage of control wire overhead.

In the minimal power section, the average path length is exactly $\sum L_{vs,vt} / (mn)$, while the total wire length is about one fourth to one third of the total connection length. Compared to traditional bus implementation in [23], the dynamic power saving is mostly over 90% even with the switching overhead added. Overhead on dynamic power increases with the number of components increasing, which requires more bandwidth and larger switches. The percentage is generally under 20% on random cases with under 30 components. So the overall dynamic power here is close to optimal. On the overhead of control wires, the percentage is mostly under 10%, because the number of control signals required is usually very low compared to the 64 bit wide data lines.

In the minimal wire section, the bus matrix graphs are reduced by the parallel line merging heuristic. As a result the wire length on most cases is greatly reduced. Compared to the reduced wire length, the increase on average path length is much lower, mostly around 10% and all under 20%. The power overhead percentage is also increased, because although the Steiner nodes are reduced, the switches along each path are not reduced as much in number, but increased in size. Still, these solutions are relatively power efficient, and we have series of intermediate solutions between minimal power and minimal wire are available for choice.

To see how the path lengths reflect communication power in SoCs, we calculate the bus power consumption with a fixed set of parameters. Assuming 1V of power voltage, $0.2\ \text{fF}/\mu\text{m}$

of wire capacitance, 4 Gb/s of transaction bit rate, and 20% of bus matrix activity rate, Table V lists the estimated power on bus matrix in each of our test cases. Again we can see a large reduction on total bus power ($P_{path} + P_{switch}$) compared to P_{tree} by traditional Steiner tree structures between certain master-slave pairs may only happen at some specific conditions. So instead of a set of arcs A in the communication graph, we can have a series of arc sets A_1, A_2, \dots, A_c , each one smaller than the original set A , denoting a set of simultaneous connections.

VII. Conclusion

We optimized on-chip communications referring to the AMBA AHB bus (matrix) architecture. The weaknesses of original bus matrices, such as low power efficiency and low wire efficiency, are resolved by using a Steiner graph structure. Compared to network-on-chip which has better bandwidth flexibility, bus matrix has much less latency. Therefore, we believe bus matrix architectures will be widely applied for efficient communications in various future systems. The principle of our work on reducing power is to minimize the data movement on the chip; and that on reducing wires is to maximize wire sharing among different connections. Devised algorithms which can

extensively exploit the on-chip physical design space for a thorough optimization on power and wire efficiency. The results show promising potentials of bus matrices for low power and high performance on-chip communications. More improvements can be explored in future works on formulations, algorithms, and the overall Optimization flow.

Abstract: Network intrusion detection system is used to inspect packet contents against thousands of predefined malicious or suspicious patterns. Because traditional software alone pattern matching approaches can no longer meet the high throughput of today's networking, many hardware approaches are proposed to accelerate pattern matching. Among hardware approaches, memory-based architecture has attracted a lot of attention because of its easy reconfigurability and scalability. In order to accommodate the increasing number of attack patterns and meet the throughput requirement of networks, a successful network intrusion detection system must have a memory-efficient pattern-matching algorithm and hardware design. In this paper, we propose a memory-efficient pattern-matching algorithm which can significantly reduce the memory requirement. For Snort rule sets, the new algorithm achieves 21% of memory reduction compared with the traditional Aho–Corasick algorithm. In addition, we can gain 24% of memory reduction by integrating our approach to the bit-split algorithm which is the state-of-the-art memory-based approach.

Index Terms: Aho–Corasick (AC) algorithm, finite automata, pattern matching.

I. Introduction

The purpose of a signature-based network intrusion detection system is to prevent malicious network attacks by identifying known attack patterns. Due to the increasing complexity of network traffic and the growing number of attacks, an intrusion detection system must be efficient, flexible and scalable. The primary function of an intrusion detection system is to perform matching of attack string patterns. Because string matching is the most computative task in network intrusion detection (NIDS) systems, many hardware approaches are proposed to accelerate string matching. The hardware approaches may be classified into two main categories, the logic [5], [8], [13],[16], [21], [26] and the memory architectures [4], [6], [7], [11], [14], [15], [22]–[24], [27]–[29] In terms of reconfigurability and scalability, the memory architecture has attracted a lot of attention because it allows on-the-fly pattern update on memory without resynthesis and relay out

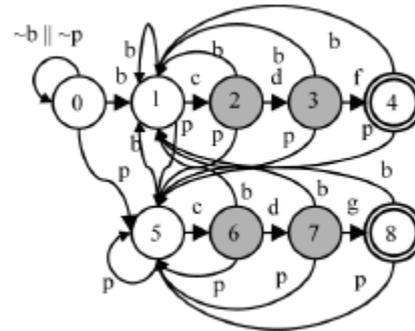

Fig 1 DFA for matching “bcd” and “pcdg”

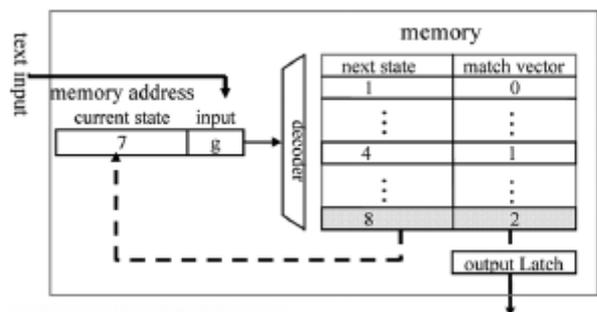

Fig 2 basic memory architecture

The basic memory architecture works as follows. First, the (attack) string patterns are compiled to a *finite-state machine* (FSM) whose output is asserted when any substring of input strings matches the string patterns. Then, the corresponding state transition table of the FSM is stored in memory. For instance, Fig. 1 shows the state transition graph of the FSM to match two string patterns “bcd” and “pcdg”, where all transitions to state 0 are omitted. States 4 and 8 are the final states indicating the matching of string patterns “bcd” and “pcdg”, respectively. Fig. 2 presents a simple memory architecture to implement the FSM. In the architecture, the memory address register consists of the current state and input character; the decoder converts the memory address to the corresponding memory location, which stores the next state and the *match vector* information. A “0” in the match vector indicates that no “suspicious” pattern is matched; otherwise the value in the matched vector indicates which pattern is matched. For example in Fig. 2, suppose the current state is 7 and the input character is . The decoder will point to the memory location which stores the next state 8 and the match vector 2. Here, the match vector 2 indicates the pattern “pcdg” is matched. Due to the increasing number of attacks, the memory required for implementing the corresponding FSM increases to the memory size, reducing the memory size has become

imperative. Certain complicated virus string patterns can be represented by regular expressions. For example, the pattern for detecting the internet radio protocol is represented as “membername*session*player” For memory architecture, only few pre-vious works [15], [29] proposed to reduce the complexity of regular expressions. Still, majority of the patterns are exact string patterns. For example in Snort V2.4, there are 85% of exact string patterns. In this paper, we focus on reducing the memory size of the exact string patterns. We observe that many string patterns are similar because of common sub-strings. However, when string patterns are compiled into an FSM, the similarity does not lead to a small FSM. Consider the same example in Fig. 1 where two string patterns have a common sub-string “cd”. Because of the common sub-string, state 2 has “similar” state transitions to those of state 6. Similarly, states 3 and 7 have “similar” transitions. However, states 2 and 6, states 3 and 7 are not equivalent states and cannot be merged directly. We call a state machine merging those non-equivalent “similar” states, *merg_FSM*.

In this paper, we propose a state-traversal mechanism on a *merg_FSM* while achieving the same purposes of pattern matching. Since the number of states in *merg_FSM* can be drastically smaller than the original FSM, it results in a much smaller memory size. We also show that hardware needed to support the state-traversal mechanism is limited. Experimental results show that our algorithm achieves 21% of memory reduction compared with the traditional AC algorithm for total string patterns of Snort [24]. In addition, since our approach is complementary to other memory reduction approaches, we can obtain substantial gain even after applying to the existing state-of-the-art algorithms. For example, after integrating with the bit-split algorithm [27], we can gain 24% of memory reduction.

II. RELATED RESEARCHES

In this section, we review several related researches in this area. In the past few years, many algorithms and hardware designs are proposed to accelerate pattern matching. The hardware approaches can be classified into two main categories, logic and memory architectures. The logic architectures mostly use on-chip logic resources of field-programmable gate array (FPGA) to convert regular expression pattern into parallel state machines or combinatorial circuits because FPGA allows for updating new attack patterns. Sidhu *et al.* [26] proposed algorithm to compile regular expression patterns into combinatorial circuits based on nondeterministic finite automaton (NFA). Hutchings *et al.* [13] developed a module generator that shared common prefixes to reduce the circuit area on FPGA. Moscola *et al.* [21] presented a content-scanning module on FPGA for an internet firewall. Clark *et al.* [8] improved area and throughput by adding predecoded wide parallel inputs to traditional NFA implementations. Baker *et al.* [5] presented a pre-decoded multiple-pipeline shift-and-compare matcher which reduced routing complexity and comparator size by converting incoming characters into many bit lines. Lin *et al.* [16] proposed a sharing architecture which significantly reduces circuit areas by sharing common infix and suffix sub-patterns. From the perspectives of reconfigurability and scalability, memory

architectures are attractive because memory is flexible and scalable. The Aho–Corasick (AC) algorithm [1] is the most popular algorithm which allows for matching multiple string patterns. Aldwairi *et al.* [2] proposed a configurable string matching accelerator based on a memory implementation of the AC FSM. Tan *et al.* [27] proposed the bit-split algorithm partitioning a large AC state machine into small state machines to significantly reduce the memory requirements. Jung *et al.* [14] presented an FPGA implementation of the bit-split string matching architecture. Piyachon *et al.* [22] proposed to reduce the memory size by relabeling states of AC state machine. Additionally, Piyachon *et al.* [23] proposed to use Label Transition Table and CAM-based Lookup Table to significantly reduce the memory size. Cho *et al.* [6], [7] proposed a hash-based pattern matching co-processor where memory is used to store the list of substrings and the state transitions. Dharmapurikar *et al.* [11] proposed a pattern matching algorithm which modifies the AC algorithm to consider multiple characters at a time. Furthermore, the content addressable memories (CAM) is also widely used for string matching because it can match the entire pattern at once when the pattern is shifted past the CAM. Gokhale *et al.* [12] used CAM to perform parallel search at a high speed. Sourdis *et al.* [25] applied the pre-decoded technique for the CAM-based pattern matching to reduce the area. Additionally, Yu *et al.* [30] presented a ternary content addressable memory (TCAM)-based multiple-pattern matching which can handle complex patterns, correlated patterns, and patterns with negation.

The hash-based approach was proposed to utilize Bloom filter for deep packet inspection. Dharmapurikar *et al.* [10] proposed a hashing-table lookup mechanism utilizing parallel bloom filters to enable large number of fixed-length strings to be scanned in hardware. Lockwood *et al.* [19] proposed an intelligent gateway based on Bloom filter that provides Internet worm and virus protection in both local and wide area networks.

III. REVIEW OF AC ALGORITHM

In this section, we review the AC algorithm. Among all memory architectures, the AC algorithm has been widely adopted for string matching in [2], [14], [15], [22], [23], [27] because the algorithm can effectively reduce the number of state transitions and therefore the memory size. Using the same example as in Figs. 1 and 3 shows the state transition diagram derived from the AC algorithm where the solid lines represent the *valid* transitions while the dotted lines represent a new type of state transition called the *failure* transitions.

The failure transition is explained as follows. Given a current state and an input character, the AC machine first checks whether there is a valid transition for the input character; otherwise, the machine jumps to the next state where the failure transition points. Then, the machine recursively considers the same input character until the character causes a valid transition. Consider an example when an AC machine is in state 1 and the input character is . According to the AC state table in Fig. 4, there is no valid transition from state 1 given the input

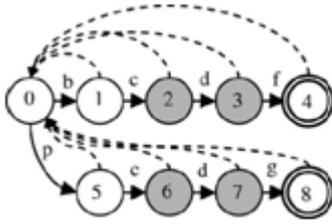

Fig. 3. State diagram of an AC machine.

	input	next state	failure	match vector
State 0:	b	1	0	00
State 0:	p	5	0	00
State 1:	c	2	0	00
State 2:	d	3	0	00
State 3:	f	4	0	01
State 5:	c	6	0	00
State 6:	d	7	0	00
State 7:	g	8	0	10

Fig4. AC state table

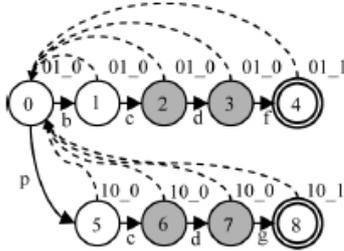

Fig 5. Merging similar states

character . When there is no valid transition, the AC machine takes a failure transition back to state 0. Then in the next cycle, the AC machine reconsiders the same input character in state 0 and finds a valid transition to state 5. This example shows that an AC machine may take more than one cycle to process an input character In Fig. 3, the double-circled nodes indicate the final states of patterns. In Fig. 3, state 4, the final state of the first string pattern “bcd f ”, stores the match vector $\{P2,P1\} = \{01\}$ and state 8, the final state of the second string pattern “pcdg”, stores the match vector of $\{P2,P1\} = \{10\}$ Except the final states, the other states store the match vector $\{P2,P1\} = \{00\}$ to simply express those states are not final states.

IV. STATE TRAVERSAL MECHANISM ONAMERG FSM

In our design, we reuse those memory spaces storing zero vectors $\{00\}$ to store useful path information called *pathVec*. First, each bit of the pathVec corresponds to a string pattern. Then, if there exists a path from the initial state to a final state, which matches a string pattern, the corresponding bit of the pathVec of the states on the path will be set to 1. Otherwise, they are set to 0. Consider the string pattern “bcd f ” whose final state is state 4 in Fig. 7. The path from state 0, via states 1, 2, 3 to the final state 4 matches the first string pattern “bcd f ”. Therefore, the first bit of the pathVec of the states on the path, $\{state\ 0, state\ 1, state\ 2, state\ 3, and\ state\ 4\}$, is set to 1. Similarly, the path from state 0, via states 5, 6, 7 to the final state 8 matches the second string pattern “pcdg”. Therefore, the second bit

of the pathVec of the states on the path, $\{state\ 0, state\ 5, state\ 6, state\ 7, and\ state\ 8\}$, is set to 1. In addition, we add an additional bit, called *ifFinal*, to indicate whether the state is a final state. For example, because states 4 and 8 are final states, the *ifFinal* bits of states 4 and 8 are set to 1, the others are set to 0. As shown in Fig. 7, each state stores the pathVec and *ifFinal* as the form, “*pathVec_ ifFinal*”. Compared with the original AC state machine in Fig. 3, we only add an additional bit to each state. We have mentioned that in this example, states 2 and 6, states 3 and 7 are similar because they have similar transitions. However, they are not equivalent. Note that two states are equivalent if and only if their next states are equivalent. In Fig. 7, states 3 and 7 are similar but not equivalent because for the same input , state 3 takes a transition to state 4 while state 7 takes a failure transition to state 0. Similarly, state 2 and state 6 are not equivalent states because their next states, state 3 and state 7, are not equivalent states. In our algorithm, we define such similar states as pseudo-equivalent states. The definition is as follows.

Definition: Two states are defined as *pseudo-equivalent states* if they have identical input transitions, identical failure transitions, and identical *ifFinal* bit, but different next states. In Fig. 7, states 2 and 6 are pseudo-equivalent states because they have identical input transitions , identical failure transitions to state 0 and identical *ifFinal* bit 0. Also, state 3 and state 7 are pseudo-equivalent states. In our algorithm, the pseudo-equivalent states 2 and 6 are merged to be state 26 and states 3 and 7 are merged to be state 37, as shown in Fig. 8. The pathVec_ ifFinal are updated by taking the union on the pathVec_ ifFinal of the merged states. Therefore, the pathVec_ ifFinal of states 26 and 37 are modified to be $\{11_0\}$ In addition, we need a register, called *preReg*, to trace the precedent pathVec in each state. The width of *preReg* is equal to the width of pathVec. Each bit of the *preReg* also corresponds to a string pattern. The *preReg* is updated in each state by performing a bitwise AND operation on the pathVec of the next state and its current value. By tracing the precedent path entering into the merged state, we can differentiate all merged states. When the final state is reached, the value of the *preReg* indicates the match vector of the matched pattern. During the state traversal, if all the bits of the *preReg* become 0, the machine will go to the failure mode and choose the failure transition as in the AC algorithm. After any failure transition, all the bits of the *preReg* are reset to 1. the string “pcdf” is applied. Initially, in state 0, the *preReg* is initialized to $\{P2,P1\} = \{11\}$ After taking the input character ,P the *merg_FSM* goes to state 5 and updates the *preReg* by performing a bitwise AND operation on the pathVec $\{10\}$ of state 5 and the current *preReg* $\{11\}$ The resulting new value of the *preReg* will be $\{P2,P1\} = \{10\ AND\ 11\} = \{10\}$ Then, after taking the input character , the *merg_FSM* goes to state 26 and updates the *preReg* by performing a bitwise AND operation on the pathVec $\{11\}$ of state 26 and the current *preReg* $\{10\}$ The *preReg* remains $\{P2,p1\} = \{11\ AND\ 10\} = \{10\}$ Further, after taking the input character , the *merg_FSM* goes to state 37 and updates the *preReg* by performing a bitwise AND operation on the pathVec $\{11\}$ of state 37 and the current *preReg* $\{10\}$ The *preReg* remains $\{P2P1\} = \{11\ AND\ 10\} = \{10\}$ Finally, after taking the input character , the *merg_FSM* goes to state 4. After performing a bitwise AND operation

on the pathVec {01} of state 4 and the current preReg{10} the preReg becomes {P2P1}={01AND10}={00} According to our algorithm, during the state traversal, if all the bits of the preReg become 0, the machine will go to the failure mode and choose the failure transition as in the AC algorithm. Therefore, the machine takes the failure transition to state 0 instead of state 4.

V. LOOP BACK IN MERGED STATES

When certain cases of multiple sections of pseudo-equivalent states are merged, it may create loop back problem in a state machine. The reason for the loop back problem comes from merging common sub-patterns with different sequences. For example, the two patterns, “abcdef” and “wdebcg,” have common sub-patterns, “bc” and “de,” which appear in different sequences. Fig. 16 shows the corresponding state machine. Because of the common sub-patterns, “bc”, states 2 and 10, states 3 and 11 are pseudo-equivalent states. And, because of the common sub-patterns, “de”, states 4 and 8, states 5 and 9 are also pseudo-equivalent states. Merging the pseudo-equivalent states will create a loop back transition from state 5 to state 2, as shown in

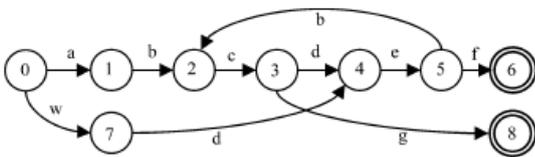

Fig. 6 Merging pseudo-equivalent states with different sequences.

The loop transition may cause false positive matching results. For example, the input string “abcdebcdef” will be mistaken as a match of the pattern “abcdef.” In other words, as long as the common substrings appear in sequence, merging the corresponding pseudo-equivalent states will not result in loop back transitions. Therefore, in our program, we record and identify the orders of common sub-patterns. If the common sub-patterns appear in sequence, the corresponding pseudo-equivalent states can be merged without loop back problems. Fig. 18 shows the pseudo code of our algorithm to find common substrings without the loop back problem. First, all common substrings are extracted by the longest common substring algorithm [9]. The algorithm can report all of the common substrings. Then, the common substrings are labeled as new sequences. Next, we use the longest common subsequence (LCS) algorithm [20] to find all of the longest subsequence common to all strings. The results from the LCS algorithm guarantee that there will be no loop back transition. For example, consider the two patterns, “abcdefghij klm” and “abcwsg h i d e f x y k l m.” Using the longest common substring algorithm, we can extract all of the common substrings of these two patterns such as “abc”, “def”, “ghi” and “klm”. Then, we label the substrings “abc”, “def”, “ghi”, and “klm” as , $\alpha\beta\gamma\delta$, and , respectively. Therefore, the sequence of substrings in “abcdefghij klm” is labeled as “ ” while the sequence of substrings in “abcwsg h i d e f x y k l m” is labeled as “ ”. We subsequently use LCS algorithm to find all of the longest common subsequences among the two new sequences, “ $\alpha\beta\gamma\delta$ ” and “

” and the results are “ $\alpha\beta\delta$ ” or “ $\alpha\gamma\delta$ ”. Therefore, we can merge the subsequences of (“abc”), (“ghi”) and (“klm”) or the subsequences of (“abc”), (“def”) and (“klm”) without the loop back problem. Notice that the result of LCS may not be unique.

VI. HARDWARE ARCHITECTURE

Fig.7 shows our hardware module which can be configured for matching 16 or 32 patterns with a state machine containing 1024 valid transitions at most. In Fig.7,8, the register, called *address_register*, is used to store the current state and the input character. The *valid_memory* is used to store the information of *valid_state*, *pathVec*, and *ifFinal* corresponding to each valid transition while the *failure_memory* is used to store the *failure_state* corresponding to each failure transition. In this prototype, we use a hardwired circuit, called *A2P*, to translate the content of the *address_register* to a contiguous scope, called *pos*, to utilize the *valid_memory*. The circuit *A2P* can be implemented using hardwired circuit or CAM [17]. In addition, the signal *n_valid* is high if there is no valid transition corresponding to the *address_register*. Furthermore, the register

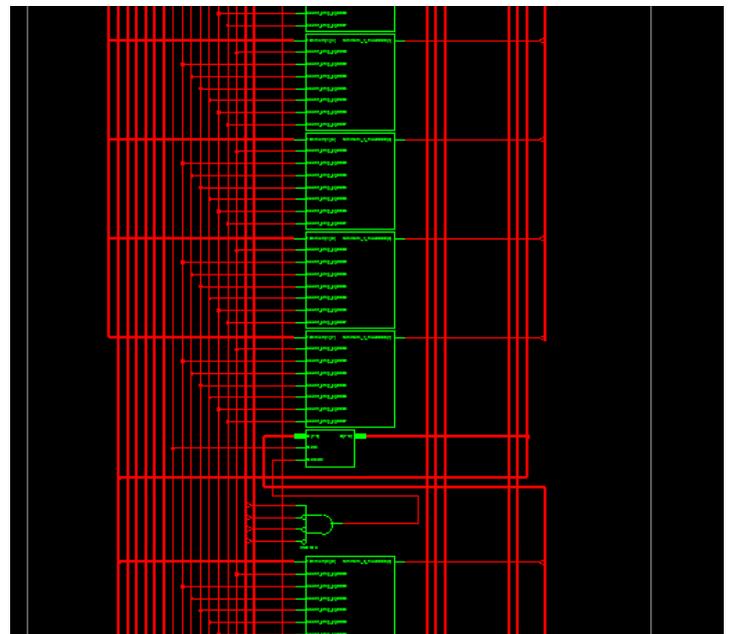

Fig. 7. Hardware module for the new algorithm.

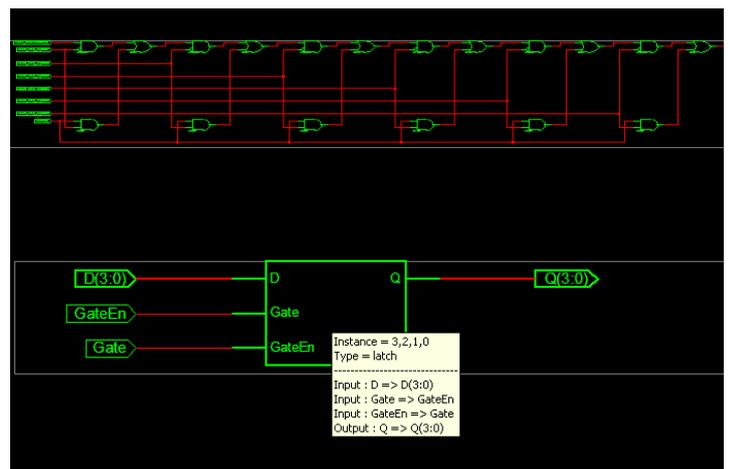

Fig 8 Internal architecture of proposed system

called *preReg*, is used to trace the precedent pathVec in each state. The *preReg* is initiated to be 1 for all bits and is updated by performing a bitwise AND operation on its current value and the pathVec from the valid_memory. The *ns_ctrl* unit is used to determine the next state by the value of *preReg* and *n_valid*. If the *preReg* is 0 for all bits or the *n_valid* is 1, the *ns_sel* will output low to let the failure_state update the current_state register. On the other hand, if the *preReg* is not zero and the *n_valid* is not 1, the *ns_sel* will output high to let the valid_state update the current_state register.

VII. EXPERIMENTAL RESULTS

Using the version 2.4 of Snort rule set, we extract 2217 exact string patterns containing 36 539 characters from the rule database. The results are compared with the methods of the AC algorithm and the bit-split algorithm.

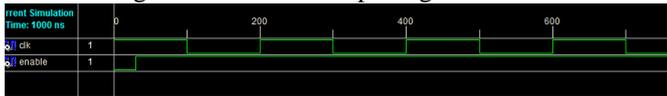

Fig 9 string patterns from Snort rule database

The flow of our experiment is shown in Fig.9. In the first stage, we obtain string patterns from Snort rule database. In the second stage, we group 32 string patterns as a module based on the similarity of string patterns. Further, in the third stage, we use LCS to extract substrings without loop back problem. Because the solution of LCS may not be unique, we select the common substrings which have the largest *sharing gain*. The *sharing gain* of common substrings is defined as the length of common substrings multiplied by the number of patterns sharing the common substrings.

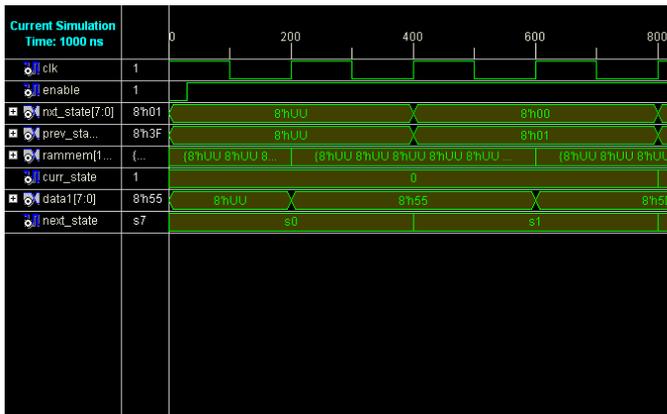

Fig 10 the selection line with clk to the pseudo random order adjustment

For example, three patterns, “1common1”, “2common2”, and “3common3” have the common substrings “common”. The sharing gain of the common substrings is because the substring “common” has six characters which are shared by three patterns. In the final stage, we merge the extracted common substrings and generate the transition table. Table I shows the results before and after integrating our algorithm to the AC algorithm. Columns one, two and three show the name of the rule set, the number of patterns, and the number of characters of the rule set. Columns four, five, and six show the number of state transitions, the number of states, and the memory size of the AC algorithm. Columns

seven, eight, and nine show the results of our approach. Column ten shows the memory reduction compared to the AC algorithm. As shown in Fig. 10, the memory requirement includes the size of the valid memory and the failure memory. Because the memory requirement is proportional to the number of states, our algorithm has reduced memory size on the traditional AC algorithm.

Fig 11 Final result of memory allocation and ram adjustment

Using the traditional AC algorithm, the number of transitions and states are 6793 and 6804, respectively. The memory size is 49 267 bytes. Integrating our algorithm to the AC algorithm, the number of transitions and states are reduced to 4432 and 3846, respectively. The memory size is reduced to 30 699 bytes, 38% of memory reduction from the AC algorithm. For total 2217 string patterns of Snort rule sets, our algorithm achieves a 21% memory reduction compared with the AC algorithm. Because the state-of-the-art bit-split algorithm is based on the AC algorithm, our algorithm can also be integrated to the bitsplit algorithm to further reduce memory requirements. Applying the bit-split algorithm which splits the traditional AC state machine into 4 state machines, the number of transitions and states are 21 949 and 21 993, respectively. The size of memory is 159 202 bytes. Integrating our algorithm to the bit-split algorithm, the number of transitions and states are reduced to 14 437 and 12 664, respectively. The size of memory is reduced to 98 400 bytes. The memory reduction achieves 38%. For total 2,217 string patterns of Snort rule sets, integrating our algorithm to the bit-split algorithm can achieve 24% of memory reduction. Furthermore, we have synthesized the hardware module in Fig. 19 using the ASIC flow of the UMC 0.18 m technology. The results are compared with [2], [6], [27], [28], [30] as shown in Fig 11, columns 2, 3, and 4 shows the number of characters, the memory size, and the throughput. Column 5 shows the memory utilization per character while column 6 shows the memory efficiency which is defined as the following equation:

$$Memory\ efficiency = \frac{(throughput \times Char.\ Num)}{Mem}$$

VIII. CONCLUSION

We have presented a memory-efficient pattern matching algorithm which can significantly reduce the number of states and transitions by merging pseudo-equivalent states while maintaining correctness of string matching. In addition, the new algorithm is complementary to other

memory reduction approaches and provides further reductions in memory needs. The experiments demonstrate a significant reduction in memory footprint for data sets commonly used to evaluate IDS systems.

Abstract: This paper gives a comparative study of parameters of symmetric and asymmetric inhomogeneous structures metamaterials, a unit cell of split ring resonator, by using standard retrieval methods that assigns electromagnetic properties electric permittivity and magnetic permeability from the calculation of scattering parameters. Scattering parameters are the means of characterizing the artificially structured metamaterials which are inhomogeneous. Based on this study it is shown that, while the difference in the magnitudes of S_{11} and S_{22} are modest but there is difference in the phases of S_{11} and S_{22} , resulting in the difference in the impedance properties of symmetric and asymmetric structures.

Keywords: SRR, METAMATERIALS, NIM, DNG

I. INTRODUCTION

The possibility of the negative refraction of electromagnetic (EM) waves by materials with simultaneous negative permittivity and negative permeability was predicted by Vesalago in 1968 [1]. This proposition was not demonstrated until recently; the main difficulty being in obtaining negative permeability. Negative permittivity is available through metals or the periodic arrangement of metallic wires [2, 3, 4, 5, 6]. On the other hand, obtaining negative permeability was an issue. Pendry et al. proposed several structures in order to obtain negative permeability [7]. Among these structures split-ring resonators (SRRs) have attracted much attention [8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18]. A single SRR is composed of two concentric rings with slits on each of them. The slits on the rings are situated on the opposite sides of the rings with respect to each other. The planar nature of the SRR structure makes it easy to fabricate and integrate into 2 and 3 dimensional structures. Several research groups have demonstrated negative indices of refraction by using the periodic arrangement of metallic wires with SRRs through several methods such as the retrieval of effective medium parameters [19, 20, 21, 22, 23, 24, 25], refraction type experiments and wedge experiments [26, 27, 28, 29, 30, 31, 32, 33, 34]. While SRR structure provides negative permeability and can be used to obtain negative refraction, it has several disadvantages. First of all, it has been shown that a medium consisting of a periodic arrangement of SRRs is bianisotropic [25, 35, 36, 37]. The bianisotropy is a result of the non-zero electric dipole moment of the SRR structure due to the asymmetric placement of slits on the rings. Second, it has been shown that the magnetic

resonance of the SRR structure can be excited via electric fields [38, 39]. The excitation of the magnetic resonance of the SRR structure results from the capacitive coupling of the electric field. The capacitive coupling of the electric field creates non-zero current along the rings. These two disadvantages make it difficult to obtain isotropic, homogeneous two or three dimensional negative refraction media by using SRRs for negative permeability.

It is conceptually convenient to replace a collection of scattering objects by a homogeneous medium, whose electromagnetic properties result from an averaging of the local responding electromagnetic fields and current distributions. Ideally, there would be no distinction in the observed electromagnetic response of the hypothetical continuous material versus that of the composite it replaces. This equivalence can be readily achieved when the applied fields are static or have spatial variation on a scale significantly larger than the scale of the local inhomogeneity, in which case the composite is said to form an *effective medium*. The electromagnetic properties of an inhomogeneous composite can be determined exactly by solving Maxwell's equations, which relate the local electric and magnetic fields to the local charge and current densities. When the particular details of the inhomogeneous structure are unimportant to the behavior of the relevant fields of interest, the local field, charge, and current distributions are averaged, yielding the macroscopic form of Maxwell's equations. To solve this set of equations, a relationship must be assumed that relates the four macroscopic field vectors that arise from the averaging—or *homogenization*—procedure. It is here that the electric permittivity and the magnetic permeability tensors are typically defined, which encapsulate the specific local details of the composite medium.

Depending on the symmetry and complexity of the scattering objects that comprise the composite medium, the permittivity and permeability tensors may not provide sufficient information to obtain a solution from Maxwell's equations, and additional electromagnetic material parameters must be introduced f6g. Such media, including chiral and bianisotropic, can couple polarization states and are known to host a wide array of wave propagation and other electromagnetic phenomena

II. S RETRIEVAL METHODS

If an inhomogeneous structure can be replaced conceptually by a continuous material, there should be no difference in the scattering characteristics between the

two. A procedure, then, for the assignment of effective material parameters to an inhomogeneous structure consists of comparing the scattered waves i.e., the complex transmission and reflection coefficients, or *S parameters* from a planar slab of the inhomogeneous material to those scattered from a hypothetical continuous material

A. S-parameter retrieval for a symmetric structure

Negative index metamaterials, which have been of recent interest, pose a significant challenge to retrieval methods because they utilize resonant elements and exhibit both an electric and magnetic response. A single unit cell of a typical symmetric in the propagation direction metamaterials structure is shown in Fig. 1. This particular structure is composed of two types of conducting elements—a split ring resonator SRR and a wire—that have been designed to yield a band of negative refractive index at microwave frequencies. We note in passing that the SRR generally exhibits bianisotropy, since an applied magnetic field induces both an electric as well as a magnetic response. This material response should properly be accounted for in a complete characterization procedure. The unit cell is cubic, with a cell dimension of $d=2.5$ mm. A 0.25 mm thick substrate of FR4 $\epsilon = 4.4$, loss tangent of 0.02d is assumed. A copper SRR and wire are positioned on opposite sides of the substrate. The copper thickness is 0.017 mm. The width of the wire is 0.14 mm, and it runs the length of the unit cell. The outer ring length of the SRR is 2.2 mm and both rings have a line width of 0.2 mm. The gap in each ring is 0.3 mm, and the gap between the inner and outer rings is 0.15 mm.

The *S* parameters for the symmetric unit cell of Fig. 2 are computed using HFSS (Ansoft), a commercial finite-element-based electromagnetic mode solver. Both the *S* parameters and the *Z* parameters are presented in Fig. 3 and Fig. 4. Note the dip in the phase of *S*₂₁, which indicates the presence of a negative index band. The retrieved index in confirms the negative index band that lies between roughly 9 and 12 GHz. The structure was designed so as to be roughly impedance matched. The retrieved impedance, shown in Fig. 4, shows that the structure is indeed roughly matched at the frequency where

$$n = -1.$$

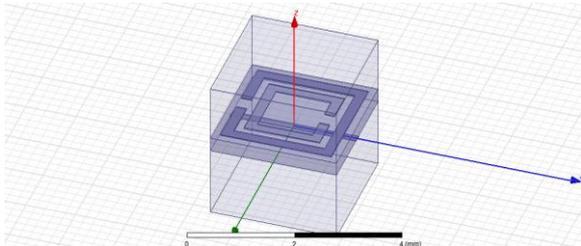

Fig 1 symmetric SRR

B. S-parameter retrieval for asymmetric structure

The unit cell in Fig. 1 can be made asymmetric by moving the wire, for example, off of the symmetry axis. The unit cell shown in Fig. 2 is identical to that of Fig. 1, except that the wire has been shifted a distance of 0.75 mm along the propagation direction. Figures 5 and 6 show the *S* parameters and *Z* parameters computed for an infinitely repeated asymmetric unit cell, one cell thick in

the direction of propagation. While the differences between the magnitudes of *S*₁₁ and *S*₂₂ are modest, there is a great contrast in the phases of *S*₁₁ and *S*₂₂, implying very different impedance properties for the structure depending on which side of the unit cell faces the incoming wave both the phases and magnitudes of *S*₁₂ and *S*₂₁ are identical.

The retrieved indices for the symmetric and asymmetric unit cells are compared, illustrating that, aside from a shift in frequency, the refractive properties of the two structures are very similar. The frequency shift is not surprising, as there is likely an interaction between the SRR and wire that leads to somewhat different material properties depending on their relative positions. While the index is nearly the same for the structures having symmetric and asymmetric unit cells, the impedance is clearly different, as indicated in Fig. 5 and Fig. 6. So different are the two solutions for *z* for the asymmetric structure that in general the assignment of values of ϵ and μ to the composite becomes counterproductive. Thus, although a well-defined refractive index exists for the composite, the manner in which a wave scatters from this material can depend strongly on how the surface is terminated.

IV. CONCLUSION

It is shown that metamaterials based on periodic structures occupy conceptually a special position between effective media and photonic crystals. The S -parameter retrieval techniques that have been utilized recently to characterize metamaterials have been shown to be valid for metamaterials having symmetric unit cells, even when the optical path length is on the order of the unit cell size. The retrieved indices for the symmetric and asymmetric unit cells are compared, illustrating that, aside from a shift in frequency, the refractive properties of the two structures are very similar. While the differences between the magnitudes of S_{11} and S_{22} are modest, there is a great contrast in the phases of S_{11} and S_{22} , implying very different impedance properties for the structure depending on which side of the unit cell faces the incoming wave. Both the phases and magnitudes of S_{12} and S_{21} are identical.

Multiple gas Analyzer and Indicator

Sheikh Rafik Manihar, Komal Prasad Dewagan, Jayant Rajpurohit

Electronics and instrumentation, Chhatrapati shivaji institute of technology, India

ABSTRACT: This project is microcontroller based project. A Gas sensor is used to detect dangerous gas leaks in the kitchen or near the gas heater or gas plant producing acetylene and so on. This implies that the gases available are the main raw materials used in gas plants, without which the existence of a gas plant. This unit detects 300 to 5000ppm of Natural Gas. Ideal to detect dangerous gas leaks in the kitchen. Sensor can be easily configured as an alarm unit. The sensor can also sense LPG and Coal Gas. Ideal sensor for use to detect the presence of a dangerous LPG leak in your car or in a service station, storage tank environment. This unit can be easily incorporated into an alarm unit, to sound an alarm or give a visual indication of the LPG concentration. The sensor has excellent sensitivity combined with a quick response time. The project is based on detect of gas concentration from 200 to 1000ppm. It has high sensitivity it consist of heater coil with which is added with resistance and the output is connected to ADC.

Keywords: Sensor, Detector, LPG, Coal Gas, Natural Gas

I. INTRODUCTION

A Gas Detector is a device which detects the presence of various gases within an area, usually as part of a safety system. Using sensor for detection like LPG & Alcohol sensor. This type of equipment is used to detect a gas leak and interface with a control system. It detects gases like common toxic gases like CO, SO₂ & natural gases. Usage for notification leakage in home & environment applications. This type of device is important because there are many gases that can be harmful to organic life, such as humans or animals. Alcohol Detector is used to detect the alcohol gas by use of alcohol sensor. It is highly sensitive and its detection range is 10-1000 ppm. LPG Detector is used to detect the LPG Gas by use of LPG Gas sensor. It is highly sensitive and its detection range is 10-10000 ppm. Natural Gas Detector is used to detect the Natural Gas by use of Natural Gas sensor. It is highly sensitive and its detection range is 300-5000 ppm. It is a known fact that a gas plant is known in accordance with its final output. So we have oxygen gas plant producing oxygen, nitrogen gas plant producing nitrogen, acetylene gas plant producing acetylene and so on. This implies that the gases available are the main raw materials used in gas plants, without which the existence of a gas plant has no meaning. Accordingly the manufacturers and suppliers are involved in the production of certain gases which are useful in various industrial and commercial, including residential applications. There are different types of gases on the basis of which a plant is installed.

II. METHODOLOGY

Gas detector senses the gas in the environment and converts it in form of voltage, this voltage level converted by ADC in digital form. This signal is input of microcontroller which displays the output.

1. HARDWARE DESCRIPTION

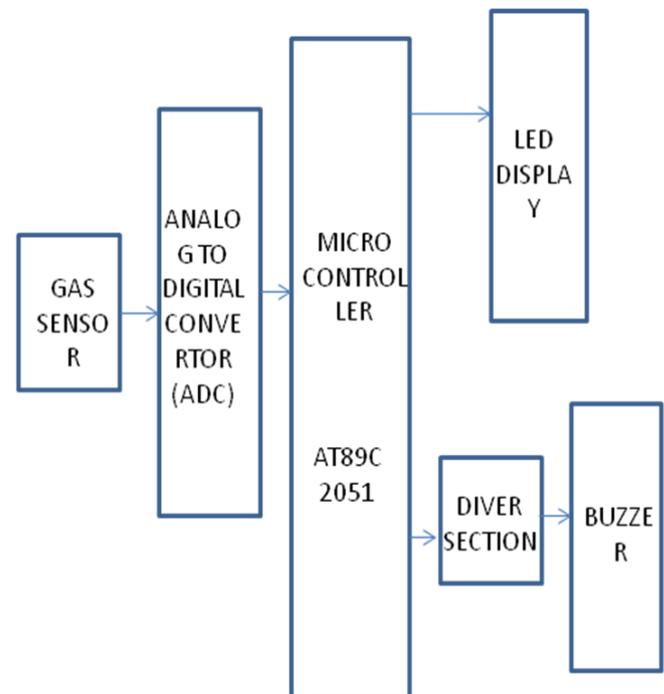

Figure1. Block Diagram.

1. A. Description of Block Diagram

The flow chart describe about the detection of gas firstly through the gas sensor (MQ2) we are detecting the alcohol present in atmosphere. Sensitive material of MQ2 gas sensor is SnO₂, which with lower conductivity in clean air. When the target alcohol gas exist, the sensor's conductivity is higher along with the gas concentration rising. This converted change of conductivity to correspond output signal of gas concentration. The advantage of using this sensor as the microcontroller and the sensor works with the same power supply voltage +5V. This certain amount of reference voltage is set by the sensor. The reference voltage which set by sensor is converted by ADC in the form of digital signal. As ADC 0808/09 we are using easily interface with the microcontroller. The signal which is converted by the ADC is provided to microcontroller through the port. The driver which is connected from the port of microcontroller act as a relay circuit. The driver circuit which helps to drive the buzzer which is connected to driver.

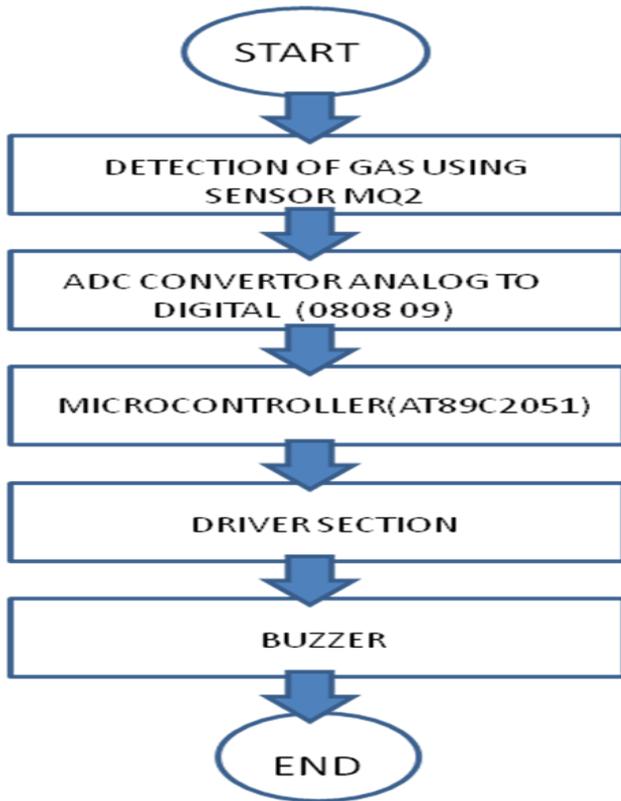

Figure1.Flow Diagram.

2. B. Description of Flow Diagram

The description of flow diagram starts with the detection of gas using sensor MQ2 & MQ3 for detecting multiple gases in our project which includes calibration process for sensors.

After the gas is detected then for further processing the voltage variation is now send to the ADC for converting the analog data to digital for further processing of microcontroller. Hence then microcontroller with different values print the output for detection. An analog-to-digital converter (abbreviated ADC, A/D or A to D) is a device that converts a continuous quantity to a discrete time digital representation. An ADC may also provide an isolated measurement. A ramp-compare ADC produces a saw-tooth signal that ramps up or down then quickly returns to zero. When the ramp starts, a timer starts counting. When the ramp voltage matches the input, a comparator fires, and the timer's value is recorded. Timed ramp converters require the least number of transistors. The ramp time is sensitive to temperature because the circuit generating the ramp is often just some simple oscillator. After the conversion it is sent to the microcontroller ports for further proceedings. Microcontrollers are used in automatically controlled products and devices, such as automobile engine control systems, implantable medical devices, remote controls, office machines, appliances, power tools, toys and other embedded systems. By reducing the size and cost compared to a design that uses a separate microprocessor, memory, and input/output devices, microcontrollers make it economical to digitally control even more devices and processes. Mixed signal microcontrollers are common, integrating analog components needed to control non-digital electronic systems. A driver typically communicates with the device through the computer bus or

communications subsystem to which the hardware connects. When a calling program invokes a routine the driver issues commands to the device. Once the device sends data back to the driver, the driver may invoke routines in the original calling program. Drivers are hardware-dependent and operating-system-specific. They usually provide the interrupt handling required for any necessary asynchronous time-dependent hardware interface. A device driver simplifies programming by acting as translator between a hardware device and the applications or operating systems that use it. Programmers can write the higher-level application code independently of whatever specific hardware device. A buzzer or beeper is an audio signaling device, which may be mechanical, electromechanical, or piezoelectric. Typical uses of buzzers and beepers include alarm devices, timers and confirmation of user input such as a mouse click or keystroke. A display device is an output device for presentation of information in visual or tactile form (the latter used for example in tactile electronic displays for blind people). When the input information is supplied as an electrical signal, the display is called an electronic display.

2. PROBLEM IDENTIFICATION

The problem which we have faced during this project is basically the calibration process and sensitivity adjustment as describe below.

2. A. Calibration of Gases

Gas sensors need to be calibrated and periodically checked to ensure sensor accuracy and System integrity. It is important to install stationary sensors in locations where the calibration can be performed easily. The intervals between calibrations can be different from sensor to sensor. It is quite unlikely that you will ever use an absolute method for gas detection. Rather, you will employ any one of dozens of "relative" [or "reference," but not necessarily EPA Reference] methods that is, methods that produce some output that must be calibrated against a known standard. Even though proper calibration is 90% of successful gas detection, it is a subject that has been neglected often purposely by the majority of instrument manufacturers. There's a good reason for this, of course: Proper calibration can often be difficult and expensive. But, we're getting a bit ahead of ourselves.

2. B. Sensitivity Adjustment

In a gas sensor sensitivity adjustment create a problem because of different gas sensor module have different sensitivity adjustment. For gas sensor to work properly sensitivity adjustment is required to be full filled. Sensitivity adjustment was necessary, without this we cannot use this sensor in a desired way. In this project we can use two gas sensor modules MQ2 and MQ3.

Its sensitivity adjustment is given below:

- Resistance value of MQ-2 is difference to various kinds and various concentration gases. So, when using these components, sensitivity adjustment is very necessary. We recommend that you calibrate the detector for 1000ppm liquefied petroleum gas<LPG>,or 1000ppm iso-butane<i-C4H10>-concentration in air and use value of Load resistance that (RL) about 20 K Ω (5K Ω to 47K Ω)

- Resistance value of MQ3 is difference to various kinds and various concentration gases. So, when using these components, sensitivity adjustment is very necessary. We recommend that you calibrate the detector for 0.4mg/L (approximately 200ppm) of Alcohol concentration in air and use value of Load resistance that (RL) about 200 K Ω (100K Ω to 470 K Ω).

III. EXPERIMENTAL RESULT

Here Shows the working of our project in proteus where we simulate it and run it before assembling the part.

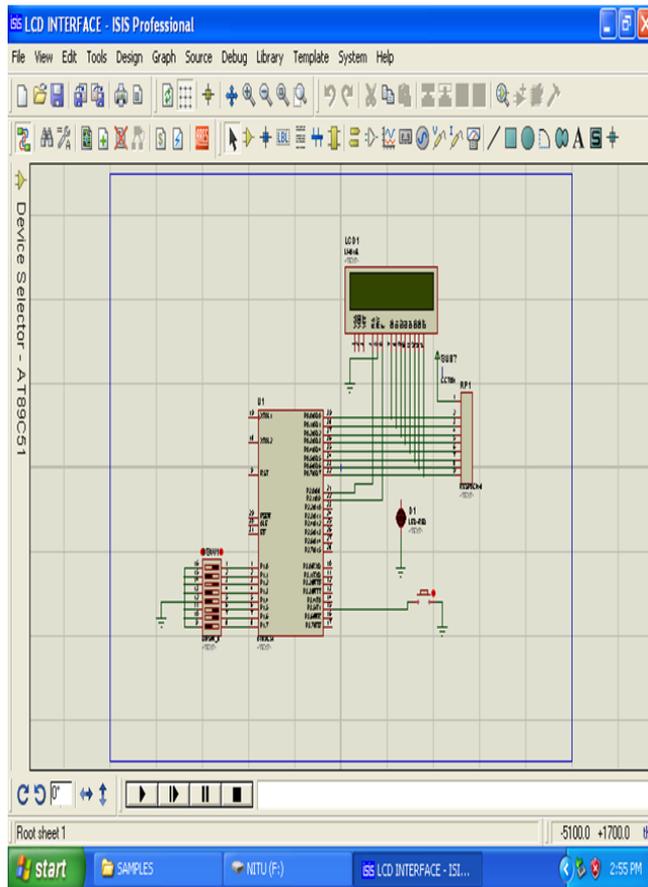

Figure6.1 -Result for describing the detection of gas

The above shows the software processing of our project in which the we simulate before assembling the hardware parts of our project in which after simulation the output shows whether the gas is detected or not and which type of gas id detected the sensor before assembling include the calibration process. Gas sensors need to be calibrated and periodically checked to ensure sensor accuracy and System integrity. It is important to install stationary sensors in locations where the calibration can be performed easily. The intervals between calibrations can be different from sensor to sensor. Generally, the manufacturer of the sensor will recommend a time interval between calibrations. However, it is good general practice to check the sensor more closely during the first 30 days after installation. During this period, it is possible to observe how well the sensor is adapting to its new environment. Also, factors that were not accounted for in the Design of the system might surface and can affect the sensor's performance. If the sensor functions properly for 30 continuous days, this provides a good degree of confidence about the installation.

Any possible problems can be identified and corrected during this time. Experience indicates that a sensor surviving 30 days after the initial installation will have a good chance of performing its function for the duration expected. Most problems such as an inappropriate sensor location, interference from other gases, or the loss of sensitivity will surface during this time. During the first 30 days, the sensor should be checked weekly. A typical calibration schedule for a fixed system may be quarterly, bi-annually or even annually with some of the more robust units. A typical calibration schedule for a portable gas detector is a daily bump test accompanied by a monthly calibration.

IV. CONCLUSION

The importance of gas sensing is set to grow with increasing requirements for safety and environmental protection across many industries. The current range of any gas sensing technologies has served us well but the future holds many new possibilities. Power and size reductions and an improvement in ruggedness will allow a new generation of body worn devices. These Ways will be developed to improve performance whilst at the same time reduce cost; new sensors will be targeted at enhancing environmental protection. For these purpose we have designed the Gas Detector for LPG senses and alcohol sensing where it detects the gas and sense it for printing the result and alerting through a buzzer. By use of Gas Detector we can detect multiple gases like CO, LPG, Natural gases like methane, propane.

An Assessment of the Environmental Impact of Brine Disposal in Marine Environment

Musfique Ahmed¹, Rifat Anwar²

¹Post-Graduate Student of Environmental Engineering, University of Melbourne, Victoria, Australia 3010

² Professional Morphologist, Center for Environmental & Geographic Information Service (CEGIS), Gulshan, Dhaka-1212, Bangladesh

Abstract: The ever increasing demand of water permits the need of alternative water sources for balancing the water supply and demand. Desalination has become a significant alternative water source due to growing demand of water and inadequate conventional water sources in many countries. Desalination is a process of removing excess salts and other dissolved solids from water in order to get clean water for human usage. Brine disposal is one of the major concerns of many environmental issues associated with desalination. The production and growth of marine organisms is severely effected by discharge of brine in the desalination process. These organisms are interrelated with each other so any distraction in their population has extreme impacts on all marine life in the area. In this paper various features of potential impacts of brine effluent in marine environment have been critically reviewed. A relative study on different brine disposal options in reducing these impacts is also prepared in this paper.

Keywords: Desalination, Brine, Disposal, Marine Organisms, Environmental Impact

I. Introduction

The Sustainable development of human and ecosystem health is in threat because of continuous depletion and pollution of freshwater sources (Furumai 2008). The scarcity of fresh water is increasing day by day with the increasing rate of world population, urbanization, pollution and climate change. To maintain the proper balance between water supply and demand, some alternative methods need to be implemented. Water covers three fourth of the earth and 97.5% of this water is saline water (Danoun 2007). One of the most effective alternative methods to utilize of this ample saline water is desalination. Desalination is a process of removing excess salts and other dissolved solids from water in order to get clean water for human usage (Haurwitz et al. 2008). The total process mainly consists of two steps which are evaporation and condensation (Danoun 2007). The three most commercially important desalination technologies are reverse osmosis (RO), multi-stage flash (MSF) and multiple-effect distillation (MED). Reverse osmosis (RO) is one of the latest examples of using membrane technologies. Technological expansion has augmented the efficiency of modern RO plants (Tularam & Ilahee 2007). Inadequate conventional water sources is the major cause of growing significance of sea water desalination in many countries (Palomar & Losada 2010). Water supply in the middle east and north America profoundly depends on desalination (Haurwitz et al. 2008). Saudi Arabia is the highest producer of desalinated water followed by United States of America (Danoun 2007). Though Australia has the lowest number of desalination facilities (Figure1), the recent water crisis has driven Australia to construct desalination plants. The Goald Coast desalination plant in Queensland, Perth seawater desalination plant in Western Australia and Kurnell desalination plant in New South Wales are currently in use and three desalination plants in Victoria, South Australia and Western Australia are in progress.

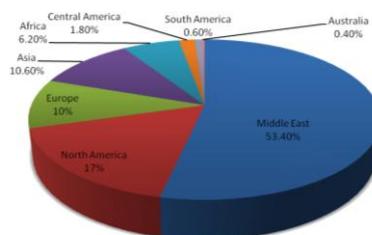

Figure 1: The existing desalination facilities worldwide by region (Source: Modified from International Desalination Association)

There are many issues related to desalination plants that have caused serious anxiety for society and in a bigger extent to the world. High energy is required for desalination processes which result in huge amounts of green house gas emissions. Many environmental issues are associated with desalination. Brine, the concentrated discharge of the desalination process, has serious impacts on the production and growth of marine organisms. The construction process of desalination plants is time consuming and operation and maintenance costs are very high. If the location of the desalination plant is not suitable then it can be inconvenient, loud and disruptive to the environment (Younos 2005). The release of Carbon monoxide (CO), nitrogen dioxide (NO₂), nitric oxide (NO) and Sulphur dioxide (SO₂) from desalination plants have a detrimental impact on environment at the same time on public health (Al-Mutaz 1991).

1.1 Objectives

To implement a proper desalination plant in a specific area all factors related to desalination need to be identified and examined for that area. This essay will deal with one of the biggest environmental concern of desalination plant – the impact of brine disposal on marine environment. Some arguments will need to be developed related to the environmental impacts to the marine life due to brine discharge. Seawater and water in bays and estuaries is full of organisms like plankton, phytoplankton, larvae and the eggs of marine species. These organisms are correlated with each other so any disruption in their population has extreme impacts on all marine life in the area (Haurwitz et al. 2008). The main objectives of this essay are-

1. To critically review the different features of potential impacts due to brine effluent in the marine environment.
2. A comparative study on the processes which can be used to minimize these environmental impacts

II. Environmental impacts of brine discharge

With the increasing importance of desalination plants, it has become indispensable to review and synthesize various researches that have inspected the environmental and ecological impact of brine discharge on marine environment (Roberts, Johnston & Knott 2010). Many literature reviews have focused on quantify the impact of brine on the physical, chemical as well as biological characteristics of marine environment (RPS 2009). Several published review articles and case studies quote ambiguous peer reviewed literature, and present little or no empirical data to support statements regarding the environmental effects of brine discharge (Roberts, Johnston & Knott 2010). A wide range of potential impacts have been identified due to the brine discharge but only few of the literature scientifically observed the authentic effect of discharge on marine communities around discharge outlets (Skinner 2008). Although so many desalination plants have been constructed in different parts of the world the availability of data on the impacts of their discharge is very little (RPS 2009). The purpose of this review is to identify the physiochemical and ecological impacts of brine on various aspects like temperature, alkalinity, dissolve oxygen, salinity, nutrients and various chemicals of seawater which resultant serious effect on marine environment as well as associated knowledge gaps on this field.

2.1 Temperature

One of the major impacts of brine discharge is thermal pollution which can occur by increasing the temperature of sea water. Numerous studies have been carried out to determine how the distribution and natural balance of marine flora and fauna species respond to an alteration in temperature (Danoun 2007). In these studies a direct correlation between temperature and marine species has been determined. The statements in the previous literatures related to the temperature changes due to desalination remain unclear whether the temperature ranges which were assessed based on field measurements or the model predictions (RPS 2009). The temperature of discharged brine is obviously much higher than the ambient sea water temperature. Temperature of the sea water generally varies between 10°C to 25°C which increases about 60% to 40°C near the area of the brine disposal (Danoun 2007). Alteration of temperature basically depends on the type of the treatment plants. Distillation plants increase the temperature more than the reverse osmosis process. Abdul-Wahab illustrated a direct connection between the temperature of the seawater and the distance from the discharge site (Wahab 2007). The distribution and extent of the temperature alteration also depends on the location of the plant discharge. If the brine discharges in a well-flushed environment, it is more efficient and effective than the brine discharges near to the water bodies (Roberts, Johnston & Knott 2010).

2.2 Salinity

A variety of published literatures and readings disclose the effect of brine on the salinity of the seawater and the resultant impact on marine environment. The centre of attention of these studies is the concentration and expansion of brine plumes on the receiving water (Roberts, Johnston & Knott 2010). It is now widely recognized that extensive brine discharge, as it constitutes a hypersaline layer that sinks towards the seabed due to its greater density, has the potential to heavily affect local marine biota (Medeazza 2005). Changes of salinity influence the propagation activity of the marine species and that consequentially affect their development and growth rate. Larval stages are very crucial transition periods for marine species and increasing salinity disrupts that period significantly (Neuparth, Costa & Costa 2002). Although marine species of the saline water are familiar to this fluctuation of salinity concentrations but they may not survive on this sudden augmentation of salinity because of brine disposal (Haurwitz et al. 2008). As discharged brine is much denser than the seawater so brine plumes have the affinity to extend further along the seafloor than the surface which contributes to greater exposure of benthic organisms to brine discharges, than pelagic and plank tonic organisms (Roberts, Johnston & Knott 2010). Though reverse osmosis processes do not impact much on the alteration of temperature, brine discharges from this process increase the salinity by twice that of the seawater (Tularam & Ilahee 2007). According to several studies the excess salinity level of seawater from brine discharge is directly correlated with the distance of the plant site. It shows that rising the salinity level up to 50 ppt could probably have an serious impact on the fish size and on their survival rate (Parry 1960).

2.3 Dissolve Oxygen

Brine disposal also has an effect on the dissolved oxygen of the seawater. As the amount of dissolve oxygen is inversely proportional to the salinity level, so with the increasing rate of salinity dissolve oxygen is decreasing which consequences hypoxia (Haurwitz et al. 2008). Hypoxia is a serious condition which results from low levels of dissolved oxygen and can cause serious harm to the aquatic organisms. According to report of California Coastal commission, 2004 if the temperature of water increases because of brine this can decrease dissolved oxygen and increase biomass resulting from the disposal of

entrained organisms (California Coastal Commission 2004; Haurwitz et al. 2008). In reverse osmosis processes temperature is not varied much so major changes in dissolve oxygen due to heating is very unlikely. Though mixing of oxygen consuming chemicals in RO plants to restrain corrosion and eliminate residual chlorine can reduce the dissolve oxygen (Lattemann & Höpner 2008).

2.4 Other Aspects

High total alkalinity is another big impact of brine discharge which increases the amount of calcium carbonate, calcium sulphate and other elements of the sea water twice to its normal level. Very few experiments have been conducted to quantify the alteration of the total alkalinity in seawater due to brine disposal and also the tolerance limit of marine life to it (Danoun 2007). The pH range of marine environments is also changing due to the brine discharge but that is very negligible compared to the other impacts (Skinner 2008). For the proper performance of desalination plants pre and post treatment processes are required whereby many chemicals are added to enhance flocculation or to avoid membrane deterioration. Antiscalant agents like polyphosphates, polymers of maleic acid, sulphuric acid and antifoaming agents like fatty acids, alkylated polyglycoles etc are used as chemical components which are discharged with brine and effect the marine species around the outlet (Medeazza 2005). Many field based monitoring and laboratory based experiment have been implemented to enumerate the ecological impact of the brine disposal.

2.5 Impingement and Entrainment

Some desalination plants need to have substantial intake of sea water which can be harmful for marine species in two ways-impingement and entrainment. Impingement refers to the collision with screen and entrainment refers to the drawn in to the plant (Lattemann & Höpner 2008). When organisms are dragged into an intake pipe and trapped in a fish screen covering the intake which cause injury or death then that is defined as impingement. Entrainment occurs when little organisms pass through the fish screen and are actually taken into the intake pipes (Haurwitz et al. 2008, p. 8). Many previous studies show that these are not threatening for the large species because of small flow rate but smaller animals like phytoplankton, zooplankton can be impinged or entrained.

2.6 Research Gaps

The main focus of this essay is on the environmental impacts caused by the brine disposal on marine environment so this review part consists of various aspects of impacts grounded because of the discharges of desalination plant. But still there are many studies in the literature which are ambiguous as well as unscientific. Some literature has tried to define the positive and negative impact both which is very much contradictory. According to Rashad Danoun, alteration of temperature can have an influence on the production rate as well as life span of the marine species which can be decreased with the increasing rate of temperature. But in the other part he has tried to portray the positive aspect by saying that increased temperature of the ambient environment leads to a positive effect on growth rate of several species of plankton (Danoun 2007). Neither very specific nor very reliable temperature ranges can be set for desalination plants. One of the prominent reasons for this is the difference between field measurement and model predictions. There is still some lack in previous investigations of the documentation of experimental data of temperature change which is affecting the marine flora and fauna. Many mathematical models have been created to inspect the salinity level in sea water. Though brine flume has the potential effect on the salinity level of sea water but other causes of rising salinity like irrigational flow, breakdown of rocks and minerals, locked down of freshwater in to the ice caps etc. also need to be taken in consideration. The salinity of bay and estuaries can also be increased by low flow of fresh water from rivers due to increased Water Rights. The previous studies have not included all these factors in conducting comparative study of rising condition of salinity level. It is stated before in many readings that salinity level and the location of the plant is correlated and salinity declines rapidly close to the outfall of the desalination plants. But precise measurements are not located in the reviews. This is a big knowledge gap because accurate distance could help to locate the suitable site for the desalination plant. In most of the previous literatures, the effect of reduced level of dissolved oxygen has been analysed for a particular plant not for different desalination plants. But with the diverse locations of plants, impact of dissolved oxygen in the receiving water can be changed. Impact on the small marine species due to brine discharge has been assessed in lots of literatures but less information is available about the large marine fauna. Impingement and entrainment are very new explored ideas and most of the desalination plants were established without considering these impacts. So, these knowledge gaps need to be overcome for the betterment of desalination system.

III. Impact minimisation

Currently the increasing rate of practice of desalination plant has led to the development of many new methods and options to minimize the impact of brine disposal. While there are many options available for minimising the impacts of brine disposal, different strategies are appropriate only for different locations. So, before using the strategy, it needs to be evaluated both environmentally and economically (SOL-BRINE 2009). In this section of the essay, different minimizing process will be depicted and some recommendations will be suggested with respect to the various conditions of the sites.

The alternative options of brine disposal can be divided in to three different categories.

1. Changing the location of brine disposal/ Treatment before discharge
2. Redesigning the desalination plant
3. Coupling the desalination plant with some existing treatment plant

3.1 Changing the location of the brine disposal/ Treatment before discharge

By changing the location of brine disposal and treating the brine before ultimate discharge the actual impact of brine in the receiving water can be reduced. Brine can be discharged in the surface water and diluted by outfall diffusion devices like diffusion nozzles or can be mixed with less saline waste streams before ultimate discharge. However this option can only be used when surface water body is located nearby to the estuary (Castillo, Sanchez & Castillo 2007; Sarté et al. 2006). Brine can be directed to the existing sewer treatment plant to dilute with municipal wastewater prior discharge. However volume and composition of the brine, the convey process and reaction of the brine with the waste water need to be taken into consideration (SOL-BRINE 2009). The High range of dissolved solids of the waste water could be of great concern for marine environments when treated water is released back into the seawater. Injecting brine via wells into confined and non-potable aquifer systems can also be a good option of disposing brine. It is important to have a monitoring well near the injection well to assure that there is no leakage from the injection well. As it naturally pre-filtrates the feed water, it lowers the saline water table (Lattemann & Höpner 2008). This option is not cost-effective because of the construction of an extra well and groundwater infectivity can be occurred because of mechanical collapse of the injection process and over pressurization resulting from the high injection rate (Haurwitz et al. 2008). Spreading brine in shallow ponds where it gradually evaporates, the concept of evaporation pond, can also be a suitable mitigation measure (Sarté et al. 2006). The residual solid that is left behind in the pond can be used for landfill or collected for re use. Solid lining or monitoring wells may be required to ensure that ponds do not drip and pollute surrounding soils or aquifers (Haurwitz et al. 2008). This process is land intensive and also cause significant loss of the basic water resource through evaporation (Younos 2005). Each of these conventional strategies is more suitable for small and medium size facilities. However these processes can reduce the salinity level of the brine so after discharging brine will not be as much harmful for marine biota.

3.2 Redesigning the desalination plant

Environmental impacts can be mitigated if the desalination plant can be designed in a sustainable way or some essential parts or mechanisms can be included or installed. Beach wells or infiltration galleries can be installed which drag in seawater through the overlying substrate. This overlying substrate works as a natural filter to keep out small marine creatures and larvae. This can improve the quality of feedwater and reduce the cost for pre-treatment. Impingement and entrainment can also be minimized by this process (Haurwitz et al. 2008). Historically 'jet' of brine released at 60° angle was adopted as standard design criteria. Recent modelling approaches has proved that shallower discharge angle 30°-45° may enhance mixing and offshore transport of desalination brines in coastal waters with moderate-to-steep bottom slopes (Jirka 2008). This can minimise the spatial extent and intensity of brine plumes which results in reduction of salinity level. Now days jetties have been constructed adjoining to the desalination plant discharges to create offshore currents which can minimize the extend of brine plumes and persuade more rapid mixing (Roberts, Johnston & Knott 2010). Advancement of nanotechnology helps to create devices and systems by using nanostructured materials like carbon nanotubes, nanowires, graphene, quantum dots, super lattices, and nano shells for desalination technology. It is Useful to separate water from salt , control the evaporation and produce next generation RO membrane (Humplik et al. 2011). Another useful system can be developing anti scaling with no biological effect by using the scale inhibitors which may assist in the production of less toxic brines in the future (Ketsetzi, Stathouloupoulou & Demadis 2008). Further research is required to understand how these techniques can be properly utilized as these are very new approaches.

3.3 Coupling the desalination plant with existing treatment plant

Desalination plants can be co located or coupled with some existing treatment plant like power plant, and salt works which can also be very useful in mitigating the impact of brine. Desalination plants can be co located with older thermocouple plant to dilute the brine with power-plant cooling water (Roberts, Johnston & Knott 2010). These options should be considered for larger plants which would limit the brine plume to be extended far and reduce its effect in receiving water (Einav & Lokiec 2003). Cooling systems are very efficient for reducing impingement and entrainment, construction problems, land use impacts and usage of chemicals (Lattemann & Höpner 2008). The desalination plant can be coupled with solar salt works by directing the brine to a salt works for brine concentration and salt production with an aim of achieving zero discharge desalination plant. Extra salt can be produced by using this process in the factories which results extra income and also minimize the transportation cost (Laspidou, Hadjibiros & Gialis 2010).

3.4 Recommendations

All these strategies cannot be suitable for every location. Suitability of the options can vary because of the location of the desalination plant-nearby or far from coast, land uses of the adjacent places of the plant, availability of idle lands, energy emitting system of the plant and also the other associated aspects of desalination. Some recommendations are made based on the previous literatures and knowledge and experience acquired by assessing various minimizing processes. For desalination plants using membrane technology, zero liquid discharge process can be a very efficient alternative option. ZLD is actually a thermal evaporative system which can reduce volume of discharge by using thermal evaporators like crystallizers, spray dryers etc. Though these processes are expensive and energy intensive which can be counterbalanced by modernizing the membrane system. Those areas where enough lands are available evaporation ponds with aquaculture and agricultural application may be worked as economically viable. Black bream, snapper, Dunaliella, brine shrimp can be successfully raised in the brine and plants tolerant to high salinity can be irrigated nearby to the evaporation pond. The land cost, monitoring cost, and lining cost related to evaporation pond can be minimized by production of fishes, plants and salts. For arid regions like Australia, evaporation ponds can be a useful option when availability of land is enough. Salinity

gradient solar pond is also a possible synergy for the evaporation pond which joins the collection of solar energy with long-term storage and produce electricity (Svensson 2005) This can reduce the electricity problem of Australia in a greater extent. If impacts cannot be minimized by using different strategies or systems, then site of least impacted needs to be identified. If enough investment is ensured then nanostructured material, anti scalant can be used in the desalination plant. These new inventions are expensive but much more valuable for reducing impacts than the conventional processes. Researchers have now invented a new process of brine management that is effective for both inland and coastal desalination plant. Solvay process is actually developed to convert the brine into reusable solid product Sodium Carbonate. It is executed by mixing the reject brine (saturated sodium chloride solution) with carbon dioxide and ammonia in a high temperature to get sodium carbonate as final product and water (El-Naas 2010). These new technologies can be very functional for Gold coast and Kurnell desalination plant of Australia as severe environmental impact of brine is being revealed there

IV. Limitations

Though several literatures are critically reviewed and analysed on this broad area of desalination, but there are some limitations of this study which requires to be emphasized more. In the literature review a wide range of impacts and their associated risks has been identified but enough data could not be analysed from laboratory-based experiments or toxicological investigations. These data could have been more useful to practically illustrate the adverse impacts of brine on marine organisms. Recommendations that have been made to mitigate the impact needs more experiments and investigations for specific regions. Irrigation of saline tolerant plant can be useful but at the time of heavy rainfall other processes need to be available. So, seasonal fluctuations were needed to be taken in to account. Economic viability of the recommended processes is not taken in to account properly which is significant from the view of decision makers. No modelling results have been used to identify proper location of brine disposal. But, modelling the plume of brine is recommended to demonstrate the dispersion area. Water quality test of the concentrated brine is essential with respect to the different factors like- temperature, salinity, dissolved oxygen, alkalinity etc. to validate the damage these could cause to the marine environment. This essay has provided overall idea about various mitigation measures but individual study is required on every process before implementation. So, experiments and case studies are required in small scale of the conventional and recommended measures to identify their suitability in large scale. Monitoring program for long term is suggested nearby to the coastal area to investigate the actual impact which may be altered with time.

V. Conclusion

With the increasing rate of water demand, desalination is now being used as an important alternative option of clean water supply. Because of this high demand of water marine environmental problems related with desalination have always been considered as secondary concern. Marine species are severely impacted by the brine disposal without proper treatment. In some cases the impact rate may be huge or in other cases it may be low. But, this impact is little regarding to the high substantial alteration of sea water because of physical and chemical changes. Other negative aspects of desalination like high energy usage, GHG emissions, huge O&M cost etc. are much more significant relative to impact of brine. Mitigation measures for these impacts are needed to be selected with respect to the suitability of the plant and conditional attributes of the particular area. Some new inventions are discussed in this essay for design, location and measurement of desalination plants to minimise or eliminate any potential impacts of brine. New technological ideas and materials are desirable to lower the impact and keep a well coastal marine environment.

Abstract: Modern VLSI technology makes it both feasible and economical to integrate a complex system on a single chip. These modules often require different data transfer speeds and parallel transmission capability. A conventional bus structure might not be adequate for these demands because, typically, only one attached module can transmit at a time, and a large capacitive load caused by attached system modules and long bus wires can make a bus very slow. A segmented bus architecture shows potential for improving both speed and power related features of a bus-based system. Due to segmentation of the bus, parallel transactions can take place, thus increasing the performance of the bus. In order to reduce arbitration and communication delay in the existing segmented bus, new reconfigurable architectures which will completely avoid the complicated higher level arbitration overhead with a small modification in local arbiter is proposed in this paper. The bus architectures are modeled using VHDL.

Key words: Reconfigurable, Segmented Bus

I. INTRODUCTION

Modern deep-submicron silicon technologies permit increasingly complex System on Chip (SoC) designs. The growing diversity of devices results in many possible interfaces. Often, the interconnection complexity of SoC modules limits both the system design process and system performance. Furthermore, these modules often require different data transfer speeds and parallel transmission capability[1]. A conventional bus structure might not be adequate for these demands because, typically, only one attached module can transmit at a time, and a large capacitive load caused by attached system modules and long bus wires can make a bus very slow. Moreover, the increase in both functional complexity and size of modern SoC devices tends to lengthen interconnect wires between system modules. As a result, synchronous system timing based on global clocks will become more difficult, if not impossible. A viable solution to these problems is a segmented bus architecture based on asynchronous communication. Such a structure provides a flexible platform for asynchronous self-timed SoC design, including globally asynchronous, locally synchronous (GALS) designs in which each distinct system module has a self-timed interface but is internally synchronized to a local optimized clock. A self-timed interface method significantly improves system scalability, automatically removing the difficult problems related to global clock distribution. Moreover, partitioning the bus into several concurrently operating segments overcomes the performance bottleneck of a conventional bus, letting modules in a particular segment exchange data

independently of modules in other segments. Simple bridges composed of tri-state buffers isolate adjacent bus segments from each other. Whenever an intersegment transfer occurs, these bridges dynamically link several successive segments to establish a connection between modules in different segments. Researchers proposed the concept of segmenting buses primarily for multicomputer architectures. More recent approaches address on-chip implementation of segmented buses. This paper targeted dynamically reconfigurable segmented-bus architecture for high-performance SoC applications. The structure not only enables faster operation than a conventional bus system but also offers lower power consumption per transferred data item. This is possible because segmentation is realized in such a way that the majority of data transfers in the system are intra-segment transactions on relatively short wires with low or moderate capacitive loads.

II. SYSTEM ARCHITECTURE

A segmented bus is a bus which is partitioned into two or more segments. Each segment acts as a normal bus between modules that are connected to it and operates in parallel with other segments. Segments can be linked dynamically to each other in order to establish connection between modules located in different segment [8]. Due to segmentation of the bus, parallel transactions can take place, thus increasing the performance of the bus. A high level block diagram of the segmented bus system is illustrated in Figure 1.

A bus-based system consists of three kinds of components (sub-systems): masters, slaves and arbiters. Generally, each of the devices connected to the bus lines may behave, depending on the situation, as either a master, or a slave. However, for simulation and assessment issues, here consider fixed functionality of these devices, that is, they will be only masters, or slaves. Only one master at a time may transfer data on the bus, thus there is need for arbitration. In a conventional single bus approach, the current master-slave connection occupies the whole length of the bus, even though the communicating devices were physically close to each other. The Segmented Bus approach would allow this kind of connection to occupy only a small portion of the bus - the segment. Arbitration at this level is provided by the Local Arbiter (LA), one for each segment. They decide which master within the segment will get access to the bus. Whenever inter-segment transfers are required, a Central Arbiter (CA) decides which of the requests can be serviced. [2]- [4]. Only one inter-segment grant is given by the central arbiter.

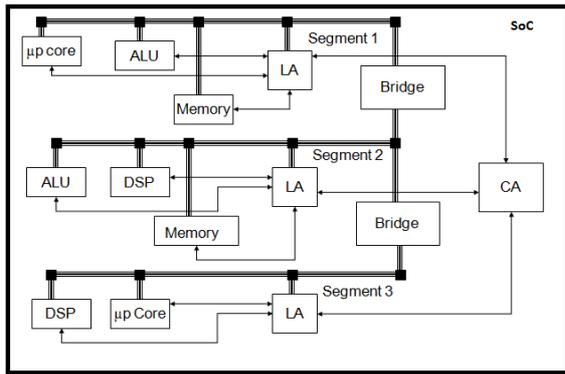

Fig 1: Segmented Bus Structure in SoC.

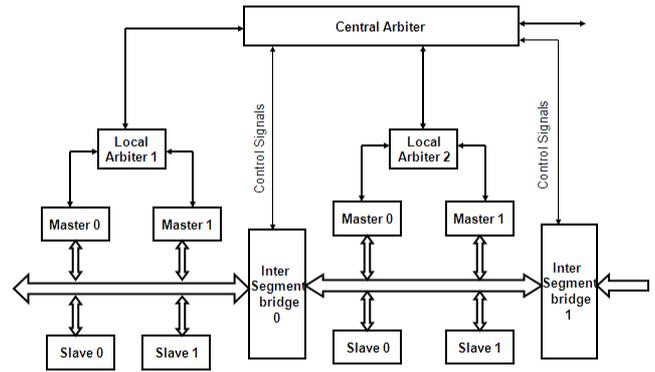

Fig 3: Structure of the Existing Segmented Bus

2.1. Existing Segmented Bus Architecture

The existing segmented bus architecture is illustrated in Fig.2. A segmented bus is partitioned into few segments. Every segment comprises of a group of masters, a group of slaves, a local arbiter, an intersegment bridge module and the physical wires for the bus address, data and control signals [8]. Modules (masters and slaves) are grouped according to their interconnection characteristics and placed on segments. Each segment operates as normal bus for modules, which are placed on it, and operates in parallel with other segments. Segments can be connected to each other in order to establish a connection between modules in different segments [8].

The segments with their components act as stand-alone buses operating in parallel, masters mostly asking services from the group of slaves placed within the same segment limits. Fig. 3 shows the structure of the existing segmented bus [8].

When a master device wants to communicate with a slave device within the same segment, the master device sends a request to its local arbiter. This requires dedicated request and grant wires between each device and the arbiter. The local arbiter grants the bus to the master and then the transaction. When multiple master devices request the bus, the arbiter grants the bus to only one device at a time. Similarly when one segment wants to communicate with other segment central arbiter gives a grant to that segment. But here only one inter-segment communication is possible at a time.

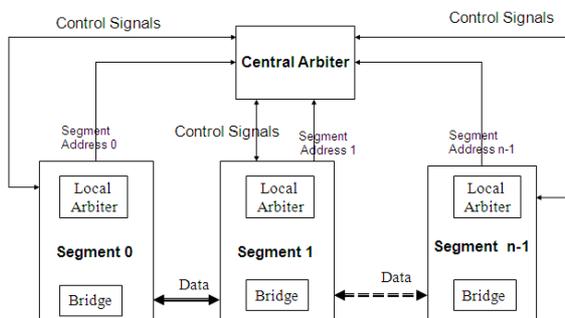

Fig 2: Block diagram of Existing Segmented Bus

2.2. Proposed Segmented Bus Architecture

The existing segmented bus architecture has a central arbitrator within it. An intersegment data transfer can be made only with the involvement of the central arbitrator. Therefore the existing segmented bus architecture has two main disadvantages. Due to the involvement of the central arbitrator, the complexity is high and so the intersegment data transfer delay is also high. This is the first disadvantage. The second disadvantage is, when the number of masters/slaves connected in the bus increases, the size and complexity of the central arbitrator increases. Due to this increase, the arbitration delay increases very much. In order to overcome these two disadvantages, new reconfigurable segmented bus architecture is proposed in this project. In the proposed reconfigurable segmented bus architecture, reconfigurability feature is incorporated in order to eliminate the disadvantages of the existing segmented bus architecture. Re-configurability feature means, adapting the topology of the bus based on the requests from the masters inside the segments. The Block diagram of Proposed Segmented Bus is shown in Figure 4.

The proposed architecture uses dynamic bridge-by-pass technique in order to incorporate dynamic re-configurability in the bus. So this architecture is named as Bridge-by-pass architecture. In this architecture, CA is eliminated. Therefore, the system complexity is reduced and arbitration delay is also reduced. The structure of Bridge-by-pass architecture is shown in Fig.5. The proposed architecture consists of a bus with two segments (Segment1, Segment2).

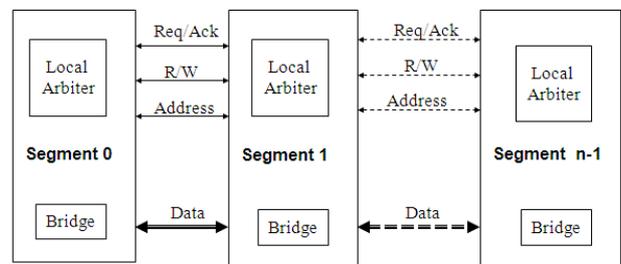

Fig 4: Block diagram of Proposed Segmented Bus

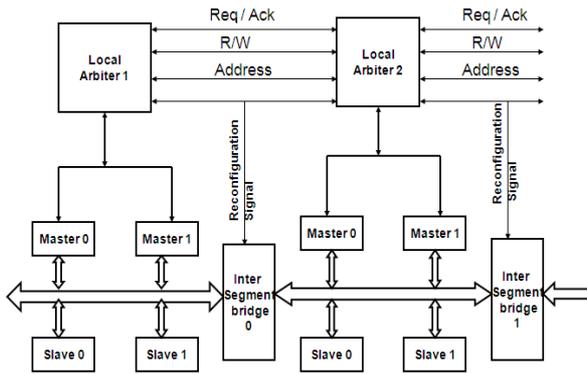

Fig 5: Proposed Segmented Bus Architecture

There are two types of data transfers that can take place in the proposed bus architecture. The first type of data transfer is intra-segment data transfer. The second type of data transfer is intersegment data transfer. In intra-segment data transfer, the data transfer occurs within the segment itself.

For example, if in Segment1, Master1 communicates either with Slave0 or Slave1 it is called intra-segment transfer. In intra-segment communication, the data transfer between a master and a slave takes place through its local arbiter. In intersegment data transfer, data transfer occurs between master of one segment and a slave of another segment. For intersegment data transfer, the existing architecture uses central arbiter for data transfer [8]. The presence of central arbiter increases the delay and system complexity. So in this Bridge-by-pass architecture, central arbiter is removed and instead local arbiter controls the data transfer. In the existing architecture, for intersegment data transfer, the master (source) sends request to its local arbiter. The local arbiter gives request, R/W and address signals to central arbiter. The central arbiter checks for the destination segment, if the destination segment is free then its corresponding local arbiter gives grant signal to the central arbiter. The central arbiter in turn gives grant signal to local arbiter of initiating segment. Then, central arbiter gives control signal to bridge so that the bridge opens and data transfer occurs between the master of source segment and slave of the destination segment.

In Bridge-by-pass architecture, for e.g. if there is an intersegment data transfer between master of Segment1 and slave of Segment2, the master sends request to its Local Arbiter (LA1 in Fig. 5). The local arbiter LA1 sends the request, R/W and address signals to the next local arbiter (LA2). LA2 checks if its bus is free. If its bus is free, LA2 sends grant signal to LA1. Then Reconfiguration unit gets ready signals from LA1 and LA2, processed it and gives reconfiguration signal to Bridge0. The Bridge0 open and data transfer takes place between Segment1 and Segment2. This is the operation of Bridge-by-pass architecture.

Consider that the existing bus architecture consists of 100 segments. Suppose 50 segments requests the central arbiter for inter segment data transfer simultaneously, the central arbiter analyzes the 50 requests and gives grant to the segment which has the highest priority. The inter segment data transfer of that highest priority segment takes place, while remaining segments wait. After the completion of data transfer, the central arbiter gives grant to the next segment which has next higher priority among all other segments. This proceeds till all the requests are processed.

In the Bridge-by-pass architecture, Segment1 has the highest priority for intersegment data transfer and Segment2 has the least priority. Within a segment, Master0 has higher priority than Master1. Suppose 50 segments requests the central arbiter for inter segment data transfer simultaneously, the local arbiter in between two segments controls the inter segment data transfer. Since the central arbiter is removed, the complexity and inter segment delay reduces. Hence when compared to existing architecture, Bridge-by-pass architecture is better in performance in terms of communication delay.

III. SIMULATION RESULTS

The bus architectures are modeled using VHDL. Simulation was done using Modelsim XE III 6.4 Simulator and the output waveforms is obtained as shown in fig.6 and 7. This model is synthesized using Xilinx ISE 9.2i. To evaluate the performance and power consumption of the bus model Xilinx Xpower analyzer is used and the results are obtained. The analysis of the results obtained is discussed in this section.

In Figure 6, Segment 1 considering which consist of two masters (Master1 & Master 2), two slaves (Slave 1 & Slave2 with address 01 and 02 respectively) and a Local Arbiter with fixed priority arbitration. Initially Master 1 and Master 2 are requesting the segment for write operation to Slave 1 and Slave 2 respectively. But Local Arbiter gives only Grant to the Master 1 and it writes the data in Slave 1. After releasing the Request of Master 1, Master 2 gets the Grant and it writes the data to Slave2

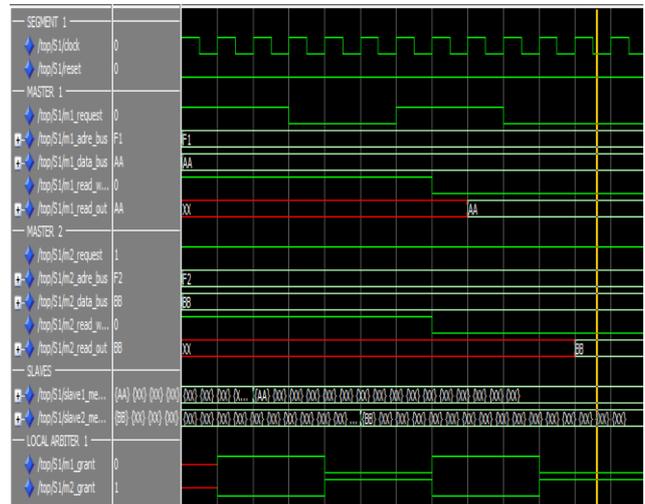

Fig 6: Intra-segment communication

In figure 7 Segment 1 considering which consist of two masters (Master1 & Master 2), two slaves (Slave 1 & Slave2 with address 01 and 02 respectively) and a Local Arbiter with fixed priority arbitration. Also Segment2 is considering with Slave 3 and slave 4 (with address 03 and 04 respectively). Initially Master 1 and Master 2 are requesting

ACKNOWLEDGEMENT

We would like to thank the Principal, HOD and all the teaching and non-teaching staffs of TKM Institute of Technology for helping to complete the work as mentioned in the paper.

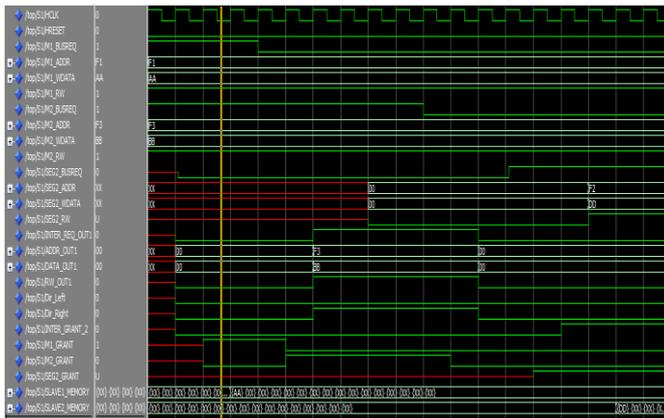

Fig 7.a.: Inter-segment Communication (segment 1)

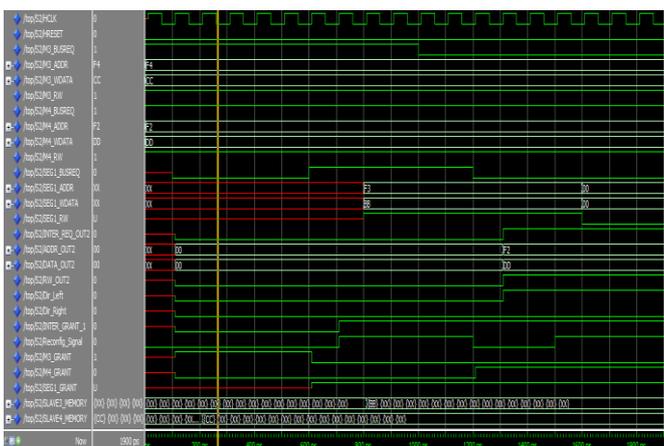

Fig 7.b.: Inter-segment Communication (segment 2)

the segment for write operation from Slave 1 and Slave 4. But Local Arbiter gives only Grant to the Master 1 it is an intra segment operation .After releasing the Request of Master 1, Master 2 gets the Grant for write operation in Slave 4. Here an inter-segment communication is needed because Master is in Segment 1 and Slave is in Segment 2.So INTER SEGMENT REQUEST becomes high and the data of the granted masters appears at the bridge. The bridge is a bi-directional buffer which will be controlled by the reconfiguration signal generated by the reconfiguration unit. After the enabling of the bridge the data is transfered from segment 1 to segment 2 and which will write on the segment 2 as shown in figure 7.a and figure 7.b.

IV. CONCLUSION

A new dynamically reconfigurable segmented bus architecture is proposed in this paper. In the proposed architecture, speed is increased and communication delay is reduced. There is no power and area overhead. Area has reduced in the proposed architectures. The bandwidth is highly improved. The bus is highly scalable. Due to these reasons, the proposed architecture seems to be highly efficient in terms of design and performance. Hence the proposed architecture can be used in high speed SoC devices.

Affect of Vibratory Welding Process to Improve the Mechanical Properties of Butt Welded Joints

Abstract: For improving mechanical properties of steels, vibration techniques have been used in the last few decades. During the welding of metals along with mechanical vibrations, uniform and finer grain structures can be produced. This increases the toughness and hardness of the metals, because of solidification effects at the weld pool surface. As the weld pool solidifies, grains are not only limited in size, but dendrites growing perpendicular to the fusion line are restricted. While the process is going on, dendrites can be broken up before they grow to become large in size. Hence, the microstructure of the weld metal is improved during the solidification process. In this work, we employed a dynamic solidification technology, by applying mechanical vibrations during the 'Arc welding' process. Analyses have been carried out for mild steel pieces having 5 mm. of thick butt joints. The results obtained from the current study pointed out that the butt welded joints fabricated with vibratory condition are found to possess relatively high hardness, without any considerable loss in its ductility.

Keywords: Arcwelding, Vibratorywelding process, Hardness, Grain size.

I. Introduction

In manual metal arc welding (MMA) process, an arc is drawn between a coated consumable electrode and the work piece. The metallic core-wire is melted by the arc and is conveyed to the weld pool as molten drops. The electrode coating is also melting to form a gas shield around the arc and the weld pool. Slag is formed on the surface of the weld pool, and the slag must be removed after each layer. Manual Metal Arc welding is still a widely used hard facing process. Due to the low cost of the equipment, the low operating costs of the process and the ease of transporting the equipment, this flexible process is ideally suited to repair work benefits of MMA Welding are: Flexible, Low Cost, and ease of Repairs.

Butt welding is used to connect parts which are nearly parallel and don't overlaps. It can be used to run a processing machine continuously, as opposed to having to restart such machine with a new supply of metals. Butt-welding is an economical and consistent way of joining process without using supplementary components. Usually, a butt-welding joint is made by slowly heating up the two weld ends with a weld plate and then combine them under specific pressure. This process suitable for prefabrication and manufacturing special fittings afterward, the material is usually ground down to a smooth finish and either sent on its way to the processing machine, or sold as a completed product.

Hardness is the Resistance of a material to deformation, indentation, or penetration by means such as abrasion, drilling, impact, scratching and/or wears. The relative toughness of the mild steel or base metal is affected by many variables including: the chemical analysis, micro structural constituents, and strength or hardness level and grain size [12].

Heat treatable steels [1] have improved strength along with good properties of toughness and fatigue strength. In situations when tensile strength and the yield strength of structural steels don't satisfy the design requirements, there is a need for heat treatable steels with higher carbon content. The improved strength allows the production of lighter structures, i.e. the usage of thin sheets. The problems that usually occur in welding of steels with higher carbon content are the following: weld cracking, weld metal porosity, high hardening of the weld metal, and cracking of the base material in HAZ [9]. The application of laser welding in industry is constantly increasing. The most important advantages of laser welding over other procedures include [5-9]: high welding speed, small or no deformations of the welded parts, and high quality of the welded joint. Laser welding of steels with higher carbon content, such as heat-treatable steels has not yet been applied in high-volume production [9].

Arc welding [2] differs regarding the power density and the volume of heat input into the material. High power density in laser welding allows welding with lower specific heat input than in other welding, which results in very high cooling rates [4]. The cooling rates in arc welding are faster than other welding, so that a lower value of maximum hardness in the welded joint is expected [10-12]. In vibratory welding, stirrer produce a disturbance in weld pool during solidification. After completion of nucleation, the solidification process will continue with nucleus growth. Increasing the growth rate will reduce the grain size of metal. In welding, as the heat source interacts with the material, the severity of thermal excursions experienced by the material varies from region to region, resulting in three distinct regions in the weldment [12].

The aim of this work is to obtain a modification of the microstructure by mechanical vibrations during the welding process. Because of microstructure changes, there is an improvement in the material's hardness and mechanical properties. This study was extended to investigate the effect of vibratory set up on the mechanical properties of 5 mm thick stainless steel (AISI202) butt joints. Low and high heat input combinations were used to study the effect of mechanical vibrations on small sized and large sized fusion zone respectively.

This paper is organised into five chapters. Chapter 2 describes the developed experimental setup and how the experiments have been performed for the considered metals; chapter 3 discusses the results obtained from the experimental analysis; chapter 4 illustrates the metallurgical effects of the various specimens and chapter 5 concludes the paper.

II. Experimental Work

The MMA welding process is an arc welding process which produces coalescence of metal by heating them with an arc between a covered metal electrode and the work. Shielding is obtained from decomposition of the electrode covering. Pressure is not used during the operation and the filler metal is obtained from the electrode. The MMA welding process can be used for welding most structural and mild steels. These include low-carbon or alloy steels; low-alloy, heat treatable steels; and high-alloy steels such as stainless steels. This welding process can be used in all positions flat, vertical, horizontal and requires only the simplest equipment. Thus, MMA welding lends itself very well to field work.

Material Used

Mild Steel, It is composed of (in weight percentage) 0.9% Carbon (C), 7.5-10.0% manganese (Mn), 1.00% Silicon (Si), 17.0-19.0% Chromium (Cr), 4.0-6.0% Nickel (Ni), 0.06% Phosphorus (P), 0.03% Sulphur (S), and the base metal Iron (Fe). Fig.1. shows a typical specimen used in the current study.

Fig 2 shows the experimental setup of the vibrator machine, its properties and welding process used for laying down the vibratory welding bead.

Fig.2 Experimental setup

2.3 Vibratory Setup for Welding

With an aim of improving the mechanical properties of weld joints through inducing of favourable changes in the weld microstructures, an auxiliary vibratory set up capable of inducing mechanical vibrations into the weld pool during manual metal arc welding is designed and developed. Different frequencies and with different amplitude are applied along the weld length, just trailing behind the welding arc so that weld pool could be mechanically stirred in order to induce favourable micro structural effects. This setup produces the required frequency with the amplitude in terms of voltages.

2.4 Butt welding by MMA welding Process

In the current investigation, 5 mm thick mild steel butt joints are used. Low and high heat input combinations are used to study the effect of mechanical vibrations. Figs.3 and 4 depict the joining of two mild steel strips during and after the welding process.

Fig.3 During welding

Fig.4 After welding

Butt Welded Joint (constant acceleration and at different voltages)

The prepared butt welded joints are under the low heat input (90-110 Amp). There are 2 number of passes to fill the gap, in which 1 main passes and 1 is root pass. During the root pass there is no role of vibratory setup. After the root pass, vibratory setup come into action and moved just behind the arc and make a disturbance during the solidification of weld bead. Table 1 and Table 2 illustrate the parameters variation with respect to acceleration & amplitude during the process.

Table 1 Parameters variation with respect to acceleration during the analysis

	70 Volts	150 Volts	230 Volts
Acceleration (m/s ²)	18.3	49.1	32.6
	16.4	49.7	31.1
	19.9	48.7	30.4
	17.7	45.3	28.4
	18.6	51.9	28.3
	19.3	50.8	29.7
RMS value	18.4	49.29	30.33
Grms value	1.875g	5.02g	3.09g

Table 2 Parameters variation with respect to amplitude during the analysis

	70 Volts	150 Volts	230 Volts
Amplitude (in mm)	0.350	0.238	0.274
	0.348	0.233	0.269
	0.347	0.230	0.266
	0.349	0.235	0.270
	0.352	0.242	0.275
	0.351	0.240	0.273
RMS Value	0.350	0.236	0.273

III. Results And Discussion

For the fabricated specimens, tests have been conducted to measure the hardness of the weld bead along and perpendicular to its bead surface. From the initially considered points, acceleration being kept constant by varying the voltage, found the RMS value in terms of GRMS. The same process is repeated for several times, by amplitude keeping constant and varying in voltage. The hardness values are observed without vibration values are smaller than the with vibration hardness values. Here 7 samples are taken to found the hardness values at different locations along the weld bead and perpendicular to the weld bead surface.

Hardness Measurement

Micro-hardness measurement can be done by Lecco Vickers Hardness (LV 700) tester. In which, a diamond indenter in the form of a right pyramid with a square base and an angle 136° between opposite faces, is forced into the material under a load F. The two diagonals X and Y of the indentation left on the surface of the material after removal of the load are measured and their arithmetic mean L is calculated.

$$H_v = \frac{0.1889F}{L^2} \text{ and } L = \frac{X + Y}{2} \quad (1)$$

Where F is the applied load (N), L is the diagonal of square impression (mm), X is the horizontal length (mm) and Y is the vertical length (mm).

IV. Metallurgical Study Of Specimens

Metallographic study shows that during conventional butt welding the uniform long dendrites which show that a uniform solidification process took place with uniform dendrites shown in the fig.7 and fig 8 with acceleration and amplitude kept constant during welding current respectively. Long dendrites show Coarse structure of the weld joint. The microstructure shows the uniform solidification process. Under vibratory conditions with acceleration and amplitude kept constant, the microstructure of vibratory butt-weld joints, long dendrites get fragmented and break in to small dendrites and forms a new nucleation sites. Here dendritic fragmentation took place due to which fine structures form. This enhances the hardness and mechanical properties of weld joints.

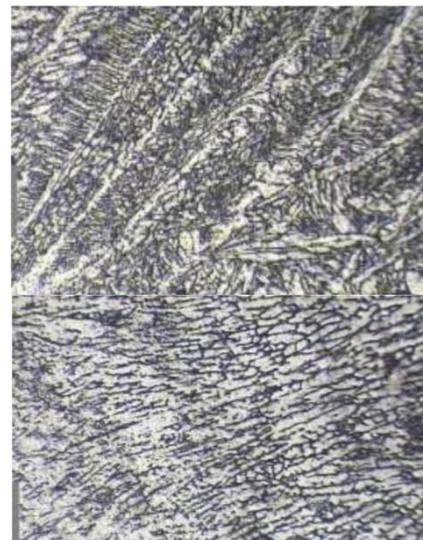

Fig.7 Microstructure of manual metal arc welding with vibratory (constant acceleration and amplitude)

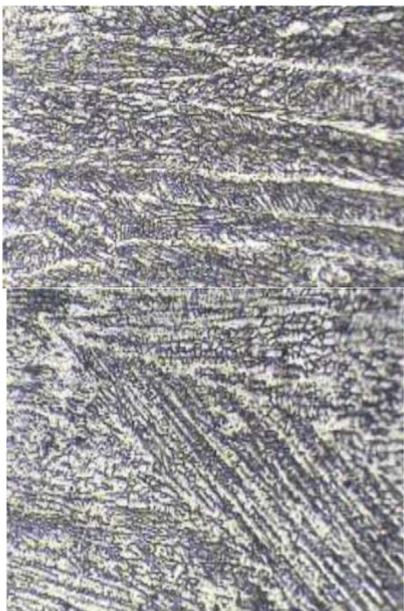

Fig.6 Microstructure of manual metal arc welding without vibration (constant acceleration and amplitude)

V. Conclusions

In the present study, welding is performed along with the vibrations for improving the mechanical properties of the base material and the weld metal micro hardness was calculated under vibratory condition. Along the weld bead the hardness value decreases when compared from without vibration. Metallurgical study showed that small grain structure is attained due to the effect of vibration.

Increase in hardness leads to crack initiation along the weld bead, so it is not preferable. During manual butt weld joints uniform long dendrites which show that a uniform solidification process took place with uniform dendrites. Due to auxiliary mechanical vibrations long dendrites break and forms a new nucleation sites. Finally, paper concludes that the Hardness of the parent metal increases under MMA welding with vibration.

Abstract: There is a wide usage of mobiles anywhere and anytime to access the multimedia data. Thus there will be more oppurtunity for wireless adhoc networks. Because, comparing with the wired networks, wireless networks provides low cost and easy accesibility. But the main disadvantage for Consumer electronic devices were generally operate on limited battery power and therefore are vulnerable to security threats like Data Flooding Attacks. These attacks leads to Denial of Service(DoS) by flooding many data packets. There were some of the defence systems to data flooding attacks. But these systems may not give guarantee to the Quality of Service. Because because of Wireless data transmission the data may be usually burst. Therefore, we propose a novel defence mechanism against data flooding attacks with the aim of enhancing the throughput. The simulation results show that the proposed scheme enhances the throughput of burst traffic.

Keywords: Data Flooding Attack, Throughput, Burst Traffic, Wireless adhoc Network.

I. INTRODUCTION

In the present world, use of electronic devices became most essential. Users want to use the compact and portatable devices such as cellular phones, laptop computers, Personal Digital Assistants (PDAs), etc. anywhere and at anytime. They like to use those devices to download multimedia data or to access real-time traffic. Those devices are used as mobile nodes in wireless ad hoc networks; hence, wireless ad hoc networks on the basis of consumer electronics are expected to be widely used in the near future. In wireless ad hoc networks, the communications take place between mobile nodes, operating under limited energy of battery power rather than through base stations. Hence, it becomes extremely hazardous to wireless ad hoc networks when mobile nodes are clogged. Meanwhile, wireless ad hoc networks are vulnerable to security threats since all signals go through bandwidth- constrained wireless links and the routing decision are taken in a decentralized manner. Therefore, it is important to provide a path with secure robustness in wireless ad hoc networks. Wireless adhoc networks can be victimized to various kinds of attacks .Among them, the ad hoc flooding attack can easily cause Denial-of-Service (DoS) attacks by flooding many Route Request (RREQ) or data packets . Since a mobile node has

limited resource capacities such as memory space, computational ability, battery power, bandwidth capacity, and so on, it cannot provide services when it receives a lot of packets. Hence, the whole network as well as the victim node can get easily paralyzed.

I. EXISTING SYSTEM

There were Some of the Existing Systems that were able to solve the Denial-of-Service(Dos) attacks by flooding many Route Requests or Data packets. Even though attackers are able to conduct ad hoc flooding attacks by flooding either RREQ packets or data packets, most researches in this field have focused their study on RREQ flooding attacks much more than data flooding attacks. Contrary to other networks, the path construction from the source node to the destination node is important in wireless adhoc networks because the communication is performed via multiple hops without any infrastructure. Besides, the data flooding attack can be performed only after constructing a path. Therefore, an attacker sets up a path to the victim node so as to conduct data flooding attacks and then forwards tremendous useless data packets to the victim node along the path. However, the size of data packets is usually much larger than that of RREQ packets; i.e., 24 bytes for RREQ packets and 1 Kbytes or 512 bytes for data packets. Hence, resource consumption and bandwidth congestion of a node or the entire network can be easily occurred by data flooding attacks.

II. PROPOSED SYSTEM

The Proposed System mainly aims for the Security and Data Flooding attacks prevention and finding the problem where the flooding is attacked by using a mechanism. The flooding attack prevention (FAP) suggested a defense system against either RREQ or data flooding attacks. The path cut off mechanism is used as defense against data flooding attacks. When the victim node realizes that it has been subjected to the data flooding attack, it may cut off the path. However, the procedure of the path cut off mechanism is not explained in detail, and FAP cuts off the path when many data packets are transmitted to the victim node. Current users like to download or access multimedia data using the consumer electronic devices so that the packets may be transferred as burst traffic. However, FAP cannot distinguish burst traffic from attack traffic since FAP distinguishes an attack by comparing the incoming packets with a threshold. Hence, the throughput of burst

traffic may degrade if a simple threshold-based defense system is used in FAP.

Therefore, this paper proposes a novel period-based defense mechanism (PDM) against data flooding attacks taking enhancing the throughput of burst traffic into account. The proposed PDM scheme is based on periods and uses a blacklist to efficiently prevent the data flooding attack, as a result of which many data packets are forwarded at a high rate for the whole duration.

The rest of the paper is organized as follows: Section IV measures the throughput of burst traffic under data flooding attacks, and then Section V presents the proposed PDM scheme. Section VI shows the performance evaluation of the PDM scheme. Finally, Section VII concludes the paper.

III. THROUGHPUT OF BURST TRAFFIC UNDER DATA FLOODING ATTACKS

In wireless ad hoc networks, handheld-based consumer electronic devices are used as mobile nodes. The data flooding attack sends many data packets in order to clog not only a victim node but also the entire network since all packets are transmitted via multiple hops. Hence, data flooding attacks are extremely hazardous to wireless ad hoc networks.

To conduct the data flooding attack, an attacker first sets up a path to the victim node since the attack can be performed only after a path is constructed. Then, the attacker forwards tremendous useless data packets along the path to make sure that the victim node cannot process packets in a normal fashion. Finally, the resources of the victim node are exhausted, so the node may get isolated from the network. In order to measure the effect of the data flooding attack on data traffic including burst traffic in wireless ad hoc networks, we calculate the throughput.

The throughput is defined as the ratio between the amount of data packets sent by the source node and the amount of data packets received by the destination node during a time span from t_s to t_d . The amount of packets sent by the source node (t_r) can be classified into control packets (C) such as RREQ, Route Reply (RREP), Route Error (RERR) packets and data packets (Dall) including traffic for conducting data flooding attacks. On the other hand, the amount of data packets received by the destination node (t_c) can be classified into normal traffic (DN) excluding the traffic meant for data flooding attacks (γ). Therefore, we can represent the throughput using the following equation:

$$\text{Throughput} = \frac{\int_{t_s}^{t_d} \frac{r_c}{t_r} dt}{\int_{t_s}^{t_d} \left(\frac{D_N}{C + D_{all}} \right) dt} \quad (1)$$

Meanwhile, we can divide the normal traffic into non-burst traffic (α) and burst traffic (β), so DN is presented as:

$$D_N = \alpha + \beta \quad (2)$$

Using (1) and (2), the throughput can be represented as follows:

$$\text{Throughput} = \int_{t_s}^{t_d} \left(\frac{\alpha + \beta - \gamma}{C + D_{all}} \right) dt \quad (3)$$

Therefore, the throughput is affected when many control packets are huge traffic are deliberately generated so as to conduct data flooding attacks.

IV. PERIOD BASED DEFENCE MECHANISM AGAINST DATA FLOODING ATTACKS

To defend the data flooding attack, the proposed PDM scheme sets up w periods for the data transmission. The PDM scheme checks data packet floods at the end of each period in order to enhance the throughput of burst traffic. Therefore, it can guarantee the Quality of Service (QoS) of burst traffic. We denote $v(nSp-nDp)$ as the variance of the number of received data packets for the source node (nSp) to the destination node (nDp) during the period $T(i+1)-T(i+2)$. Here, p denotes the number of sessions taken for data transfer.

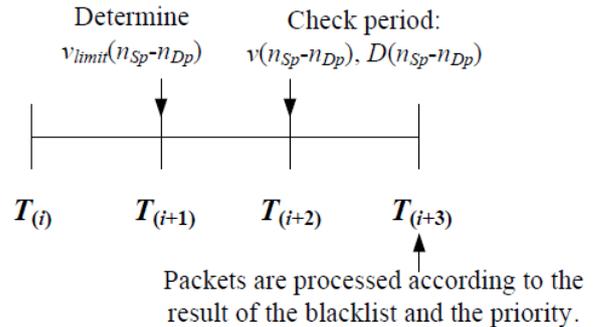

Fig: Procedures of each Period in the PDM Scheme

This shows procedures of each period in the PDM scheme. The mobile node nu initiates the variance coordinator ($h(nSpnDp)$) for data packet floods from nSp to nDp according to its data type so as to guarantee the QoS of the data packets. We also assume that $ave(all)$ is the average number of all received data packets during $T(i)-T(i+1)$. Then, we determine the variance limit of data packet floods from nSp to nDp ($vlimit(nSp-nDp)$) using the following equation:

$$v_{limit}(n_{Sp} - n_{Dp}) = ave(all) + h(n_{Sp} - n_{Dp}) \quad (4)$$

The procedure of the PDM scheme is following as:

Step 1) At the end of the period $T(i+2)$, nu compares the variance of received data packets, according to the $nSp-nDp$ pair ($v(nSp-nDp)$), with the variance limit ($vlimit(nSp-nDp)$). In wireless ad hoc networks, all packets are transferred via links between mobile nodes so that we can defend against data flooding attacks through the entire network by performing the defense at each mobile node.

Step 2) When $v(nSp-nDp)$ is greater than $vlimit(nSp-nDp)$, it checks whether data packets for $nSp-nDp$ pairs ($D(nSp-nDp)$) are in the blacklist or not. The Blacklist is maintained by each mobile node, which is initially empty. The maximum number of received data packets for a certain source node – destination node pair is listed in the blacklist. It aims to detect data flooding attacks.

- i) If $D(nSp-nDp)$ is in the blacklist, it is not transmitted until the next period ($T(i+3)$).
- ii) Else, the priority is determined by the inversion of the number of received packets and nu processes the data packets according to priority.

Step 3) nu updates the blacklist by the greatest number of received data packets in the period.

Step 4) *nu* checks the period is the last period of the data transmission.

- i) If it is the last period, the procedure of the PDM scheme is stopped.
- ii) Else Goto Step1.

VI. PERFORMANCE EVALUATIONS

We investigate the performance of the proposed PDM scheme by measuring the throughput. Then, we simulate the throughput of the PDM scheme according to the number of attackers and the number of transferred packets per second by ns-2 simulations.

A. Throughput Comparison

The performance of the proposed PDM scheme is measured by the throughput as given in (1). The PDM scheme sets up *w* periods for the data session from *ts* to *td* to defend the data flooding attack. The PDM scheme guarantees the QoS of non-burst traffic as well as burst traffic by determining () *limit Sp Dp v n - n* depending on the data type. The PDM scheme utilizes the blacklist since the data packet flooding attacker sends a high rate of data packets all times rather than certain given durations.

Moreover, the PDM scheme collects the information for calculating () *limit Sp Dp v n - n* at the first period and then performs the defense mechanism. Therefore, the expected probability of the received malicious data traffic in the PDM scheme at *nu* ($[\gamma]$ *PDM E*) is as:

$$E_{PDM}[\gamma] = \sum_{v=2}^n \{ \int_{t=T_v}^{T_{v+1}} (E[\gamma]) dt \}. \tag{5}$$

The PDM scheme can defend against malicious traffic which are burst and listed in the blacklist. Moreover, it processes the rest of data packets according to priority so that it can defend some of other malicious traffic. Hence, we can rewrite (5) as (6).

$$E_{PDM}[\gamma] \approx \sum_{v=2}^n \{ \int_{t=T_v}^{T_{v+1}} (E[U \times L]) dt \}. \tag{6}$$

Here, we denote $U \times L$ as the burst malicious traffic which are also listed in the blacklist. Hence, the malicious traffic (γ') that the victim node receives can be presented as follows:

$$\gamma' = U \times L. \tag{7}$$

The PDM scheme can prevent bandwidth congestion caused by the data flooding attack, so the amount of control packets of the PDM scheme (C') is reduced much more than C (the amount of control packets when the defense system against the data flooding attack is not operated). Hence, $C' \ll C$. Moreover, the PDM scheme can reduce the total generated number of data packets so that *all all D' << D* where *all D'* is *all D* of the PDM scheme. By reducing the received traffic for conducting the data flooding attack at the victim node, the received normal traffic regardless of burst traffic are increased. Hence, the victim node receives much larger number of received non-burst traffic (α') and burst traffic (β') than the case when the PDM scheme is not conducted. Therefore, according to (3), the throughput of the PDM

scheme (*ThroughputPDM*) under the data flooding attack can be presented as the following equation:

$$Throughput_{PDM} \approx \sum_{v=2}^n \{ \int_{t=T_v}^{T_{v+1}} (\frac{\alpha' + \beta' - \gamma'}{C' + D'_{all}}) dt \}. \tag{8}$$

Since malicious data packet floods are usually generated at a high rate all the time, β' is extremely improved but γ' is decreased as in (3). Therefore, the throughput of the PDM scheme is improved.

B. Simulations

We evaluate the throughput of the PDM scheme using the ns-2 simulation [13]. We conduct the simulation for 100 times and then draw the mean value on the graphs. We use 50 mobile nodes which move based on the random waypoint model with the speed of 20 m/s in a 1000 m by 1000 m area for 500 seconds. The transmission range of each node is 250 m. There are 20 CBR sources which send 512-byte UDP packets. We use the AODV as the basis routing protocol and compare its performance with that of our PDM scheme. We define $h(nSp-nDp)$ as 0 and 10 to investigate how the PDM scheme can guarantee QoS of burst traffic and non-burst traffic, respectively.

Fig. 2 shows the throughput varying with the number of attackers from 0 to 20 attackers. To compare the affect of the number of attackers to the throughput, each node including attackers sends 20 packets per second. The throughput of the PDM scheme regardless of $h(nSp-nDp)$ is higher than AODV so that it can defend against malicious data packet flooding attacks.

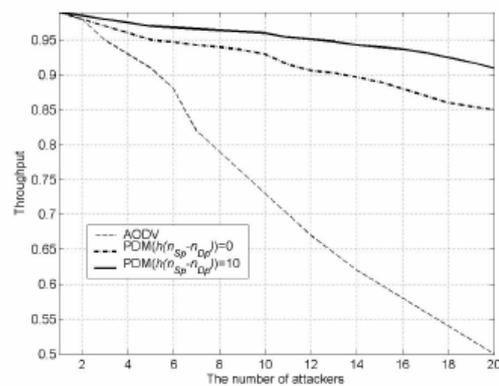

Fig. 2 Throughput vs. the number of attackers.

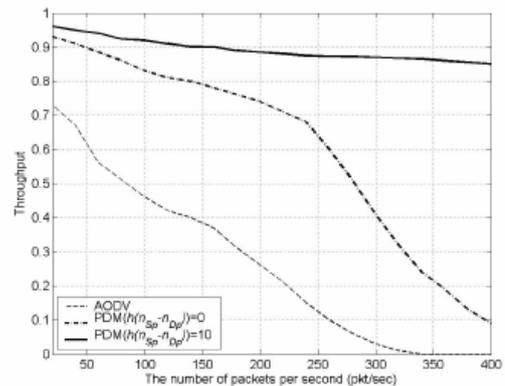

Fig. 3 Throughput vs. the number of packets per second.

Fig. 3 shows that PDM with $h(nSp-nDp)=10$ can guarantee QoS of burst traffic better than others. To investigate how much QoS of burst traffic are guaranteed, we increase the number of data packets per second from 20 packets/sec to 400 packets/sec. We assume that there are 5 attackers. When the number of packets per second is high (burst traffic), AODV cannot process packets because of the resource exhaustion.

VII. CONCLUSION

We have proposed the period-based defense mechanism against data flooding attacks. The data flooding attack paralyzes a victim node by consuming its resources. Hence, the throughput of the victim node is significantly reduced. However, the current defense systems focus on RREQ flooding attacks rather than the data flooding attack. They easily reduce the throughput of burst traffic by comparing with the simple threshold. Hence, we aim to enhance the throughput of burst traffic under the data flooding attack. The proposed scheme uses a blacklist, considers the data type, and processes packets according to the priority so as to defend against data flooding attacks; since the attacker forwards many data packets at a high rate for the whole session. Recently, many users like to download and share multimedia data, so we expect that the proposed scheme is useful to networks where burst traffic are transferred.

Determination of Camber and Leaf Span of a Parabolic Leaf Spring for Optimized Stress and Displacement Using Artificial Neural Networks

Manas Patnaik¹, L.P. Koushik², Manoj Mathew³

¹(Department of Mechanical Engineering, Rungta College of Engineering & Technology, Raipur, India

^{2,3}(Department of Mechanical Engineering, Christian College of Engineering & Technology, Bhilai, India

Abstract : This work has been carried out on a parabolic leaf spring of a mini loader truck. The spring has been analyzed by applying a load of 3800 N and the corresponding values of stress and displacement are computed. In this work, Design of experiments has been applied under various configurations of the spring (i.e by varying camber & eye distance). Camber and Leaf span of a Parabolic Leaf Spring was found for Optimized Stress and Displacement value using Artificial Neural Networks. Various networks with different architecture were trained and the network giving the best performance was used for optimization.

Keywords: Artificial neural networks (ANN), Computer Aided Design (CAD), Camber, Design of Experiments (DOE), Eye Distance, Finite Element Analysis (FEA), Parabolic Leaf Spring (PLS).

I. Introduction

Parabolic Leaf springs are essential suspension elements used on mini loader trucks necessary to minimize the vertical vibrations, impacts and bumps due to road irregularities and to ensure safety of the loaded cargo. Parabolic Leaf springs are widely used for automobiles. The Parabolic leaf spring absorbs the vertical vibrations and impacts due to road irregularities by means of variations in the spring deflection so that the potential energy is stored in spring as strain energy and then gradually released to maintain comfort. The finite element analysis (FEA) is a computing technique that is used to obtain approximate solutions to the boundary value problems in engineering. It uses a numerical technique called the finite element method (FEM). It is now accepted by major industries across the world and a company that is able to verify a proposed design will be able to perform to the clients specifications prior to manufacturing or construction. In the present work, leaf spring has been analyzed for static strength and deflection using 3D finite element analysis. CATIA V5 R20 has been utilized in the creation of the three dimensional model and its static structural workbench for analysis when subjected to vertical loads. The variation of bending stress and displacement values are computed. To add on the different combinations of input parameters (camber & eye distance) have been taken into account & its influence on bending stress and max deflection has been studied.

II. Parabolic Leaf Spring & Dimensions

A more modern implementation of old leaf springs is the parabolic leaf spring for automobiles. The new innovative design is characterized by the use of less leaves whose thickness varies from the center to the outer

side following a parabolic pattern. The mathematical equation between the thickness & the length of the spring is that of a parabola & hence it has been named as parabolic leaf spring.

1. Camber – 90.81mm
2. Distance between eyes(Eye Distance) : 1025mm
3. Thickness at the central part : 10.81mm

Note: The above dimensions have been taken with the help of an inextensible measuring tape and a vernier caliper and then the procedure of modeling the spring was initiated. The basic views of the considered parabolic leaf spring are shown in fig. 1.

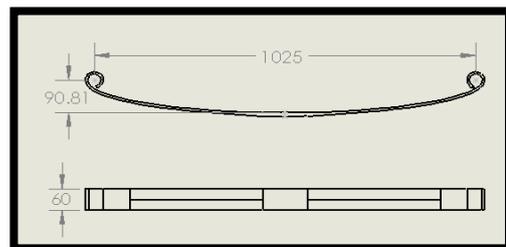

Fig.1 Front & Top view

Note : All dimensions are in mm

III. Existing Material

The material used for experimentation is EN45 and its mechanical properties has been mentioned in Table-1

Table--1

Material		Youn gs Mod ulus (E) Gpa	Pois son's Ratio (M)	Den sity (Kg/ M ³)	Yiel d Stre ngt h(M pa)
EN	IS(OI d)				
EN 45	55Si2 Mn90	200	0.3	785 0	150 0

IV. Result And Analysis Using Method Of Finite Elements

4.1 Meshing

Meshing is basically the process of breaking the CAD model into very small elements. It is also known as piecewise approximation. Meshing are of different types, it may be comprising of 1D, 2D or 3D elements. In present case selected is shown in Table-2

Table--2

Mesh			Element type	
S. N.	Entity	Size	Connectivity	Statistics
1	Nodes	12084		
2	Elements	5905	TE10(Tetrahedron element)	5905 (100.00 %)

4.2 Boundary Conditions

As shown in Fig. 2, one eye of the leaf spring will be fixed and the other eye will have certain degree of rotation to allow the leaf spring to deflect by some amount. It has been mathematically calculated that the maximum load which the spring will be subjected to 3800 N. This particular calculation has been done on the basis of GVW (Gross Vehicle Weight), which may be defined as the total weight of the loaded vehicle. This includes the vehicle itself and the cargo that is loaded within that vehicle.

In order to perform static structural analysis it is very essential to restraint the CAD model in the same manner as it is done physically. As far as parabolic leaf springs are concerned it has two eye ends, one of which is fixed with the upper body of the mini loader truck, while the other end is attached to a shackle which allows the spring to expand along its leaf span thereby causing some degree of rotation in the shackle.

Similarly we have applied constraints to our CAD model of parabolic leaf spring shown in Fig. 3 & 4.

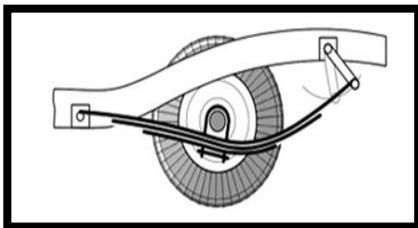

Fig.2 Suspension and Constraints

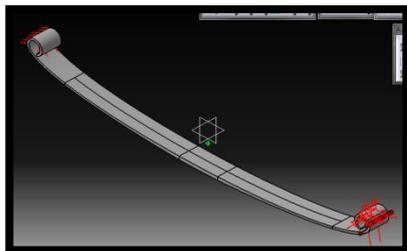

Fig.3 Applying Constraints.

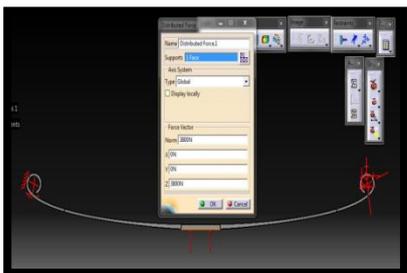

Fig.4 Applying Load

As shown in Fig. 4, the leaf spring is being treated as a simply supported beam which has a central load of 3800 N directed upwards.

4.3 Static Structural Analysis in CATIA V5 R20

After applying the boundary conditions the maximum von mises stress and maximum displacement is shown in Fig. 5 & 6.

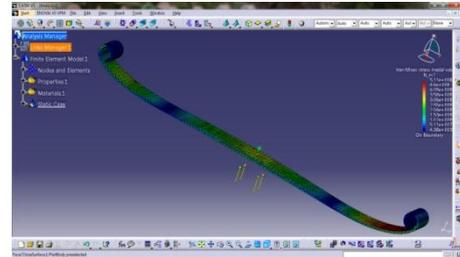

Fig.5 Von Mises Stress

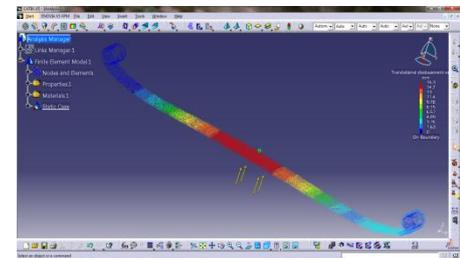

Fig.6 Displacement

Outputs on the basis of existing dimensions has been mentioned in Table-3 :

Table--3

S.N	Output Parameter	Value
1	Maximum Displacement	16.3079mm
2	Maximum Von mises stress	5.11017e+008 N_m2
3	Energy	30.008 J
4	Mass	4.549kg

V. Design Of Experiments

The Design of experiments (DOE) is a tool for determining the significance of different factors affecting process quality and for calculating optimal settings for controllable factors. For example we may believe that operating temperature and wave height affects the number of defects from a wave solder machine. DOE provides a fast & efficient means for determining the values of these parameters that would produce the fewer number of defects.

DOE Procedure:

- Select factors to be tested & a measure of process outcome.
- Select test setting for each factor.
- Select the appropriate orthogonal array.
- Run the tests.
- Analyze the results.
- Calculate optimum setting for each factor.
- Run confirmation test(s).

In this work camber and eye distance are selected as input parameters and max displacement, max von mises

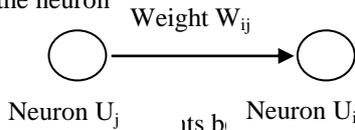

stress as output parameters. Design of experiments has been implemented by varying camber from 90 mm to 95 mm in steps of 10 and by varying eye distance from 1020 mm to 1030 mm in steps of 10.

VI. Artificial Neural Networks And Training

An Artificial Neural Network (ANN) is an information processing paradigm that is inspired by the way biological nervous systems, process information. An artificial neuron is composed of five main parts: inputs, weights, sum function, activation function and outputs. Inputs are information that enters the neuron from other neurons or from the external world. Generally connections between the units are defined by a weight w_{ij} . Weights are adaptive coefficients inside the network and they determine the intensity of the input signal as registered by the artificial neuron. Sum function is a function that calculates the effect of inputs and weights totally on this process element. This function calculates the net input that comes to a cell. The weighted sums of the input components is calculated by using Eq. 1

$$(net)_j = \sum_{i=1}^n W_{ij} I_i + b \quad \dots (1)$$

Where $(net)_j$ is the weighted sum of the j neuron for the input received from the preceding layer with n neurons, W_{ij} is the weight between the j^{th} neuron in the preceding layer and i^{th} neuron in the layer, I_i is the input to the preceding layer and b is a fix value as an internal addition known as bias. Figure 7 shows the connection between the neuron

6.1 Training by Artificial Neural Networks.

Training has been with the help of neural network tool box in MATLAB 2009b. Different combinations were taken into account to create the network which best suits our need. The neural network created is two layered and consists of 10 neurons in layer 1. The network initialization has been done below:

Feed forward back propagation network

- a) Training Function- TRAINLM
- b) Adaptive Learning Function- LEARNGDM
- c) Architecture- 2X10X2
- d) Hidden Layer- Tansig
- e) Output Layer- Purelin

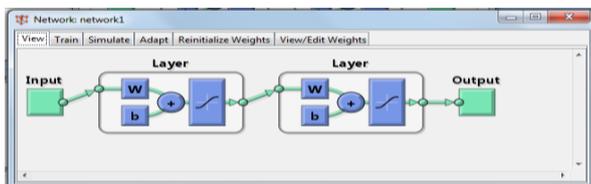

Fig.8 Neural Network Model

Several neural network models with different architecture were trained and tested using different configurations but the one in shown in Fig.8 above showed minimum Mean square error amongst all.

6.2 Performance

The assessment of any neural network model is done with the help of Mean Square error and it is found that amongst all the different configurations trained and tested, the minimum value of MSE was 0.91786.

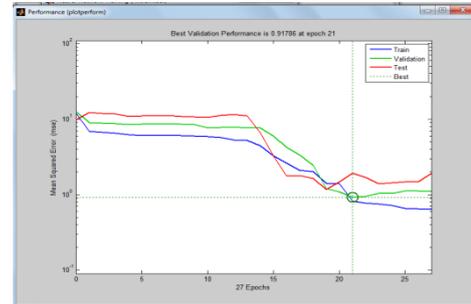

Fig.9 Mean Square Error is 0.91786 at epoch 21

VII. Conclusion

After successful creation of the neural network model it is imperative to optimize the stress and displacement in order to achieve the corresponding values of camber and leaf span. Following conclusion has been derived from the Neural Network Model:

Table--3

Min Stress (N/m ²)	Max Displacement(mm)	Camber (mm)	Leaf Span(mm)
50740000 0	16.596	90.8623	1029.1062

The values of camber and leaf span for optimized stress and displacement are shown in table-3 above.

Somewhat almost αg -continuous functions and Somewhat almost αg -open functions

S. Balasubramanian¹ and Ch. Chaithanya²

¹Department of Mathematics, Govt. Arts College(A), Karur – 639 005, Tamilnadu

²Sri Mittapalli college of Engineering, Tummalapalem, Guntur, Andhrapradesh

Abstract: In this paper we tried to introduce a new variety of continuous and open functions called Somewhat almost αg -continuous functions and Somewhat almost αg -open functions. Its basic properties are discussed.

AMS subject classification Number: 54C10, 534C08, 54C05.

Keywords: Somewhat αg -continuous functions and Somewhat αg -open functions, Somewhat almost αg -continuous functions and Somewhat almost αg -open functions

I. Introduction:

b-open[1] sets are introduced by Andrijevic in 1996. K.R.Gentry[9] introduced somewhat continuous functions in the year 1971. V.K.Sharma and the present authors of this paper defined and studied basic properties of ν -open sets and ν -continuous functions in the year 2006 and 2010 respectively. T.Noiri and N.Rajesh[11] introduced somewhat b-continuous functions in the year 2011. Inspired with these developments we introduce in this paper somewhat almost αg -continuous functions, somewhat almost αg -open functions and study its basic properties and interrelation with other type of such functions available in the literature. Throughout the paper (X, τ) and (Y, σ) (or simply X and Y) represent topological spaces on which no separation axioms are assumed unless otherwise mentioned. For $A \subset (X; \tau)$, $cl\{A\}$ and A° denote the closure of A and the interior of A in X, respectively.

II. Preliminaries

Definition 2.1: A subset A of X is said to be

(i) b-open[1] if $A \subset (cl\{A\})^\circ \cap cl\{A^\circ\}$.

(ii) αg -dense in X if there is no proper αg -closed set C in X such that $M \subset C \subset X$.

Definition 2.2: A function f is said to be

(i) somewhat continuous[9][resp: somewhat b-continuous[11]; somewhat gs-continuous[6]] if for $U \in \sigma$ and $f^{-1}(U) \neq \emptyset$, there exists an open[resp: b-open; gs-open] set V in X such that $V \neq \emptyset$ and $V \subset f^{-1}(U)$.

(ii) somewhat open[11][resp: somewhat b-open[9]; somewhat gs-open] provided that if $U \in \tau$ and $U \neq \emptyset$, then there exists an open[resp: b-open; gs-open] set V in Y such that $V \neq \emptyset$ and $V \subset f(U)$.

Definition 2.3: (X, τ) is said to be resolvable[8][b-resolvable[11]] if there exists a set A in (X, τ) such that both A and $X - A$ are dense[b-dense] in (X, τ) . Otherwise, (X, τ) is called irresolvable.

Definition 2.4: If X is a set and τ and σ are topologies on X, then τ is said to be equivalent[resp: αg -equivalent] to σ provided if $U \in \tau$ and $U \neq \emptyset$, then there is an open[resp: αg -open] set V in X such that $V \neq \emptyset$ and $V \subset U$ and if $U \in \sigma$ and $U \neq \emptyset$, then there is an open[resp: αg -open] set V in (X, τ) such that $V \neq \emptyset$ and $U \supset V$.

III. Somewhat almost αg -continuous function

Definition 3.1: A function f is said to be somewhat almost αg -continuous if for $U \in RO(\sigma)$ and $f^{-1}(U) \neq \emptyset$, there exists a non-empty αg -open set V in X such that $V \subset f^{-1}(U)$.

It is clear that every almost continuous function is somewhat almost continuous and every somewhat almost continuous is somewhat almost αg -continuous. But the converses are not true.

Example 1: Let $X = \{a, b, c\}$, $\tau = \{\emptyset, \{a\}, \{b, c\}, X\}$ and $\sigma = \{\emptyset, \{a\}, X\}$. The function $f: (X, \tau) \rightarrow (X, \sigma)$ defined by $f(a) = c$, $f(b) = a$ and $f(c) = b$ is somewhat almost αg -continuous, somewhat αg -continuous but not somewhat continuous.

Example 2: Let $X = \{a, b, c\}$, $\tau = \{\emptyset, \{b, c\}, X\}$, $\sigma = \{\emptyset, \{b\}, \{a, c\}, X\}$ and $\eta = \{\emptyset, \{a\}, X\}$. Then the identity functions $f: (X, \tau) \rightarrow (X, \sigma)$ and $g: (X, \sigma) \rightarrow (X, \eta)$ and $g \circ f$ are somewhat almost αg -continuous.

However, we have the following

Theorem 3.1: If f is somewhat almost αg -continuous and g is continuous[r-continuous; r-irresolute], then $g \circ f$ is somewhat almost αg -continuous.

Theorem 3.2: For a surjective function f , the following statements are equivalent:

- (i) f is somewhat almost αg -continuous.
 - (ii) If C is regular closed in Y such that $f^{-1}(C) \neq X$, then there is a proper αg -closed subset D of X such that $f^{-1}(C) \subset D$.
 - (iii) If M is a αg -dense subset of X , then $f(M)$ is a dense subset of Y .
- Proof:** (i) \Rightarrow (ii): Let $C \in RC(Y)$ such that $f^{-1}(C) \neq X$. Then $Y - C \in RO(Y)$ such that $f^{-1}(Y - C) = X - f^{-1}(C) \neq \emptyset$. By (i), there exists $V \neq \emptyset \in \alpha GO(X)$ and $V \subset f^{-1}(Y - C) = X - f^{-1}(C)$. Thus $X - V \supset f^{-1}(C)$ and $X - V = D$ is a proper αg -closed set in X .
- (ii) \Rightarrow (i): Let $U \in RO(\sigma)$ and $f^{-1}(U) \neq \emptyset$. Then $Y - U \in RC(\sigma)$ and $f^{-1}(Y - U) = X - f^{-1}(U) \neq X$. By (ii), there exists a proper $D \in \alpha GC(X)$ such that $D \supset f^{-1}(Y - U)$. This implies that $X - D \subset f^{-1}(U)$ and $X - D$ is αg -open and $X - D \neq \emptyset$.
- (ii) \Rightarrow (iii): Let M be a αg -dense set in X . If $f(M)$ is not dense in Y . Then there exists a proper $C \in RC(Y)$ such that $f(M) \subset C \subset Y$. Clearly $f^{-1}(C) \neq X$. By (ii), there exists a proper $D \in \alpha GC(X)$ such that $M \subset f^{-1}(C) \subset D \subset X$. This is a contradiction to the fact that M is αg -dense in X .
- (iii) \Rightarrow (ii): If (ii) is not true, there exists $C \in RC(Y)$ such that $f^{-1}(C) \neq X$ but there is no proper $D \in \alpha GC(X)$ such that $f^{-1}(C) \subset D$. Thus $f^{-1}(C)$ is αg -dense in X . But by (iii), $f(f^{-1}(C)) = C$ is dense in Y , which contradicts the choice of C .

Theorem 3.3: Let f be a function and $X = A \cup B$, where $A, B \in RO(X)$. If $f_A: (A; \tau_A) \rightarrow (Y, \sigma)$ and $f_B: (B; \tau_B) \rightarrow (Y, \sigma)$ are somewhat almost αg -continuous, then f is somewhat almost αg -continuous.

Proof: Let $U \in RO(\sigma)$ such that $f^{-1}(U) \neq \emptyset$. Then $(f_A)^{-1}(U) \neq \emptyset$ or $(f_B)^{-1}(U) \neq \emptyset$ or both $(f_A)^{-1}(U) \neq \emptyset$ and $(f_B)^{-1}(U) \neq \emptyset$. Suppose $(f_A)^{-1}(U) \neq \emptyset$, Since f_A is somewhat almost αg -continuous, there exists $V \neq \emptyset \in \alpha GO(A)$ and $V \subset (f_A)^{-1}(U) \subset f^{-1}(U)$. Since $V \in \alpha GO(A)$ and $A \in RO(X)$, $V \in \alpha GO(X)$. Thus f is somewhat almost αg -continuous. The proof of other cases are similar.

Theorem 3.4: Let $f: (X, \tau) \rightarrow (Y, \sigma)$ be a somewhat almost αg -continuous surjection and τ^* be a topology for X , which is αg -equivalent to τ . Then $f: (X, \tau^*) \rightarrow (Y, \sigma)$ is somewhat almost αg -continuous.

Proof: Let $V \in RO(\sigma)$ such that $f^{-1}(V) \neq \emptyset$. Since f is somewhat almost αg -continuous, there exists $U \neq \emptyset \in \alpha GO(X, \tau)$ such that $U \subset f^{-1}(V)$. But by hypothesis τ^* is αg -equivalent to τ . Therefore, there exists $U^* \neq \emptyset \in \alpha GO(X; \tau^*)$ such that $U^* \subset U$. But $U \subset f^{-1}(V)$. Then $U^* \subset f^{-1}(V)$; hence $f: (X, \tau^*) \rightarrow (Y, \sigma)$ is somewhat almost αg -continuous.

Theorem 3.5: Let $f: (X, \tau) \rightarrow (Y, \sigma)$ be a somewhat almost αg -continuous surjection and σ^* be a topology for Y , which is equivalent to σ . Then $f: (X, \tau) \rightarrow (Y, \sigma^*)$ is somewhat almost αg -continuous.

Proof: Let $V^* \in RO(\sigma^*)$ such that $f^{-1}(V^*) \neq \emptyset$. Since σ^* is equivalent to σ , there exists $V \neq \emptyset \in RO(Y, \sigma)$ such that $V \subset V^*$. Now $\emptyset \neq f^{-1}(V) \subset f^{-1}(V^*)$. Since f is somewhat almost αg -continuous, there exists $U \neq \emptyset \in \alpha GO(X, \tau)$ such that $U \subset f^{-1}(V)$. Then $U \subset f^{-1}(V^*)$; hence $f: (X, \tau) \rightarrow (Y, \sigma^*)$ is somewhat almost αg -continuous.

IV. Somewhat αg -irresolute function

Definition 4.1: A function f is said to be somewhat αg -irresolute if for $U \in \alpha GO(\sigma)$ and $f^{-1}(U) \neq \emptyset$, there exists a non-empty αg -open set V in X such that $V \subset f^{-1}(U)$.

Example 3: Let $X = \{a, b, c\}$, $\tau = \{\emptyset, \{a\}, \{b, c\}, X\}$ and $\sigma = \{\emptyset, \{a\}, \{a, b\}, X\}$. The function $f: (X, \tau) \rightarrow (X, \sigma)$ defined by $f(a) = c, f(b) = a$ and $f(c) = b$ is somewhat αg -irresolute but not somewhat-irresolute.

Example 4: Let $X = \{a, b, c\}$, $\tau = \{\emptyset, \{a\}, \{a, b\}, X\}$ and $\sigma = \{\emptyset, \{a\}, \{b, c\}, X\}$. The function $f: (X, \tau) \rightarrow (X, \sigma)$ defined by $f(a) = c, f(b) = a$ and $f(c) = b$ is not somewhat αg -irresolute and somewhat-irresolute.

Note 1: Every somewhat αg -irresolute function is slightly αg -irresolute.

Example 5: The identity functions f, g and $g \circ f$ in Example 2 are somewhat αg -irresolute.

However, we have the following

Theorem 4.1: If f is somewhat αg -irresolute and g is irresolute, then $g \circ f$ is somewhat αg -irresolute.

Theorem 4.2: For a surjective function f , the following statements are equivalent:

- (i) f is somewhat αg -irresolute.
 - (ii) If C is αg -closed in Y such that $f^{-1}(C) \neq X$, then there is a proper αg -closed subset D of X such that $f^{-1}(C) \subset D$.
 - (iii) If M is a αg -dense subset of X , then $f(M)$ is a αg -dense subset of Y .
- Proof:** (i) \Rightarrow (ii): Let $C \in \alpha GC(Y)$ such that $f^{-1}(C) \neq X$. Then $Y - C \in \alpha GO(Y)$ such that $f^{-1}(Y - C) = X - f^{-1}(C) \neq \emptyset$. By (i), there exists $V \neq \emptyset \in \alpha GO(X)$ and $V \subset f^{-1}(Y - C) = X - f^{-1}(C)$. This means $X - V \supset f^{-1}(C)$ and $X - V = D$ is proper αg -closed in X .

(ii) \Rightarrow (i): Let $U \in \alpha GO(\sigma)$ and $f^{-1}(U) \neq \emptyset$. Then $Y - U \neq \emptyset \in \alpha GC(Y)$ and $f^{-1}(Y - U) = X - f^{-1}(U) \neq X$. By (ii), there exists $D \neq \emptyset \in \alpha GC(X)$ such that $D \supset f^{-1}(Y - U)$. This implies that $X - D \subset f^{-1}(U)$ and $X - D$ is αg -open and $X - D \neq \emptyset$.

(ii) \Rightarrow (iii): Let M be a αg -dense set in X . If $f(M)$ is not αg -dense in Y . Then there exists a proper $C \in \alpha GC(Y)$ such that $f(M) \subset C \subset Y$. Clearly $f^{-1}(C) \neq X$. By (ii), there exists a proper $D \in \alpha GC(X)$ such that $M \subset f^{-1}(C) \subset D \subset X$. This is a contradiction to the fact that M is αg -dense in X .

(iii) \Rightarrow (ii): Suppose (ii) is not true. there exists $C \in \alpha GC(Y)$ such that $f^{-1}(C) \neq X$ but there is no proper $D \neq \emptyset \in \alpha GC(X)$ such that $f^{-1}(C) \subset D$. This means that $f^{-1}(C)$ is αg -dense in X . But by (iii), $ff^{-1}(C) = C$ must be αg -dense in Y , which is a contradiction to the choice of C .

Theorem 4.3: Let f be a function and $X = A \cup B$, where $A, B \in RO(X)$. If $f|_A: (A; \tau|_A) \rightarrow (Y, \sigma)$ and $f|_B: (B; \tau|_B) \rightarrow (Y, \sigma)$ are somewhat αg -irresolute, then f is somewhat αg -irresolute.

Proof: Let $U \in \alpha GO(\sigma)$ such that $f^{-1}(U) \neq \emptyset$. Then $(f|_A)^{-1}(U) \neq \emptyset$ or $(f|_B)^{-1}(U) \neq \emptyset$ or both $(f|_A)^{-1}(U) \neq \emptyset$ and $(f|_B)^{-1}(U) \neq \emptyset$. If $(f|_A)^{-1}(U) \neq \emptyset$, Since $f|_A$ is somewhat αg -irresolute, there exists $V \neq \emptyset \in \alpha GO(A)$ and $V \subset (f|_A)^{-1}(U) \subset f^{-1}(U)$. Since $V \in \alpha GO(A)$ and $A \in RO(X)$, $V \in \alpha GO(X)$. Thus f is somewhat αg -irresolute.

The proof of other cases are similar.

If f is the identity function and τ and σ are αg -equivalent. Then f and f^{-1} are somewhat αg -irresolute. Conversely, if the identity function f is somewhat αg -irresolute in both directions, then τ and σ are αg -equivalent.

Theorem 4.4: Let $f: (X, \tau) \rightarrow (Y, \sigma)$ be a somewhat αg -irresolute surjection and τ^* be a topology for X , which is αg -equivalent to τ . Then $f: (X, \tau^*) \rightarrow (Y, \sigma)$ is somewhat αg -irresolute.

Proof: Let $V \in \alpha GO(\sigma)$ such that $f^{-1}(V) \neq \emptyset$. Since f is somewhat αg -irresolute, there exists $U \neq \emptyset \in \alpha GO(X, \tau)$ with $U \subset f^{-1}(V)$. But for τ^* is αg -equivalent to τ , there exists $U^* \neq \emptyset \in \alpha GO(X; \tau^*)$ such that $U^* \subset U$. But $U \subset f^{-1}(V)$. Then $U^* \subset f^{-1}(V)$; hence $f: (X, \tau^*) \rightarrow (Y, \sigma)$ is somewhat αg -irresolute.

Theorem 4.5: Let $f: (X, \tau) \rightarrow (Y, \sigma)$ be a somewhat αg -irresolute surjection and σ^* be a topology for Y , which is equivalent to σ . Then $f: (X, \tau) \rightarrow (Y, \sigma^*)$ is somewhat αg -irresolute.

Proof: Let $V^* \in \sigma^*$ such that $f^{-1}(V^*) \neq \emptyset$. Since σ^* is equivalent to σ , there exists $V \neq \emptyset \in (Y, \sigma)$ such that $V \subset V^*$. Now $\emptyset \neq f^{-1}(V) \subset f^{-1}(V^*)$. Since f is somewhat αg -irresolute, there exists $U \neq \emptyset \in \alpha GO(X, \tau)$ such that $U \subset f^{-1}(V)$. Then $U \subset f^{-1}(V^*)$; hence $f: (X, \tau) \rightarrow (Y, \sigma^*)$ is somewhat αg -irresolute.

V. Somewhat almost αg -open function

Definition 5.1: A function f is said to be somewhat almost αg -open provided that if $U \in RO(\tau)$ and $U \neq \emptyset$, then there exists a non-empty αg -open set V in Y such that $V \subset f(U)$.

Example 6: Let $X = \{a, b, c\}$, $\tau = \{\emptyset, \{a\}, X\}$ and $\sigma = \{\emptyset, \{a\}, \{b, c\}, X\}$. The function $f: (X, \tau) \rightarrow (X, \sigma)$ defined by $f(a) = a$, $f(b) = c$ and $f(c) = b$ is somewhat almost αg -open, somewhat αg -open and somewhat open.

Theorem 5.1: Let f be r -open and g be somewhat almost αg -open. Then $g \circ f$ is somewhat almost αg -open.

Theorem 5.2: For a bijective function f , the following are equivalent:

- (i) f is somewhat almost αg -open.
 - (ii) If C is regular closed in X , such that $f(C) \neq Y$, then there is a αg -closed subset D of Y such that $D \neq Y$ and $D \supset f(C)$.
- Proof:** (i) \Rightarrow (ii): Let $C \in RC(X)$ such that $f(C) \neq Y$. Then $X - C \neq \emptyset \in RO(X)$. Since f is somewhat almost αg -open, there exists $V \neq \emptyset \in \alpha GO(Y)$ such that $V \subset f(X - C)$. Put $D = Y - V$. Clearly $D \neq \emptyset \in \alpha GC(Y)$. If $D = Y$, then $V = \emptyset$, which is a contradiction. Since $V \subset f(X - C)$, $D = Y - V \supset (Y - f(X - C)) = f(C)$.
- (ii) \Rightarrow (i): Let $U \neq \emptyset \in RO(X)$. Then $C = X - U \in RC(X)$ and $f(X - U) = f(C) = Y - f(U)$ implies $f(C) \neq Y$. Then by (ii), there is $D \neq \emptyset \in \alpha GC(Y)$ and $f(C) \subset D$. Clearly $V = Y - D \neq \emptyset \in \alpha GO(Y)$. Also, $V = Y - D \subset Y - f(C) = Y - f(X - U) = f(U)$.

Theorem 5.3: The following statements are equivalent:

- (i) f is somewhat almost αg -open.
 - (ii) If A is a αg -dense subset of Y , then $f^{-1}(A)$ is a dense subset of X .
- Proof:** (i) \Rightarrow (ii): Let A be a αg -dense set in Y . If $f^{-1}(A)$ is not dense in X , then there exists $B \in RC(X)$ such that $f^{-1}(A) \subset B \subset X$. Since f is somewhat almost αg -open and $X - B \in RO(X)$, there exists $C \neq \emptyset \in \alpha GO(Y)$ such that $C \subset f(X - B)$. Therefore, $C \subset f(X - B) \subset f(f^{-1}(Y - A)) \subset Y - A$. That is, $A \subset Y - C \subset Y$. Now, $Y - C$ is a αg -closed set and $A \subset Y - C \subset Y$. This implies that A is not a αg -dense set in Y , which is a contradiction. Therefore, $f^{-1}(A)$ is a dense set in X .
- (ii) \Rightarrow (i): If $A \neq \emptyset \in RO(X)$. We want to show that $\alpha g(f(A)) \neq \emptyset$. Suppose $\alpha g(f(A)) = \emptyset$. Then, $\alpha g cl\{f(A)\} = Y$. Then by (ii), $f^{-1}(Y - f(A))$ is dense in X . But $f^{-1}(Y - f(A)) \subset X - A$. Now, $X - A \in RC(X)$. Therefore, $f^{-1}(Y - f(A)) \subset X - A$ gives $X = cl\{f^{-1}(Y - f(A))\} \subset X - A$. Thus $A = \emptyset$, which contradicts $A \neq \emptyset$. Therefore, $\alpha g(f(A)) \neq \emptyset$. Hence f is somewhat almost αg -open.

Theorem 5.4: Let f be somewhat almost αg -open and $A \in RO(X)$. Then $f_{/A}$ is somewhat almost αg -open.

Proof: Let $U \neq \emptyset \in RO(\tau_A)$. Since $U \in RO(A)$ and $A \in RO(X)$, $U \in RO(X)$ and since f is somewhat almost αg -open, there exists $V \in \alpha GO(Y)$, such that $V \subset f(U)$. Thus $f_{/A}$ is somewhat almost αg -open.

Theorem 5.5: Let f be a function and $X = A \cup B$, where $A, B \in RO(X)$. If $f_{/A}$ and $f_{/B}$ are somewhat almost αg -open, then f is somewhat almost αg -open.

Proof: Let $U \neq \emptyset \in RO(X)$. Since $X = A \cup B$, either $A \cap U \neq \emptyset$ or $B \cap U \neq \emptyset$ or both $A \cap U \neq \emptyset$ and $B \cap U \neq \emptyset$. Since U is regular open in X , U is regular open in both A and B .

Case (i): If $A \cap U \neq \emptyset \in RO(A)$. Since $f_{/A}$ is somewhat almost αg -open, there exists a αg -open set V of Y such that $V \subset f(U \cap A) \subset f(U)$, which implies that f is a somewhat almost αg -open.

Case (ii): If $B \cap U \neq \emptyset \in RO(B)$. Since $f_{/B}$ is somewhat almost αg -open, there exists a αg -open set V in Y such that $V \subset f(U \cap B) \subset f(U)$, which implies that f is somewhat almost αg -open.

Case (iii): Suppose that both $A \cap U \neq \emptyset$ and $B \cap U \neq \emptyset$. Then by case (i) and (ii) f is somewhat almost αg -open.

Remark 1: Two topologies τ and σ for X are said to be αg -equivalent iff the identity function f is somewhat almost αg -open in both directions.

Theorem 5.6: If $f: (X, \tau) \rightarrow (Y, \sigma)$ is somewhat almost open. Let τ^* and σ^* be topologies for X and Y , respectively such that τ^* is equivalent to τ and σ^* is αg -equivalent to σ . Then $f: (X; \tau^*) \rightarrow (Y; \sigma^*)$ is somewhat almost αg -open.

VI. Somewhat M- αg -open function

Definition 6.1: A function f is said to be somewhat M- αg -open provided that if $U \in \alpha GO(\tau)$ and $U \neq \emptyset$, then there exists a non-empty αg -open set V in Y such that $V \subset f(U)$.

Example 7: f as in Example 6 is somewhat M- αg -open.

Theorem 6.1: Let f be r -open and g be somewhat M- αg -open. Then $g \circ f$ is somewhat M- αg -open.

Theorem 6.2: For a bijective function f , the following are equivalent:

(i) f is somewhat M- αg -open.

(ii) If $C \in \alpha GC(X)$, such that $f(C) \neq Y$, then there is a $D \in \alpha GC(Y)$ such that $D \neq Y$ and $D \supset f(C)$.

Proof: (i) \Rightarrow (ii): Let $C \in \alpha GC(X)$ such that $f(C) \neq Y$. Then $X - C \neq \emptyset \in \alpha GO(X)$. Since f is somewhat M- αg -open, there exists $V \neq \emptyset \in \alpha GO(Y)$ such that $V \subset f(X - C)$. Put $D = Y - V$. Clearly $D \neq \emptyset \in \alpha GC(Y)$. If $D = Y$, then $V = \emptyset$, which is a contradiction. Since $V \subset f(X - C)$, $D = Y - V \supset (Y - f(X - C)) = f(C)$.

(ii) \Rightarrow (i): Let $U \neq \emptyset \in RO(X)$. Then $C = X - U \in \alpha GC(X)$ and $f(X - U) = f(C) = Y - f(U)$ implies $f(C) \neq Y$. Then by (ii), there is $D \in \alpha GC(Y)$ such that $D \neq Y$ and $f(C) \subset D$. Clearly $V = Y - D \neq \emptyset \in \alpha GO(Y)$. Also, $V = Y - D \subset Y - f(C) = Y - f(X - U) = f(U)$.

Theorem 6.3: The following statements are equivalent:

(i) f is somewhat M- αg -open.

(ii) If A is a αg -dense subset of Y , then $f^{-1}(A)$ is a αg -dense subset of X .

Proof: (i) \Rightarrow (ii): Let A be a αg -dense set in Y . If $f^{-1}(A)$ is not αg -dense in X , then there exists $B \in \alpha GC(X)$ in X such that $f^{-1}(A) \subset B \subset X$. Since f is somewhat M- αg -open and $X - B$ is αg -open, there exists a $C \neq \emptyset \in \alpha GO(Y)$ such that $C \subset f(X - B)$. Therefore, $C \subset f(X - B) \subset f(f^{-1}(Y - A)) \subset Y - A$. That is, $A \subset Y - C \subset Y$. Now, $Y - C$ is a αg -closed set and $A \subset Y - C \subset Y$. This implies that A is not a αg -dense set in Y , which is a contradiction. Therefore, $f^{-1}(A)$ is a αg -dense set in X .

(ii) \Rightarrow (i): Let $A \neq \emptyset \in \alpha GO(X)$. To prove $\alpha g(f(A)) \neq \emptyset$. Assume $\alpha g(f(A)) = \emptyset$. Then, $\alpha g cl\{f(A)\} = Y$. Then by (ii), $f^{-1}(Y - f(A))$ is αg -dense in X . But $f^{-1}(Y - f(A)) \subset X - A$. Now, $X - A \in \alpha GC(X)$. Therefore, $f^{-1}(Y - f(A)) \subset X - A$ gives $X = cl\{f^{-1}(Y - f(A))\} \subset X - A$. Thus $A = \emptyset$, which contradicts $A \neq \emptyset$. Therefore, $\alpha g(f(A)) \neq \emptyset$. Hence f is somewhat M- αg -open.

Theorem 6.4: If f is somewhat M- αg -open and A is r -open in X . Then $f_{/A}: (A; \tau_A) \rightarrow (Y, \sigma)$ is somewhat M- αg -open.

Proof: Let $U \neq \emptyset \in \alpha GO(\tau_A)$. Since $U \in \alpha GO(A)$ and $A \in RO(X)$, $U \in RO(X)$ and since f is somewhat M- αg -open, there exists $V \in \alpha GO(Y)$, such that $V \subset f(U)$. Thus $f_{/A}$ is somewhat M- αg -open.

Theorem 6.5: Let f be a function and $X = A \cup B$, where $A, B \in \alpha GO(X)$. If $f_{/A}$ and $f_{/B}$ are somewhat M- αg -open, then f is somewhat M- αg -open.

Proof: Let $U \neq \emptyset \in RO(X)$. Since $X = A \cup B$, either $A \cap U \neq \emptyset$ or $B \cap U \neq \emptyset$ or both $A \cap U \neq \emptyset$ and $B \cap U \neq \emptyset$. Since U is regular open in X , U is regular open in both A and B .

Case (i): If $A \cap U \neq \emptyset \in RO(A)$. Since $f_{/A}$ is somewhat M- αg -open, there exists a αg -open set V of Y such that $V \subset f(U \cap A) \subset f(U)$, which implies that f is a somewhat M- αg -open.

Case (ii): If $B \cap U \neq \emptyset \in RO(B)$. Since $f_{/B}$ is somewhat M- αg -open, there exists a αg -open set V in Y such that $V \subset f(U \cap B) \subset f(U)$, which implies that f is somewhat M- αg -open.

Case (iii): If both $A \cap U \neq \emptyset$ and $B \cap U \neq \emptyset$. Then by case (i) and (ii) f is somewhat M - α g-open.

Remark 2: Two topologies τ and σ for X are said to be α g-equivalent iff the identity function f is somewhat M - α g-open in both directions.

Theorem 6.6: If $f: (X, \tau) \rightarrow (Y, \sigma)$ is somewhat M -open. Let τ^* and σ^* be topologies for X and Y , respectively such that τ^* is equivalent to τ and σ^* is α g-equivalent to σ . Then $f: (X; \tau^*) \rightarrow (Y; \sigma^*)$ is somewhat M - α g-open.

VII. CONCLUSION

In this paper we defined Somewhat- α g-continuous functions, studied its properties and their interrelations with other types of Somewhat-continuous functions.

Study of Crane Hook Having Trapezoidal Section by Finite Element Method & Design of Experiments

Santosh Sahu¹, Ritesh Dewangan², Manas Patnaik³, Narendra Yadav⁴

^{1, 2, 3, 4}(Department of Mechanical Engineering, Rungta College of Engineering & Technology, Raipur-492001-India)

Abstract : In the industrial processes Crane Hook is used as lifting member. In the present paper crane hook of trapezoidal section is modeled in CATIA V5R20, then 2 ton load equivalent to 19620 N on it is applied. The location of maximum stress produced within the member is located and identified using Finite Element Method (FEM). Further Design of Experiment (DOE) is applied by varying the length of two parallel sides of the Trapezoidal Hook and its effects are studied on the basis of Stress , Mass, Displacement and Energy stored within the hook.

Keywords - Crane Hook, DOE, FEM , Trapezoidal Hook, AISI 4140

I. INTRODUCTION

Crane hook is the member used for lifting the mass using wire ropes and crane. In this paper we have used a CAD model of Trapezoidal section Crane Hook in CATIA V5R20 and assigned the material having mechanical properties of AISI 4140 used for manufacturing of crane hook . Finite Element Analysis is applied to find out the stress in the critical section where maximum stress is induced . Design of Experiments is applied in Matlab, by varying the parallel length of the trapezoidal section and its effects is studied in terms of Energy stored, displacement, stress induced and mass accumulated within the crane hook in the form of output parameters. The results obtained from Design of experiment is plotted to know the nature of the output parameters with respect to the varying parallel length of outer as well as inner surface. By this we established the relation between the cross section and the output parameters which are useful for selection of the cross section dimensions during manufacturing with respect to the desired output parameters .

II. CRANE HOOK DIMENSIONS AND MATERIAL

The CAD model of Crane hook is shown in Figure1.

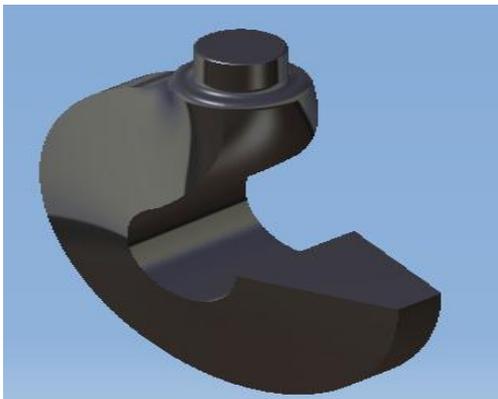

Fig.1 CAD Model of crane hook

The dimension of the trapezoidal section is shown in Figure2.

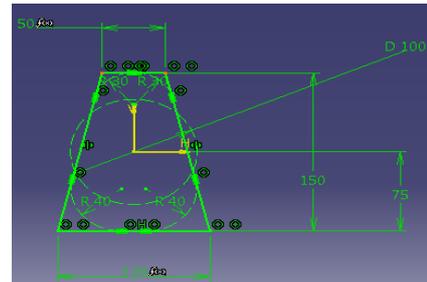

Fig.2 Dimensions of Trapezoidal section.

The material used for crane hook is forged steel the material selected in this cad model is AISI 4140 . The Mechanical properties of AISI is mentioned in Table 1.

Table 1. Mechanical properties of AISI 4140

MECHANICAL PROPERTIES	VAUES	UNIT
Elastic Modulus	2.05E+11	N/m ²
Poisson's ratio	0.285	N/A
Shear Modulus	8.00E+10	N/m ²
Density	7850	kg/m ³
Tensile Strength	560000000	N/m ²
Yield Strength	460000000	N/m ²
Thermal Conductivity	42.7	W/(m·K)
Specific Heat	477	J/(kg·K)

III. RESULT AND ANALYSIS BY FEM

The Finite Element Method is a Numerical Analysis Technique used to obtain solutions .Meshing is important part of Finite Element Method. The mesh details done in the CAD model is shown in Table. The mesh taken has Tetrahedron shape (Te4)

Table 2. Mesh details

Entity	Size
Nodes	9163
Elements	40630

Von Mises Stress distribution in cad model is shown in Figure 3.

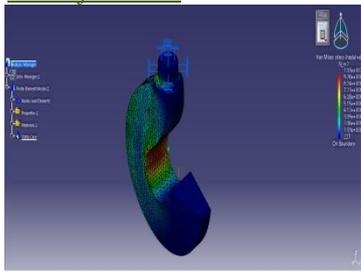

Fig. 3 Von Mises Stress Distribution

Translational displacement of nodes is shown in Figure 4.

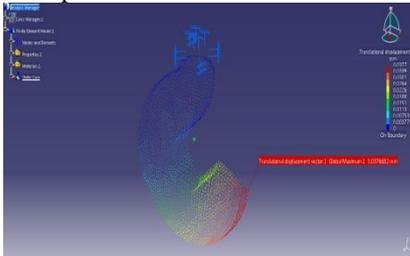

Fig. 4 Shows Translational displacement of nodes

The Sensors showing values of Energy, Maximum Displacement Maximum Von Mises', and Mass obtained by FEM is shown in Figure 5.

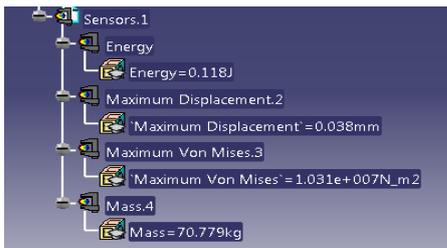

Fig. 5 Sensors Details after analysis

The maximum Von Mises stress location and magnitude is shown in Figure 6.

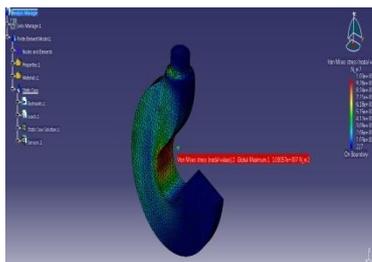

Fig. 6 Maximum Von Mises Stress.

IV. DESIGN OF EXPERIMENTS

DOE is Concerned with planning and conduction of experiments to analyze the resulting data by applying principles and techniques at the initial data collection stage to generate valid, defensible objective engineering conclusions.

We have taken two variable input values which are length of two parallel sides of Trapezoidal section namely 'B' and 'b'. The value of B which is at the inner side of the hook varies from 110 mm to 130 mm, whereas the value of b which is the outer side of the hook varies from 45 mm to 55 mm. Figure 7 shows the command window where input parameters B and b are assigned the minimum and maximum values and Output parameters are selected here

are Energy, Maximum Displacement, Maximum Von Mises and Mass. DOE is then performed and the results in the form of Graph has been plotted.

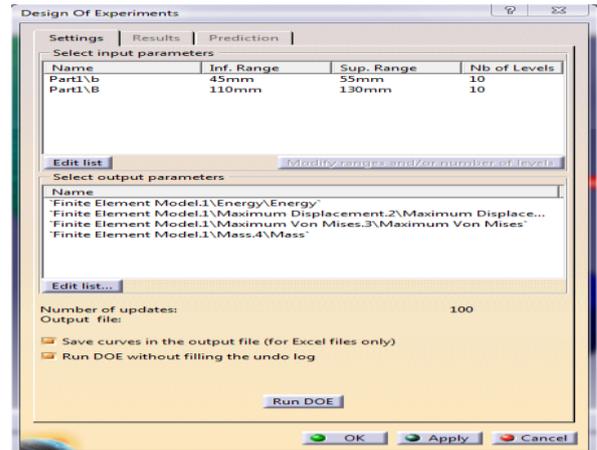

Fig. 7 Input Parameters and their Range With the selected output parameters

On running the DOE the results obtained are shown in the form of graphs between input variables and the selected output parameters

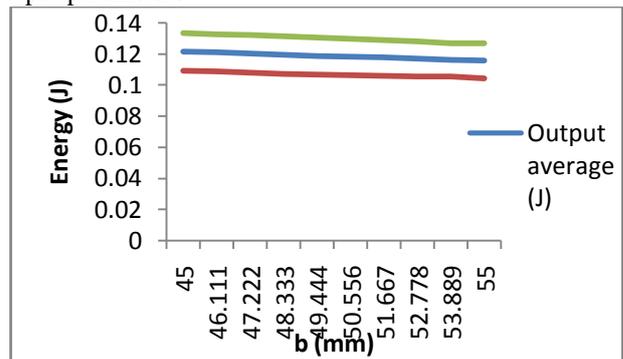

Fig.8 Graph Plotted Between Energy stored and b

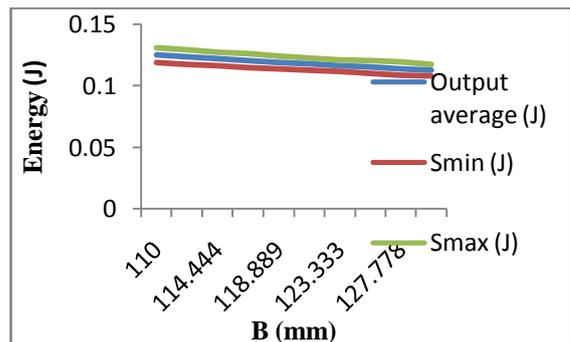

Fig.9 Graph Plotted Between Energy stored and B

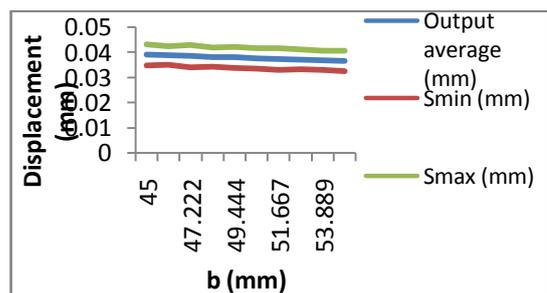

Fig.10 Graph Plotted Displacement and b

V. CONCLUSION

We have reached to the following conclusions on the basis of the results obtained from Finite element analysis and Design of Experiment performed for the trapezoidal cross section crane hook;

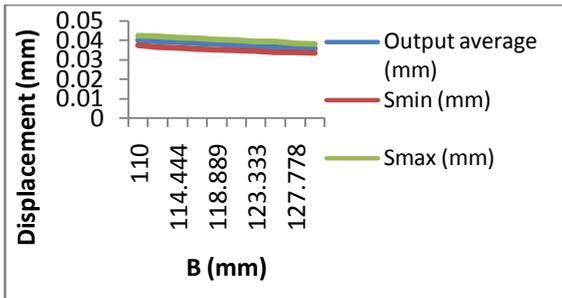

Fig.11 Graph Plotted between Displacement and B

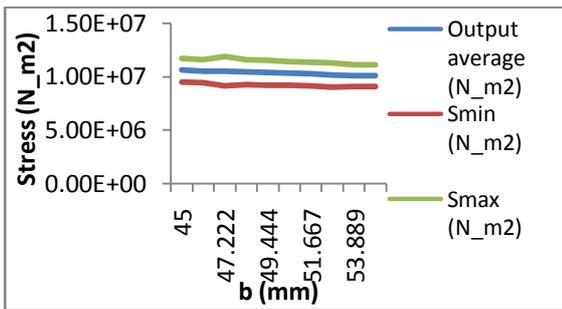

Fig.12 Graph Plotted between Stress and b

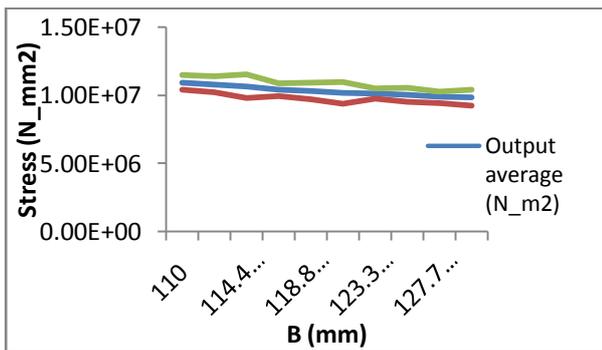

Fig.13 Graph Plotted between Stress and B

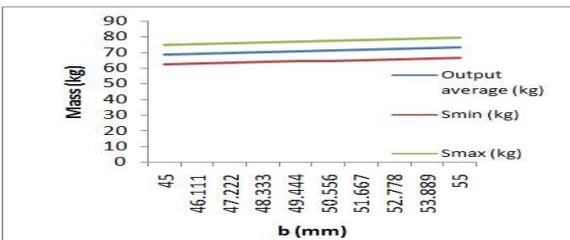

Fig.14 Graph Plotted between Mass and b

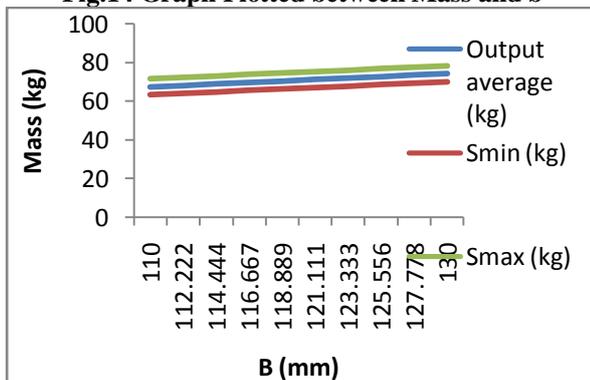

Fig.15 Graph Plotted between Mass and B

1. The Figure 6 shows the point where Maximum stress has been produced and the magnitude of maximum stress.
2. The Figure 8 shows the magnitude of energy stored within the crane hook decreases on the increase of outer parallel length (b) of trapezoidal section .
3. The Figure 9 shows the magnitude of energy stored within the crane hook decreases on the increase of Inner parallel length (B) of trapezoidal section .
4. The Figure 10 shows the magnitude of displacement within the crane hook decreases on the increase of outer parallel length (b) of trapezoidal section
5. The Figure 11 shows the magnitude of displacement within the crane hook decreases on the increase of inner parallel length (B) of trapezoidal section
6. The Figure 12 shows the magnitude of stress induced within the crane hook decreases on the increase of outer parallel length (b) of trapezoidal section
7. The Figure 13 shows the magnitude of stress induced within the crane hook decreases on the increase of Inner parallel length (B) of trapezoidal section.
8. The Figure 14 shows the magnitude of the mass of the crane hook increases on the increase of outer parallel length (b) of trapezoidal section.
9. The Figure 15 shows the magnitude of the mass of the crane hook increases on the increase of inner parallel length (B) of trapezoidal section

Advanced Direct Power Control Method of UPFC by Using Matrix Converter

D. Jagan¹, K. Suresh²

^{1,2}(EEE dept, RGM CET Nandyal/JNTUA, AP, INDIA)

Abstract: This paper presents a direct power control (DPC) for three-phase matrix converters operating as unified power flow controllers (UPFCs). Matrix converters (MCs) allow the direct ac/ac power conversion without dc energy storage links; therefore, the MC-based UPFC (MC-UPFC) has reduced volume and cost, reduced capacitor power losses, together with higher reliability. Theoretical principles of direct power control (DPC) based on sliding mode control techniques are established for an MC-UPFC dynamic model including the input filter. As a result, line active and reactive power, together with ac supply reactive power, can be directly controlled by selecting an appropriate matrix converter switching state guaranteeing good steady-state and dynamic responses. Experimental results of DPC controllers for MC-UPFC show decoupled active and reactive power control, zero steady-state tracking error, and fast response times. Compared to an MC-UPFC using active and reactive power linear controllers based on a modified Venturing high-frequency PWM modulator, the experimental results of the advanced DPC-MC guarantee faster responses without overshoot and no steady state error, presenting no cross-coupling in dynamic and steady-state responses.

Index Terms: Direct power control (DPC), matrix converter (MC), unified power-flow controller (UPFC).

I. INTRODUCTION

In the last few years, electricity market deregulation, together with growing economic, environmental, and social concerns, has increased the difficulty to burn fossil fuels, and to obtain new licenses to build transmission lines (rights-of-way) and high-power facilities. This situation started the growth of decentralized electricity generation (using renewable energy resources).

Unified Power-Flow Controllers (UPFC) enable the operation of power transmission networks near their maximum ratings, by enforcing power flow through well-defined lines. These days, UPFCs are one of the most versatile and powerful flexible ac transmission systems (FACTS) devices.

The UPFC results from the combination of a static synchronous compensator (STATCOM) and a static synchronous series compensator (SSSC) that shares a common dc capacitor link.

The existence of a dc capacitor bank originates additional losses, decreases the converter lifetime, and increases its weight, cost, and volume. These converters are capable of performing the same ac/ac conversion, allowing bidirectional power flow, guaranteeing near sinusoidal input and output currents, voltages with variable amplitude, and adjustable power factor. These minimum energy storage ac/ac converters have the capability to allow independent

reactive control on the UPFC shunt and series converter sides, while guaranteeing that the active power exchanged on the UPFC series connection is always supplied/absorbed by the shunt connection.

Recent nonlinear approaches enabled better tuning of PI controller parameters. Still, there is room to further improve the dynamic response of UPFCs, using nonlinear robust controllers. In the last few years, direct power control techniques have been used in many power applications, due to their simplicity and good performance. In this project, a matrix converter-based UPFC is proposed, using a direct power control approach (DPC-MC) based on an MC-UPFC dynamic model (Section II).

In order to design UPFCs, presenting robust behavior to parameter variations and to disturbances, the proposed DPC-MC control method, in Section III, is based on sliding mode-control techniques, allowing the real-time selection of adequate matrix vectors to control input and output electrical power. Sliding mode-based DPC-MC controllers can guarantee zero steady-state errors and no overshoots, good tracking performance, and fast dynamic responses, while being simpler to implement and requiring less processing power, when compared to proportional-integral (PI) linear controllers obtained from linear active and reactive power models of UPFC using a modified Aventura high-frequency PWM modulator.

The dynamic and steady-state behavior of the proposed DPC-MC P, Q control method is evaluated and discussed using detailed simulations and experimental implementation (Sections IV and V). Simulation and experimental results obtained with the nonlinear DPC for matrix converter-based UPFC technology show decoupled series active and shunt/series reactive power control, zero steady state error tracking, and fast response times, presenting faultless dynamic and steady state responses.

II. MODELING OF THE UPFC POWER SYSTEM

A. General Architecture

A simplified power transmission network using the proposed matrix converter UPFC is presented in Fig. 1, where a_0 and a_r are, respectively, the sending-end and receiving-end sinusoidal voltages of the and generators feeding load . The matrix converter is connected to transmission line 2, represented as a series inductance with series resistance (and), through coupling transformers and . Fig. 2 shows the simplified three-phase equivalent circuit of the matrix UPFC transmission system model. For system modeling, the power sources and the coupling transformers are all considered ideal. Also, the matrix converter is considered ideal and represented as a controllable voltage source, with amplitude and phase . In the equivalent circuit,

is the load bus voltage? The DPC-MC controller will treat the simplified elements as disturbances. Considering a symmetrical and balanced three-phase system and applying Kirchhoff laws to the three-phase equivalent circuit(Fig. 2), the ac line currents are obtained in coordinates

$$\frac{dI_d}{dt} = \omega I_q - \frac{R_2}{L_2} I_d + \frac{1}{L_2} (V_{Ld} - V_{ROd}) \quad (1)$$

$$\frac{dI_q}{dt} = -\omega I_d - \frac{R_2}{L_2} I_q + \frac{1}{L_2} (V_{Lq} - V_{ROq}). \quad (2)$$

The active and reactive power of end generator are given in dq coordinates by

$$\begin{bmatrix} P \\ Q \end{bmatrix} = \begin{bmatrix} V_d & V_q \\ V_q & -V_d \end{bmatrix} \begin{bmatrix} I_d \\ I_q \end{bmatrix}. \quad (3)$$

The active and reactive power P and Q are given by (4) and (5) respectively

$$P = V_d I_d \quad (4)$$

$$Q = -V_d I_q. \quad (5)$$

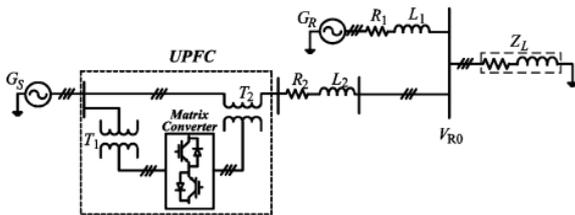

Fig. 1 Transmission network with matrix converter UPFC

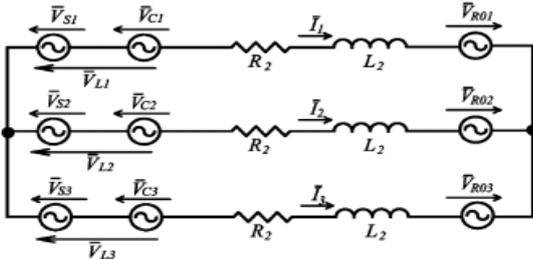

Fig.2.Three-phase equivalent circuit of the matrix UPFC and transmission line.

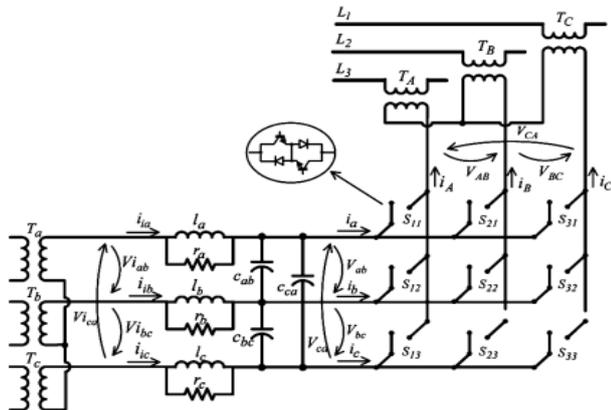

Fig. 3. Transmission network with matrix converter UPFC.

B.Matrix Converter Output Voltage and Input Current Vectors

A diagram of the UPFC system (Fig. 3) includes the three-phase shunt input transformer (with windings Ta, Tb, Tc),the three-phase series output transformer (with windings) and the three-phase matrix converter,

represented as an array of nine bidirectional switches with turn-on and turn-off capability, allowing the connection of each one of three output phases directly to any one of the three input phases. The three-phase input filter is required to re-establish a voltage-source boundary to the matrix converter, enabling smooth input currents.

Applying coordinates to the input filter state variables presented in Fig. 3 and neglecting the effects of the damping resistors, the following equations are obtained.

Where V_i represent, respectively, input voltages and input currents in dq components (at the shunt transformer secondary) and V_i are the matrix converter voltages and input currents in components, respectively.

Assuming ideal semiconductors, each matrix converter bidirectional switch can assume two possible states: “Sk=1” if the switch is closed or “Skj=0” if the

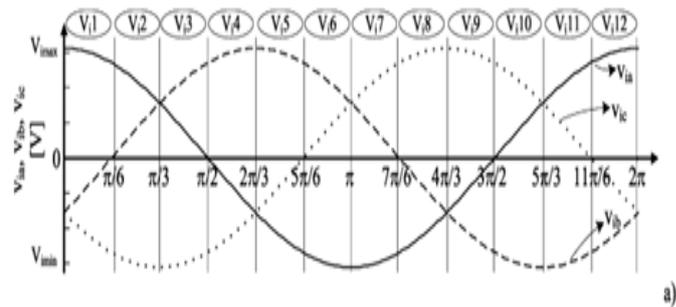

Fig. 4. (a) Input voltages and their corresponding sector

switch is open. The nine matrix converter switches can be represented as a 3× 3 matrix (7)

$$\begin{cases} \frac{di_{id}}{dt} = \omega i_{iq} - \frac{1}{2l} V_d - \frac{1}{2\sqrt{3}l} V_q + \frac{1}{l} V_{id} \\ \frac{di_{iq}}{dt} = -\omega i_{id} + \frac{1}{2\sqrt{3}l} V_d - \frac{1}{2l} V_q + \frac{1}{l} V_{iq} \\ \frac{dV_d}{dt} = \omega V_q - \frac{1}{2\sqrt{3}C} i_{iq} + \frac{1}{2C} i_{id} - \frac{1}{2C} i_d + \frac{1}{2\sqrt{3}C} i_q \\ \frac{dV_q}{dt} = -\omega V_d + \frac{1}{2\sqrt{3}C} i_{id} + \frac{1}{2C} i_{iq} - \frac{1}{2\sqrt{3}C} i_d - \frac{1}{2C} i_q \end{cases} \quad (6)$$

$$S = \begin{bmatrix} S_{11} & S_{12} & S_{13} \\ S_{21} & S_{22} & S_{23} \\ S_{31} & S_{32} & S_{33} \end{bmatrix}. \quad (7)$$

The relationship between load and input voltages can be expressed as

$$[v_A \ v_B \ v_C]^T = S[v_a \ v_b \ v_c]^T. \quad (8)$$

The input phase currents can be related to the output phase currents (9), using the transpose of matrix (9)

$$[i_a \ i_b \ i_c]^T = S^T[i_A \ i_B \ i_C]^T. \quad (9)$$

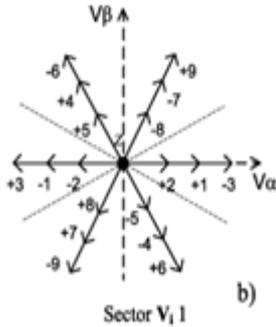

From the 27 possible switching patterns, time-variant vectors can be obtained (Table I) representing the matrix output voltages and input currents coordinates, and plotted in the frame [Fig. 4(b)].

The active and reactive power DPC-MC will select one of these 27 vectors at any given time instant.

III. DIRECT POWER CONTROL OF MC-UPFC

A. Line Active and Reactive Power Sliding Surfaces

The DPC controllers for line power flow are here derived based on the sliding mode control theory. From

(b) Output voltage state-space vectors when the input voltages are located at sector.

Fig. 2, in steady state, is imposed by source . From (1) and (2), the transmission-line currents can be considered as state variables with first-order dynamics dependent on the sources and time constant of impedance . Therefore, transmission-line active and reactive powers present first-order dynamics and have a strong relative degree of one [25], since from the control viewpoint, its first time derivative already contains the control variable (the strong relative degree generally represents the number of times the control output variable must be differentiated until a control input appears explicitly in the dynamics) [26]–[29].

From the sliding mode control theory, robust sliding surfaces to control the and variables with a relatively strong degree of one can be obtained considering proportionality to a linear combination of the errors of between the power references and the actual transmitted powers , respectively the state variables [29]. Therefore, define the active power error and the reactive power error as the difference

$$e_P = P_{ref} - P \tag{10}$$

$$e_Q = Q_{ref} - Q. \tag{11}$$

Then, the robust sliding surfaces must be proportional to these errors, being zero after reaching sliding mode

$$S_P(e_P, t) = k_P(P_{ref} - P) = 0 \tag{12}$$

$$S_Q(e_Q, t) = k_Q(Q_{ref} - Q) = 0. \tag{13}$$

The proportional gains and are chosen to impose appropriate switching frequencies

B. Line Active and Reactive Power Direct Switching Laws

The DPC uses a nonlinear law, based on the errors and to select in real time the matrix converter switching states (vectors). Since there are no modulators and/or pole zero-based approaches, high control speed is possible. To guarantee stability for active power and reactive power controllers, the sliding-mode stability conditions (14) and (15) must be verified

$$S_P(e_P, t) \dot{S}_P(e_P, t) < 0 \tag{14}$$

$$S_Q(e_Q, t) \dot{S}_Q(e_Q, t) < 0. \tag{15}$$

According to (12) and (14), the criteria to choose the matrix vector should be

1. If $S_P(e_P, t) > 0 \Rightarrow \dot{S}_P(e_P, t) < 0 \Rightarrow P < P_{ref}$, then choose a vector suitable to increase P .
2. If $S_P(e_P, t) < 0 \Rightarrow \dot{S}_P(e_P, t) > 0 \Rightarrow P > P_{ref}$, then choose a vector suitable to decrease P .
3. If $S_P(e_P, t) = 0$,

To design the DPC control system, the six vectors of group I will not be used, since they require extra algorithms to calculate their time-varying phase [14]. From group II, the variable amplitude vectors, only the 12 highest amplitude voltage vectors are certain to be able to guarantee the previously discussed required levels of and needed to fulfill the reaching conditions. The lowest amplitude voltages vectors, or the three null vectors of group III, could be used for near zero errors. If the control errors and are quantized using two hysteresis comparators, each with three levels (and), nine output voltage error combinations are obtained. If a two-level comparator is used to control the shunt reactive power, as discussed in next subsection, 18 error combinations will be defined, enabling the selection of 18 vectors. Since the three zero vectors have a minor influence on the shunt reactive power control, selecting one out 18 vectors is adequate. As an example, consider the case of and Then, and imply that and . According to Table I, output voltage vectors depend on the input voltages (sending voltage), so to choose the adequate output voltage vector, it is necessary to know the input voltages location [Fig. 4(a)]. Suppose now that the input voltages are in sector [Fig. 4(b)], then the vector to be applied should be 9 or 7. The final choice between these two depends on the matrix reactive power controller result , discussed in the next subsection. Using the same reasoning for the remaining eight active and reactive power error combinations and generalizing it for all other input voltage sectors, Table II is obtained. These P, Q controllers were designed based on control laws not dependent on system parameters, but only on the errors of the controlled output to ensure robustness to parameter variations or operating conditions and allow system order reduction, minimizing response times [26].

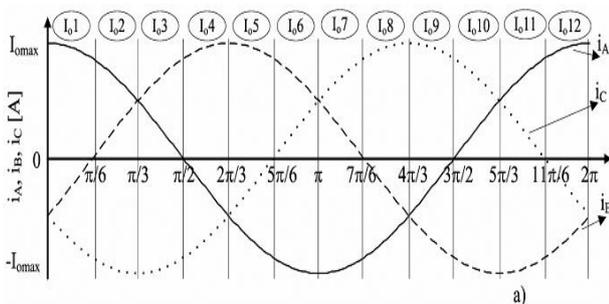

Fig. 5. (a) Output currents and their corresponding sector.

C. Direct Control of Matrix Converters Input Reactive Power

In addition, the matrix converter UPFC can be controlled to ensure a minimum or a certain desired reactive power at the matrix converter input. Similar to the previous considerations, since the voltage source input filter (Fig. 3) dynamics (6) has a strong relative degree of two [25], then a suitable sliding surface (19) will be a linear combination of

the desired reactive power error and its first-order time derivative [29] (19) The time derivative can be approximated by a discrete time difference, as has been chosen to obtain a suitable switching frequency, since as stated before, this sliding surface

$$S_{Q_i}(e_{Q_i}, t) = (Q_{i_{ref}} - Q_i) + K_{Q_i} \frac{d}{dt} (Q_{i_{ref}} - Q_i).$$

$$\begin{aligned} \dot{S}_{Q_i}(e_{Q_i}, t) = & V_{id} \left(\frac{di_{iq}}{dt} + K_{Q_i} \frac{d^2 i_{iq}}{dt^2} \right) = V_{id} \left(-\omega i_{id} + \frac{1}{2\sqrt{3}l} V_d - \frac{1}{2l} V_q \right) + \\ & V_{id} K_{Q_i} \left(-\omega^2 i_{iq} + \frac{\omega}{l} V_d + \frac{\omega}{\sqrt{3}l} V_q - \frac{\omega}{l} V_{id} - \frac{i_{iq}}{3lC} + \frac{i_q}{3lC} \right). \end{aligned}$$

The sliding mode is reached when vectors applied to the converter have the necessary current amplitude to satisfy stability conditions, such as (15). Therefore, to choose the most adequate vector in the chosen reference frame, it is necessary to know the output currents location since the input current depends on the output currents (Table I). Considering that the α -axis location is synchronous with the input voltage (i.e., reference frame depends on the input voltage location), the sign of the matrix reactive power can be determined by knowing the location of the input voltages and the location of the output currents (Fig. 5).

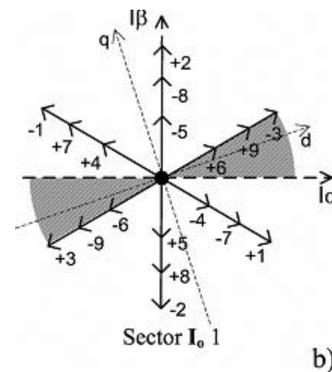

Fig. 5. (a) Output currents and their corresponding sector.

1. If $S_{Q_i}(e_{Q_i}, t) > 0 \Rightarrow \dot{S}_{Q_i}(e_{Q_i}, t) < 0$, then select vector with current $i_q < 0$ to increase Q_i
2. If $S_{Q_i}(e_{Q_i}, t) < 0 \Rightarrow \dot{S}_{Q_i}(e_{Q_i}, t) > 0$, then select vector with current $i_q > 0$ to decrease Q_i .

Considering the previous example, with the input voltage at sector and sliding surfaces signals and both vectors or would be suitable to control the line active and reactive powers errors (Fig. 4). However, at sector , these vectors have a different effect on the value: if has a suitable amplitude, vector leads to while vector originates So, vector should be chosen if the input reactive power sliding surface is quantized as 1, while vector 7 should chosen when is quantized as 1. When the active and reactive power errors are quantized as zero, 0 and 0, the null vectors of group III, or the lowest amplitude voltages vectors at sector at Fig. 4(b) could be used. These vectors do not produce significant effects on the line active and reactive power values, but the lowest amplitude voltage vectors have a high influence on the control of matrix reactive power. From Fig.

5(b), only the highest amplitude current vectors of sector should be chosen: vector 1 if is quantized as , or vector 2 if is quantized as

IV. IMPLEMENTATION OF THE DPC-MC AS UPFC

As shown in the block diagram (Fig. 6), the control of the instantaneous active and reactive powers requires the measurement of voltages and output currents necessary to calculate and sliding surfaces. The output current

measurement is also used to determine the location of the input currents component. The control of the matrix converter input reactive power requires the input currents measurement to calculate. At each time instant, the most suitable matrix vector is chosen upon the discrete values of the sliding surfaces, using tables derived from Tables II and III for all voltage sectors.

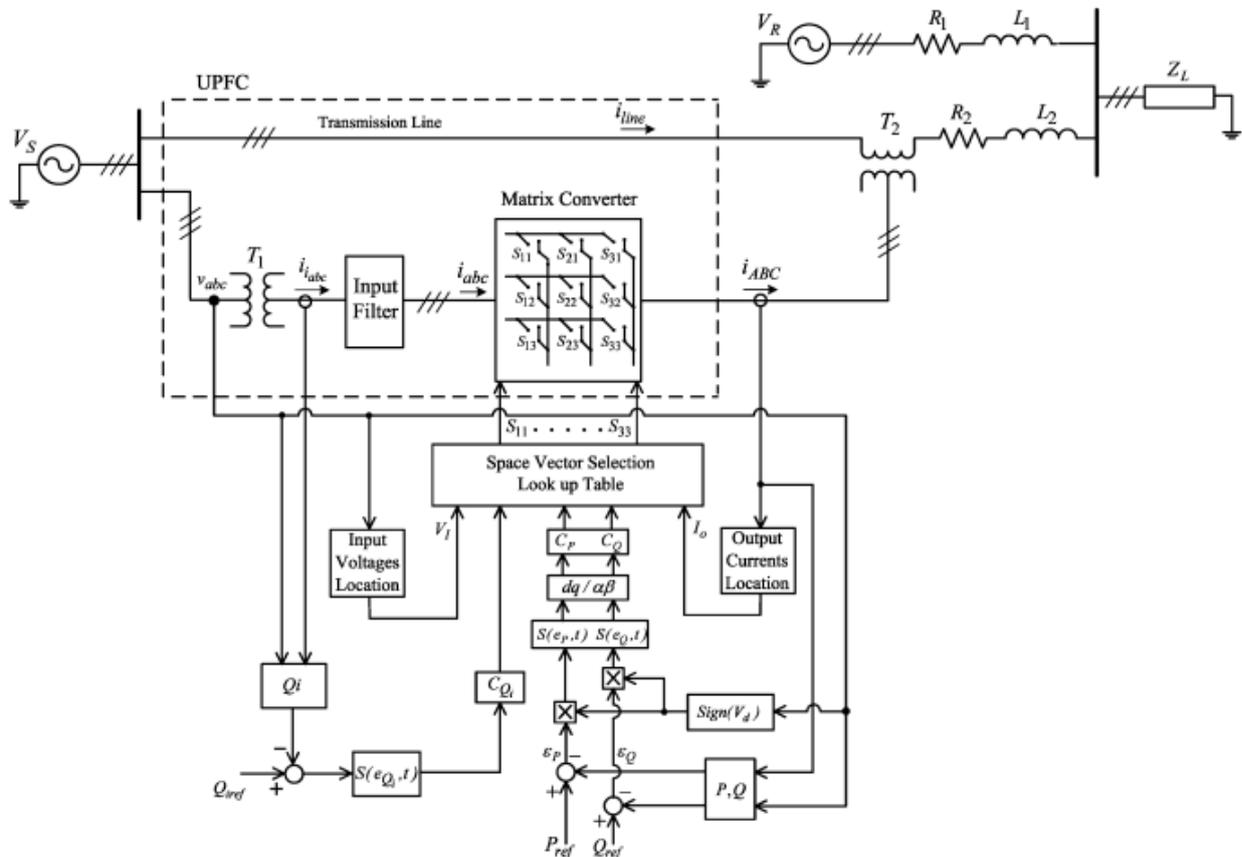

Fig. 6. Control scheme of direct power control of the three-phase matrix converter operating as a UPFC.

V. SIMULATION AND EXPERIMENTAL RESULTS

The performance of the proposed direct control system was evaluated with a detailed simulation model using the*-MATLAB/Simulink Sim Power Systems to represent the matrix converter, transformers, sources and transmission lines, and Simulink blocks to simulate the control system. Ideal switches were considered to simulate matrix converter semiconductors minimizing simulation times.

The second-order input filter is 4.2 mH, 6.6 F, 25 . This prototype was connected to the laboratory low-voltage network operating as UPFC, (Fig. 6) by using three-phase transformers T1 and T2 (2-kVA transformers with voltage ratio 220/115 V and 66.5/66.5 V, respectively). Current sensors were used to measure the matrix converter input and output currents (Hall effect LEM, LA25NP), and voltage sensors were used to measure the power network phase-to-phase voltages (Hall effect LEM, LV 25-P).

To achieve safe commutation between matrix converter bidirectional switches, the four-step output current commutation strategy [18] was implemented in a field-programmable gate array (FPGA) using a Xilinx board (Virtex-5).

Algorithm was implemented in a digital signal processor PowerPC board (DS1103 of dSPACE) with a sampling time approximately equal to 17 s. The load power is 1.5kW(1 p.u.) and transmission lines 1 and 2 are simulated as inductances mH 15 mH, and series resistances , respectively for line 1 and 2. Sliding mode DPC gains are 1, selected to ensure the highest switching frequencies around 2.5 kHz. Experimental and simulation results of the active and reactive power UPFC controller are obtained from the step reMONTEIRO.

The experimental power spectral density of transmission line and matrix converter current [respectively, Fig. 8(c) and (d)] shows that the main harmonics are nearly 30 dB below the 50-Hz fundamental for the line current, and 22 dB below the 50-Hz fundamental for the matrix converter current. The power spectral density shows switching frequencies mainly below 2.5 kHz as expected. Simulation and experimental results confirm the performance of the proposed controllers, showing no cross-coupling, no steady-state error (only switching ripples), and fast response times for different changes of power references. DPC active and reactive power step response and line currents results were compared to active and reactive power linear PI controllers [11] using a Aventurine high-frequency PWM modulator [17], working at 5.0-kHz switching frequency. Experimental implementation of this control algorithm at the same microprocessor required 21- s sampling time (higher than the 17 s of DPC) due to the complexity of the modulator (needs 4 s more when compared to the proposed DPC). Experimental and simulation results [Fig. 9(a) and (b)], for 0.4 p.u. and 0.2 p.u. show cross-coupling between active and reactive power control, which introduces a slowly decaying error in the response. Longer response times are also present, when compared to DPC experimental and simulation results presented in Fig. 9(c) and (d), showing the claimed DPC faster dynamic response to step active and reactive power reference change. To test the DPC controller ability to operate at lower switching frequencies, the DPC gains were lowered and the input filter parameters were changed accordingly (5.9 mH F) to lower the switching frequency to nearly 1.4 kHz. The results (Fig. 10) also show fast response without cross coupling between active and reactive power.m This confirms the DPC-MC robustness to input filter parameter variation, the ability to operate at low switching frequencies, and insensitivity to switching nonlinearity.

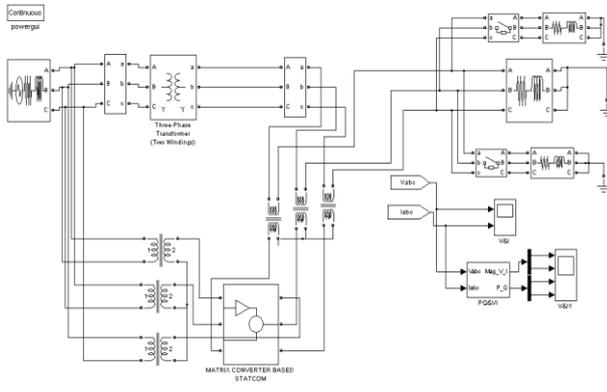

Fig 7. Modeling of UPFC with matrix convertor

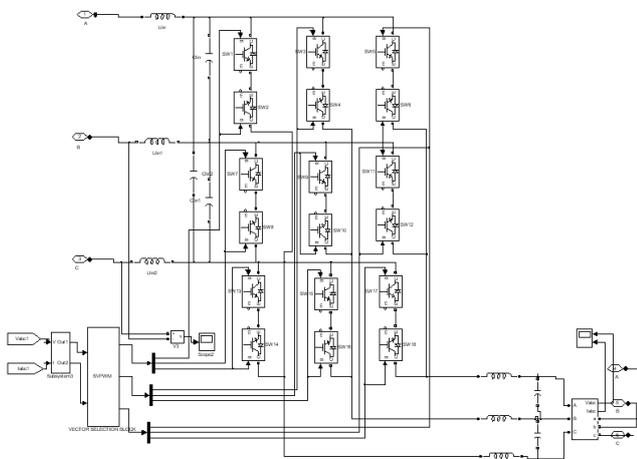

Fig 8. Modeling of matrix convertor

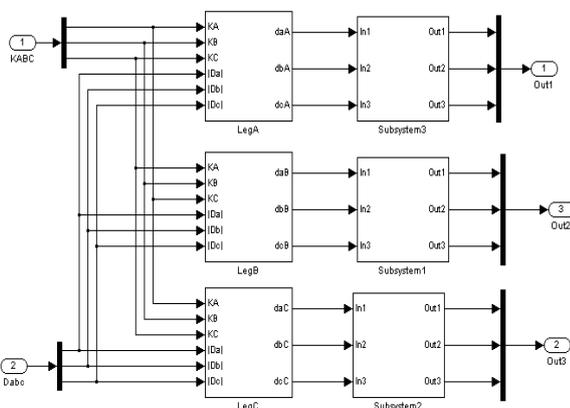

Fig 9. Modeling of vector selecton block

To experimentally validate the simulations, a low-power prototype matrix converter was built [14] by using three semiconductor modules from DANFOSS, each one with six 1200-V 25-A insulated-gate bipolar transistors (IGBTs) with an antiparallel diode in a common collector arrangement, driven by optical isolated drives (TLP250).

V. CONCLUSION

This paper derived advanced nonlinear direct power controllers, based on sliding mode control techniques, for matrix converters connected to power transmission lines as UPFCs. Presented simulation and experimental results show that active and reactive power flow can be advantageously controlled by using the proposed DPC. Results show no steady-state errors, no cross-coupling, insensitivity to no modeled dynamics and fast response times, thus confirming the expected performance of the presented nonlinear DPC methodology. The obtained DPC-MC results were compared to PI linear active and reactive power controllers using a modified Venturini

Optimal Agc of Deregulated Interconnected Power System with Parallel Ac/Dc Link

Naimul Hasan

Department of Electrical Engineering Jamia Millia Islamia New Delhi-110025, India

Abstract : This paper presents optimal AGC regulator design of deregulated power system based on the full state feedback control strategy. The two-area interconnected power system of identical nature consisting of non-reheat turbine is considered for the investigations. The area-interconnection of the power system via parallel EHVAC/HVDC transmission link is considered. The proposed controller is applied to two-area interconnected power system and its feasibility is demonstrated by investigating the dynamic response plots obtained various system states of the power system models under consideration. The patterns of closed-loop eigenvalues are obtained to analyze the stability of the power system models.

Keywords- AGC, Deregulated power system, interconnected power system, parallel EHVAC/HVDC.

I. INTRODUCTION

The electric power industry is in transitional phase moving from centrally regulated utilities to deregulated environment that will inject competition in the power sector among all the companies to sale the unbundled power at very reasonable rates to the distribution companies. The restructuring and deregulation of power sector is to create a competitive environment where generation and transmission services are bought and sold under demand and supply market conditions. This has unbundled the electric utility services into its basic components and offering each component separately for the sale with separate rates. The unbundling of the vertical entity creates the separate entity for generation, transmission and distribution for the transaction of electric power. Before deregulation ancillary services were provided by a single entity possessing owns generating resources, transmission and distribution capacities located within its territories.

The deregulated power system will have the generating power station separated from transmission and distribution entities. All the power generating stations will be recognized as independent power producers (IPPs). These will be known as GENCOs which will have a free market to compete each other to sell the electrical power. The retail consumers are supposed to buy the electrical power from the distribution companies known as DISCOs. There is also a third player between the GENCOs and DISCOs for wheeling the between them which is designated as TRANSCO. So in the deregulated power system instead of having single vertical entity it will have three players as GENCOs, DISCOs and TRANSCO operating separately with their own set functionalities. To supply the regulation between Disco and Genco, a contract will be established between these entities. In the deregulated power system structure, a distribution company has the freedom to have a contract with any generation companies for purpose of transaction of

power. The different companies may have the bilateral transactions and these will have to be monitored through an independent system operator which will control the number of ancillary services.

The main task of automatic generation control is to maintain the reliability of the system at the desired frequency even to the varying load demand. The generation companies in deregulated environment may or may not participate in the AGC task. As far as the optimal AGC schemes for interconnected power systems operating in deregulated environment are concerned, a considerable work has been reported in literature [1-5]. V. Donde et al. in [5] have presented an AGC of interconnected power systems in deregulated environment. The distribution companies may contract for the transaction of power with generation companies in its area or other areas. This transaction of power among the generation and distribution companies is done under the supervision of the independent system operators.

The frame work of the deregulated power system is as follows:

1. Unbundling of electrical power system separating Vertically Integrated Utility into GENCOs, TRANSCO and DISCOs as independent entities.
2. Annulling of exclusive rights
3. Third party shall get access to transmission or supply grids.

However, in all the above articles power system models interconnected via EHV AC transmission links only. But due to the obvious of merits of HVDC transmission line, the interconnection with HVDC link has been utilized for the power system model under consideration. One of the most useful applications of HVDC link is its operation in parallel with EHVAC transmission line between two power networks. This makes the system makes the more stable. The HVDC transmission link an area interconnection has also been demonstrated as a viable tool to improve dynamic performance of the system [6-9].

In the work presented in this paper, optimal controllers are designed and compared based on the interconnected between the two areas. In one power system model the AC tie-line is considered and in the second power system model a parallel AC/DC tie line is considered. The dynamic performance of the power system models considered is analyzed for the designed regulators.

II. Power System Model

A two-area interconnected power system operating under deregulated environment with parallel EHVAC/HVDC for exchanging of power between control areas is considered for investigation. The structure of power system model consists of two identical non-reheat thermal

power plants as GENCOs and two distribution system as DISCOs.

The transfer function model of power system model under investigation is developed and presented in Fig. 8. In this model, the actual and scheduled steady state power flows on the tie line are given by;

$$\Delta P_{tie12}^{scheduled} = (\text{Demand of DISCOs in area-2 from GENCOs in area-1}) - (\text{Demand of DISCOs in area-1 from GENCOs in area-2}) \quad (1)$$

$$\Delta P_{tie12, schedule} = \sum_{i=1}^2 \sum_{j=3}^4 cpf_{ij} \Delta P_{Lj} - \sum_{i=3}^4 \sum_{j=1}^2 cpf_{ij} \Delta P_{Lj} \quad (2)$$

The tie line power error ($\Delta P_{tie12, error}$) is defined by;

$$\Delta P_{tie12, error} = \Delta P_{tie12, actual} - \Delta P_{tie12, scheduled} \quad (3)$$

The area control errors (ACEs) in deregulated environment in both areas are defined as;

$$ACE_1 = B_1 \Delta f_1 + \Delta P_{tie12, error} \quad (4)$$

$$ACE_2 = B_2 \Delta f_2 + \alpha_{12} \Delta P_{tie12, error} \quad (5)$$

As there may be many GENCOs in each area, the ACE signal is being distribute among them and their ACE participation factor (apf) for automatic generation control and also sum of all apfs in a particular area should be unity.

In steady state, the demand of DISCOs in contract with GENCOs generation must be matched and expressed as:

$$\Delta P_{L1, Loc} = \Delta P_{L1} + \Delta P_{L2} \quad (8)$$

$$\Delta P_{L1, Loc} = \Delta P_{L1} + \Delta P_{L2} \quad (9)$$

$$\Delta P_{L2, Loc} = \Delta P_{L3} + \Delta P_{L4} \quad (9)$$

$$\Delta P_{L2, Loc} = \Delta P_{L3} + \Delta P_{L4} \quad (10)$$

$$\Delta P_2 = cpf_{21} \Delta P_{L1} + cpf_{22} \Delta P_{L2} + cpf_{23} \Delta P_{L3} + cpf_{24} \Delta P_{L4} \quad (11)$$

$$\Delta P_3 = cpf_{31} \Delta P_{L1} + cpf_{32} \Delta P_{L2} + cpf_{33} \Delta P_{L3} + cpf_{34} \Delta P_{L4} \quad (12)$$

$$\Delta P_4 = cpf_{41} \Delta P_{L1} + cpf_{42} \Delta P_{L2} + cpf_{43} \Delta P_{L3} + cpf_{44} \Delta P_{L4} \quad (13)$$

ΔP_{UC1} and ΔP_{UC2} are disturbance signal for un-contracted load in case of contract violation. In case un-contracted loads are absent, ΔP_{UC1} and ΔP_{UC2} are zero.

2.1. Case Study

In the present work, two different power system models are identified as follows:

Power system Model-I: Two- area interconnected power system consisting of non-reheat turbine via EHVAC tie-line only.

Power system Model-II: Two area interconnected power system of non-reheat turbine via parallel EHVAC/HVDC tie-line.

III. State Variable Model

The two-area power system model operating under deregulated environment is shown in Fig. 8 can be described by the following controllable and observable linear time-invariant state space representation;

$$\frac{d}{dt} \underline{x} = \underline{A} \underline{x} + \underline{B} \underline{u} + \underline{\Gamma} \underline{P}_d \quad (14)$$

$$\underline{Y} = \underline{C} \underline{x} \quad (15)$$

For power system model under investigation, the system state, control and disturbance vectors are selected as follows:

- **State vector**

$$\underline{X} = [\Delta f_1, \Delta f_2, \Delta P_{tie12}, \Delta P_{g1}, \Delta X_{g1}, \Delta P_{g2}, \Delta X_{g2}, \Delta P_{g3}, \Delta X_{g3}, \Delta P_{g4}, \Delta X_{g4}, \int ACE_1 dt, \int ACE_2 dt]$$

- **Control vector**

$$\underline{u} = [\Delta P_{C1} \quad \Delta P_{C2}]^T$$

- **Disturbance vector**

$$\underline{P}_d = [\Delta P_{L1} \quad \Delta P_{L2} \quad \Delta P_{L3} \quad \Delta P_{L4} \quad \Delta P_{UC1} \quad \Delta P_{UC2}]^T$$

- **System Matrices**

The structure of system matrices A, B, Γ_d and C can be obtained from the transfer function model shown in fig8.

IV. Design of Optimal AGC Regulator

The design of optimal AGC regulators reported in literature [10]. The continuous time dynamic model in the state variable form is given as;

$$\frac{d}{dt} \underline{x} = \underline{A} \underline{x} + \underline{B} \underline{u} + \underline{\Gamma} \underline{P}_d \quad (16)$$

$$\underline{y} = \underline{C} \underline{x} \quad (17)$$

Where, x, u, P_d and y are state, control, disturbance and output vector respectively. A, B, C and Γ are system, control, output and disturbance matrices of compatible dimensions.

In the application of optimal control theory, the term in equation (16) is eliminated by redefining the states and controls in terms of their steady-state values occurring after the disturbance. It can be rewritten as;

$$\frac{d}{dt} \underline{x} = \underline{A} \underline{x} + \underline{B} \underline{u}, \underline{x}(0) = x_0 \quad (18)$$

Moreover eq. (17) will remain the same. The control signal u is such that to minimize the performance index (J):

$$J = \int_0^{\infty} \frac{1}{2} [\underline{x}^T \underline{Q} \underline{x} + \underline{u}^T \underline{R} \underline{u}] dt \quad (19)$$

Where, Q and R are weighting matrices for the state variables and the input variables. This optimal control problem is referred to as the linear quadratic regulator design problem. To solve this LQ optimal control problem, let us first construct a Hamiltonian function.

$$J = -\frac{1}{2} [\underline{x}^T \underline{Q} \underline{x} + \underline{u}^T \underline{R} \underline{u}] dt + \underline{\lambda}^T [\underline{A} \underline{x} + \underline{B} \underline{u}] \quad (20)$$

When there is no constraint on the input signal, the optimal (in this case, the minimum) value can be solved by taking the derivative of H with respect to u and then solving the following equation;

$$\frac{\partial H}{\partial \underline{u}} = -\underline{R} \underline{u} + \underline{B}^T \underline{\lambda} = 0 \quad (21)$$

Denote by \underline{u}^* the optimal control signal u. Then, \underline{u}^* can be explicitly written in the following form:

$$\underline{u}^* = \underline{R}^{-1} \underline{B}^T \underline{\lambda} \quad (22)$$

On the other hand Lagrangian Multiplier ($\underline{\lambda}$) can be written as; $\underline{\lambda} = \underline{S} \underline{x}$ (23)

Where, S is the symmetrical solution of the well known DRE.

$$\frac{d\underline{S}}{dt} = -\underline{S} \underline{A} - \underline{A}^T \underline{S} + \underline{S} \underline{B} \underline{R}^{-1} \underline{B}^T \underline{S} - \underline{Q} \quad (24)$$

The solution matrix S will tend to a constant matrix i.e. $ds/dt=0$, In this case DRE reduced to so called algebraic Riccatti Equation:

$$SA + A^T S - SBR^{-1}B^T S + Q = 0 \quad (25)$$

Now (22) can be written as;

$$\underline{u}^* = R^{-1}B^T S \underline{x} \quad (26)$$

With a full state vector feedback control problem, a control law is stated as;

$$\underline{u}^* = -\Psi^* \underline{x} \quad (27)$$

Using (26) and (27), the desired optimal feedback gain matrix (Ψ^*) is given by;

$$\Psi^* = R^{-1}B^T S \quad (28)$$

How to determine the feedback gain matrix [Ψ^*], which minimizes the values of J is an important optimization problem. The value of [Ψ^*] is usually obtained from the solution of matrix Riccati equation [11]

V. Simulation Results

The optimal gains of AGC regulators are obtained by using MATLAB software. The patterns of closed loop eigenvalues is reported in Table-1 where as the optimal gains of AGC regulators designed and performance index obtained are presented in Table-2 and Table-3 respectively. The dynamic response plots with the implementation of optimal AGC regulators are shown by Figs. (1-7).

VI. Discussion of Results

The MATLAB software is used to obtain pattern of closed-loop eigenvalues, optimal gains of AGC regulators, performance index and dynamic response plots for both the models. The inspection of closed-loop eigenvalues as shown in Tables-1 inferred that all the eigenvalues have negative real part, thereby ensuring the system stability in closed-loop fashion.

The response curves of Figs. (1-2) represent frequency deviations of respective areas. Observations carried out from these plots reveal that the proposed optimal AGC regulators are capable to mitigate the deviations in frequency of both areas caused due to instantaneous load demands from DISCOs. The tie line power deviation settles to a zero value. The proposed AGC regulators are found to demonstrate their ability to bring the system state deviation as per the desired ones in an effective manner.

The response curves in Figs. (4-7) show the deviations in power generation by GENCOs of respective areas. From the inspection of these Figs., it has been inferred that the proposed optimal AGC regulators are effective in settling the change in power generation to the required value in reasonably small time.

VII. Conclusions

In this paper, the gains of optimal AGC regulators are obtained using modern control theory through state space model technique. The patterns of closed-loop eigenvalues are obtained for power system models in deregulated environment and their investigation reveals that system is stable. The responses are associated with more number of oscillations coupled with larger settling time degraded the system dynamic response in case of power system model-I having AC tie line only are reduced tremendously in the power system model-II with AC/DC parallel tie lines.

ABSTRACT: Almost all crude oils are known to contain sulphure in varying amount. The amount of sulphure can vary from 0.04 % to nearly 10 %. The sulphure in petroleum has been defined as consisting of hydrogen sulphide, free sulphure and organic sulphure compound viz mercaptans, organic sulphide R-S-R, disulphide's R-S-S-R, carbon disulphide, thiophene and its homologues. The presence of these compound in petroleum fraction is not desirable due to their foul odour, corrosiveness, interferences with combustion characteristics of fuels, aggravation of atm. pollution byproduct of combustion etc.

The process used to reduce sulphure content of petroleum fraction may broadly classified as sweetening process and catalytic desulphurization.

Catalytic desulphurization process are those which destroy and remove all sulphure compound, hydrogen sulphide, mercaptance. Although the use of zinc oxide as a part of sandwich catalyst in the catalytic HDS is beneficial,; Also no hydrogen is required for desulphurization by zinc oxide and this is attractive point in the view of what have been said above concerning modern researcher in catalytic HDS(hydrodesulphurization).

I. INTRODUCTION

Petroleum fraction used as final product for chemical processing have to meet stringent specification regarding their sulphure content. Even at the level of crude oil, crude is divided into sour and sweet on the basis of sulphure content. Sour crude are define as those contain sulphure more than 0.5 wt %. It has been estimated that large proportions of crude reserves contain more than 1 wt % sulphur. Even accordingly to recent estimate of crude oil availability in our country, considerable amount of crude oils will continue to be imported in the future and all these would have to come from West Asian sour crude containing 1 to 2.6 % sulphure. Hydrodesulphurization process are now a day's used not only to pretreat the charge stock to catalytic reformer(hydrodesulphurization of low boiling distillate is almost always carried out for this purpose) but also as finishing process in case of middle distillate(200-410 °C) and even high boiling feed stock which may have sulphure content up to 5 wt %. Considerable research has been and being carried out in the field of composition of hydrodesulphurization catalysts, improving the selectivity of hydrodesulphurization and reducing the amount of hydrogen consumed by hydrogenation reaction.

II. MATERIAL AND METHODS

The reactor was packed with materials given below in an ascending order.

- a) Initial 12 cm pyrex tubing.(2.5 x 0.4 x 0.1 cm)
 - b) 3 m thick layer of silica chip to make surface of lower packing horizontal.
 - c) Nearly 36.8 gm ZnO Catalyst pellets.
- The pellets were arranged at random but the top surface was made as horizontal as possible.
- d) 3-5 mm thick layer of silica chips.
 - e) 15-17 cms glass tubing (2.5 x 0.4 x 0.1)

The catalyst is the constant temp region. Reactor was heated nearly for 2-3 hr to bring it to the required (350°C) temperature and held at this temp for 30 min. Two 5 x 1.5 cm strips of whatman 40 filter paper were soaked in freshly prepared (10 %) solution of lead acetate in water and placed in the tube. The first drop collected in 45 sec after it separated from tip. Liquid product were drawn out every 15 min, each portion was collected graduated tube, volume noted and then transferred to stoppered conical flask. In this way four samples for flowrate 30 ml/hr was transferred to separate conical flask. Gas flow rate was also read every 20 min interval. Runs were carried out in most cases for 210- 300 min. Balandine burette was disconnected, reactor was flushed with nitrogen to displace hydrocarbon vapours(for 20 min at rate of 1 lit/10 min) and allowed to cool to room temp in the current of nitrogen. If necessary run was recommended in this manner as described above, runs were carried out for further 210-240 min. Long runs with interruption were carried out in this manner.

III. RESULT AND DISSCUSSION

The aim is to investigate the effect of following factor on desulphurization of hydrocarbon stream by a fixed bed of Zinc oxide. 1) Effect of presence of nonsulphure non hydrocarbon compound in feed. With n-heptane as feed and n-amyl mercaptan as sulphure compound the effect of presence of following compound was investigated.

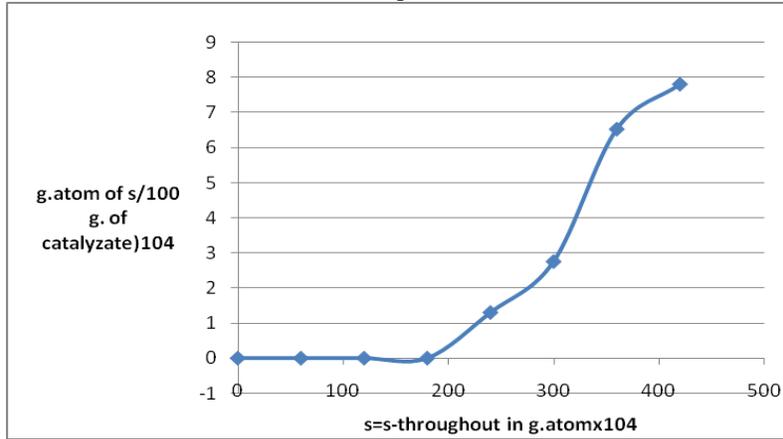

- a) Distilled water b) Sodium chloride c) carbon dioxide d) Nitrogen compound

2) Effect of hydrocarbon feed were tried.

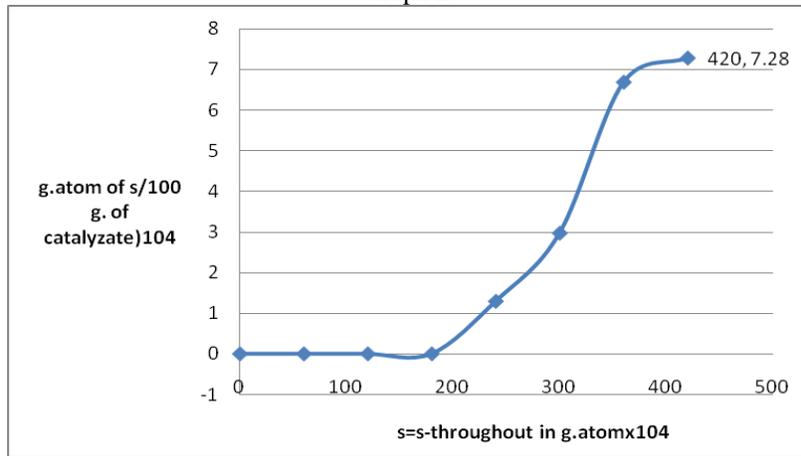

- a) n heptanes alone b) Hexane(Petroleum fraction) c) Benzene + Heptane d) Toluene + heptanes.

The result of experiment carried out to investigate these aspect are given below on which breakthrough curves are drawn .All the following graph are plotted (gm.atom of S/100 gm of catalyzate)10⁴ against (S-throughout in gm. Atom x 10⁴)

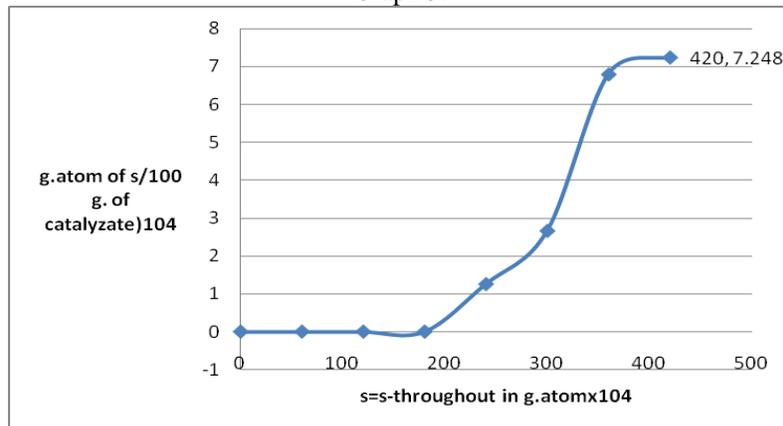

Graph 1

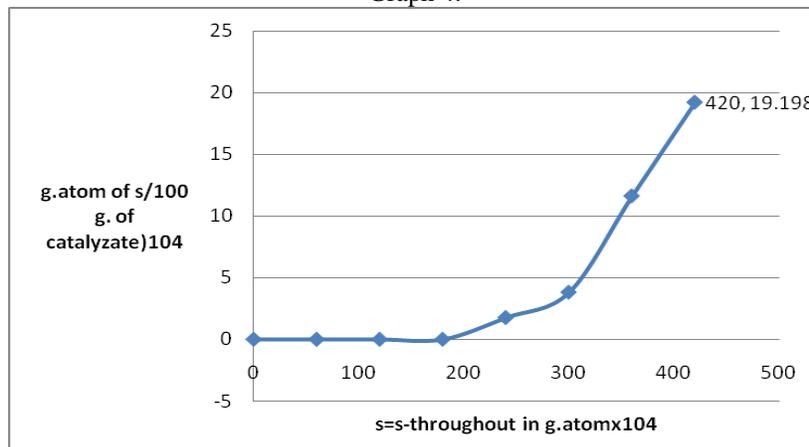

Graph 2:

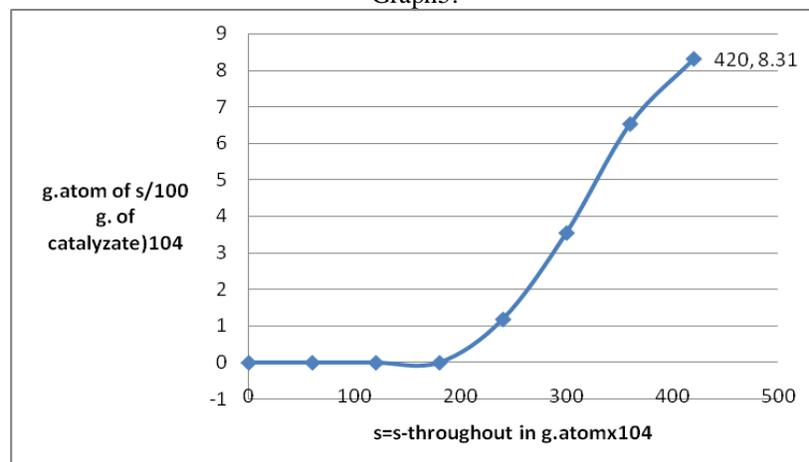

Graph 3:

Graph 4:

Graph5:

IV. CONCLUSION:

The objective of these studies is to make possible prediction of sulphure breakthrough curve in the desulphurization of hydrocarbon stream by fixed bed of zinc oxide and thus aid in the design of industrial units means for desulphurization.

The theoretical basis of breakthrough curve for a system in flow of these type studied here ie with fixed bed catalystr is well developed in chemical engineering literature with regards to sorption.

Abstract: Security challenges have been raised by private and public sectors related to exchange digital data electronically. In the current state, protocols such as the simple mail transfer protocol (SMTP), post office protocol (POP), and internet message access protocol (IMAP) transfer and store email messages in plaintext. Therefore, the confidentiality of email messages cannot be assured. Email sent using these protocols and without using any other security tool, must be assumed to have been read and compromised, because its confidentiality and integrity cannot be assured. Thus in this paper a new approach as a tool for improvement of current popular email protocols is proposed. The novel proposed protocol will be manifested in the Email Security Protocol (ESP) which is designed to add a layer of security and confidentiality to email messages transmitted over unsecured public networks. ESP is designed in three models to allow efficient and effective implementation upon various information system architectures. The result of testing the new proposed approach showed superior performance comparing to the existing one.

Keywords - Electronic Email, Digital data, Protocol, Security Tool.

I. Introduction

Email has become an integral part of today's digital life. Individual send and receive a vast mass of email messages every day. However, email is one of the most insecure types of communication media. Common configurations of email clients enable attackers to steal user names and passwords used to access email easily. The content of Web-based email Not encrypted and is passed in the network in plain text. Messages deleted from an email server might Still be retrievable from other servers halfway around the world without owner knowledge. This paper presents email security issues and proposes a new tool on how to improve email systems security. The rest of the paper is divided into the following sections. Second, background which presents the current state of email security protocols . Third, the need for a new protocol which presents the challenges of the exiting protocols throughout two cases. Fourth, the new approach which presents its descriptions and features and the fifth is the conclusion and future research.

II. Background

There are currently a number of email protocols in use. Some of these are the simple mail transfer protocol (SMTP), post office protocol (POP), and internet message access protocol (IMAP) [5]. The SMTP and POP protocols

are very popular protocols and are used by many who use email.

A typical person likely has their email program configured to send and receive email using the SMTP and POP protocols. The main reason for this is because their internet service provider (ISP) or email service provider uses these protocols and in order for the email program to communicate with the email server, their program needs to be configured to use these protocols. The SMTP protocol is used when sending email and the POP protocol is used when receiving email.

Internet message access protocol (IMAP) is similar to POP but allows email to remain on the server [6]. The email remains on the server until the user specifically deletes them from the server. Furthermore, with the use of IMAP, email has the ability to be organized on the server and accessed from any computer with access to the internet.

A major drawback of these protocols in terms of information security is the lack of protection that is provided to email that is transmitted and received. Email is transmitted in plaintext and confidentiality and integrity are nearly non-existent. For example, email servers communicate with each other using SMTP and store email messages in plain, unencrypted text [5].

III. Need For A New Protocol

There is a need for email security protocols and tools to protect the confidentiality and integrity of email. Without any form of encryption in place, email transmitted in plaintext over unsecured networks must be assumed to have been read and compromised because of the ease and ability adversaries have in using network protocol analyzers (sniffers) to capture traffic on unsecured networks. Mark Vanden wauver and Frank Jorissen demonstrate the need for security measures in their paper titled Securing Internet Electronic Mail [8]. The authors state that "Each message can be intercepted by a trained computer user connected to the net ... using tools to check the functionality of the network (Protocol Analyzers also known as network sniffers) which also can be used to listen in on any traffic on the internet."

Another example that demonstrates the need for enhanced email security protocols is given by Marvin Cetron and Owen Davies in their article titled Ten Critical Trends for Cyber security. The major theme of the paper states "Technological advances and greater connectivity may be making our systems less rather than more secure. A special panel of military, intelligence, and forecasting experts analyzes the trends that may be leading the world to cyberwar." Since electronic mail travels over the same networks as other packets of information, this topic includes email and should be a major concern to organizations and corporations that value the confidentiality of their electronic

communications and information. Furthermore, if email communications are not adequately secure, adversaries gain the ability to compromise the confidentiality and integrity of email, which in turn allows them to collect information from these communications that can be brought together to gain enough proprietary information to launch a larger and more damaging attack against an organization. Secure email transmission through the use of a tool such as the Email Security Protocol can reduce the risks of such an event from occurring by securing email and making it unreadable and unusable to adversaries that may intercept it in transit.

IV. Esp Proposed Protocol

The security problems associated with the SMTP, POP, and IMAP protocols warrants the consideration of a new protocol that would eliminate some of the security risks associated with using these protocols. This protocol would be used for the secure transmission of email from one person to another through a public network (i.e., internet). Furthermore, this protocol is shown to protect the confidentiality of email that travels from one SMTP server to another while on its way to its intended recipient.

The proposed name for this protocol is the email security protocol (ESP). Its purpose is to add a layer of security and confidentiality to email in which it is used. The ESP is configured and implemented in an email program so that its functions are carried out automatically with minimal interaction with the user being required.

A. ESP ARCHITECTURE

The Email Security Protocol (ESP) is designed in three models to allow efficient and effective implementation upon various information system architectures. Model I is designed based on a single server architecture which will process the encryption and the decryption procedures. It would be good on a network system isolated from the internet. The main feature of this model is that the email would stay encrypted on the server until the recipient decided to retrieve them. The email would thus be secure while being stored on the server. This model could also be used in a simulation in a computer laboratory; especially if the number of available servers for research is limited.

B. ESP PROCESS:

ESP uses asymmetric encryption to encrypt the contents of email messages before they are transmitted to the SMTP server. In this manner, the contents and subject line of an email message are encrypted and are protected from adversaries that otherwise would have been able to read the email in its plaintext. Thus, a major benefit is provided by the use of the ESP because if used properly, there is an assurance that email messages have been transmitted with confidentiality intact.

The email is encrypted using the public key (PK) of the recipient. A feature of the ESP is that if the PK of the recipient is unknown, then an automatic request for the PK will be sent to the recipient. When the recipient receives this request, and if the email program is configured correctly and also using the ESP, then the PK is automatically returned to the sender. Then the email can be encrypted using the PK and securely transmitted through the gamut of SMTP servers and maintain its confidentiality while in route to its intended recipient.

Figure 1: Model Architecture

Model II is designed to be used with the architecture associated with several servers and via the internet cloud. It would be good for sending email from one internal network system (corporation) to another. Its main feature is that the email would be secure in transit (encrypted) over the internet (public domain) from Server to another. This would greatly enhance the security of email sent from one corporation to another; or from one corporation to the same corporation with offices at a different geographical location.

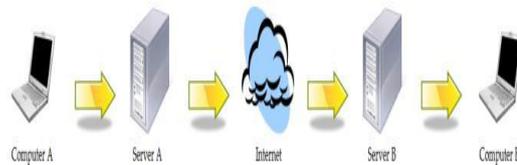

Figure 2: Model II Architecture

Model III is designed based on the Internet cloud architecture and for sending encrypted email directly from one computer to another. This model will serve better when an internal network server is not present or used for email traffic. Its main feature is that the email would be encrypted and secure from one computer to another; encryption would be present for the entire trip over the networks, including the internet.

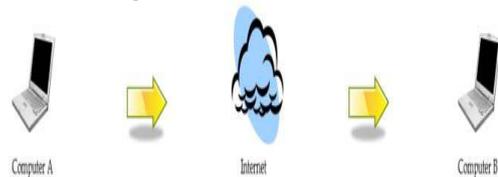

Figure 3: Model III Architecture

For simplicity, Alice and Bob will be the entities used in describing the transfer of email from one person to the other. Traditionally in cryptography texts, Alice and Bob have been denoted as good guys [6]. A more detailed description of how the ESP will work can best be illustrated in the following scenario.

Alice desires to send an email to Bob using ESP. Alice also knows that Bob is using ESP. However, Alice does not have Bob's public key (PK). Since Alice does not know Bob's PK, the process will take three emails (steps) to be completed. After Alice finishes composing the email she intends to send to Bob, she clicks the send button on her email program.

A feature of the email security protocol is that the process takes place automatically and an asymmetrically encrypted email may be sent to a recipient whose public key had previously been unknown. Also, under the correct circumstances, this process can be completed very quickly. Also, most importantly, the contents of the email message remains secure while in transit through the internet and the gamut of SMTP servers until it reaches its intended

destination; email messages are asymmetrically encrypted before being transmitted. The confidentiality of the email has been preserved through the use of the ESP. Furthermore, the convenience of an automatic and secure process makes for ease of use.

C. Esp Advantages And Drawbacks

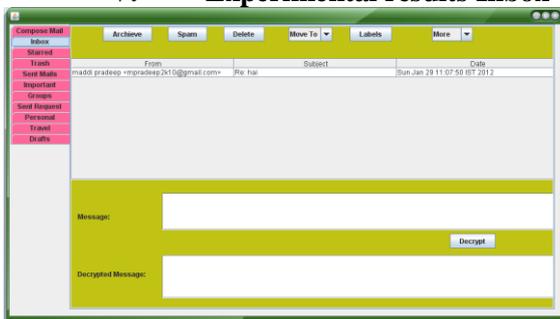

An advantage of the ESP is the ease of use for the end users. For example, in an organization that has a local area network (LAN) administered by information technology (IT) personnel, the IT staff can install and configure the ESP as needed, depending on the model used (I, II, or III), on the required computers, workstations, and servers that make up the LAN. Once the ESP is properly configured, users can send and receive email as they normally would and have the assurance that their email will be (1) securely (encrypted) stored on the server until retrieved by the intended recipient, (2) securely transmitted from one ESP configured server to another (e.g., one corporate office to another), or (3) securely transmitted from one ESP configured computer to another. If a combination of models I, II, and III are used then security can be provided at all of the above mentioned levels.

Another advantage is the transparency to the user. The user will not be required to perform any extra steps or manually execute and run any special program for the ESP to work properly on their computer. Once properly configured, the ESP will run in the background and automatically perform the required tasks as needed, depending on the configuration and model used. The user will not have to worry about forgetting to encrypt their email transmissions because the ESP will perform the task automatically for them. This eliminates the risk of human error and gives confidence that all email transmissions from a particular computer or server are secure.

A drawback of the ESP is that in order for the encryption and secure transmission of email to take place, the servers and computers need to be properly configured. If they are not configured correctly, then the secure transmission of email will not be able to take place.

Another drawback with the ESP is that it mainly provides security from outside threats. For example, in model II email transmissions are secure in their travel over the internet from server A to server B; server A being one regional organization office and server B being another regional organization office. Once the email is requested for retrieval by computer B (recipient), then the email is transmitted in plaintext inside the LAN to computer B. There is a risk that an inside threat can intercept this email. However, by using a combination of models II and III, this drawback and risk can be eliminated.

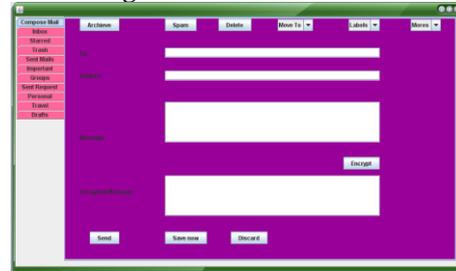

V. Experimental results Inbox

Sending Mails

Encryption Message

Drafts

VI. Conclusion And Future Research

It has been shown that the new proposed protocol (ESP) would be an enhancement and great email security tool to preserve the confidentiality of email messages in transit over the internet. Furthermore, it is evident that it provides a high degree of security which includes email securely stored on a server. Our future research is to investigate the ESP in depth using a large scale of data and advance it to eliminate any drawback.

A Novel Approach for Image Fusion in JPEG Domain

Venkata Santhosh kumar A.¹, Ch. Ramesh²

**(M.Tech Student, computer science department, AITAM, Tekkali, India*

*** (Professor, AITAM, Tekkali, India*

ABSTRACT: Image fusion is a procedure of combining relevant information from more than one image into a single image. The resulting image will have more information than any of the input images. Fusion is a popular approach for producing an image without under- and over-exposed areas is to capture several input images with varying exposure settings, and later combine them into a single high-quality image. This technique is used in various disparate fields such as remote sensing, robotics and medical applications. In this paper, we proposed a method to fuse multiple images taken with varying exposure times. The key component of the method is a single pass sigmoidal booster is applied on the shorter exposed images implemented as LUT, unlike other methods which require two or more passes. We used this technique to capture high dynamic range images from a set of photographs taken at different exposures, where misalignments can produce blurring and artifact and prevent achieving high quality HDR images. We present our implementation of the technique and the results of tests made for variety of photographs.

Keywords: Artifact removal, HDR capture, High Dynamic Range Imaging, Image Stabilization, Image Fusion

I. INTRODUCTION

Due to tremendous growth towards the production of high dynamic range (HDR) images. Modern image processing and graphics software becomes HDR enabled. Also HDR digital photography replaces low dynamic range (LDR) technologies. HDR photographs have better quality and easier to process in a digital darkroom, when compared to LDR. Unfortunately, HDR cameras are very expensive and not available for average users.[1] On the other hand, taking HDR photographs seems to be legitimate and crucial. In the near future LDR images may become almost obsolete due to the progress in LCD technology and it will not be easy to display LDR image correctly. LDR photographs will look pale and not interesting on HDR LCD displays. The multi-exposure HDR capture technique seems to be a good alternative to HDR cameras, which is used to create an HDR image from photographs taken with a conventional LDR camera. The technique uses differently exposed photographs to recover the response function of a camera. From the response function, the algorithm creates an HDR image whose pixel values are proportional to the true radiance value of a scene.[2] Because this technique requires multiple input photographs, there is a high likelihood of misalignments between pixels in the sequence of exposures due to moving of a hand-held camera or dynamic object in a scene. It is crucial that misalignments

between input photographs should be removed before fusing an HDR image.

Image fusion is a procedure of combining relevant information from more than one image into a single image. The resulting image will have more information than any of the input images. Fusion is a popular approach for producing an image without under- and over-exposed areas is to capture several input images with varying exposure settings, and later combine them into a single high-quality image. The need for image fusion arises in many applications, including digital image stabilization and HDR image capture. In stabilization, the motion blur that occurs in a long exposure-time image is corrected by fusing it with a short exposure-time image of the same scene.[3] The benefit of fusion is that the higher signal-to-noise ratio (SNR) of the long exposure image is combined with the sharp details of short exposure image, giving digitally the stabilization that is normally available only through opto-mechanical means. In HDR photography, a set of images with varying exposure times or ISO settings are fused to capture a wide range of scene luminance, which would otherwise result in saturated regions or dark features of interest in a single exposure.[4] In the proposed technique short, long and normal exposure images are used. The long exposure image should be taken prior to the shorter exposure images. The long exposure image is processed as normal on the digital camera, converted to JPEG, and then written to a file in secondary storage. The short and normal exposure images which are taken consecutively is boosted in brightness by using a lookup table (LUT) modelling a sigmoidal function combined with tonemapping.[5] The boosting process requires only one LUT transformation per pixel. Boosting is applied to all pixels in the image, and the boosted image is converted to JPEG as usual. However, instead of writing a separate JPEG file for the short-exposure image, we modify the file write operation to selectively overwrite parts of the long exposure's JPEG file with relevant portions of the short-exposure JPEG. Since the JPEG file interchange format (JFIF), which is the standard file format for storing JPEG images, places the luminance (Y) channel in separate 8*8 blocks of DCT values from the corresponding chrominance (Cb,Cr) blocks, it is relatively easy to calculate the addresses of the two types of blocks within the file, and to overwrite selectively. If portions of the long-exposure JPEG file are replaced with suitable portions of the short-exposure JPEG, then the result, upon decompression and display, is a fused image. Hence, the JPEG file format serves as a medium for image fusion, and the JPEG decoder performs the actual fusion prior to display.

The rest of the paper is organized as follows. Section 2 deals with Related work, Section 3 discuss on Proposed Algorithm, Section 4 on Image fusion, Section 5

on Sigmoidal function, Section 6 discuss about Artifact removal, Section 7 brief Image saturation detection, Section 8 discuss about Results and Section 9 concludes the paper.

II. RELATED WORK

In recent years significant progress has been made in the development of algorithms that allow to capture HDR images using low dynamic range sensors (standard LDR cameras) [20, 21, 22, 23]. These algorithms retrieve high dynamic range information from a sequence of photographs. The authors suggest using tripod to avoid camera movement and they do not address the problem of eliminating misalignments. The problem of image alignment and matching was intensively studied during last year's [24, 25] but not for registration of images of different exposures. The only solution that addressed exactly the problem of capture of HDR photographs was proposed in [26, 27]. The technique employs conversion of input photographs into percentile threshold bitmaps. The bitmaps are analyzed and then aligned horizontally and vertically using shift and difference operations over each image. Kang et al. [28] described a technique for creating high dynamic range video from a sequence of altering light and dark exposures. A part of the technique is a HDR stitching process, which includes global and local alignment to compensate for pixel motion. The stitching process can be also used to compensate for camera movement when creating an HDR still from a series of bracketed still photographs. However, the presented technique seems to be suitable for video where there are no large differences between consecutive frames.

In [29] Sand and Teller present a global and local matching algorithm, which is robust to changes in exposure of photographs. The key idea behind this technique is to identify which parts of the image can be matched without being confused by parts that are difficult to match. Such assumption seems to be not valid for images with large differences in exposures, where there is usually not enough information for correct matching. The technique was designed for matching two video sequences and was not tested on still photographs.

Recently, Cerman and Hlavac [30] presented an alignment method based on unconstrained nonlinear optimization. In this method, each image is linearized using the estimated camera response function and multiplied by the exposure ratio. Then, a normalized difference summed across all corresponding pixels is used to estimate misalignments. The method can compensate global rotation and horizontal and vertical shifts. There are a few techniques which compute camera response function based on misaligned photographs [31]. However, these methods are not meant to create HDR images. The problem of removing ghosting artifacts in a multi-exposure sequence of photographs was also investigated [32] but proposed algorithms do not take into consideration a compensation of camera movements.

III. PROPOSED ALGORITHM

The proposed technique uses three images and fuses them in the JPEG domain. We assume that the images are taken in immediate succession to minimize the need for registration, and that the exposure ratios between them are

known prior to the second image being taken. That assumption is reasonable for cameras operating in exposure bracketing mode, in which the ratios are set beforehand; typically the ratios are powers of two, but the values may be programmable. We assume that the exposures vary only in exposure time, while aperture and ISO setting are held constant. We use the well-known logarithmic exposure value (EV) notation of describing ratios of exposures. In that notation, $EV(0)$ represents the exposure time determined by the camera's auto exposure routine, and relative to that time, $EV(D)$ represents an exposure time that is 2^D larger.[7] For example $EV(+1)$ is twice the exposure time of $EV(0)$, and $EV(-1)$ is one-half the exposure time of $EV(0)$. It is well-known that the human visual system is more sensitive to details in the luminance channel, which in the JPEG literature is denoted as Y in the Y,Cb,Cr color system. JPEG takes advantage of this by subsampling the two chrominance channels, denoted Cb, Cr usually by a factor of two in each direction.

Proposed Algorithm:

Step 1: convert the longest exposure image into Y_l, Cb_l, Cr_l
Step 2: Apply Sigmoidal boosting and tone-mapping for Shortest and normal exposure images.

Step 3: convert the shortest, normal exposure images into Y_s, Cb_s, Cr_s and Y_n, Cb_n, Cr_n respectively.

Step 4: write the file into secondary storage device.

Step 5: Overwrite Y_l with Y_b in the file

Step 6: At Edges, Overwrite Cb_l, Cr_l with Cb_s and Cr_s in the file.

Step 7: Detect saturation in image based on data-driven threshold on luminance of fused image.

Step 8: check whether block is saturated or not. If it is YES Overwrite Chroma in step 6, with Cb_n, Cr_n otherwise stop the process

In the proposed technique for correcting motion artifacts selects the $8*8$ chrominance (Cb,Cr) blocks of the long-exposure image where the corresponding luminance (Y) block contains significant high frequency information representing edges or texture, and replaces them with the corresponding (Cb,Cr) blocks of the boosted short-exposure image. Image saturation is detected in the case of day light scenes. Saturation is detected on fused image containing luminance from short exposed image and chrominance from long exposed image, block by block basis based on a data-driven threshold as explained in sections below. If the image is saturated, chrominance from the mid-exposed also called as normal exposed image replaces the chrominance in the fused image.[11] [10]

IV. IMAGE FUSION

In modern digital cameras we can preview the captured photo immediately, after capture. Hence we perform the image merging directly on the camera. The proposed algorithm must be robust to camera motion during capture. While this was not an issue for viewfinding, where the low

resolution and high frame rate make misalignment artifacts barely noticeable, such artifacts become objectionable in the high-resolution case. So to compensate for camera motion using the image alignment algorithm which is discussed in [9] the input images are merged into the final result using an adaptation of the exposure fusion algorithm introduced by Mertens et al. [6]. Given an input images, exposure fusion computes a scalar-valued weight map for each image, and performs a weighted blend of the inputs to obtain the final HRD image which is described in Figure 1.

Let (I_1, \dots, I_n) be n images captured by the camera. The weight for each pixel (i, j) of image k is computed as:

$$W_k(i, j) = \exp\left(-\frac{(I_k(i, j) - \mu \cdot 255)^2}{2(\sigma \cdot 255)^2}\right).$$

We set the parameters $\mu = 0.5$, $\sigma = 0.2$ and normalize the maps so that the sum of mask values for every pixel is 1.

The result consists of multiplying the images by their weight maps and blending:

$$R(i, j) = \sum_{k=1}^n W_k(i, j) \cdot I_k(i, j).$$

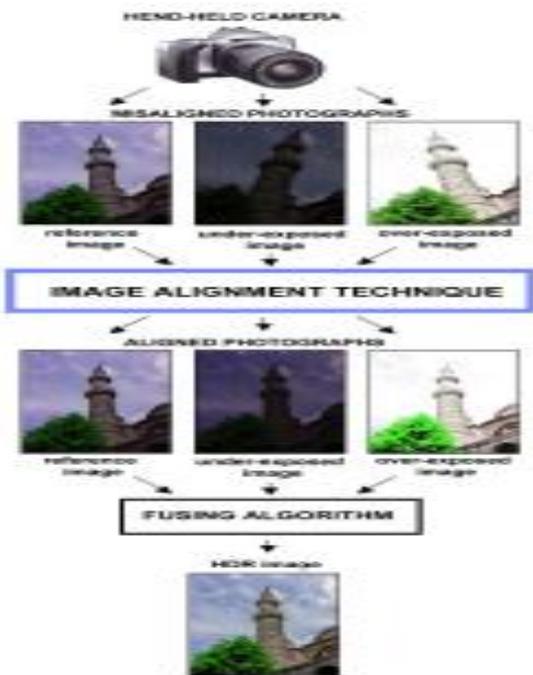

Figure 1: Image Fusion Technique

V. SIGMODIAL FUNCTION

When images of varying exposure are to be fused, the luminance of the shorter exposure images is boosted to match that of the longer one by estimating a compensating function that matches the camera's response. M. Tico and K. Pulli proposed a compensating function the brightness transfer function (BTF).[12] The BTF is estimated by plotting the pixel values of longer exposed image against the corresponding luminance values in the shorter exposed image, applying basic curve fitting and by smoothing the mean of pixel values for the longer exposure for the same pixel value in the shorter exposure. Both methods require

two passes over the shorter exposure image, the first to estimate the BTF and the second to boost the image accordingly.[8]

VI. ARTIFACT REMOVAL

The chrominance from longer exposure image, denoted by Cb_l, Cr_l is merged with the boosted luminance of shorter exposed image denoted by Yb_s . The merged image (Yb_s, Cb_l, Cr_l) contains motion artifacts like ghosting and color bleeding due to mismatch of luminance and chrominance values at the edges from images taken at two different times. Proposed technique for artifact removal works on the shorter exposure image and takes advantage of JPEG's built-in frequency analysis using DCT, to perform texture or edge detection. That DCT coefficients may be used to detect 8×8 blocks containing strong edges is well-known which is proposed by W. L. Pennebaker and J. L. Mitchell [16] and R. Kakarala and R. Bagadi.[17] The JPEG compression algorithm computes the DCT of each 8×8 block, which are then quantized and subsequently compressed by using run-length encoding in a "zig-zag" scan. The End of Block (EOB) symbol, which occurs in every block as part of JPEG syntax, indicates the location of the last non-zero AC coefficient in the 64-coefficient zig-zag scan. The classification of blocks as smooth or edge blocks may be accomplished simply by noting whether the EOB signal occurs early or late in the scan. Apply the detection to the EOB location in the DCT coefficients of the luminance blocks Yb_s of the boosted short-exposure image.[13] An empirically determined EOB location threshold of 15 (out of 64) is used for all experiments in this paper, and the quantization matrices used are the defaults described in W. L. Pennebaker and J. L. Mitchell [16]. If the EOB occurs after this threshold location, then the block is classified as an edge block for which the chrominance comes from the short exposure, otherwise it is considered a smooth block and the chrominance from the long exposure is used.[14]

For macroblocks where an edge is detected in the Yb_s component, the chrominance from the boosted shorter exposure (Cb_s, Cr_s) image is used to overwrite the corresponding values from the longer exposed image in the merged HDR image. In the standard 4:1:1 color format, there are four 8×8 luminance (Y) blocks in each 16×16 macroblock, and one each of Cb, Cr block. Our algorithm overwrites the two chrominance blocks of the long image with those of the boosted short exposure if any of the four Yb_s blocks contains an edge. Since we replace one block by another, we do not require RAM memory for the algorithm beyond the storage of a JPEG macroblock.[15] which is described in Figure 2, 3,4 and 5.

VII. IMAGE SATURATION DETECTION

The fused image is obtained by combining the luminance from shortest exposed image and chrominance from the longest exposed image which is described by R. Kakarala and R. Hebbalaguppe [14]. Data-driven threshold is used to calculate average of the difference between the maximum and minimum luminance values of the fused image. If the luminance value in the fused image is greater than the data driven threshold given then replace the chrominance of the

fused image by the chrominance of the normal exposed image.[18,19]

VIII. RESULTS

We evaluate the performance of the algorithm by taking three images at various exposure times called as Longest, Normal and Shortest exposure time images and the technique efficiently fuses multiple images taken at various exposure times in the JPEG domain which has shown in Figure 6,7,8 and 9.

IX. CONCLUSION

Image fusion is a procedure of combining relevant information from more than one image into a single image. The resulting image will have more information than any of the input images. Fusion is a popular approach for producing an image without under- and over-exposed areas is to capture several input images with varying exposure settings, and later combine them into a single high-quality image. The proposed technique efficiently fuses multiple images taken at various exposure times in the JPEG domain. The technique has categorized images into three types based on the exposure time, they are longest, normal

and shortest exposure images. A single pass sigmoidal booster is applied on the shorter exposed images implemented as LUT. Reuse of edge detection which is a part of JPEG for removal of artifacts further optimizes the algorithm. Lastly, the method requires no more than a single macro block to be kept in memory, because the image fusion is performed essentially in the JPEG file and rendered only on decoding the image. Experimental Results shows our proposed technique has efficiently fused multiple images into single image with better quality HRD.

Abstract: in many cases scene's dynamic range is greater than digital camera dynamic range. In such cases the user needs to capture multiple exposures of the same scene, then combines them together. Exposure can be varied either by changing the shutter speed or by changing the aperture. In this paper we preferred to change the shutter speed over aperture. The main reason for that is changing aperture leads to depth of field problems.

Keywords: Aperture ;Dynamic range; Shutter speed;

I. INTRODUCTION

In general dynamic range refers to the ratio between the maximum and minimum measurable light. For an imaging sensor dynamic range dynamic range refers to the ratio between full well capacity and noise. Naturally scene's dynamic range can be up to 100,000 and the sensor dynamic range is always less than that.

Fig 1: Image captured with shutter speed 1\3200 sec

In order to get the full dynamic range of the scene, we must combine several exposures together. Different exposures can be achieved by changing the shutter speed or by changing the aperture. Shutter speed refers to the amount of time shutter remains open in order to acquire the image. If the shutter remains open for long amount of time then the sensor collects more amount of light and the picture appears too bright. If the shutter closes quickly then the sensor collects less amount of light and the picture appears dark.

We can clearly observe that the figure 1 darker and the figure 2 is brighter. In the figure 1 background details are clearly visible and in the figure 2 the tree details are correctly visible.

Fig 2: Image captured with shutter speed 1\50 sec

Fig 3: Image captured with F#-32

We can also change the exposure values by changing the f-number. Figure 3 and 4 are captured with different f-numbers and different shutter speed values. We can clearly see that background is unfocused. During the fusion phase these details will be completely not useful. Hence we preferred to change the shutter speed values. Both figure 3 and 4 are collected from Wikipedia.

Fig 4: Image captured with F#-5

II. RELATED WORK

Different auto exposure algorithms are introduced in order to correctly expose the scene. However, if the scenes dynamic range is greater than the imaging device dynamic range it is not possible to get the all details in a single image.

Many AE algorithms have been developed [1-4] to deal with high-contrast lighting conditions. Some of them employ fuzzy method while others use various ways of segmentation. However, most of these algorithms have some drawbacks on either their accuracy or on the complexity, or both while estimating lighting conditions.

According to [1], it is difficult to discriminate backlit conditions from front-lit conditions using histogram methods [2], [3]. Further simulations in this paper shows that the tables and criteria used to estimate lighting conditions are confusing and not consistent. Other algorithms [3], [4] used fixed-window segmentation methods to estimate the brightness and lighting conditions. Besides, these papers and [1] only considered images with only one main object. Therefore, these algorithms are not flexible and do not work well with other images in which a main object does not exist [5].

In real implementation, the idea works as follows: The authors, proposed different optimum brightness values (Bl_{opt}) for different lighting conditions. To identify the lighting conditions, after capturing the first frame, the brightness value mean (Bl_{mean}) and median (Bl_{med}) are calculated. The difference of these two values is represented with D_L . In order to obtain the most suitable optimal values of Bl_{opt} for normal lighting (Bl_{opt}^{norm}), back lighting or high contrast (Bl_{opt}^{bkdr}) lighting conditions, and lighting conditions when the current picture is over exposed (Bl_{opt}^{over}), many pictures were taken by the authors, in different lighting conditions. The mid-tone range Bl_{mt} is set to [100, 130].

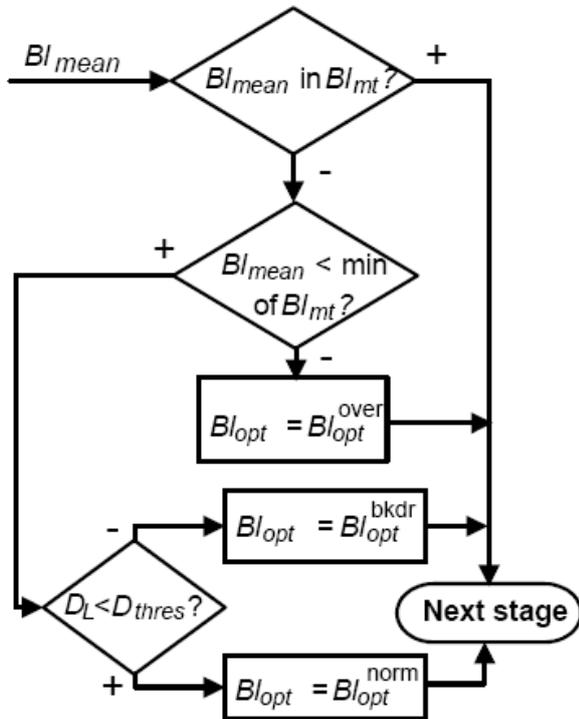

Fig 5: Deciding value for Bl_{opt}

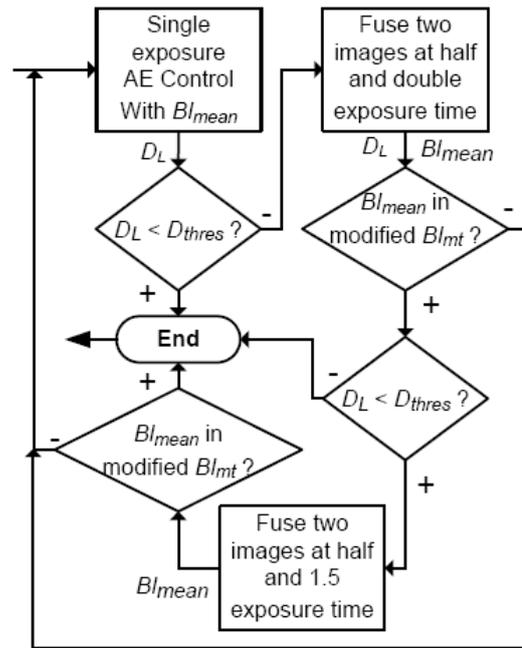

Fig 6: Multiple Exposure algorithm

III. PROPOSED ALGORITHM FOR HDR CAPTURING

Our algorithm basically consists of four parts. In the first part the end user should capture the image with the exposure settings suggested by the digital camera. Currently most of the digital cameras come up with the auto mode. If the user selects auto mode then automatically camera suggests shutter speed, aperture, ISO for a given scene. Once the camera suggests the exposure values, based on the exposure values suggested by the camera the end user captures a photograph.

Fig 7: Image captured with auto mode

In the second step HDR algorithm tries to identify the under exposed regions. In the under exposed region pixel values are close to zero. Once the algorithm identifies those regions it tries to find the proper exposure values. Proper exposure values can be found by increasing the shutter speed values. Once we increase the shutter speed values all the shadow details will be correctly exposed and the remaining details will be over exposed. Once we found the correct exposure settings for the under exposed regions the user need to capture the image.

Fig 8: All the shadow details are correctly captured

In the third step HDR algorithm tries to find the over exposed regions. In the over exposed region pixel values are close to 255. Once the algorithm finds the over exposed regions, it tries to find the correct exposure values. By decreasing the shutter speed we can correctly capture the highlight details. Once the camera identifies the correct exposure values

Fig 9: All the highlight details are captured

We fused all the above three images and the result is displayed in the Figure 10. We can clearly observe that all the high light details and shadow details are captured.

Abstract: The Z-Source network, as a DC-link energy storage sub-circuit, was proposed to be used in DC-AC power conversion circuits (inverters) due to its advantages compared to the traditional LC DC-link. In this paper a new modified Z-source (MZS) network is proposed in order to reduce the number of switches in a single-phase inverter, from four switches, in a full-bridge converter, to only two switches, as well as to maintain the desired average voltage level in the DC-link. This paper presents the novel topology and the operating principle of the new MZS single-phase inverter with two switches, and an application of this converter in a motor drive system to a single-phase PM synchronous motor. The proposed system topologies are validated by digital simulations of the circuits in PSIM and SIMULINK, with tests due soon.

I. Introduction

One of the major problems in single-phase voltage source inverters, having in the input stage batteries, photovoltaic, and fuel cells or a diode rectifier fed by the 230 V ac line, is the DC link voltage level, which could be smaller than the desired level, imposed by the application. Single phase voltage source inverters are used in photovoltaic or fuel cell grid-connected inverter systems as well as in inverter based motor drive systems. A growing interest is also shown in the field of hybrid electric vehicles. Some of the solutions to boost the DC link voltage are transformer-less boost circuits or circuits with high frequency transformers which are introduced between the DC voltage source and the inverter.

The main reasons why the Z-source network seems to be a good choice for the intermediate circuit between the DC link voltage and the inverter are the following: it provides a greater voltage than the DC link voltage if it is necessary, it makes the inverter immune to short circuits produced by the conduction of both transistors on the same phase leg (caused by EMI or bugs in the control software of the transistors), it reduces the inrush current and harmonics in the current thanks to the two inductors in the Z-source network, and it forms a second order filter and handles the undesirable voltage sags of the DC voltage source [1-7]. In this paper, the Z-source network is modified and a two power switch single phase PWM inverter, which self boosts the input voltage twice to keep the output voltage at input level (and mitigate for voltage sags), is proposed. Fig. 1 presents the electrical circuit of the Z-source network connected to a single-phase full bridge inverter. The diode D at the front end of the Z-source network makes the circuit unidirectional. The electrical energy flows from the DC voltage source to the load. The two equivalent schemes for the two possible operating modes of the Z-source network are shown in Fig. 2. [3]

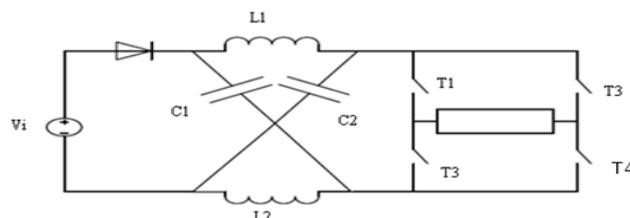

Fig.1. Z-source network with 4 switch single-phase inverter.

In the non-shoot through mode, in case of a single-phase inverter, two of the four transistors are switching: T1 and T4 or T2 and T3. With T4 on if T1 is on the output voltage is positive. Turning off T1 and turning on T3 (with T4 conducting) a through short circuit is produced to charge the inductances L1 and L2 and thus produce voltage boost.

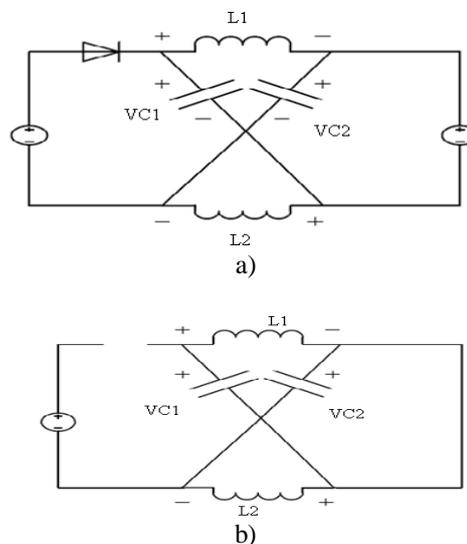

Fig.2. Equivalent schemes of the Z-source network in (a) non-shoot through state (b) shoot-through mode

In the shoot-through state:

$$V_{L1} = V_{C1} \quad V_{L2} = V_{C2} \quad V_i = 0$$

In the non shoot-through state:

$$V_{L1} = V_{DC} - V_{C1} \quad V_i = 2V_{C1} - V_{DC}$$

If $L1=L2$ and $C1=C2$ then the voltage drops across the inductors are equal and the voltage drops on the capacitors are equal as well.

To control the voltage at the input of the single-phase inverter we need to control the voltage of one capacitor, because the average voltage across the inductors in steady state is zero [1].

$$V_c = \frac{1 - \frac{T_{ST}}{T_s}}{1 - 2 \frac{T_{ST}}{T_s}} V_{DC}$$

where TST is the shoot-through time. To obtain the required TST/TS a PI controller can be used [1].

II. Modified Z-Source Single-Phase Inverter With 2 Switches

The proposed modified Z-source network (MZS) is presented in Fig. 3. In many electrical circuits, instead of a high voltage rated electrolytic capacitor, series smaller voltage rated capacitors are used. It can be noticed that this change in the Z-source network reduces the number of transistors. The load is connected between the common node of the two series capacitors and the common node of the two switches (Fig. 3).

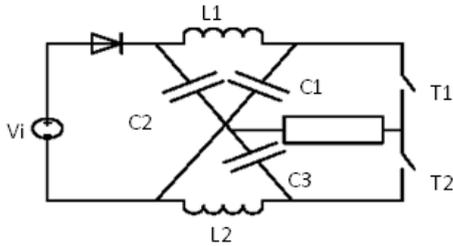

Fig. 3 .MZS single-phase inverter with two switches.

III. Operating Principle

The introduced MZS single-phase inverter with two switches has three different states, two active and one shoot-through. The three equivalent circuits for the three states are illustrated in Fig. 4.

[State 1]: The converter is in one of the two active states. The upper transistor is conducting and the lower transistor is substituted by its freewheeling diode.

The voltage on the load is:

$$V_{LOAD} = V_{C2} - V_{L1} = V_{C1}/2 - V_{L1}$$

$$\text{If } V_{C2} = V_{C3}$$

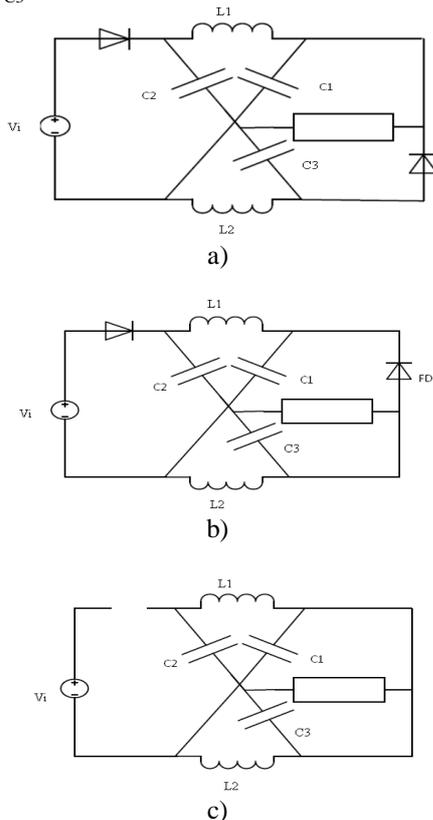

Fig.4. Equivalent circuits of MZS single-phase inverter for (a) State 1 (b) state 2 (c) state 3.

[State 2]: The converter is in the other non-shoot-through state. The lower transistor is conducting and the upper transistor is acting like a diode.

The voltage on the load is:

$$V_{LOAD} = -V_{C3} = -V_{C1}/2$$

$$\text{If } V_{C2} = V_{C3}$$

[State 3]: In this operating mode the demanded load voltage boost is realized. Both the upper and the lower switches are conducting; therefore an energy transfer is realized from the capacitors to the inductors. It can be seen that the circuit is asymmetrical (because the load is connected in parallel with the capacitor C3), so that the energy transfer from the capacitors to the inductors is not the same on the upper and on the lower side.

IV. Modified Z-Source Single-Phase Inverter With Single Phase Pm Synchronous Machine

Because of the complexity of the equations for each state of the MZS, the converter was modeled with discrete elements in PSIM. The single phase synchronous machine was modeled as a series connection of the following elements: the stator resistance R, the stator inductance L and a programmable voltage source which is the EMF, calculated in “Simulink” based on the motor equations at every sample time. We used three sensors in total: one load current sensor, one motor speed transducer and one voltage sensor for the measurement of C1 capacitor voltage (which is the average DC link voltage in steady state). So we have three control loops. For speed regulation a PI controller was used, for the load current control a hysteresis current controller. The hysteresis current controller commands one of the two transistors all the time. This means that there are no “inactive states” (e.g. the time duration for zero state vectors in case of a three phase inverter) during which the shoot-through states could be generated. In conclusion the shoot through states will take place during the active states. By connecting the motor between the common node of the two transistors T1 and T2 and the common node of the capacitors C2 and C3 the maximum voltage which can be delivered to the motor in our case study is 150 V if the voltages on the two capacitors C2 and C3 are equal to each other. In order to be able to supply the motor from 300 V with the block V* we prescribe 600 V average DC link voltage. To reduce the inrush current spikes in the inductors the V* voltage was increased from 300 V to 600 V in 300 ms. The output of the PI regulator in the DC link voltage control loop in Fig. 5a gives the ratio of the input DC voltage and the average DC link voltage. Based on equation (3) the block after the PI regulator calculates the shoot through time.

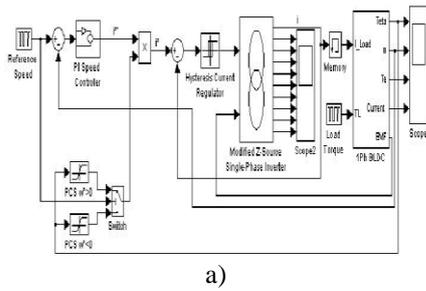

The shoot through time generation can be seen in Fig.6. It should be noticed that the shoot through time is calculated with a 10 kHz sampling rate and the shoot through pulses are distributed equally over the 100 is period at the beginning and at the end of the sampling period. The shoot-through pulses override the pulses generated by the hysteresis current controller thanks to the two or gates at the gate of each transistor.

$$V_S = I_S \cdot R_S + L_S \cdot \frac{dI_S}{dt} + \omega_r \cdot \lambda_{PM}(\theta_{er})$$

$$\frac{1}{p} \cdot \frac{d\omega_r}{dt} = T_e + T_{cog} - T_{load}$$

$$T_e = P \lambda_{PM}(\theta_{er}) I_S(t)$$

$$\frac{d\theta_{er}}{dt} = \omega_r$$

a)

To demonstrate that the proposed MZS single phase inverter is suitable for motor drives with single phase PM synchronous machines, different perturbations on the drive were simulated. For example, it can be seen in Fig. 7 that for a 10% voltage sag of the nominal DC voltage source (fall from 300V to 270V) the C1 capacitor voltage remains unchanged. At the start of the converter one of the two series capacitors (C2) is discharged and the second (C3) is charged with electrostatic energy. The C1 capacitor voltage smoothly follows the prescribed average DC link voltage; it has a very small overshoot. Even if the prescribed average DC link voltage is raised gradually from 300V to 600V in 300ms, we do have some inrush current spikes in the inductors L1 and L2 (Fig. 8.). A longer ramping time could reduce these inrush current spikes.

Fig. 8 shows that the inductors peak currents are about two times greater than the peak load current. The difference between the two currents instantaneous values is the effect of the converter's asymmetry (see Fig. 4 state 2 and state3).

In Fig.8 b) can be seen that the instantaneous voltage across the load is asymmetrical, the positive part is two times greater than the negative part.

Fig. 9 shows the motor reference and measured speed while the motor accelerates to the nominal speed 3000 rpm in about 1.5 seconds. A breakpoint in the speed ramping is visible at 300 ms the moment when the C1 capacitor voltage reaches 600V. From this moment the motor has a steeper acceleration ramp, until it reaches 3000 rpm. A step load torque of 0.35 Nm is applied to the motor at t = 2 seconds until t = 8 seconds. This load torque is not reflected in the capacitor voltages and the speed does not suffer a speed drop, which indicates that the speed and current loops work well. At t = 3 seconds, the motor is decelerated to 33% of its nominal speed for 3 seconds. A voltage boost is visible in the capacitor voltages during the deceleration process.

At t = 6 seconds the motor speed increases again to the nominal speed. This time the acceleration time duration is longer than the deceleration time duration because we have a torque load which goes to zero at t = 8 seconds and the acceleration ramp gets steeper, again.

In Fig. 10 shows the variation in time of the load torque, electromagnetic torque and the cogging torque of the motor.

The transistors voltage and current stresses are illustrated in Fig. 11. The collector peak current is twice the inductor peak current. The peak instantaneous voltage across the transistor is two times bigger than the voltage across C1.

Table I presents the peak currents and voltages in the transistors for the following converter topologies: full bridge single-phase inverter with 4 transistors (A) and modified Z-source single-phase inverter with 2 transistors (B) for single-phase PM synchronous motor drives. The 2 transistor topology is payed for in addition V and A ratings.

The motor parameters:

- Stator resistance RS [ohm]: 40
- Stator inductance LS [H]: 0.2913
- Total inertia J [kg/m2]: 0.004
- Viscous friction coefficient B[Nm s] : 0.001
- Number of pole pairs: 1
- Nominal voltage [V]: 300 .

The MZS converter parameters:

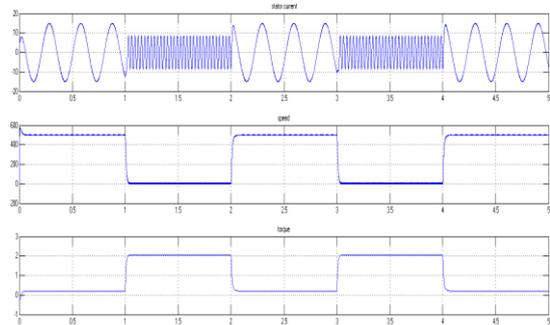

- L1=L2=6mH;
- C1=C2=C3=470iF.
- The PI speed controller parameters:
- KP=2; Ki=20.

The PI controller parameters in the shoot-through-time control block:

- Gain: 0.009;
- Time Constant: 2.5 ms.

Simulation results:

Stator current, speed & torque with respective to time are shown as follows:

Voltages across inductors and capacitors are as follows:

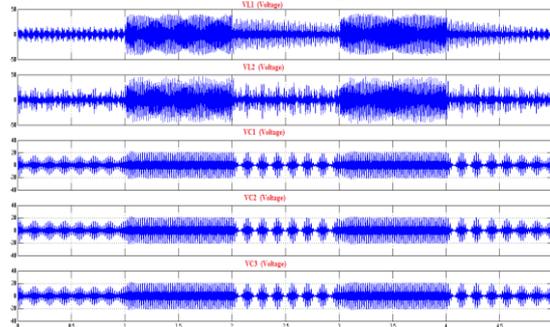

TABLE I

Topologies	No. of transistors	Peak transistor current	peak transistor voltage[v]
A	4	2	300
B	2	6	900

V. Conclusions And Discussions:

The proposed modified Z-source single phase inverter is a possible solution for motor drives with single phase permanent magnet synchronous machines. The converter is able to override the DC voltage sags. The inductors peak currents are approximately twice the load peak current.

The voltage boost of the intermediate DC link it can be produced even if there are no "inactive states".

ABSTRACT: This paper reports on the punching shear behavior of simply supported recycled aggregate concrete two-way slabs. The experimentation was conducted on 15 Recycled Coarse Aggregate Concrete (RCAC) slab specimens and 3 Natural Aggregate Concrete (NCAC) slabs were cast tested as control specimens. All the slabs were simply supported on all four edges and tested under a central patch load. Six replacement percentages (0, 20, 40, 60, 80 and 100%) of Natural Coarse Aggregate (NCA) replacements with Recycled Coarse Aggregate (RCA) were considered in this investigation. The results showed that as the replacement of NCA with RCA increases, the Ultimate load, deflection at ultimate load, Stiffness degradation and Energy absorption decreases and the cracking was premature. A Regression model has been developed to predict the ultimate punching shear of RCA slabs.

Keywords: Deflections, Energy absorption, Loads, Natural Coarse Aggregate (NCA), Natural Coarse Aggregate Concrete (NCAC), Recycled Coarse Aggregate (RCA), Recycled Coarse Aggregate Concrete (RCAC), Stiffness degradation, Two-way Slabs.

NOMALNCLATURE

f'_c	Cylinder compressive strength (N/mm ²)
τ	Shear stress (N/mm ²)
r	replacement ratio of NCA with RCA

I. INTRODUCTION

Recycled coarse aggregate concrete (RCAC) can be recognised as a new kind of concrete, in which broken pieces of waste concrete are used as aggregate. The use of RCA is one such an attempt to solve some of the problems in the field of construction industry. The concept of using RCA is now gaining popularity and research in this field has gained some momentum. Most of the findings have been extensively reviewed and discussed by Nixon [1], Hansen [2] and ACI committee 555 [3]. Due to the low strength, low elastic modulus, bad workability, high water infiltration, high shrinkage and creep of RCAC, it is mostly used for only non structural concrete [4, 5]. However, RCAC is well recognised in view of its low thermal conductivity, low brittleness as well as the low specific gravity that reduces the self weight of the structures. It was revealed that the relevant material properties of RCAC are generally lower than those of conventional concrete, but they are still sufficient for practical applications. Most importantly the use of RCA

can save natural resources and protect our living environment [6, 7].

The studies of properties of RCAC have been ongoing over the last few decades, leading a number of countries to establish standards or recommendations supporting their views. With regard to popularised RCAC, the structural behaviour of RCAC ought to be investigated. In fact some studies concerning the performance of beams were conducted by Mukai [8], Yagishita [9], Gonzalez-Fontebao [10], performance of columns were studied by Yang [11] and studies on seismic performance of frame structure by Xiao [12] made with RCAC. This paper reports studies on punching shear behavior of RCAC slab specimens.

II. RESEARCH SIGNIFICANCE

In this investigation, experiments were designed to provide a comprehensive understanding of the structural behavior of RCAC. The tests were particularly focused on the real punching shear behaviour of simply supported reinforced RCAC slabs under action of central patch load and also studied the influence of NCA replacement with RCA on the failure pattern, ultimate loads, load deflection curves, stiffness, stiffness degradation, energy absorption and comparison with the codes of practice of slabs under punching shear. The results presented in this paper may promote the use of RCA in practical applications.

III. EXPERIMENTAL PROGRAM

3.1 Materials

Ordinary Portland cement of 43 grade, confirming to IS 8112:1989 [13], locally available river sand as fine aggregate (zone-II) confirming to IS-2386 [14], coarse aggregates are natural coarse aggregate (NCA) and recycled coarse aggregate (RCA). RCA is obtained from the waste concrete brought from the runway of an Airport in Kadapa, Andhra Pradesh, India (10 to 12.5mm accounting for 50%, and 12.5 to 20mm accounting for 50% in weight) and is used in this investigation. The physical properties of the NCA and RCA are presented in Table 1. Fe415 HYSD bars confirmed to IS-1786:1985[15] with 6mm diameter have been used as slab reinforcement.

Table1. Physical properties of NCA and RCA

Coarse aggregate	Grading (mm)	Bulk density (kg/m ³)	Apparent density (kg/m ³)	Water absorption (%)
NCA	4.75–20	1520	2680	0.52
RCA	4.75 -20	1360	2560	5.02

3.2 Mix proportions of RCAC

Due to the high water absorption capacity of RCA, they were presoaked by additional water before mixing. The amount of water used to presoak the RCA was calculated according to the saturated surface dry conditions. The target designed strength for 28 days of all the concretes was set as around 25 MPa. The ACI mix design procedure [16] is adopted. The mixtures were divided in to six groups. The main difference among these six groups is the NCA replacement percentage with RCA which is 0, 20, 40, 60, 80 and 100%, respectively. In case of NCA replacement percentage with RCA equating 0, the specimens are termed as NCAC slab specimens, which are served as the control specimens for comparison. The mix proportions of the concrete are shown in Table 2.

3.3 Preparation of test specimens

Steel moulds were used to cast the slab specimens of required size. Two L-shaped frames with a depth of 50mm were connected to a flat plate at the bottom using nut and bolts. Cross stiffeners were provided to the flat plate at the bottom to prevent any possible deflection while casting the specimens. The gaps were effectively sealed by using thin card boards and wax to prevent any leakages.

In the experiment, a total 18 (3 on each group) approximately one-sixth scale square isotropically reinforced concrete slab specimens were made with the NCA replacement with RCA in different percentages and tested under punching shear. The thickness of the slab specimen and the spacing of longitudinal reinforcement was accomplished in accordance with IS 456-2000 [17]. All the slabs are of size 1100 x 1100 x 50mm. All the slab specimens are reinforced with (0.63%) Fe-415 HYSD 6mm diameter bars, with a cover of 10mm and the bars are equally distributed in both the directions.

The test slab specimens were de-moulded after 3 days. Before de-moulding, the slab specimens are cured with wet jute bags. The de-moulded slab specimens were water cured for 28 days in curing pond. After removing the slab specimens from the curing pond, they were allowed to dry under shade for a while and then they were coated with white paint on both sides, to achieve clear visibility of cracks during and after testing. By preserved cubes and cylinders in each group, the measured average mechanical properties of the concrete related to the slab specimens are illustrated in Table 3. From Table 3 it is observed that as the replacement of RCA with NCA increases the compressive strength and split tensile strength decreases.

3.4 Loading arrangement and testing

The slab specimen is placed over the loading platform and steel rods of 16 mm diameter have been kept below the slab along the four edges to simulate the simply supported edge condition. Placing of steel rods allow free rotation

along the edges thus simulating the simply supported edge condition. A single concentrated patch load was applied at the geometric center of each slab with a rigid bearing plate of 100x100x20 mm with a 3-mm thick plywood packing between the slab and the bearing plate. Over this rigid plate, solid circular rod of 50 mm diameter was kept to distribute the load from the hydraulic jack to the slab specimen. The load was applied through hydraulic jack was measured in increments of 200N which corresponds to one unit of calibrated proving ring with 500 kN capacity, vertical deflections at the geometrical center of the slab specimens were measured by using dial gauge with a least count of 0.01 mm. The load at the first crack and the corresponding deflection at the bottom centre of the slab were recorded. The ultimate punching shear load and corresponding deflection at the centre were also observed and recorded. The overall view of a specimen in position ready for testing is shown in Figure 1.

IV. RESULTS AND DISCUSSION

4.1 General

The load versus central deflection curves for the slabs are presented in Figure 2. It may be seen that the typical relationship was linear until flexural cracking, which occurred just below the loading point. This event was characterized by a noticeable reduction in slab stiffness. With increasing load, new cracks were formed and the existing ones kept propagated in the radial direction, predominantly towards the corners of the slab. The slope of the load-deflection curve also kept decreasing until punching failure occurred. A sudden drop in the applied load marked this event. At this stage, punching shear failure was clearly visible on the top face but, on the bottom face, only an outline of the truncated failure cone with a much larger perimeter had formed. Table 3 reveals that the mechanical properties of the recycled concrete slabs decreases with an increase of the NCA replacement percentage with RCA.

The results of the experimental investigation are summarized in Table.4. The values presented here represent the average of punching shear strengths, load and deflection obtained for three specimens in each group. From the Table.4 it is observed that there is a decrease in first crack load as the replacement of NCA with RCA increases. The first crack load of NCAC-S is 14.60kN and for the RCAC-20-S to RCAC-100-S is between 14.20 to 12.20kN. The first crack load of RCAC-20-S to RCAC-100-S decreases by 2.74 to 16.44%, when compared with NCAC-S. The first crack occurs first in RCA than that of natural aggregate, it is due to the presence of adhered mortar over the RCA. Hence, as the percentage replacement increases the first crack load decreases.

The ultimate load of NCAC-S is 48.20kN and for the RCAC-20-S to RCAC-100-S is between 47.20 to 41.40kN. The ultimate load of RCAC-20-S to RCAC-100-S decreases by 2.07 to 14.11%, when compared with NCAC-S. This shows that as the replacement of NCA with RCA increases the ultimate load decreases linearly. It should be noted that the reduction in the ultimate loads are less than at material level, i.e. the mechanical properties as

described in Table.3; this may be due to the contribution of steel reinforcement.

The central deflection response of various slab specimens is shown in Figure.4. Central deflection corresponding to first crack load and ultimate load are presented in Table.4. It is observed that the central deflections corresponding to first crack load of RCAC-20-S to RCAC-100-S decrease by 3 to 30%, when compared with NCAC-S. The central deflections corresponding to ultimate load of RCAC-20-S to RCAC-100-S decrease by 3 to 15%, when compared with NCAC-S. Similar trends are observed at first crack stage and ultimate load stage. But, rate of decrease of deflections at first crack stage is more when compared to ultimate stage. At the first cracking stage, rate of decrease of deflections are more due to presence of old mortar over the RCA, but at ultimate stage rate of decrease of deflections are less due to the contribution of steel reinforcement. Typical view of failure slab specimens is shown in Figure 3 and Figure 4.

4.2 Stiffness

From the load-deflection curves, two values of the stiffness of the tested slabs were obtained. The un-cracked stiffness K_i is indicated by the slope of the line of a value less than the first crack load, and the ultimate stiffness K_u is measured by the slope of the line at about 90% of the ultimate load. These values are given in Table 5. From the deflection curves, it can be seen that the slope becomes steeper when the percentage replacement of NCA with RCA increases. This indicates that the un-cracked stiffness increased as the percentage replacement of NCA with RCA increases. Stiffness degradation is defined as the ratio between the ultimate stiffness and the un-cracked stiffness as given in Table 5. As the stiffness degradation increased, the specimen indicated lower ductility. Out of RCAC slab specimens RCAC-100-S shows 9% decrease in stiffness degradation when compared with NCAC-S slab specimens.

4.3 Energy absorption

The energy absorption is defined as the area under the load-deflection curve. The values were determined from test results, and are listed in Table 5. RCAC-20-S to RCAC-100-S show 4.17 to 27.50% decrease in the energy absorption when compared with NCAC-S. Therefore, it can be concluded that as the replacement percentage of NCA with RCA increases energy absorption decreases.

V. REGRESSION MODEL FOR PUNCHING SHEAR STRESS

A simple regression model has been developed from the results of present investigation for predicting the punching shear strength of RCAC slabs. To develop the punching shear strength model, linear regression technique has been adopted. The linear regression is in the form of $Y=A+BX$ where Y is independent variable, X is dependent variable and A and B are called regression coefficients. The A and B are determined from regression analysis in accordance with the principle of least squares method.

For predicting the shear stress IS code [17] and ACI [18] code uses cube and cylinder compressive

strength, respectively. Hence, the proposed models for punching shear stress with f_c and f'_c are as given below

$$\tau = A + BX \quad \dots (1)$$

From the results of the present study, a simple regression models has been developed connecting shear stress with cube compressive strength f_c and cylinder compressive strength f'_c and are presented as equation 3 and 4 with a standard deviation of 0.0020 and 0.0025, respectively

$$\tau = (0.359 - 0.0067 r) \sqrt{f_c} \quad \dots (2)$$

$$\tau = (0.403 - 0.0091 r) \sqrt{f'_c} \quad \dots (3)$$

A comparison of the ultimate shear stress by regression models (Eq. 3 and 4) and experimental values are presented in Table 6 and Figure 5. From the Table 6 and Figure 5 it can be observed that the proposed model compared well with the experimental shear stress. The experimental and regression model values give more conservative predictions.

VI. CONCLUSIONS

The following observations and conclusions can be made on the basis of the current experimental results.

- 1- As the percentage replacement of natural coarse aggregate with recycled coarse aggregate increases the compressive strength and split tensile strength increases. Up to 40% replacement of NCA with RCA there is a marginal decrement in compression and split tensile strength when compared with natural coarse aggregate concrete.
- 2- All the slabs behave similar in the aspect of failure patterns under punching shear regardless of the replacement percentage of natural coarse aggregate with recycled coarse aggregate. The presence of recycled coarse aggregate reduces the first crack and ultimate loads of slab specimen. However, this reduction is less than that of the mechanical properties of the recycled coarse aggregate.
- 3- Slab specimens up to 40% replacement of NCA with RCA there is a marginal decrement in first crack and ultimate loads when compared with natural coarse aggregate concrete.
- 4- As the percentage replacement of natural coarse aggregate with recycled coarse aggregate increases the stiffness degradation decreases and energy absorption decreases.
- 5- A Regression model is developed for predicting the ultimate punching shear and is given as

$$\tau = (0.359 - 0.0067 r) \sqrt{f_c}$$

$$\tau = (0.403 - 0.0091 r) \sqrt{f'_c}$$

Design of a Neural Network Based Image Recognition System Using Configurable VLSI

Vidya G. S¹, Sarath Raj S², Manu T S³

^{1, 2, 3}(Dept.of Electronics and Communication, TKM Institute of Technology, Affiliated to CUSAT, India.)

Abstract: This paper describes the initial steps in the development of an object detection system for manipulation purposes to be embedded in a mobile robot. The goal is to design a neural network based recognition module. The neural network module and additional image processing algorithms which are used to convert the image into useful information for the neural network and the control of the whole system is designed using the soft core processor in the FPGA. The neural network implementation can be performed using the VHDL coding and processor can be designed using the Xilinx EDK tool.

Keywords: EDK, embedded systems, FPGA, image processing, Neural Network, SoPC, visual servoing

I. INTRODUCTION

Image recognition systems are widely used in different industries such as production plants to detect faulty components, to select a piece on a conveyor or as surveillance systems that are capable of detecting intrusion, differentiating people or observing their motion. Object positions and environmental conditions have to be acquired in real-time. The term Visual Servoing refers to a useful capability for both manipulator arms and mobile robots [1]. Visual Servoing involves moving a robot or some part of a robot to a desired position using visual feedback [2].

However, fast and computation intensive tasks are difficult to implement in small and low power consumption electronic systems required in robot-like systems. The goal of this research is to develop an efficient hardware/software implementation of an object recognition system for an autonomous robot. This recognition system is based on an artificial neural network. In addition, some image processing modules to provide the network with useful data have been designed. Some other works that use neural network based systems for Visual Servoing can be found in [3], [4], [5]. However, in general most of such implementations are PC-based architectures.

The implementation presented here is carried out in a FPGA (Field Programmable Gate Array). The very high integration of present FPGAs enable the accommodation of all the components of a typical embedded system (processor core, memory blocks, peripherals, specific hardware,...) on a single chip, commonly referred to as system-on-a-programmable chip (SoPC). The design described here is based on such a SoPC. In particular the neural network module together with the control of the whole system are implemented as software in the embedded processor core

II. SYSTEM ARCHITECTURE

The initial approach to afford the recognition problem has been limited to the recognition of simple shapes, but in such a way that it could be extrapolated to any shape, for example those of hand tools. For the experiments performed up to now, some different colour wood pieces (cubes, cylinders, rectangular prisms and triangular prisms) have been used. Hence, four possible shapes have to be recognized: square, circle, rectangle and triangle.

Usually, image processing algorithms are implemented in software and run on a PC. However, in applications with high restrictions in response time or low consumption requirements (like the system described here), hardware specific implementations are needed. The main objection of the image recognition techniques for its realization in hardware is the high complexity of the existent algorithms. For this reason, in this paper a method optimized for its hardware implementation is presented.

2.1. IMAGE PRE-PROCESSING

The pre-processing stage converts the images into useful information for the neural classification system. Once a binary image is obtained, the amount of information contained in it is reduced to preserve only the information considered more relevant for the recognition. An edge extraction technique grounded on the chain-code algorithm [6] has been chosen. The bases of the chain-code algorithm were introduced in 1961 by H. Freeman [7], who described a method which permits the encoding of arbitrary geometric configurations, as a way to make it easier for a digital computer to manipulate them. It is a lossless compression algorithm for binary images, which provides a useful way to depict an object and to derive its features for later applications in pattern recognition.

Chain-codes are used to represent the contour of an object by means of a sequence of small vectors of unit length, each one representing the direction of the contour at that point. The number of possible directions is determined, being the 8-connected neighborhood and the 4-connected neighborhood configurations the most commonly used. The 4-connected set of directions, also referred to as external chain-code or crack code in some sources, is the one employed in this work (Figure 1).

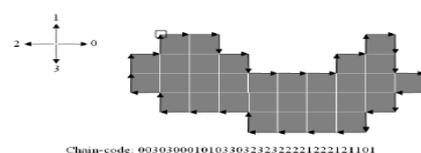

Figure1: Example of the external chain code of a binary image

First of all, the region of the image where the object lays must be determined, in terms of the density of white pixels. Then, the origin of the object in the image must be fixed. In the algorithm presented in this paper, the origin is considered to be the left-most white pixel of the first line in the object region. Once the origin is fixed, the object is outlined in clockwise manner and the directions of the boundary are stored until the algorithm reaches back the initial point.

Using this algorithm, each object is represented by a sequence of numbers, which length is different for each case, depending on the size of the object in the image and its shape.

In order to make the lengths equal and to reduce even more the codification, in such a way that it can be used as the input for the neural network, the sequence is normalized by dividing it into a fixed number of smaller sequences. Each of them is processed to obtain the slope between its end points. Thus, each object is represented by a fixed length sequence which contains the slopes of the contour. In turn, these slopes can only take a definite number of values, so that the translation to a digital system is more direct.

2.2. NEURAL CLASSIFICATION

The classification module consists of an artificial neural network where the inputs are the values provided by the image pre-processing stage. Based on these data the neural network classifies the shape of the target object. The neural network has multi-layer perceptron architecture [8], consisting of an input layer, a hidden layer and an output layer.

The number of input neurons has been set to 16, which forces the sequence obtained from the image processing stage to be of this length. The hidden layer has 32 neurons with a tan-sigmoid activation function. Lastly, the output layer consists of 4 output neurons, one for each possible shape, and no activation function is applied. The architecture of the neural network is presented in Figure 2.

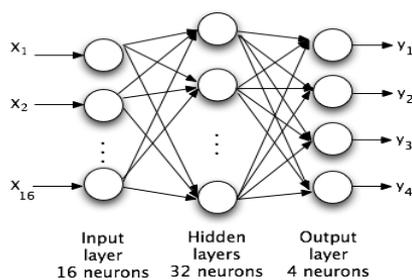

Figure 2: Architecture of the proposed neural network

The network is trained by means of the back-propagation algorithm, using the gradient-descent method. The training set is made up of 16 sequences obtained from different images of different object shapes, along with the corresponding target output for each sequence. This set is divided into three different subsets: the 60% of the samples are used for training, the 20% for validation (useful for early-stopping of the training process) and the remaining 20% for test (for estimating the network's ability to generalize). The training algorithm of the network is performed in Matlab, by means of the Neural Network Toolbox [9].

III. HARDWARE/SOFTWARE PARTITION

Nowadays, the so called SoPC (system-on-a-programmable chip) take advantage from the flexibility of software and the high performance of hardware. Their proliferation has been possible thanks to the high integration levels achieved in the microelectronic industry, which allow the inclusion of a small microprocessor inside the programmable chip. This fact allows the designing of efficient heterogeneous hardware/software architectures on a single chip. Historically, the most common way for the implementation of neural networks has been a program running on a personal computer or a workstation. This is due to the fact that software implementations offer a high flexibility and give the users the possibility of modifying the topology of the network, the type of the processing elements or the learning rules, according to the requirements of their application. However, biological neural networks, in which artificial neural networks are inspired, operate highly in parallel. Hence, implementing them on a sequential computer does not seem the most efficient way to do it.

Dedicated hardware implementations, on the other hand, offer a number of important advantages, because they exploit the inherent parallelism of neural networks and also are much faster and robust if compared to software solutions.

Furthermore, they provide a physically reduced and low-power solution, useful for applications where including a personal computer or a workstation might not be feasible (such as the case of autonomous robots). These are the main reasons why it has been decided to implement the recognition algorithms on an embedded system and, more specifically, the neural network on the hardware partition of the system.

The architecture is as shown in Figure3..

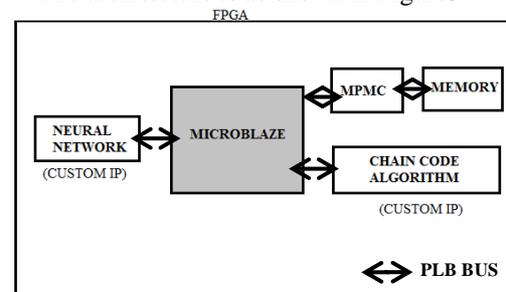

Figure 3: Internal Architecture of SoPC

The software partition is built on a MicroBlaze (the softcore processor from Xilinx) [10] and includes the control of the complete system and, also the image pre-processing algorithms.

3.1. INTERFACE BETWEEN MODULES

The interface between both partitions is based on the PLB (Processor Local Bus) bus [11], that provides a fast and efficient communication mechanism. The Processor Local Bus (PLB) consists of a bus control unit, a watchdog timer, and separate address, write and read data path units with a three-cycle-only arbitration feature. The PLB supports read and write data transfers between master and slave devices equipped with a PLB bus interface and connected through PLB signals. Bus architecture supports multiple master and slave devices. Each PLB master is attached to the PLB through separate address, read-data,

and write-data buses. PLB slaves are attached to the PLB through shared, but decoupled, address, read-data, and write-data buses and a plurality of transfer control and status signals for each data bus.

The Processor Local Bus (PLB) consists of a bus control unit, a watchdog timer, and separate address, write and read data path units with a three-cycle-only arbitration feature. The PLB supports read and write data transfers between master and slave devices equipped with a PLB bus interface and connected through PLB signals. Bus architecture supports multiple master and slave devices. Each PLB master is attached to the PLB through separate address, read-data, and write-data buses. PLB slaves are attached to the PLB through shared, but decoupled, address, read-data, and write-data buses and a plurality of transfer control and status signals for each data bus.

Access to the PLB is granted through a central arbitration mechanism that allows masters to compete for bus ownership. This arbitration mechanism is flexible enough to provide for the implementation of various priority schemes. Additionally, an arbitration locking mechanism is provided to support master-driven atomic operations. PLB arbiters can be implemented on the FPGA fabric and are available as soft IP cores. The PLB is a fully synchronous bus.

The PLB arbiter multiplexes signals from masters onto a shared bus to which all the inputs of the slaves are connected. The PLB arbiter handles bus arbitration and the movement of data and control signals between masters and slaves. The PLB-to-PLB bridge is required when two PLB segments are connected. The bridge translates PLB transactions on one side into the PLB transactions of the other side. The bridge functions as a slave on one PLB side and a master on the other. For a typical system with two PLB segments, one bridge is necessary for transactions originating from the processor. A second bridge is required if a peripheral on the other side is master capable and wants to address a peripheral on the processor side. Figure 4 provides an example of the PLB connections for a system with three masters and three slaves.

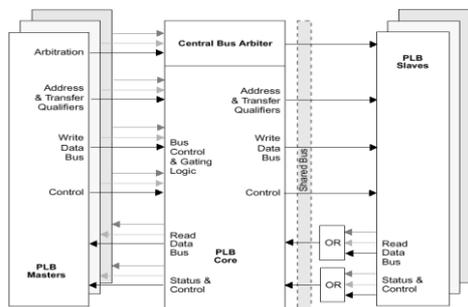

Figure 4: PLB Interconnection Diagram

3.2 ARCHITECTURE OF THE NEURAL NETWORK

The architecture of the network is the one presented in Figure 2. In a hardware implemented neural network, the processing elements (i.e., neurons) have to be independent and operate in parallel. They should be designed in such a way that their internal calculations are optimized, while they should be so simple that the chip area occupied by them is the minimum possible. Following these requirements, a very small but high performance system can be achieved.

The architecture proposed in this paper comprises the following modules.

- A two-layer processing module: the hidden layer and the output layer (the input layer merely transmits the inputs)
- Three ROM modules, which store the network parameters (weights) for the hidden layer, the output layer and the sigmoid function, respectively.
- Additional components, such as a multiplexer and a block that calculates the maximum of its inputs.
- A circuit controller that governs the whole operation of the system.

The main component of the processing module is the neuron, which is just a MAC (multiply-accumulate) block. The MAC is loaded with an initial value (offset or bias) and then multiplies each input with its corresponding weight and accumulates these values to obtain the sum of all them. It is a two-cycle synchronous component (see Figure 5). The total number of these MAC blocks is 36 (32 for the hidden layer and 4 for the output layer).

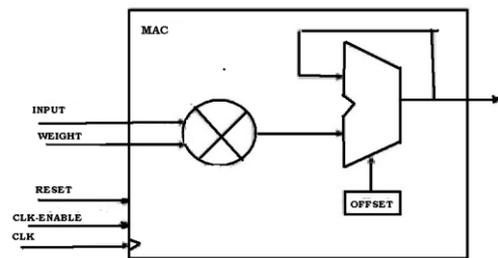

Figure 5: MAC schematic. .

As for the ROM modules, the one that contains the weights of the first layer (ROM1) has a size of 512 weights with a word length of 12 bits, whilst the one corresponding to the second layer (ROM2) contains 128 weights of a word length of 8 bits. ROM1 is organized in 16 blocks of 32 weights, so that for each of the inputs the corresponding block of 32 weights is addressed and sent to the first layer of neurons. In the same way, ROM2 is divided into 32 blocks of 4 weights each. Finally, ROM3 is the memory that stores the pre-computed sigmoid function and contains 256 values with a word length of 8 bits.

The system controller, whose main component is a six-bit counter, provides the control signals for the whole system. Such signals are the reset signals for all the modules, the signals to enable each block, the address signals for ROM1 and ROM2 and the selection signal for the multiplexer.

The detailed operation of the whole system is described next. The 16 input data come serially through the PLB bus. Each neuron (MAC block) receives the inputs serially, multiplies each of them with the corresponding weight (stored in the ROM1 memory) and adds them up. The neuron needs only one clock cycle per input to process the MAC operation, because while the accumulate operation is being done, the next data are already being multiplied, creating a pipeline. Furthermore, the 32 neurons of the layer work in parallel. Hence, only 17 clock cycles (one for each input and one more for the first data, before starting the pipeline operation) are needed to perform the calculations of the first layer, in spite of the fact that the inputs enter the system serially.

REFERENCES

Once the outputs of the first layer are available, they are used to address ROM3, which contains the activation function. This memory is the same for all the neurons of the first layer. The outputs of this block are the sigmoid functions of their inputs. All the accesses to the ROM3 are made in parallel, so just a clock cycle is required. This ROM module provides 32 outputs that act as the inputs to a 32 to 1 multiplexer. The multiplexer makes it possible for the inputs to the following layer of neurons to arrive serially, in such a way that this layer would work like the first one. Thus, each of the 4 neurons of the last layer receives the 32 incoming data serially and performs the MAC operation, needing 33 clock cycles to finish this task (one for each input and an additional one, as in the previous layer).

Finally, the result of these MAC operations are carried to a module that calculates which of them has the maximum value, needing only one cycle to do so. The output of this module represents the shape recognized by the network, codified in 2 bits. This data is sent back to the software partition through the PLB bus.

The final output showing the recognition of four basic shapes is as shown in Figure 6, which is obtained using the Chipscope Pro tool.

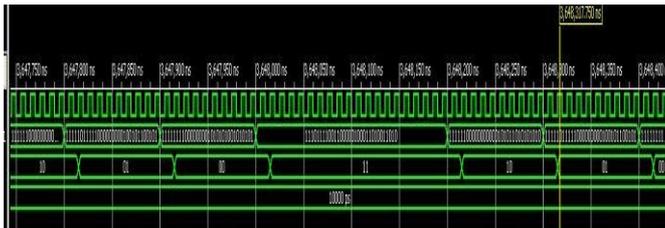

Figure 6: Results showing the recognition of four basic shapes

IV. CONCLUSION AND FUTURE SCOPE

In this paper a prototype of a vision system for a robotic platform to assist in manipulation activities has been presented. An FPGA module for embedding the object recognition module within a robotic mobile platform is being designed. The FPGA module includes the neural network and the control and the image processing modules are built on a Microblaze. More work will be done to strengthen the overall performance of this system, taking into account more variability in object shape and colour (real objects). Up to now, the FPGA module includes the implementation of the neural network. As further work, the rest of the image processing algorithms should also be implemented on the chip. They would be included preferably on the hardware partition of the SoPC for performance reasons, but to do so, a previous analysis has to be made in order to study the feasibility of this option. In addition, the whole system has to be integrated with the robotic platform in order to perform the manipulation activities.

ACKNOWLEDGEMENT

We would like to express my sincere gratitude to the Principal, Head of the department, all teaching and non teaching staffs of Electronics and Communication department of TKMIT for their guidance and valuable suggestions for the successful completion of this paper.

Abstract: This paper presents the effect of Titanium oxide coating on the performance characteristics of the bio-diesel fuelled engine. The engine used was four strokes, single cylinder direct injected diesel engine. The engine was tested with diesel & at different proportionality of diesel with Honge bio-diesel and by varying torque without coating. Then, the piston head was coated with thermal barrier material. The layer of thermal coating was made of Alumina-Titanium oxide (Al_2O_3/TiO_2) plasma coated on to the base of NiCrAl. Then the coated piston was tested at the same operation conditions as the standard (without coating) engine. The results indicate a reduction in specific fuel consumption and an improved brake thermal efficiency for titanium oxide coated piston.

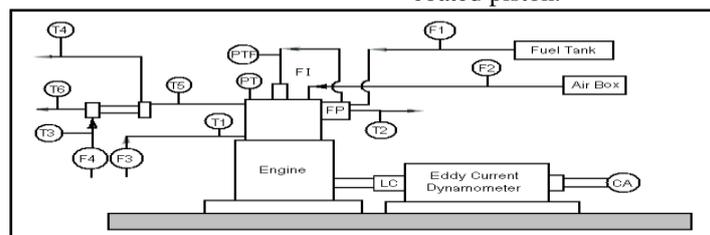

Keywords- Bio-diesel, Performance characteristics, Thermal barrier coating, Titanium Oxide

I. INTRODUCTION

Thermal barrier coatings have been apply to the internal combustion engine in particular the combustion chamber and cylinder lands to act as a low heat rejection engine, heat engine is improvement of their thermal efficiency. One of the methods to an engine is to cover the surface of the combustion chamber with a thermal barrier coatings, the thermal insulation obtained leads to an development of engines heat efficiency and a reduction in consumption. High temperature in the combustion can have a positive effect in diesel engines due to reduction in delay and hardness of engine operation, all though an increasing the emission of NO_x .

The resources of petroleum as fuel are dwindling day by day and increasing demand of fuels, as well as increasingly stringent regulations, pose a challenge to science and technology. With the commercialization of bioenergy (bio-diesel), it has provided an effective way to fight against the problem of petroleum scarce and the influence on environment. Bio-diesel can be used in diesel engine with little or no modification in the engine [1]. The properties of bio-diesels are not same as diesel as it is having high viscosity, high volatility and Low cetane number [2]. In order to improve the combustion, there should be minimum heat loss from the combustion chamber. Minimum heat loss can be achieved by coating thermally insulated materials to the surfaces of combustion chamber. Mohd.F.Shabir, P. Tamilporai, and B. Rajendra Prasath used low heat rejection engine by coating the piston crown, cylinder head inside with valves and cylinder liner with partially stabilized zirconia coating of 0.5 mm thickness [3]. Imdat Taymaz used thermally insulated material such as $CaZrO_3$ and $MgZrO_3$ for insulation of different surfaces of combustion chamber. An improvement of efficiency of 2-5% was observed [4]. Abdullah Uzun used $CaZrO_3$ on cylinder head and valves and $MgZrO_3$ on piston. Thermal efficiency was improved by 10% and reduction of CO emission was 35 to 40% [5].

The purpose of this study is to evaluate the brake thermal efficiency and brake specific fuel consumption at different loads with and without thermal barrier coating. The experiments were conducted with a single cylinder, four stroke and direct injected diesel engine. The results showed an increase in brake thermal efficiency, decrease in brake specific fuel consumption for titanium oxide coated piston.

II. EXPERIMENTAL WORK

A four stroke, direct injected single cylinder diesel engine was used for experimentation (Table 1). The schematic experimental set up is shown in Fig 1. Engine torque was measured by eddy current dynamometer. The engine has a conventional fuel injection system. A piezoelectric pressure transducer was mounted with cylinder head surface to measure the in cylinder pressure. It is also provided with temperature sensors for the measurement of jacket water, calorimeter water, and calorimeter exhaust gas inlet and outlet temperatures. An encoder is fixed for crank angle record. The signals from these sensors are interfaced with a computer to an engine indicator to display P-θ, P-V, mass fraction burnt and heat release versus crank angle plots. The provision is also made for the measurement of volumetric fuel flow. The built in program in the system calculates indicated power, brake power, thermal efficiency, volumetric efficiency and heat balance. The software package is fully configurable and averaged P-θ diagram, P-V plot and other diagram can be obtained for various operating conditions.

First, standard piston (without coating) was tested. The tests were performed at different loads and for diesel and different proportionality of diesel with Honge bio-diesel (i.e. B10, B20 and B30) for a compression ratio of 17.5:1 and injection pressure of 200 bar.

Then the Piston head was coated with thermal barrier material. The piston head was coated with a 150µm Alumina-Titanium oxide (Al₂O₃/TiO₂) plasma coated on to the base of 60µm NiCrAl. Then the coated piston was tested at the same operation conditions as the standard (without coating) piston.

TABLE 1: ENGINE SPECIFICATION

SL NO	ENGINE PARAMETERS	SPECIFICATION
01	Engine Type	TV1(Kirloskar)
02	Number of cylinders	Single Cylinder
03	Number of strokes	Four-Stroke
04	Rated power	5.2KW (7 HP) @1500RPM
05	Bore	87.5mm
06	Stroke	110mm
07	Cubic Capacity	661cc
08	Compression ratio	17.5:1
09	Rated Speed	1500 RPM

III. RESULTS AND DISCUSSION

3.1 Brake thermal efficiency:

The comparison charts for brake thermal efficiency with respect to brake power for coated piston and base piston for diesel and various biodiesel blends are plotted as shown in figures 2 to 5.

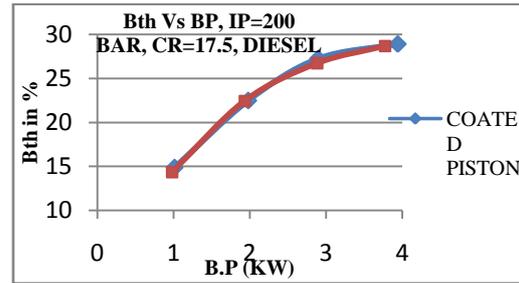

FIG 2: Bth Vs B.P for Diesel

Fig 2 shows the variation of Bth with Brake power for Diesel for coated piston and base piston. We can see that as the load increases the Bth also increases. In the above fig we don't find much difference only a slight increase in the Bth for the coated piston. This is because of the titanium oxide which acts as catalyst to enhance the combustion and also due to the thermal barrier coating which heat transfer. And hence the Bth of the coated piston is better than base piston.

Fig 3 shows the variation of Bth with Brake power for H10 (i.e. 10% Honge+ 90% Diesel) for coated piston and base piston. We can observe from the graph that the Bth of the coated piston is high when compared to standard piston. Maximum efficiency was found to be around 27% at high load for coated piston.

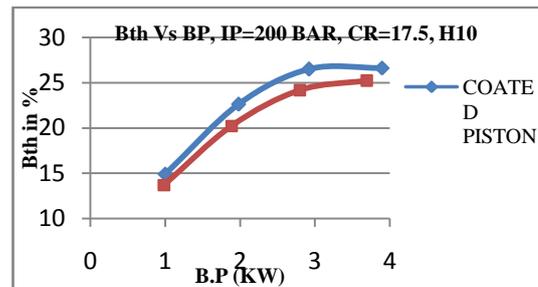

FIG 3: Bth Vs B.P for H10

Fig 4 shows the variation of Bth with Brake power for H20 (i.e. 20% Honge + 80% Diesel) for coated piston and base piston. From the graph we can see that the Brake thermal efficiency of the coated piston is high. Maximum efficiency was found to be around 28% at high load for coated piston.

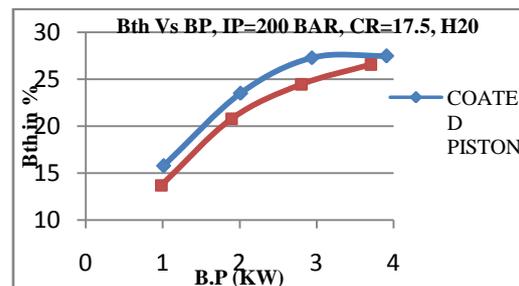

FIG 4: Bth Vs B.P for H20

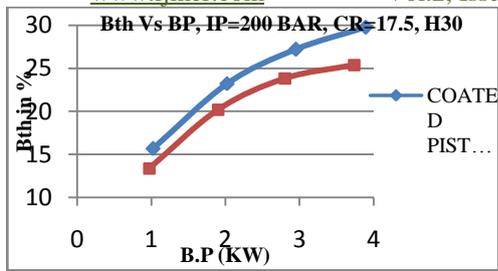

FIG 5: Bth Vs B.P for H30

Fig 5 shows the variation of Bth Vs B.P for H30 (i.e. 30% Honge+70% Diesel) for coated piston and base piston. In fig 5 we can see that the Bth for coated piston is high.

FIG 2 to 5 shows the variation of Brake thermal efficiency with Brake Power for Diesel, H10, H20 and H30 for coated piston and base piston. It is observed from all the above graphs that the Bth for coated piston for all fuels is high. This may be due to the high temperature in the combustion chamber due to the thermal resistance of the coated piston where heat loss is minimal. It may be also because of percentage of titanium oxide which acts as catalyst to enhance the combustion and hence efficiency of coated piston is high for all the fuels.

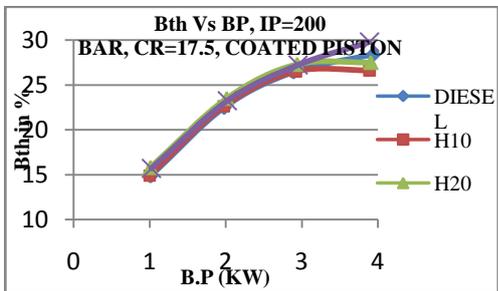

FIG 6: Bth Vs BP for Coated Piston

Fig 6 shows the variation of the Bth with Brake Power for coated piston for different fuels. It is observed from the graph that we don't find much difference only slight variation in the Bth for H30 than the other biodiesel blends and pure diesel. Only at high loads we can find the clear difference. This is because of the increased oxygen content in H30 fuel which accounts for better combustion and also due to decrease in fuel consumption. It may be also because of high temperature reached in combustion chamber due to minimal heat loss which accounts for better combustion.

3.2 Brake Specific Fuel Consumption:

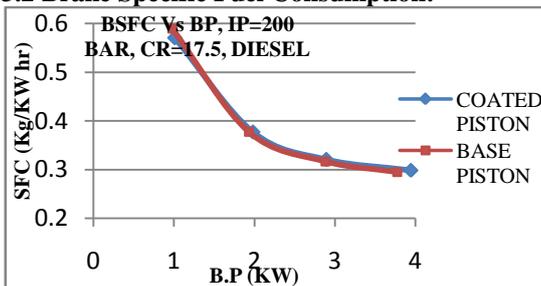

FIG 7: BSFC Vs BP for Diesel

Fig 7 shows the graph of B.S.F.C Vs B.P for coated pistons and base piston for Diesel fuel. In the

graph we don't find much difference between the SFC of coated piston and base piston for diesel.

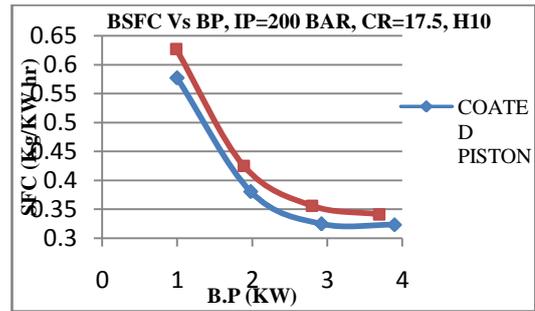

FIG 8: BSFC Vs BP for H10

Fig 8 shows the graph of B.S.F.C Vs B.P for coated piston and base piston for H10 fuel. In the graph we can see that the SFC for coated piston is low when compared to base piston.

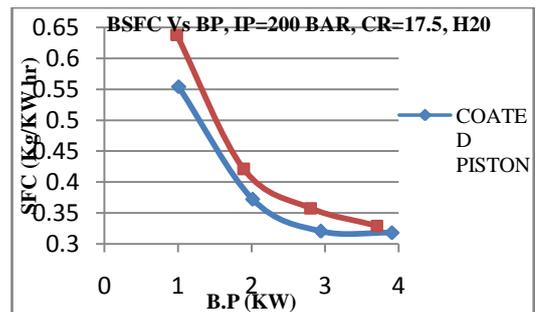

FIG 9: BSFC Vs BP for H20

Fig 9 shows the graph of B.S.F.C Vs B.P for coated pistons and base piston for H20 fuel. In the graph we observe that the SFC for coated piston is less than that of the base piston.

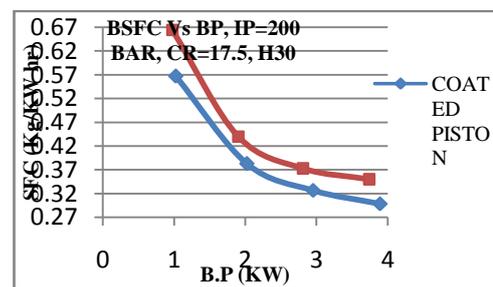

FIG 10: BSFC Vs BP for H30

Fig 10 shows the graph of B.S.F.C Vs B.P for coated piston and base piston for H30 fuel. In the graph we see that the SFC for coated piston is low than the base piston.

FIG 7 to 10 shows the variation of Brake specific fuel consumption with Brake Power for Diesel, H10, H20 and H30. We can observe from the above graphs that the S.F.C for coated piston for all the fuels is low when compared to base piston. This is because of better combustion of the fuel due to high temperature in combustion chamber because of thermal resistant due to the coated material and also due to composition of titanium oxide which acts as catalyst to enhance combustion and thus reduces the fuel consumption for titanium oxide coated piston.

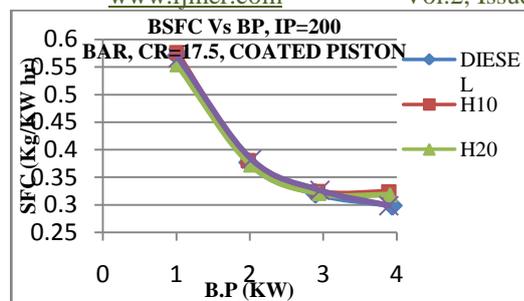

FIG 11: BSFC Vs BP for Coated Piston

Fig 11 shows the variation of B.S.F.C with B.P for coated piston for different fuels. We can't find much difference only a slight variation can be observed from the graph that the S.F.C for H20 gives good result but at high load H30 gives good result for coated piston.

IV. CONCLUSION

Experimental investigations of the effect of the titanium oxide coating on performance characteristics was conducted on single cylinder, 4 stroke, direct injected, constant speed diesel engine. Tests were conducted for the base piston and coated piston for different loads and compression ratio of 17.5 and injection pressure of 200 bar. The major conclusions drawn from these experiments are as follows:

1. The Brake thermal efficiency of the coated piston is increased when compared to base piston. Also biodiesel H30 giving higher thermal efficiency when compared to other biodiesel blends and pure diesel.
2. The Specific fuel consumption is lower for the coated piston when compared to base piston. Biodiesel blend H30 at high loads and blend H20 giving better results at low loads.

A method for signalling block-adaptive quantization in baseline sequential JPEG

B. Aruna¹, Ch. Ramesh²

¹(M.Tech) AITAM (INDIA)

²(Professor) AITAM (INDIA)

Abstract: The traditional JPEG compression standard doesn't have a means for spatially-variable quantization of transform coefficients. This prevents important features such as region-of-interest (ROI) coding. In this paper, we show how the quantization may be adapted in each block and how we may signal to the decoder in a memory-efficient manner. This allows ROI coding of subject and background. The method takes advantage of unused slots in the Huffman tables. In this paper we show how the encoder may be modified to produce an output that is in compliant with the standard and how the decoder may be modified to correctly recover the adaptively quantized image. Also we show how to use adaptive quantization as a means to perform spatially adaptive filtering of the image.

I. Introduction

The JPEG standard [1], relies on method of separating an image into chrominance and luminance color planes, each plane is partitioned into 8×8 blocks and which are compressed using quantization of discrete cosine transform (DCT) coefficients. The compression is achieved by applying the quantization (Q) matrix, to each set of DCT coefficients. The Q matrix may be varied from image to image and also different Q matrices may be used for the luminance and chrominance color planes. However, the Q matrix must not change within a color plane, i.e., spatially-variable quantization is not allowed in JPEG. This prevents the encoder from varying the quantization within an image or quantizing subject information and background information in image separately to achieve ROI coding and also to get desired output file size. These important features are not available in JPEG standard. If we implement these features in baseline JPEG, then it would lead to useful and significant changes in old JPEG standard.

In this paper we demonstrated a method, of varying the quantization matrix from block to block, and described the signaling of adaptive quantization to the decoder in a way that is compliant with the JPEG standard. To recover the exact image by Adaptive quantization, the decoder should vary the Q matrix exactly as the encoder, over the image. After Adaptive Quantization the encoder must signal to the decoder on each block which Q matrix that it used, also the signalling must be compliant with the JPEG standard if any "standard" decoder is able to process the adaptively-quantized image. Huffman table in JPEG standard has few unused slots for end-of-block(EOB) symbols. Our method has taken advantage of those unused slots for end-of-block (EOB) symbols in the Huffman table. This allow us to signal up to 14 different levels of quantization within a color plane. standard decoder treats all 14 EOB symbols as the same. However, to recover image that is Adaptively Quantized we need to modify the decoder in a way that it recognizes the EOB symbol and modify the

decoding Q matrix appropriately. The modification demonstrated below is simple. There is no need for the encoder or the decoder to keep more than one block in memory at a time, as the EOB symbols by definition come as the end of a 8×8 block, This important factor plays a crucial role in hardware design of encoders and decoders, as memory consumes a large amount of chip area in embedded cameras. Adaptive quantization within JPEG has been a subject of interest since it was published. Different methods for signalling the adaptation have been proposed. one method searches up to 64 coefficients in a 8×8 block to find the coefficient whose quantized value, whose fractional portion, is closest to 0.5, for example, a fractional value of 10.499 may be rounded to either 10 or 11 approximately with the same error. Sum of quantized coefficients can be made either even or odd by rounding up or down, and the parity of the sum therefore becomes a method of signalling one of two possible Q matrices to the decoder. However, the scheme requires a search to be carried out prior to quantization, and does not extend to more than two Q matrices which might not help in all cases. [5][11]. Since the JPEG standard allows any number of color planes to be stored in the output file, Pennebaker [2] proposed to use an extra "color" plane whose purpose is to contain a spatial map of how the quantization matrices are varied but this requires that the decoder reads more than one color plane at a time to vary the Q matrix appropriately. Few other methods use rate-distortion based thresholding of DCT coefficients. These proposed methods are not suitable for embedded applications. In this paper we show how previously unused slots in the baseline JPEG Huffman table may be used to signal Q matrix adaptation. This allow us to signal up to 14 different EOB codes to be used on each block. In this paper we described the method to construct the Huffman codes to efficiently encode the adaptively-quantized image. We also show how it is compatible with the baseline sequential JPEG standard, so that any standard decoder may decode the adaptively quantized image.

II. Background

Baseline sequential and progressive are two compression formats available in JPEG. The baseline format stores the full resolution of the image in a single sequential scan and it is universally adopted on the other hand progressive format stores several scans of the image. In progressive format each scan has increased resolution over the previous scan. Progressive JPEG is not widely used. In JPEG standard Huffman table is designed to accommodate both progressive and baseline sequential formats. This nature allow us to modify the feature of progressive format to allow signalling of adaptive quantization in baseline sequential format. The below method describes the

operation of baseline sequential JPEG compression of a color image.

- 1) The image is converted from RGB to YCbCr, usually followed by sub-sampling of the Cb, Cr planes.
- 2) Each of the Y, Cb, Cr planes are partitioned into blocks of size 8×8 .
- 3) The DCT of each 8×8 block is calculated. Let $x(i, j)$ denote the (i, j) -th pixel in block, and $X(u, v)$ the (u, v) -th frequency in the DCT and $X(1, 1)$ is the "DC" coefficient, and remaining are "AC" coefficients. The quantization of DCT coefficients using a 8×8 matrix Q as follows:

$$X_Q(u, v) = \text{round} \left\{ \frac{X(u, v)}{Q(u, v)} \right\} \quad u, v = 1, \dots, 8. \quad \dots(1)$$

Y, Cb, Cr planes may have different Q matrices but they do not vary spatially.

- 4) The quantized block X_Q is scanned in "zig-zag" order. DC value of the previously coded block is subtracted from the quantized DC coefficient and then it is stored. The scan of AC coefficients is stored in (R, S) format, where R is the number of consecutive zeros followed by the non-negative value S indicating the size of the next non-zero value. If V is the value of the quantized coefficient, then $S = \log_2[|V|] + 1$... (2)

Here $[.]$ is the floor function also two special symbols are also allowed

- 1). a ZRL symbol represents a run of 16 consecutive zeros.
- 2). EOB symbol indicates and represent that all subsequent coefficients in the scan are zero.
- 5) Each scan is Huffman coded, where AC coefficients are organized as a 16×11 structure in the Huffman table. This structure is designed to accommodate 16 different R values and 11 values of S. This structure is shown in table I. The Huffman code for each (R, S) pair in a scan is emitted, followed by S additional bits to indicate the actual value of the coefficient.

 HUFFMAN TABLE LAYOUT FOR AC COEFFICIENTS IN BASELINE SEQUENTIAL MODE. ENTRIES MARKED "X" CONTAIN CODES FOR OTHER VALUES.

R \ S	0	1	2	...	9	10
0	EOB	x	x	x	x	x
1	Not used	x	x	x	x	x
⋮	Not used	x	x	x	x	x
14	Not used	x	x	x	x	x
15	ZRL	x	x	x	x	x

From Table I slot for $R = 0, S = 0$ is used for the EOB symbol, while $R = 15, S = 0$ indicates 15 consecutive zeros followed by a size 0 (ZRL symbol) but the slots for $S = 0$ and $R = 1$ to 14 are reserved for the progressive format and are not used in baseline sequential format. We utilized those unused slots for signalling adaptive quantization to decoder thus making it JPEG standard-compliant..

In JPEG standard if $S = 0$ and $R = 15$ then 16 consecutive zeros are appended to the zig-zag scan in reconstruction. Otherwise the symbol is treated an EOB. all slots in Table I with $S = 0$ and $R < 15$ are considered to be the same EOB symbol. Therefore, additional codes for different conditions may adopted by using the 14 unused slots in Table I.

III. Quantization

In the Quantization, The Q matrix is fixed across the color plane. This limits the possibilities of ROI coding. We have overcome the limitation by signalling to the decoder with proper EOB codes exploiting the unused slots in Huffman table, to say which Q was used. But if we use a standard decoder then it dequantizes an input block with a improper Q matrix. Suppose that the DCT of an 8×8 block, $X(u, v), 1 \leq u, v \leq 8$, is quantized at the encoder using matrix Q as in eq.(1). At the decoder, the quantized matrix X_Q is used to reconstruct the DCT matrix X using the equation

$$\hat{x}(u, v) = Q(u, v)X_Q(u, v), \quad u, v = 1, \dots, 8. \quad \dots(3)$$

\hat{x} will not the same as X due to rounding. If we let $P = \alpha Q$, where α is a scale factor, then the effect of dequantizing X_Q with P instead of Q is as follows:

$$\begin{aligned} \tilde{X} &= P(u, v)X_Q(u, v) \\ &= \alpha Q(u, v) \text{round} \left\{ \frac{X(u, v)}{Q(u, v)} \right\} \\ &= \alpha X(u, v) + \alpha \text{Eq}(u, v) \end{aligned} \quad \dots(4)$$

where $\text{Eq} = Q \text{round}\{X_Q/Q\} - X$ is the quantization error introduced by rounding.

If we apply $P = \alpha Q$, we can see that scaling factor is same for every element instead if we choose $P = H \circ Q$, where \circ denotes the elementwise product of H and Q. Here H acts as filtering matrix.

$$\tilde{x}(u, v) = H(u, v)X(u, v) + H(u, v)\text{Eq}(u, v) \quad \dots(5)$$

we see that dequantization with $H \circ Q$ is equivalent to filtering by H in the DCT domain ignoring the noise term. We may therefore use adaptive quantization as a means to perform spatially adaptive filtering of the image.

A. DC coding and Prediction

Adaptive quantization is the dependent on adjacent blocks,. After quantization, the DC coefficient in baseline sequential JPEG is treated separately from the 63 AC coefficients. The DC coefficient is a measure of the average value of the 64 image samples. Because there is usually strong correlation between the DC coefficients of adjacent 8×8 blocks, the quantized DC coefficient is encoded as the difference from the DC term of the previous block in the encoding order as shown in Figure 3. This may lead to complications. If adaptive quantization is used, prediction will accumulate error when the DC coefficient is dequantized differently than it was quantized. The DC coefficient is unique in this respect: all other coefficients in a block are coded independently of adjacent blocks and therefore varying the Q matrix has no effect. We therefore constrain the quantization change matrix H discussed above so that $H(1, 1) = 1$, which ensures that $eX(1, 1) = X(1, 1) + \text{Eq}(1, 1)$.

B. Reduction of artifacts

Adaptive quantization may be applied to remove few JPEG compression artifacts:

- 1) visible boundaries between 8×8 blocks
- 2) ringing around edges (Gibbs phenomenon) .

For example we may apply a "larger" matrix Q2 for edge blocks and "smaller" matrix Q1 for smooth blocks,.we can determine smooth vs edge blocks by observing the occurrence of last non-zero coefficient early or late in a zig-

zag scan compared to a threshold. From above we get $Q2(u, v) > Q1(u, v)$.

IV. Huffman Table Modification

we must modify the entire Huffman codebook to allow for unique decoding . this allow us to use the empty slots in the Huffman table to signal adaptive quantization to the decoder. One method is to substitute a Huffman table for progressive coding in place of the baseline table. This allows us to signal 15 different Q matrices to the decoder. Standard progressive table is shown in Table II. We may or may not use all the empty slots , so we can design Huffman table to support fewer EOB codes.

TABLE II
 HUFFMAN TABLE LAYOUT FOR PROGRESSIVE ENCODING

R \ S	0	1	2	...	9	10
0	EOB0	x	x	x	x	x
1	EOB1	x	x	x	x	x
⋮	⋮	x	x	x	x	x
14	EOB14	x	x	x	x	x
15	ZRL	x	x	x	x	x

V. EXPERIMENTAL RESULTS

We used the EOB signalling method to apply adaptive quantization on gray scale image. We used two levels of quantization on the luminance (Y) component of the image.MATLAB was used as the programming platform.

VI. Conclusion

In this paper, we demonstrated a simple method for signalling adaptive quantization to the decoder, using the empty slots in standard baseline Huffman table. The proposed method is efficient as encoder and decoder do not require to keep more than one block in memory at a time. A standard decoder will treat all EOB codes as the same, and if adaptive quantization is performed, will perform frequency-domain filtering upon dequantization. This is useful for ROI coding. which has the advantage of improving image quality in selected regions.

Determination of the test frequency causing significant hearing loss of the mine workers of an open cast chromite mine

Kerketta S.¹, Gartia R.², Bagh S.²

¹Ministry of Environment and Forests, ERO, Bhubaneswar, Odisha – 751 023, India, ²Statistics Department, Sambalpur University, Odisha – 768 019, India

Abstract: In this paper an attempt has been made to estimate the hearing loss of workmen (subjects) in an open cast chromite mines with respect to age, working experience and work stations. The study reveals that there is a significant difference among the different test frequencies with respect to hearing loss on both the ears of the subjects. The test frequency 4 kHz is found to be the most influencing frequency causing significant hearing loss on the right ear of the workmen due to age, work experience and work stations. While the test frequency, 6 kHz is found to be the most influential frequency causing significant hearing loss on the left ear of the subjects due to age and work station. Moreover, there is no significant difference of hearing loss exhibited to the subjects on both ears at test frequency of 4 kHz due to work experience.

Keywords: Asymmetry hearing loss, high fence, noise induced hearing loss.

I. Introduction

Exposure to excessive noise is a major cause of hearing disorders worldwide, 16% of the disabling loss in adults is attributed to occupational noise [1-4]. Excessive noise can damage several cell types in the ear and lead to tinnitus, temporary or permanent hearing loss. Noise induced hearing loss is a sensory neural hearing loss as a result of chronic exposure to excessive sound [5] over a long period of time. A review of the earlier works reveals that many attempts have been made to evaluate the noise generation due to transportation [6,7] and aircrafts [8,9] and its annoyance [10-12] to the people living nearby. Similarly, investigation of different noise sources and its noise levels has also been made in the Gold mines [13], Stone quarry [14], Textile mills [15], Coal mines [16], Bauxite mines [17], Power plants [18] and Steel plants [19]. There are many environmental factors [20] which affect hearing [21] sensitivity, but hearing loss [22,23] is mainly associated with age [24,25], exposure [26] to different noise sources and working at different stations [27,28] and the hearing loss has been evaluated systematically for claiming compensation [29,30] by the workmen.

Therefore, this paper aimed to estimate the hearing loss at 4, 6 and 8 KHz (this frequency range henceforth be referred as high fence) of the subjects based on their age, working experience and working areas of a chromite mine. Audiometry data from 2002 to 2008 of 500 subjects have been used to estimate the hearing loss. The study also sought to find the most influential test frequency which causes the hearing loss significantly with respect to age, experience and work stations of the subjects.

II. Materials and Methods

2.1 Study Area

The mine site in the Sukinda valley is located in the Jajpur district in the state of Odisha, India. The mine produces chromite ore of both friable and lumpy varieties with a chrome ore beneficiation (COB) plant at the mine site. The mine is 130 km from Bhubaneswar, the state capital of Orissa, 65 km from NH-5 and 52 km from JK Road, the nearest railway station.

2.2 Study Design

A cross sectional study of hearing threshold of the mine workers of a chromite mine was carried out with the aim of gaining insight into factor associated with hearing loss. The audiometric data of 500 mine workers were taken from the records of the hospital at the mine. The subjects were included in the study having audiometry data at 0.5, 1, 2, 4, 6 and 8 KHz frequency for the period 2002 to 2008. Such audiometry data of all the mine workers were considered in the statistical analysis and if completed data of some subjects were not available from the hospital records than those subjects have been excluded in the design study. Since, the shift and duration of work hours affect noise exposure level, monitoring of noise level was performed in the mine site, inside the cabin and 7 m away from the Heavy Earth Moving Machineries (HEMMs) and also at different ambient locations from 7 AM to 10 PM to know the noise levels in these areas. The study period for monitoring of noise levels at different locations was from 2008 to 2010. Though, the period of audiometry data and that of monitoring of noise levels are not same, but the present study estimated the noise levels at different locations to know the likely exposure of noise by all subjects.

2.3 Audiometry Test

Screening audiometry was carried out by an audiometer (6025A of TRIVENI TAM-25 make) in a quiet environment by qualified technicians, audiologists, or physicians. The frequency range of the pure tone for air conduction measurement is 250 Hz to 8 KHz. The range of masking intensity is 0 to 100 dB having attenuator in steps of 5 dB. The 3% is the frequency accuracy of the instrument and that of hearing level of the instrument is 2 dB. Tests were conducted on the workers after a complete rest of 16 hours or more from their day shift. Audiometric air conduction tests were performed by presenting a pure tone to the ear through an earphone and threshold of hearing (dB) was recorded at which this tone was

perceived 50% of the time. The better ear was first tested at 1 kHz and then at 2, 4, 6, 8 and 0.5 kHz in that order. Retest was done at 1 kHz in the first ear. In case, the test value was more than 5 dB or more acute than the original, a retest was done at the next frequency and so on. Audiometry tests were conducted in the opposite ear in the same manner except for retesting at 1 kHz. The duration of the presented tone was between 1-3 seconds. The same duration was maintained between the tones. The total time taken to perform the audiometry test of one subject was 3-5 minutes.

2.4 Noise Measurements

A digital sound level meter from M & K, Denmark (Bruel & Kjaer) was used throughout the entire noise survey. The accuracy of the frequency weighting of the instrument meets IEC 651 Type 2 which represents sound level meters suitable for general field applications. The measuring range is 25 to 130 dBA. The wide measurement range allows the instrument to be used for a diverse range of noise investigation where both high and low sound levels occur. Great care was taken to retain a distance between the instrument and the surrounding areas or any obstacles that could intensify or reduce the received noise. In this present study, the sound level meter was placed on rigid stand at 1.2 to 1.5 m above the ground surface, and 6 m away from the road side or 7 m away from the HEMMs, avoiding obstacles or reflecting objects. The air temperature varied between 19.38 and 34.31 °C and the wind velocity was less than 1.02 m/s. Measurements were taken in conditions of clear sky and a sustained wind to avoid any background noise level differences that were greater than 10 dBA.

2.5 Ambient Noise

To know the present noise situation in the mining areas, in the ambient and inside the cabin and 7 m away from the HEMMs, a systematic noise monitoring was performed in summer (June 2008) and in winter (November 2009) between 7 AM to 10 PM. However, for blasting operation noise survey was carried out for three consecutive days in April, 2010 and half an hour before and after the blasting operations at 100 m away from the blasting site. A time gap of 60 s was observed between two readings during the first monitoring and 15 s during second and third noise survey. The working areas of all the subjects (500) have been divided into four groups such as work zone, industrial area, commercial area, residential area and silence zone based on the administrative records as exhibited in Tables 1 (a & b). The minimum and maximum equivalent noise levels (L_{eq}) surveyed in these areas have also been shown to know the likely exposure of each category of subjects. The equivalent noise level, L_{eq} over a particular monitoring time has been estimated using the following equation:

$$L_{eq} = 10 \log_{10} \sum 10^{L_i/10}$$

Where

- L_i = the i^{th} sound pressure level, dBA
- i = 1, 2, 3, …, N
- N = number of readings of a particular parameter

Tables 1 (a & b) show that the maximum L_{eq} levels at commercial area and minimum L_{eq} levels at residential area and silence zone exceeded the prescribed limits. Similarly, the maximum noise levels in case of large and medium HEMMs and also at the Operator’s positions of the HEMMs was found to be even more than danger limit of 90 dBA.

In the present study, audiometric data of 500 subjects (481 males and 19 females) have been taken for the period 2002 to 2008 of an open cast chromite mining complex in Sukinda area in the state of Odisha (India). As the hearing loss of a subject begins at 4, 6 and 8 KHZ frequency, the retrospective data have been used to estimate the possibility of a dip or notch at these frequencies due to exposure to different levels of noise by the subjects. The subjects were divided into 4 age groups, 8 experience groups and 5 work stations as depicted in the Table 1(c). It has been seen that the minimum age of the group is 29 years and maximum age is 59 years. Similarly, 4 years is the minimum working experience and 37 years is the maximum working experience of the group. The Table 1(c) shows the descriptive statistics of the subjects for both the ears at different frequency levels. To meet the research objectives, the data so obtained are analyzed through SPSS (16.0) package under Window-XP environment. Generalized Linear Model ANOVA, Post hoc analysis, Gabriel Multiple comparison for mean difference and paired t-test were used as statistical tools to meet the objectives of the present study.

Table 1 (a): Area code, category of area, work settings and noise levels (dBA) in different areas

III. Statistical Analysis

Descriptive statistics on t-test (2-tailed) of the whole subjects at high fence (4, 6 and 8 kHz) has been shown in Table 2.

Table 2: t-test (2-tailed) of the whole subjects, n=500 at high fence

Ear	Mean Hearing Threshold (dB HL) at											
	4.0 kHz				6.0 kHz				8.0 kHz			
	Mean	SD	t-value	p	Mean	SD	t-value	p	Mean	SD	t-value	p
Right	21.37	7.33	0.347	>0.01	23.48	7.37	0.258	>0.01	22.38	8.43	0.814	>0.01
Left	21.54	7.42			23.36	7.80			21.95	8.67		

i) A two tailed t-test was performed for the whole subjects between the left and right ears at high fence by assuming the following hypothesis:

Null Hypothesis (H_0): The hearing threshold does not differ between left and right ears at high fence.

Alternate Hypothesis (H_1): The hearing threshold differs between left and right ears at high fence.

Since, $p > 0.01$, both the ears do not exhibit any significant hearing difference at 4, 6 and 8 kHz, the hypothesis is accepted at 1% level of significance. Thus, it can be concluded that asymmetric hearing loss may be attributed either in the left or the right ear at 4, 6 or 8 kHz.

Table 3: ANOVA for the hearing loss at high fence with different groups

Category	Mean Hearing Threshold Left Ear, dB HL			Mean Hearing Threshold Right Ear, dB HL		
	4 kHz	6 kHz	8 kHz	4 kHz	6 kHz	8 kHz
<u>Age (years)</u>

>35	29.38	30.00	29.38	30.00	29.38	28.75
p- value	<0.01	<0.01	<0.01	<0.01	<0.01	<0.01
<u>Work Stations</u>						
W	20.95	22.77	21.25	20.90	22.92	22.06
A	22.34	23.83	22.66	21.95	23.83	22.54
B	21.92	24.15	21.95	21.54	23.77	21.77
C	23.50	24.50	25.00	22.75	25.00	25.50
D	21.00	24.20	23.00	21.80	25.60	24.00
p- value	<0.01	<0.01	<0.01	<0.01	<0.01	<0.01

ii) To test if there exists any significant difference at the test frequency on both the ears of the subjects with respect to age, experience and work station.

ANOVA was performed to find out any significant difference in hearing loss in both the ears at high fence and the most influential frequency was determined by using Gabriel multiple comparison method. Table 3 shows the hearing loss of the subjects with respect to the different groups of age, experience and work stations. The following hypothesis has been assumed to carry out ANOVA test for different groups:

Null Hypothesis (H_0): Various groups of age, years of experience and Work stations are independent with regard to hearing loss for both the ears of the workers at high fence.

Alternate Hypothesis (H_1): Various groups of age, years of experience and Work stations are dependent with regard to hearing loss for both the ears of the workers at high fence.

Since, $p < 0.01$, various groups of age, years of experience and Work stations are dependent with regard to hearing loss for both the ears of the workers at high fence, the hypothesis is rejected at 1% level of significance.

iii) Post hoc analysis, Gabriel Multiple comparison for mean difference was used to find out the most influential frequency where a dip or notch is exhibited for different groups.

The Post hoc analysis was performed to find out the most significant frequency among all test frequencies. The results of the multiple comparisons of mean differences in hearing loss by Gabriel method at 4, 6, and 8 kHz have been depicted in Table 4.

iv) As the most significant frequency is 4 kHz for both right and left ears with respect to work experience, paired t-test was performed to evaluate any significant hearing difference of the group.

Null Hypothesis (H_0): There is no significant hearing threshold at 4 kHz in either ear due to work experience.

Alternate Hypothesis (H_1): There is significant hearing threshold at 4 kHz in either ear due to work experience.

Since, $p > 0.01$, so it may be inferred that there is no significant difference in hearing loss for both the ears at 4 kHz with 1% level of significance with respect to experience. Thus, concluded that there is no significant hearing loss in the experience group.

Table 4: Post doc analysis for Hearing Loss at high fence and with different groups

Frequency pair, kHz	Right Ear		Left Ear	
	Absolute Mean Difference	<i>p-value</i>	Absolute Mean Difference	<i>p-value</i>
<u>Age Group</u>				
8 and 6	0.8233	<0.01	0.9759	<0.01
8 and 4	1.0760	<0.01	0.5349	<0.01
6 and 4	1.8993	<0.01	1.5108	<0.01
<u>Experience Group</u>

IV. Results

The maximum L_{eq} levels at commercial area and minimum L_{eq} levels at residential area and silence zone exceeded the prescribed limits. Similarly, the maximum noise levels found to be even more than danger limit of 90 dBA for large and medium HEMMs and also at the Operator's positions of the HEMMs.

From Table 4, it is clear that the most significant frequencies with respect to the hearing loss of age are 4 and 6 kHz for the right and left ears, respectively at 1% level of significance. In case of experience groups, the most significant frequency is 4 kHz for both the ears at 1% level of significance. Similarly, the most significant frequencies are 4 and 6 kHz for the right and left ears, respectively, in respect of working stations at 1% level of significance. With paired t-test, p -value is found to be >0.01 and so it may be inferred that there is no significant difference in hearing loss for both the ears at 4 kHz with 1% level of significance with respect to experience.

V. Discussion

From Tables 1(a & b), it is found that the subjects are exposed to noise levels more than the prescribed standards those working at large, medium and inside the Cabins of HEMMs, Administrative Buildings, Weigh Bridge, Project and Construction Area, Airfield and Hospital.

The t-test reveals that there is no significant difference in hearing loss on both ears due to age, experience and various work stations at all test frequencies and thus, asymmetric hearing loss may be attributed in either ear. However, from ANOVA test, it is clear that there exists a significant difference among all the test frequencies with respect to hearing loss. The hearing loss is found to be not homogeneous i.e. it is dependent in respect of age, experience and working stations. In other words, hearing loss is increasing for every 10 years interval of age, for every 5 years of work experience and with different work stations at high fence. The most influential frequency with respect to age for the right and left ears are found to be at 4 and 6 kHz, respectively. In case of different working experience, 4 kHz is found to be the most influential frequency for both the ears. Similarly, 4 and 6 kHz are the most significant frequencies for right ear and left ear, respectively for the subjects working at different working areas. This asymmetry [31] hearing loss may be attributed to the presence of a subgroup (Operators of the Heavy Earth Moving Machineries) who generally exposed to higher noise level i.e., more acoustic energy of the sound reaching to the right ear [9,32,33] than to the left ear. It has also been found that though the cabin of the HEMMs is air conditioned, operator of the vehicle always keeps the door open for more comfort and easy drive. Therefore, the right ear is exposed outside and possible asymmetric hearing loss.

Since, the most significant frequency is 4 kHz for both right and left ears, paired t-test was performed to evaluate whether there is any significant difference between the right and left ears of the subjects with reference to experience. With paired t-test, p -value is found to be >0.01 and so it may be inferred that there is no significant difference in hearing loss for both the ears at 4 kHz with 1% level of significance with respect to experience.

The subjects, grouped in Sensitive Zone are mainly Staff Nurses, Hospital Attendants and Drivers working in the hospital and Arms Guards. The mean age of this group is found to be more than the mean age across all the subjects. Thus,

the hearing threshold may not be always noise-induced, it may be due to Presbycusis also. However, this group works in the hospital and is located near the mining complex and lot of loaded/empty dumpers and trucks ply through this area. Therefore, hearing loss of the subjects has been estimated for which one of the reasons of hearing loss may be attributed to the noise generation by heavy earth moving machineries including dumpers and trucks when plying everyday through this station.

VI. Recommendations

The following recommendations suggested to minimise exposure to different noise source and also to reduce hearing loss:

- i) The subjects whose hearing loss is found to be at 6 kHz, the working areas of the subjects should be changed to lesser noisy areas to reduce the exposure level.
- ii) Provisions for regular audiometry test of all the subjects should be conducted to identify the hearing loss of those subjects occurring at 6 kHz.
- iii) Periodic maintenance of all the HEMMs is essential to keep all the vehicles in good condition and less noisy.

VII. Conclusion

In our study population, the maximum noise levels for large and medium HEMMs and inside the cabin of HEMMs were found to be more than 95 dBA. Hearing loss is increasing for every 10 years interval of age, for every 5 years of work experience and with different work stations at high fence. Age and experience of subjects have significant difference with hearing loss at 4.0, 6.0 and 8.0 kHz. The study also reveals that there is a significant difference among the different test frequencies with respect to hearing loss on both the ears of the subjects. The test frequency 4 kHz is found to be the most influencing frequency causing significant hearing loss on the right ear of the workmen due to age, work experience and work stations. While the test frequency, 6 kHz is found to be the most influential frequency causing significant hearing loss on the left ear of the subjects due to age and work station. The characteristic frequency due to noise induced hearing loss is 4 kHz where a dip or notch occurs. In the present study also, this frequency is the most influential frequency among different groups of workmen and are the relatives of some of the general public. Therefore, the general public can participate in reducing the noise induced hearing loss of these workmen by advocating them the causes of hearing loss, sources of hearing loss and also how to reduce it by using hearing protective devices while at work.

ABSTRACT: In today's Fast growing commercial word Social network Websites (SNW) like FaceBook, Twitter etc, are the major source for maintain social communication, doing e-business. Now a day's dynamic data discovery is a part of it's activity for many organizations in banking sector, content providing sites and ecommerce websites. Interestingly on the other side we can see that most of the users are having more than one registration on social networks with two fold effect both positive and negative. Many students and young people are using these social networking websites for adolescents or to download some study materials, music etc^{10,11}, from different blogs. This leads to lot of fake user registrations⁷. Just receiving invitation to their emails, creates some of the user profiles and it pops the user data of the mail account. The profile created may not be correct and this was copied may lead to false or duplicate information on the network domain. This became a bitter problem to find many facts like user identity, number of users registered and visitors tracking etc. there by it leads to ambiguity. As one person may have more than one profile created by him intentionally or unknowingly generated by anyone way specified above. This became a common identification problem to every organization and most researchers are mainly concentrating on providing efficient techniques for linking of records. There are many solutions of this kind, to propose the best we are attempting to analysis and identify the optimization techniques with clustering and algorithms for fake user data discovery in SNW.

Keywords: Social network Web sites, social communication, PAN, query data base, cluster based analysis, SLINK, MST

I. INTRODUCTION

Record linkage for remote database is a commonly identified problem from many years, which is used to analyze remote data supporting a variety of decisions in different organizations. How ever, since heterogeneous databases are usually designed and managed-where all the records are available either locally or remote by the organizations. They can be accessed by using some common key like email address or PAN number etc.. Although it may be possible to use they would involve transferring the entire remote relation. As a matching data from various sources in a batch. The key question here is one of record. The databases exhibiting entity heterogeneity are distributed, and it is not possible to create and maintain a linkage: given a record in a local database (often called the central data repository or warehouse where pre computed enquiry record), how do we find records from a

remote linkage results can be stored. A centralized solution database that may match the enquiry record? Traditional maybe impractical for several reasons. First, if the record linkage techniques, however, are designed to link databases span several organizations, the ownership and cost allocation issues associated with the ware-house. Even if the warehouse could be developed, it would be difficult to keep it up-to-date. As updates occur at the operational databases, the linkage results would become stale, if they are not updated immediately. This staleness maybe unacceptable in many situations. The systems may agree to transmit incremental changes to the data warehouse on a real-time basis. Even if such an agreement is reached, it would be difficult to monitor and enforce it. The staleness of the linkage tables and limiting their usefulness due to certain overhead delays and time consuming due to many databases, each with many records, undergoing real-time changes. This is because the warehouse must maintain a linkage table for each pair of sites, and must update them every time for the associated databases changes.

. The participating system allows controlled sharing of portions of their databases using standard database queries, but they do not allow the processing of scripts, stored procedures, or other application programs from another organization. Here our intention is not to discuss on ability of existing systems but to suggest a system that is more efficient for record linkage with clustering and MST.

1.1 INITIATION

When I am searching for one popular personality on twitter, linked-in and FaceBook⁸. This situation Initiated me to concentrate on this work. In this work I identified problems like: (1) Identifying a person having more than one account (2) real active identity. These things encouraged me to identify a system that can determine user genuinely. And also I understood that most of the users are not in a position to readily available to project their correct information onto SNW and many youngsters may have more than one account for different purposes. So how do we get the exact user data? This gave a way to propose a solution of that kind where both the end users will be satisfied. As a part of this process I had come across many similar problems like e-banking, downloading e-books, ecommerce with SNW login etc^{11,12}, and understood that there is a need for better system to handle user data.

In the Data discovery process, cluster analysis has been used to create groups of documents with the goal of improving the efficiency and effectiveness of data retrieval. The terms in a document collection can also be clustered to show their relationships.

A recent review (Willett 1988) provides a comprehensive summary of research on term-based document clustering². Terms may be clustered on the basis of the documents in which they co-occur, in order to aid in the construction of a thesaurus or in the enhancement of queries (e.g., Crouch [1988]). If the collection to be clustered is a dynamic one, the requirements for update must be considered.

II. RELATED WORK

This paper consists of two parts where first part is addressing the efficiency and effectiveness of data retrieval using database re ranking based on cluster analysis, and then algorithm best fit to implement the system and finally results base on the system implemented to check the feasibility.

2.1 MATHEMATICAL APPROACHES

In this part, my approach is to identify and avoid fake users on social network by 1.) Database re-ranking based on cluster analysis¹ and 2. Record linkage with Slink.

As the degree of matching of evidences in data bases is higher, the two database entries are more similar. In database clustering, databases with similar entries or more likely are classified as one cluster⁴. Therefore, relevant db table entries are in the same cluster according to the cluster hypothesis (van Rijsbergen) which states that relevant documents tend to be more similar to each other than to non-relevant documents.

The documents in a cluster have effect on cluster centroid. The cluster centroid for a pair of clusters Ci and Cj is given by:

$$\frac{m_i C_i + m_j C_j}{m_i + m_j}$$

where m is the size of a cluster.

The same query-cluster similarity value is applied to all the database tables in the cluster at the re-ranking stage. In this way, the databases in a cluster can affect one another through calculation of cluster centroids so that context retrieval is possible, due to the interaction of evidences contained in databases.

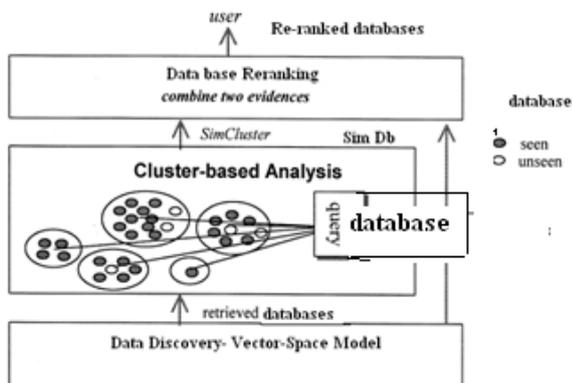

Fig 1. Clustering based data base re-ranking

In record linkage process the single link method merges at each stage the closest previously unlinked pair of points (here records) in the data set. Since the distance between two clusters is defined as the distance between the closest pair of records each of which is in one of the two clusters, no cluster centroid or representative is required, and there is no need to recalculate the similarity matrix

during processing. This shows how clustering efficiency. So that this makes the method more attractive for non redundant computation⁴ and a storage perspective wise. Database re ranking avoid similar entries in the clusters and Slink will improves record linkage of data discovery process in Vector Space model.

A number of algorithms for the single link method have been reviewed by Rohlf (1982), including related minimal spanning tree algorithms. The computational requirements range from $O(N \log N)$ to $O(N^2)$. Many of these algorithms are not suitable for information retrieval applications where the data sets have large N and high dimensionality.

2.2 ALGORITHMIC APPROACH

2.2.1. VAN RIJSBERGEN ALGORITHM

Van Rijsbergen (1971) developed an algorithm⁵ to generate the single link hierarchy that allowed the similarity values to be presented in any order and therefore did not require the storage of the similarity matrix. It is $O(N^2)$ in time and $O(N)$ in storage requirements. It generates the hierarchy in the form of a data structure that both facilitates searching and is easily updated, and was the first to be applied to a relatively large collection of 11,613 documents (Croft 1977).

2.2.2 SLINK ALGORITHM⁵

The SLINK algorithm (Sibson 1973) is optimally efficient, $O(N^2)$ for computation and $O(N)$ for time, and therefore suitable for large data sets. It is simply a sequence of operations by which a representation of the single link hierarchy can be recursively updated; the dendrogram is built by inserting one point at a time into the representation. The hierarchy is generated in a form known as the pointer representation, which consists of two functions Π and Δ for a data set numbered 1..N, with the following conditions:

- $\Pi(N) = N$
- $\Pi(i) > i$
- $\Delta(N) = \infty$
- $\Delta(\Pi(i)) > \Delta(i)$ for $i < N$

In simple terms, $\Delta(i)$ is the lowest level (distance or dissimilarity) at which i is no longer the last (i.e., the highest numbered) object in its cluster, and $\Pi(i)$ is the last object in the cluster it joins at this level; a mathematical definition for these parameters is provided by Sibson (1973).

In the pseudo code for SLINK below, three arrays of dimension N are used: *ptr* (to hold the pointer representation), *dp* (to hold the distance value associated with each pointer), and *distance* d (to process the current row of the distance matrix); *next* indicates the current pointer for a point being examined.

```
ptr [0] = 0;
dp[0] = MAXINT;
/*iteratively add the remaining N-1 points to the hierarchy
*/
for (i = 1; i < N; i++)
{ ptr [i] = i; dp[i] = MAXINT;
/* calculate and store a row of the dist_matrix for i */
for (j = 0; j < i-1; j++) d[j] = calc_distance(i,j);
for (j = 0; j < i-1; j++)
{ next = ptr[j];
```

```

if (dp[j] < d[j])
d[next] = min(d[next],d[j]);
else
{ d[next] = min(dp[j],d[next]);
ptr[j] = i;dp[j] = d[j];}
/* relabel clusters if necessary */
for (j = 0; j < i-1; j++)
{ next = ptr [j];
if (dp[next] < dp [j])
ptr[j] = i;
}}

```

For output in the form of a dendrogram, the pointer representation can be converted into the *packed representation*. This can be accomplished in $O(N^2)$ time (with a small coefficient for N^2) and $O(N)$ space.

2.2.3 MINIMAL SPANNING TREE ALGORITHM

Another attempt is with an MST. A minimal spanning tree (MST) which is a sub graph (known as tree here) generated from the given graph linking N objects with $N - 1$ connections without any cycles and the sum of the $N - 1$ dissimilarities is minimized. It can be shown that all the information required to generate a single link hierarchy for a set of points is contained in their MST (Gower and Ross 1969). Once an MST has been constructed, the corresponding single link hierarchy can be generated in $O(N^2)$ operations; or the data structures for the MST can be modified so that the hierarchy can be built simultaneously (Rohlf 1982).

The Prim-Dijkstra algorithm⁵ (Dijkstra 1976) consists of a single application of principle 1, followed by $N - 1$ iterations of principle 2, so that the MST is grown by enlarging a single Cluster: Let records unique values (record key) are taken as points for MST.

1. Place an arbitrary record in the MST and connect its nearest neighbor to it.
2. Cluster will grow in size by finding the record not in the MST, closest to any record in the MST and add it to the cluster.
3. If a record remains that is not in the cluster, return to step 2.

Prim-Dijkstra algorithm is provided by Whitney (1972). The algorithm here uses arrays *npoint* and *ndistance* to hold information on the nearest in-tree neighbor for each record, and *notintree* is a list of the *nt* unconnected records. *Lastestpt* is the latest record added to the tree.

```

/* initialize lists */
/*define infinity =9999 */
for (i = 0; i < n; i++)
{ ndistance[i] = infinity; notintree[i] = i;}
/* arbitrarily place the Nth point in the MST */
latestpt = n; nt = n-1;
/* grow the tree an object at a time */
for (i = 0; i < n-1; i++)
{
/*consider the latestpt in the tree for the NN list */
for (j = 0; j < nt; j++)
{ D = calculate_distance(latestpt, notintree[j]);
if (D < ndistance[j])
{ npoint[j] = latestpt;
ndistance[j] = D; } }
/* find the unconnected point closest to a point in the tree */
*/

```

```

nj = index_of_min(ndistance);
/* add this point to the MST; store this point and their
clustering level */
lastpoint = notintree[nj];
store_in_MST ( lastpoint, npoint[nj], ndistance[nj]);
/* remove lastpoint from notintree list; */
/* close up npoint and ndistance lists */
notintree[nj] = nt;
npoint[nj] = npoint[nt];
ndistance[nj] = ndistance[nt];
nt = nt - 1; } }

```

2.3 PROPOSED SYSTEM

The clustering architecture was designed and implemented with an assumption that it will be invoked, when a user creates a registration on the SNW it automatically starts monitoring user inputs by giving initial ranking and maintains a dataset at a **query database** as a pivotal elements like PAN, Adhar card and Driving license which are issued by government departments and had a unique id number., once the data is inserted it considers the PAN number or email-ID and mobile number as set of keys to identify the user and data is mined from different databases available on internet and they are maintained as different clusters. Finally the query database is re ranked done using cluster analysis which is show in fig 1.

III. RESULTS

After the user gets registered in SNW

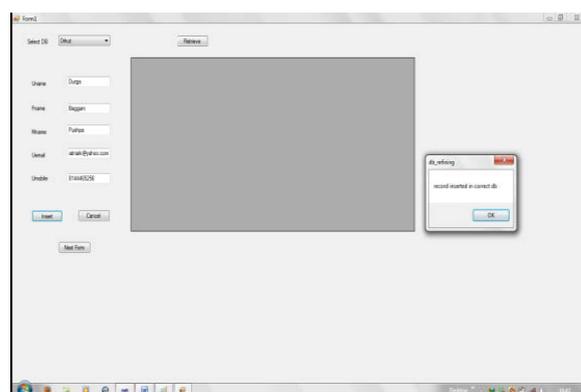

Fig 2.user details inserted in Query DB

The details gets inserted in the query database and initial ranking is given for the records which is show in Fig.2. while querying user data from **query db** for user records similarity checking to form clusters the data queried is shown in fig.3.

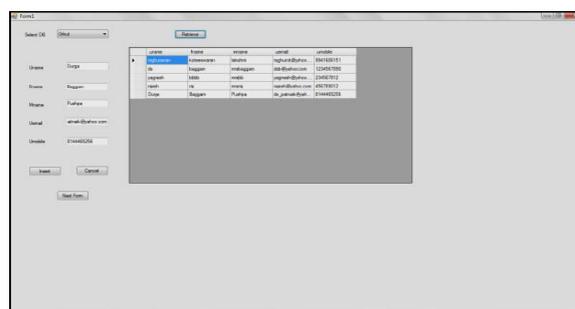

Fig.3 queried user data for clustering

IV. CONCLUSION

Research on social networking and their implications are attracting more researcher's because it is a social area depends on behavior of large set of people in different age groups of different demographic sizes and their activities result in different areas like dynamic change in Database size, complexity in analysis for OLAP, redundancy and many more DB issues. Some of the most interesting factor that motivated me is to identify a persons by avoiding unauthorized entry for adolescent action and to provide security for e-transaction associated with banking⁸ and ebay, snap-deal and flipkart⁹ etc., like shopping websites. This is our preliminary work to have a better understanding of the system. As a result we had studied many papers related to it and accessed to many SNW's by registering on entering fake user data interestingly found that most of the sites are not processing any verification other than email-id which can be created by anyone as they like by giving any details(invalid or fake). We proposed a clustering architecture which acts as a preliminary gateway for any user registration by giving initial ranking. The complexity here is all registration pages should undergo this process. Future enhancement for this technique is to implement a internal indexing with R-trees for query database so that retrieval from query database becomes faster so that it may improves the overall performance.

A Novel Watermarking Technique Using Visual Cryptography with Blow Fish Techniques

Ramamohan .B

M. Tech student,

Dadi Institute of Engg &Tech, Anakapalli

P. Srihari

M. Tech,(P.hd) Head Of The Department,ECE,

Abstract: Information security is not just to provide an authenticity and integrity to the data, but there is also a need to seek identity, rights of use and origin of information, which may require some degree of process re-engineering. Rarely security technologies like digital data can be simply “plugged in” without streamlining the process. In this paper we address the problem of information security and protecting the rights of originator of the structured document from ill-intentioned recipient who can modify the received decrypted information. At sender end, a public key signature is generated using SHA-1 or SHA-2. Signature is embedded into raster image of the document using non-invertible robust public key watermarking technique based on orthogonal signals concepts. The document is then encrypted with public key of the receiver using RSA algorithm to achieve confidentiality and authorization. The proposed scheme uses correlation analysis to detect embedded signature to authenticate message. This scheme also uses Gauss-Jordan method to derive the signature from the watermarked image to verify ownership. The study is corroborated with result and application of the proposed technique to prevent forgery and alteration in data

Keywords: Digital data, watermarking, Information Security, Rights Protection,

I. Introduction

Over the past few years there has been tremendous growth in computer networks especially in the field of World Wide Web. This phenomenon coupled with the exponential increase of computer performance, has facilitated on-line business operations like shopping, trading, truncation, bill presentment. Due to massive use of personal computers, network and the Internet, new features of security are in need. In addition to confidentiality, authentication, integrity and control, one must think of new security requirements like protecting the rights of originator against tampering and illegal distribution of the information by the intended recipient, as an ill intentioned authorized recipient can modify and redistribute the decrypted information. It is well known that cryptography deals with unauthorized access but there are functional limitations like requirement of global clock synchronization, handshaking and costly tamper proof hardware. Digital watermarking is a technique based on digital signal processing which inserts extra signal to digital contents for discouraging illicit modification and distribution of information and to authenticate watermarked contents. But, digital watermarking has the following limitations

(a) No transmission security due to lack of public key algorithms.

(b)Text information - Due to binary block format of the text, embedding new bits in the text may introduce irregularities that are visually noticeable. This paper presents a technique, which contains strengths of digital data and digital watermarking both so as to provide a secure transmission of messages. Thus the rights of sender on digital content are protected.

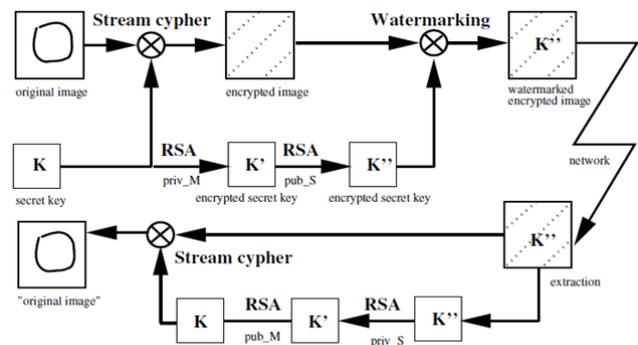

Figure 1 illustrates an approach that uses RSA and Blowfish process representation

The document in which digital data is embedded as watermark. Public key signature protects the document from any intruder, while embedding it as resilient, noninvertible and robust watermark prevents non trusted receiver to modify the contents of the document. Figure 1 Public Key Cryptosystem with embedded digital data. The rest of the paper is organized as follows. Section 2 presents digital data embedding in to image and watermarking, section 3 describes embedding procedures, section 4 verification detection of watermark to prove authenticity, and section 5 conclusion

II. Digital watermarking

The ownership protection, authentication and integrity of structured document is necessary and important. Encryption and digital data techniques protect against eavesdroppers, for sure, but the main attacks are likely to be from validly connected end-users who go on to redistribute the received data more than they are entitled to. Digital data uses “Public-Key Cryptography” which employs an algorithm using two different but mathematically related “keys” one for creating signature, and, another for verifying signature. Compare this to information hiding the cryptographic signature is embedded into the information itself. Watermarking [1] is a security technique in context of protecting content of information from authorized user. It is as old as paper production is and protects rights of

author/originator. This technique is basically used to identify any processing and modification in the contents. 2.1 Digital data have been accepted in several national and international corporations, banks and government agencies. The fundamental process involved in digital data is a hash function. A number of hash functions are proposed in the literature. The MD5 message digest algorithm, [2] was developed by Ren Rivest at MIT. MD5 generates a 128 bits message digest out of a variable length message. Another hash algorithm SHA (Secure Hash Algorithm) was developed by National Institute of Standards and Technology (NIST) and published as a federal information processing standard [3] in 1993. Revised version of SHA is implemented in C language and referred as SHA-1 [4]. It generates 160 bits message digest. SHA-1 has achieved level of Standard because it generates 32 bits longer message digest than MD5, using a brute force technique for a given digest the difficulty in achieving message is of the order of 2160 operations in comparison to 2128 operations in MD5. In the draft FIPS 180-2 NIST published SHA-2 as a new version of secure hash algorithm. SHA-2 offers, SHA-1, SHA-256, SHA-384 and SHA-512. In other words SHA-2 may have outputs 160, 256, 384, and 512 bits of message digest. However, SHA-2 algorithm uses fixed and predefined parameters that may be vulnerable to attack. Digital data can save the message from third parties [5] but once an encrypted message is at receiver end, easily decrypt, modify and distribute the message for commercial benefits. This means the sensitive information in these messages cannot be protected from modification and redistribution from the authorized receiver using encryption, access restriction and hiding information behind firewalls.

A digital watermark is a distinguished piece of information that is adhered to the data that it is intended to protect. Several embedding techniques [1, 6-8] have been specially developed for use with text but most of these techniques either change word or line spacing or make change on the character boundary which require original document to detect watermark to authenticate sender. These techniques cannot be simply used to embed digital data due to involvement of integrity issues with digital data applications.

Tao Chen, et al suggests a combined digital data and digital watermarking scheme [9] for image authentication and content protection. In this scheme content dependent random k bits are extracted from N blocks of image to obtain $K \times N$ bits signature, which is embedded back to the image using secret key. Due to requirement of large number of keys this method cannot be used in applications requiring transmission of data. Ding Huang presents a text watermarking technique [10] that expands and shrinks widths between words to represent inter word distance, as sine wave. In this method sine wave is coded as watermark. This technique cannot be used to send confidential message, as it does not use any key. Chang & Chang presented a sender-buyer protocol [11] where digital data containing sender, buyer and trading information is embedded in the image as barcode image. This scheme protects the embedded trading message and ensures integrity of image but does not authenticate the sender, as digital data is not based on content of the information. Cor et al [12] proposed secure spread spectrum watermarking

scheme. A two-dimensional spectrum signal is generated. 128 low bits of the spectrum signal are modulated with 128 bits of the owner's secret key. Adding modulated signal back to the image generates the watermark signal. Inverting spectrum signal, which is then added to the image, generates watermark signal. Drawbacks of this scheme are (1) it requires original image to detect the watermark and (2) Every time new binary key is needed to protect new image.

A paper for watermarking of digital images to detect or verify ownership [13]. In this method most common RSA & DSS public key signature generation algorithms are used to generate public and private keys of user. This method involves computing message digest using MD5 of image I of M rows and N columns. Message digest is encrypted with private key to generate digital signature. Low order bits of DS are modulated to as watermark and inserted back into the image. We can summarize that, in order to protect document integrity and rights of owner on the document the crypto signature should be content based and public in order to avoid the large number of secret keys. Secondly such a scheme should not require original document to detect and verify the ownership and should be computationally inexpensive. The goal of this work is to design a cipher model that contains strengths of digital data and digital watermarking both to provide secure structured document transmission and to detect and verify ownership to prevent alteration and forgery. The approach uses raster representation of the document in which digital data is embedded as watermark. Public key digital data protects the document from third party while embedding it as watermark prevents non Trusted receiver trusted receiver to modify the contents of document.

III. Embedding a digital data in to image

Image representation of a message The process starts with calculating size of the text information and then converting it into its digital image representation. Input text is stored in string format before conversion. Size of the text is calculated in the form of an invisible drawing in the context of memory device.

height and width are calculated as shown in figure 2..

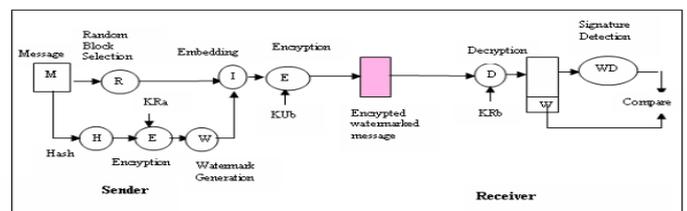

Figure 2: Image size Measurement

Image height = (Ascent+ Descent+ bearing) * No. of lines in text message (1)

Image width = = Max (x [i]); 0<= i <=no. of lines (2)

True color RGB model is used to represent image as a bit frame of size width*height, where, each square represents a value of bit as function

$$f(x, y) = \{f(x, y) = [0,1], | x = 0 \text{ to width}, y = 0 \text{ to eight}\} \quad (3)$$

A total number of 32 frames for a single image are used [14]. The first 8 frames represent transparency; the next 24 frames (8 per color) are used to represent Red, Green and Blue colors respectively. The binary values (0 or 1) in corresponding bits from each of the 32 bit planes result in a binary number to represent pixel's intensity level from 0 to $2^{32}-1$ (full intensity). For each bit, in all 32 bit frames, value of function $f(x, y)$ is set to 0 to create a black background. Value of function $f(x, y)$ is manipulated at a specific location in all the bit frames to draw text pattern on the background image. Intensity of the image is set in all 32-bit frames to get a specific pixel value [15-17]. Values of pixels stored in memory are grabbed into a vector of size $=$ width * height.

III.1 Generation and Embedding of Digital signatures

This process starts with calculating a message digest from two-dimensional message signal M of m rows and n columns. One-way hash function H operates on input message M of arbitrary length and returns a fixed length hash value h , i.e. $H(M) = h$. It has additional characteristics as follows:

- (i) Given M it is easy to compute h , (ii) Given h it is hard to compute M such that $H(M) = h$
- (iii) Given M it is hard to compute another message M' such that $H(M) = H(M')$. Several methods are developed to find hash function [2-4]. Here SHA-1 algorithm is used to generate unique 160 bits.

Then RSA algorithm is used to encrypt fixed length message digest using owner's private key to generate owner's public key signature vector [5]. Since RSA algorithm is based on the fact that there is insufficient way to factorize very large number, deducing the RSA key, therefore, requires very high computer processing time. RSA algorithm has also become de facto standard for industrial strength and built into many of the software products like Netscape Navigator and Internet Explorer. Next, the bits of digital data are modulated and transformed to compute watermark signal. Length of the watermark signal may be same as that of digital data or it may be based on first, middle or last bits of the digital data as long as they are consistent. This selection is based on the criteria that too small watermark signal is vulnerable to attack and too large watermark signal takes large computer power. Embedding watermark signal X_s into message M involves selecting a random block of m nonoverlapping continuous rows and averaging these m rows to find average row vector R referred to as reference vector. Original watermark signal X_s is orthogonalized with respect to vector R to make inserted signal independent from the reference signal and eliminate cross talk [18]. Thus, the vector W_s constructed out of W entries by modulating digital data [12, 19, 20]

$$W_s = X_s - (X_s \cdot R) R \quad (5)$$

A gain factor is calculated from W_s across all m rows to ensure that strength of the watermark varies smoothly. $I_i = c \cos(2\pi i/m)$ (6) Value of c is adjusted to maintain quality metric PSNR to minimum 30 DB, to avoid white visible marks on message signal. This small scaled version of the W_s is added back to m rows of the original signal to generate watermarked signal M' , where value of the bit function $f(x, y)$ is given as.

It is possible to find values of e, d, n such that $m^{ed} = m \pmod n$ for all $m < n$;

- It is relatively easy to calculate m^e and c^d for all values of $m < n$.
- It is infeasible to determine d given e and n .

$$m^{ed} = M \pmod n \quad \text{where } n \text{ is no of sub pixels}$$

Where m is decryption key

A corollary to Euler's theorem, $n=pq$

Where $\Phi(n)$ is the Euler totient fun.

$$\Phi(p, q) = (p-1)(q-1) \quad ed = 1 \pmod{\Phi(n)}$$

$$d = e^{-1} \pmod{\Phi(n)}$$

$w - m \leq r$ and $0 \leq w \leq h$ Other blocks of m rows can be selected pseudo randomly to embed additional watermarks using same X_s signal. All X_s and corresponding reference vectors are stored for detection purpose.

III.2 Encrypting watermark image

Encryption of watermarking with the help of RSA algorithm [5] is used to further encrypt watermarked signal M' using public key (d, n) of the receiver to achieve data integrity and confidentiality over network

$$I. \quad M = \{f(x, y) \mid x = 0 \text{ to width}, y = 0 \text{ to height}\} \quad C = M^d \pmod n \quad (8)$$

IV. Detection of Watermark to prove authenticity

The message received is decrypted using private key (e, n) of the receiver to assure for the sender that only authorized receiver can access message and data in the message has not been modified during transmission. To assure the receiver that message has come from the authentic sender. The watermark inserted in the message is detected.

$$M = C^e \pmod n \quad (9)$$

A detection criterion is established using correlation analysis [19, 20]. Watermark is detected using the reference vector R and the watermark vector X_s sent with message itself. X_s is orthogonalized with respect to R to obtain W_s . Watermarked message is scanned from starting in blocks of m rows. An average vector is calculated from each block and orthogonalized with respect to reference vector R to find expected watermark vector EW_s . EW_s is correlated with the watermark vector W_s to test relative closeness.

If correlation coefficient is above a threshold value (between 0.5 & 1) then received document contains the watermark and assumed to have sent by an authentic sender.

Hundreds of random watermarks are synthesized with the same spectral properties as X_s . Correlation of each of these watermarks is computed with watermarked image. If later and former correlations are far apart it is likely that image contains watermark.

V. Verification to prove ownership

The procedure to protect rights of sender by deriving watermark from the watermarked image of the signal. Signature derivation will prove ownership of the sender if message is redistributed. At the same time it will restrict authorized receiver to illegally modify the message because in case of modification extracted signature will not match

with the original signature of the sender. Claimant can prove the ownership by presenting original image and the position where watermark was inserted. Gain factor is constructed by subtracting original image from watermarked image and orthogonal watermark W_s / is also constructed.

$$(X_s \ R) \ R = (X_s \cdot R) \ R - (R \cdot R) \ X_s \quad (11)$$

(12) Gauss Jordan method is applied to equation (12) to find components of vector X_s , where m_r is length of vector R . Digital data S of sender is constructed from X_s after removing all modulations and transformations. If, S and X_s are same, ownership of the sender is proved. 6 Implementation and Results In this section we present the simulation results by implementing orthogonal signals based public-key watermarking algorithm.. We used a 32-bit RGB model to represent the original image using MATLAB. We used SHA-1 algorithm to find message digest and RSA algorithm to encrypt message digest. We orthogonalized signature with respect to average vector found from selected block and embedded a scaled version of orthogonalized signature back to the selected block. PSNR was set to minimum 30 DB to avoid white noise. Overall image was encrypted with public key of the recipient to achieve confidentiality and integrity. Signature was detected using correlation analysis. Figure 4 shows 32-bit raster image of the document. Figure 5 shows watermarked image with PSNR 76DB and figure 6 shows the decrypted image. This image is used to detect the watermark using correlation

The performance of the proposed algorithm is shown in figure 7. Correlation factor is found corresponding to the true signature derived from the original document and corresponding to the 100 randomly selected signatures. The correlation factor corresponding to true signature is between 0.9 and correlation factor corresponding to false signatures is negative or below 0.6.

Figure 7: Decrypted image of the retrieve process done with blowfish process

V. Conclusion

Most of the trading, banking and investment applications are based on exchanging structured documents over global network. For technical excellence and business values of these applications, security of information and sender's rights on information plays an essential role in overall transmission system. Cryptography alone can be an effective solution to all these problems but in most of instances in the form of costly and specialized hardware to create tamper proof devices. In this paper we have presented a software-based approach, which combines digital datatechnology with robust watermarking technique to achieve authenticity, confidentiality, integrity and restricting alteration and forgery in information. The proposed technique is tested to prevent forgery of signature and alteration of information in images.

Cross Layer Optimization for Multiuser Video Streaming Using Distributed Cross Layer Algorithm

Mr. R. Raju¹, J. Vidhya Shankardevi²

*(Associative Professor, Sri Manakula Vinayagar Engineering College, India)

** (M.Tech, Department of Information Technology, Sri Manakula Vinayagar Engineering College, India)

Abstract: The Multimedia and networking are inseparable. The integration of multimedia services into wireless communication networks is a major source of future technological advances. Due to the integration of multimedia services, the increasing energy consumption of a mobile unit is also becoming a dominant factor in the design of communication systems. Video streaming over wireless networks is must for many applications, ranging from home entertainment to surveillance to search-and-rescue operations. Due to the increased energy requirement of signal processing and wireless transmission, the limited battery capacity of mobile devices has become a major drawback. This paper proposes a cross layer optimization algorithm, which includes routing based on neighbor discovery and dual congestion control for improving QoS. It helps in minimizing the energy required in transmission of video packets. This in turn leads to green computing

Keywords - Cross layer, Congestion control, Green computing, HCCA

I. INTRODUCTION

This section provides a brief introduction about Wireless networks and multimedia

1.1 WIRELESS NETWORKS

Wireless network is a network set up by using radio signal frequency to communicate among computers and other network devices. It referred to as WiFi. They are of three types Wide area networks (WAN) that the cellular carriers create, Wireless local area networks (WLAN), that you create, and Personal area networks (PAN), that create themselves. The components of wireless network are Antennas, Transceivers, Integrated Circuits, Analogue-Digital Converters, LCD Screens and Batteries. Infrastructure of wireless network is Cell Towers, Base Stations (access points), Filters, Routers & Switches, Power Amplifiers and Edge Packets. Working of wireless networks is two computers each equipped with wireless adapter and wireless router. When the computer sends out the data, the binary data will be encoded to radio frequency and transmitted via wireless router. The receiving computer will then decode the signal back to binary data. IEEE 802.11 standards specify two operating modes: infrastructure mode and ad hoc mode. Infrastructure mode is used to connect computers with wireless network adapters, also known as wireless clients, to an existing wired network with the help from wireless router or access point. Ad hoc mode is used to connect wireless clients directly together, without the need for a wireless router or access point. An ad hoc network consists of up

to 9 wireless clients, which send their data directly to each other

1.2 MULTIMEDIA

Multimedia means that computer information can be represented through audio, video, and animation in addition to traditional media (i.e., text, graphics drawings and images).

Multimedia is the field concerned with the computer-controlled integration of text, graphics, drawings, still and moving images (Video), animation, audio, and any other media where every type of information can be represented, stored, transmitted and processed digitally. A Multimedia Application is an Application which uses a collection of multiple media sources e.g. text, graphics, images, sound/audio, animation and/or video. Hypermedia can be considered as one of the multimedia applications

1.2.1 GENERAL CHARACTERISTICS OF MULTIMEDIA SYSTEM

The four basic characteristics of multimedia systems are Multimedia systems must be computer controlled, Multimedia systems are integrated, the information they handle must be represented digitally, and the interface to the final presentation of media is usually interactive.

1.2.2 VIDEO STREAMING

Streaming video is content sent in compressed form over the Internet and displayed by the viewer in real time. With streaming video or streaming media, a Web user does not have to wait to download a file to play it. Instead, the media is sent in a continuous stream of data and is played as it arrives. The user needs a player, which is a special program that uncompresses and sends video data to the display and audio data to speakers. A player can be either an integral part of a browser or downloaded from the software maker's Web site. Major streaming video and streaming media technologies include Real System G2 from Real Network, Microsoft Windows Media Technologies

II. OBJECTIVE OF THE PAPER

This paper proposes an algorithm called distributed cross layer optimization and cross layer optimization in order to prevent more amount of energy used in forwarding the video packets across the network.

When streaming live video across wireless links, two main sources of energy consumption are video coding and wireless transmission. In most of the state-of-the-art video encoders and wireless transmitters, there are configuration parameters which can be tuned based on varying channel conditions and/or video characteristics. It is desirable to minimize the energy consumption of all users,

including both video coding and wireless transmission, while satisfying the video quality requirement imposed by the end-user.

Streaming can be more complex in a packet based network because they have strong and specific requirements. The QOS of the video streaming can specify some requirement which is the video data flows must be formatted, denoting that the latency between consecutive packets must be the same, the data bit rate has to be high and constant, and the video packet loss rate must be close to zero. Constant bit rate is needed to feed the decoder application in a proper way, and to see the video without interrupt.

III. Related Works

The main areas, the previous work concentrated are Low power design and changing the configuration parameters to reduce the energy during transmission of video packets.

3.1 LOW POWER DESIGN ISSUES

In the wireless network low power design issues have been addressed in the following four areas.

3.1.1 DEVICE LEVEL OPTIMIZATION

Low power VLSI design [2] and low power RF circuitry [3] optimization are the main technologies for energy saving approaches. Dramatic reduction in power dissipation requires architectural, algorithmic, and circuit design optimization, which are limited by semiconductor and device technologies.

3.1.2 MEDIUM ACCESS CONTROL (MAC) PROTOCOL DESIGN

Energy-efficient MAC protocol design principle has three constraints [4]

Packet structure. It partitions a packet into two parts: the low-bit-rate part for control information and the high-bit-rate part for data; due to the different error tolerant requirements of each part, one can achieve total energy saving.

Awake/Doze mode. It puts the system into the sleep mode while not receiving or sending data.

Error Control design. The description of this design can be found in the next item.

3.1.3 COMMUNICATION SYSTEM LEVEL OPTIMIZATION

A communication system-level optimization approach is devised called, global interference minimization [5]. Global interference minimization refers to the transmitter power control problem in cellular radio systems. This has provided an optimal solution in the sense that it minimizes interference (or outage) probability. The optimal solution for the power control problem involves solving eigen values of path gain matrices. This solution is computationally expensive and impractical in the real world.

There comes [6], [7] a simplified distributed power control algorithm to tackle this problem. The distributed power control algorithm differs from the centralized power control problem in which each mobile adaptively adjusts its transmitter power according to the received interference. The distributed method releases the computational task performed by each base station.

The CDMA power control strategy also provides a simple solution to the interference minimization problem. There are two types of power control algorithms, close-loop, and open-loop control [8], [9]. Close-loop control refers to the feedback made from the base station to mobile stations for adjusting mobiles' transmitted power. Open-loop control refers to the self transmission power adjustment of mobile stations by comparing the received signal strength from the base station with a reference signal level.

3.1.4 APPLICATION LEVEL DESIGN

Engineers are developing low complexity software or hardware for multimedia processing algorithms [10], [11]. Usually low complexity algorithms yield low energy consumption, provided that less iterations or looping are involved in the computation.

One of the reasons for not considering the power consumption issue in the resource management strategy has been the failure to acknowledge the importance of the interaction between the processing power and the associated transmission power.

3.2 HCF CONTROLLED CHANNEL ACCESS (HCCA)

The HCF (hybrid coordination function) controlled channel access (HCCA) works a lot like PCF(Point Coordination Function) it contrast to PCF, in which the interval between two beacon frames is divided into two periods of CFP (Contention Free Period) and CP(Contention Period), the HCCA allows for CFPs being initiated at almost any time during a CP. This kind of CFP is called a Controlled Access Phase (CAP) in 802.11e.

A CAP is initiated by the AP whenever it wants to send a frame to a station or receive a frame from a station in a contention-free manner. The other difference with the PCF is that Traffic Class (TC) and Traffic Streams (TS) are defined. This means that the HC (Hybrid Coordinator) is not limited to per-station queuing and can provide a kind of per-session service. Also, the HC can coordinate these streams or sessions in any fashion it chooses (not just round-robin). Moreover, the stations give info about the lengths of their queues for each Traffic Class (TC). The HC can use this info to give priority to one station over another, or better adjust its scheduling mechanism.

3.3 MULTIMODE ADAPTIVE POWER SAVING (MAPS) PROTOCOL

In protocol assumptions to be made are, i) The cellular network has a feedback power control mechanism, i.e., the base station commands mobile users to increase or decrease transmitted power through the control channel at a period of time. ii) The system is set for multimode transmission where radio frequency (RF) signal-to-noise (SN) ratios are different from mode to mode.

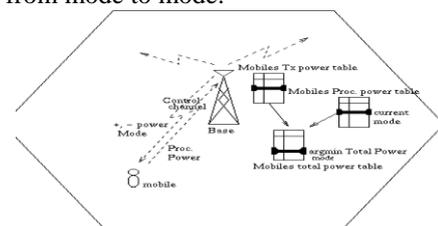

Figure.1 Base station controlled adaptive method
MAPS protocol can be summarized as,

Mobile ready to send, exchanging information between the base station and the mobile for the initial transmission power level and modes (e.g., in H.263 video transmission, one can set initially mode0 with intra coding frame).

After one frame is coded, the corresponding processing power is measured and sent to the base station, and it is stored in the processing power table. The remaining processing power levels of other modes are estimated by multiplying the pre-estimated inter mode factors.

The base station estimates the required transmitted power level of the mobile through the power control mechanism and stores the result in the transmission power table. Power levels of other modes can be easily found by multiplying different RF SN ratios.

Add the processing power table and the transmission power table to form a total power table. Find the minimum in the total power table and the corresponding mode.

The base station sends power and mode updates to the mobile; the mobile uses the new mode for next frame coding. Go back to step 2.

3.4 MULTIRATE TRANSMISSION SCHEME: MULTISTAGE CODED MODULATION (MCM)

To integrate a multimode coder into the power-saving system, an efficient transmission scheme has to be built. The beneficial transmission scheme is used here, therefore source/channel (S/C) rate optimized coding and multirate modulation (MM) are left as potential candidates.

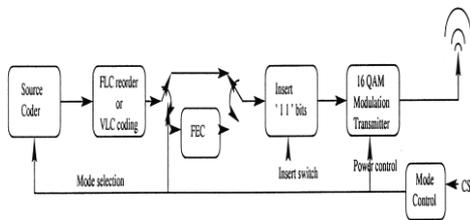

Figure.2 Multistage coded modulation

It has the simple reconfigurable QAM scheme and FEC coding that guarantee a given quality while minimizing transmission power consumption [12]. To make the switch between higher level and lower level modulation settings simpler, we introduce so-called inserted MQAM.

3.5 ISSUES IN THE RELATED WORK

Energy or power saving criteria is approached either from an information-theoretic perspective or from an implementation-specific viewpoint. Modulation strategies are derived for delay-bounded traffic. It is shown that when the transmit power and circuitry power are comparable, the transmission energy decreases with the product of bandwidth and transmit duration.

They however only consider an idealized network restricted to a single flow with no medium access controller (MAC) or link layer retransmissions, and with ideal constellation sizes.

Non-multimedia applications will experience degraded performance, cannot be universally applied to all network configuration.

IV. Problem Definition

In the proposed scheduling algorithm, we include routing based on neighbor discovery and dual congestion control

for improving QoS. After receiving the request the resource server can schedule the request .that is the form a table for which node needs which data. After scheduling the resource server can perform three steps which are Analyze the nearest requested node by use of shortest path, check the requested nodes are neighbors of each other, Form the index for avoiding neighboring collision

If the requested nodes are neighbors of each other Resource server sent the RTS (ready to sent) and ID of the neighbor requested node and then Requested node can check the ID is a neighbor's ID. If the ID is a neighbor's ID the process move to congestion control otherwise the process move to routing component. If the requested nodes are not a neighbors of each other the process move to congestion control First Congestion Control Form the queue and sent RTS to first requested node and then Node can send the CTS (clear to sent) to the resource server Second Congestion Control Form the queue and sent requested data to that first sent CTS by the node and then Requested node can receive the data

4.1 DISTRIBUTED CROSS-LAYER ALGORITHM

In the Distributed Cross-Layer Algorithms for the Optimal Control scheduler implements joint application and fabric layer optimization scheduling algorithm. Cross-layer design introduces interlayer coupling across the application layer and the fabric layer and allows the exchange of necessary information between the application layer and the fabric layer.

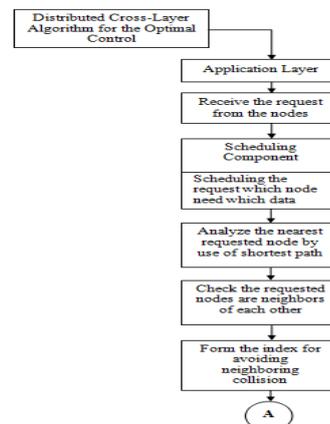

Figure 3 Distributed cross layer algorithm

First, calculate Cross-layer optimization of resource allocation throughput and Distributed Cross-Layer Algorithms for the Optimal Control throughput. Then Compare Joint optimization of resource allocation and User QOS satisfaction control & Distributed Cross-Layer Algorithms for the Optimal Control For wireless military mobile ad hoc networks, it requires a routing protocol that can dynamically adapt topology, and various other hierarchical changes of the network node.

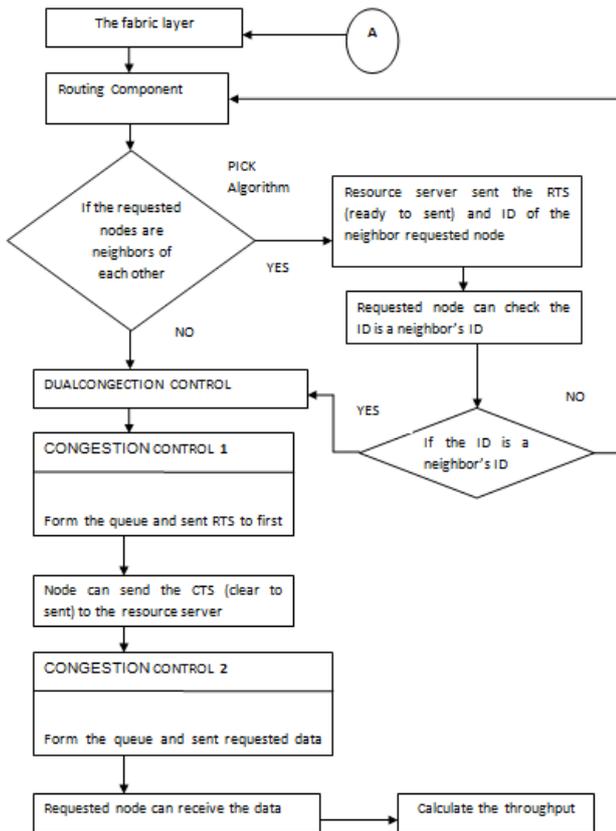

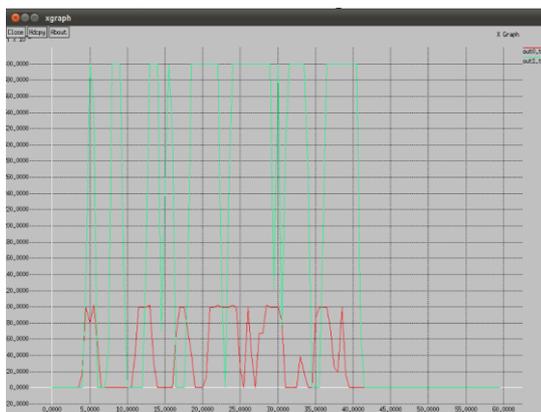

Figure.3 Distributed cross layer algorithm

4.2 ADVANTAGES OF PROPOSED WORK

This algorithm also helps in avoiding congestion control with the help of dual congestion control. To reduce the runtime computation load, the fast greedy algorithm will be employed. Transfer the data packets. Each terminal finds the maximum quality factor for all its possible complexities, and the base station searches in the space of compression complexity. The parameters to be adjusted are source coding bit rates, compression complexity, and transmitter power for all users.

V. Graph

The graph shows that the throughput is high; also the time taken for delivering the packets is less. In this X-axis denotes the time and Y-axis denotes the number of packets.

VI. Conclusion

This proposed a cross-layer optimization scheme for multi-user video streaming using distributed cross layer optimization algorithm. The goal is to minimize total energy consumption of all users, including both video coding and wireless transmission energy, while satisfying video quality target. Source coding bit rates, and transmission power corresponding to the best compression complexity are taken together as the operating parameters. Since the energy consumption is reduced it achieves green computing.

Abstract: The purpose of this paper is to introduce the concepts of semi*-connected spaces, semi*-compact spaces and semi*-Lindelöf spaces. We investigate their basic properties. We also discuss their relationship with already existing concepts.

Mathematics Subject Classification: 54D05, 54D30.

Keywords - semi*-compact, semi*-connected, semi*-Lindelöf.

I. Introduction

In 1974, Das defined the concept of semi-connectedness in topology and investigated its properties. Compactness is one of the most important, useful and fundamental concepts in topology. In 1981, Dorsett introduced and studied the concept of semi-compact spaces. Since then, Hanna and Dorsett, Ganster and Mohammad S. Sarsak investigated the properties of semi-compact spaces. In 1990, Ganster defined and investigated semi-Lindelöf spaces.

In this paper, we introduce the concepts of semi*-connected spaces, semi*-compact spaces and semi*-Lindelöf spaces. We investigate their basic properties. We also discuss their relationship with already existing concepts.

II. Preliminaries

Throughout this paper (X, τ) will always denote a topological space on which no separation axioms are assumed, unless explicitly stated. If A is a subset of the space (X, τ) , $Cl(A)$ and $Int(A)$ denote the closure and the interior of A respectively.

Definition 2.1: A subset A of a topological space (X, τ) is called

- (i) **generalized closed** (briefly g-closed)[11] if $Cl(A) \subseteq U$ whenever $A \subseteq U$ and U is open in X .
- (ii) **generalized open** (briefly g-open)[11] if $X \setminus A$ is g-closed in X .

Definition 2.2: Let A be a subset of X . The **generalized closure** [6] of A is defined as the intersection of all g-closed sets containing A and is denoted by $Cl^*(A)$.

Definition 2.3: A subset A of a topological space (X, τ) is called

- (i) **semi-open** [10] (resp. **semi*-open**[14]) if $A \subseteq Cl(Int(A))$ (resp. $A \subseteq Cl^*(Int(A))$).
- (ii) **semi-closed** [1] (resp. **semi*-closed**[15]) if $X \setminus A$ is semi-open (resp. semi*-open) or equivalently if $Int(Cl(A)) \subseteq A$ (resp. $Int^*(Cl(A)) \subseteq A$).
- (iii) **semi-regular** [2] (resp. **semi*-regular** [15]) if it is both semi-open and semi-closed (resp. both semi*-open and semi*-closed).

The class of all semi-open (resp. semi-closed, semi*-open, semi*-closed) sets is denoted by $SO(X, \tau)$ (resp. $SC(X, \tau)$, $S^*O(X, \tau)$, $S^*C(X, \tau)$).

Definition 2.4: Let A be a subset of X . Then the **semi*-closure** [15] of A is defined as the intersection of all semi*-closed sets containing A and is denoted by $s^*Cl(A)$.

Theorem 2.5[14]: (i) Every open set is semi*-open.
(ii) Every semi*-open set is semi-open.

Definition 2.6: If A is a subset of X , the semi*-frontier [13] of A is defined by $s^*Fr(A) = s^*Cl(A) \setminus s^*Int(A)$.

Theorem 2.7[13]: Let A be a subset of a space X . Then A is semi*-regular if and only if $s^*Fr(A) = \emptyset$.

Theorem 2.8[15]: If A is a subset of X , then

- (i) $s^*Cl(X \setminus A) = X \setminus s^*Int(A)$.
- (ii) $s^*Int(X \setminus A) = X \setminus s^*Cl(A)$.

Definition 2.9: A topological space X is said to be connected [18] (resp. semi-connected [3]) if X cannot be expressed as the union of two disjoint nonempty open (resp. semi-open) sets in X .

Theorem 2.10 [18]: A topological space X is connected if and only if the only clopen subsets of X are \emptyset and X .

Definition 2.11: A collection B of open (resp. semi-open) sets in X is called an open (resp. semi-open) cover of $A \subseteq X$ if $A \subseteq \bigcup \{U_\alpha : U_\alpha \in B\}$ holds.

Definition 2.12: A space X is said to be compact [18] (resp. semi-compact [4]) if every open (resp. semi-open) cover of X has a finite subcover.

Definition 2.13: A space X is said to be Lindelöf [18] (resp. semi-Lindelöf [8]) if every cover of X by open (resp. semi-open) sets contains a countable sub cover.

Definition 2.14: A function $f: X \rightarrow Y$ is said to be

- (i) semi*-continuous [16] if $f^{-1}(V)$ is semi*-open in X for every open set V in Y .
- (ii) semi*-irresolute [17] if $f^{-1}(V)$ is semi*-open in X for every semi*-open set V in Y .
- (iii) semi*-open [16] if $f(V)$ is semi*-open in Y for every open set V in X .

- (iv) semi*-closed [16] if $f(V)$ is semi*-closed in Y for every closed set V in X .
 (v) pre-semi*-open [16] if $f(V)$ is semi*-open in Y for every semi*-open set V in X .
 (vi) pre-semi*-closed [16] if $f(V)$ is semi*-closed in Y for every semi*-closed set V in X .
 (vii) totally semi*-continuous [17] if $f^{-1}(V)$ is semi*-regular in X for every open set V in Y .
 (viii) strongly semi*-continuous [17] if $f^{-1}(V)$ is semi*-regular in X for every subset V in Y .
 (ix) contra-semi*-irresolute [16] if $f^{-1}(V)$ is semi*-closed in X for every open set V in Y .
 (x) contra-semi*-irresolute [17] if $f^{-1}(V)$ is semi*-closed in X for every semi*-open set V in Y .

Theorem 2.15: Let $f: X \rightarrow Y$ be a function. Then

- (i) f is semi*-continuous if and only if $f^{-1}(F)$ is semi*-closed in X for every closed set F in Y . [16]
 (ii) f is semi*-irresolute if and only if $f^{-1}(F)$ is semi*-closed in X for every semi*-closed set F in Y . [17]
 (iii) f is contra-semi*-continuous if and only if $f^{-1}(F)$ is semi*-open in X for every closed set F in Y . [16]
 (iv) f is contra-semi*-irresolute if and only if $f^{-1}(F)$ is semi*-open in X for every semi*-closed set F in Y . [17]

Remark 2.16: [14] If (X, τ) is a locally indiscrete space, then $\tau = S^*O(X, \tau) = SO(X, \tau)$.

Theorem 2.17: [14] A subset A of X is semi*-open if and only if A contains a semi*-open set about each of its points.

III. Semi*-connected spaces

In this section we introduce semi*-connected spaces and investigate their basic properties.

Definition 3.1: A topological space X is said to be *semi*-connected* if X cannot be expressed as the union of two disjoint nonempty semi*-open sets in X .

Theorem 3.2: (i) If a space X is semi*-connected, then it is connected.

(ii) If a space X is semi-connected, then it is semi*-connected.

Proof: (i) Let X be semi*-connected. Suppose X is not connected. Then there exist disjoint non-empty open sets A and B such that $X=A \cup B$. By Theorem 2.5(i), A and B are semi*-open sets. This is a contradiction to X is semi*-connected. This proves (i).

(ii) Let X be semi-connected. Suppose X is not semi*-connected. Then there exist disjoint non-empty semi*-open sets A and B such that $X=A \cup B$. By Theorem 2.5(ii), A and B are semi-open sets. This is a contradiction to X is semi-connected. This proves (ii).

Remark 3.3: The converse of the above theorem is not true as shown in the following example.

Example 3.4: Consider the space (X, τ) where $X=\{a, b, c, d\}$ and $\tau=\{\phi, \{a\}, \{b\}, \{a, b\}, \{b, c\}, \{a, b, c\}, X\}$. Clearly, (X, τ) is connected but not semi*-connected.

Example 3.5: It can be verified that the space (X, τ) where $X=\{a, b, c, d\}$ and $\tau=\{\phi, \{a\}, \{b\}, \{a, b\}, \{a, b, c\}, X\}$ is semi*-connected but not semi-connected.

Theorem 3.6: A topological space X is semi*-connected if and only if the only semi*-regular subsets of X are ϕ and X itself.

Proof: Necessity: Suppose X is a semi*-connected space. Let A be non-empty proper subset of X that is semi*-regular. Then A and $X \setminus A$ are non-empty semi*-open sets and $X=A \cup (X \setminus A)$. This is a contradiction to the assumption that X is semi*-connected.

Sufficiency: Suppose $X=A \cup B$ where A and B are disjoint non-empty semi*-open sets. Then $A=X \setminus B$ is semi*-closed. Thus A is a non-empty proper subset that is semi*-regular. This is a contradiction to our assumption.

Theorem 3.7: A topological space X is semi*-connected if and only if every semi*-continuous function of X into a discrete space Y with at least two points is a constant function.

Proof: Necessity: Let f be a semi*-continuous function of the semi*-connected space into the discrete space Y . Then for each $y \in Y$, $f^{-1}(\{y\})$ is a semi*-regular set of X . Since X is semi*-connected, $f^{-1}(\{y\})=\phi$ or X . If $f^{-1}(\{y\})=\phi$ for all $y \in Y$, then f ceases to be a function. Therefore $f^{-1}(\{y_0\})=X$ for a unique $y_0 \in Y$. This implies $f(X)=\{y_0\}$ and hence f is a constant function. **Sufficiency:** Let U be a semi*-regular set in X . Suppose $U \neq \phi$. We claim that $U=X$. Otherwise, choose two fixed

points y_1 and y_2 in Y . Define $f: X \rightarrow Y$ by $f(x)=\begin{cases} y_1 & \text{if } x \in U \\ y_2 & \text{otherwise} \end{cases}$

Then for any open set V in Y , $f^{-1}(V)=\begin{cases} U & \text{if } V \text{ contains } y_1 \text{ only} \\ X \setminus U & \text{if } V \text{ contains } y_2 \text{ only} \\ X & \text{if } V \text{ contains both } y_1 \text{ and } y_2 \\ \Phi & \text{otherwise} \end{cases}$

In all the cases $f^{-1}(V)$ is semi*-open in X . Hence f is a non-constant semi*-continuous function of X into Y . This is a contradiction to our assumption. This proves that the only semi*-regular subsets of X are ϕ and X and hence X is semi*-connected.

Theorem 3.8: A topological space X is semi*-connected if and only if every nonempty proper subset of X has non-empty semi*-frontier.

Proof: Suppose that a space X is semi*-connected. Let A be a non-empty proper subset of X . We claim that $s^*Fr(A) \neq \emptyset$. If possible, let $s^*Fr(A) = \emptyset$. Then by Theorem 2.7, A is semi*-regular. By Theorem 3.6, X is not semi*-connected which is a contradiction. Conversely, suppose that every non-empty proper subset of X has a non-empty semi*-frontier. We claim that X is semi*-connected. On the contrary, suppose that X is not semi*-connected. By Theorem 3.6, X has a non-empty proper subset, say A , which is semi*-regular. By Theorem 2.7, $s^*Fr(A) = \emptyset$ which is a contradiction to the assumption. Hence X is semi*-connected.

Theorem 3.9: Let $f: X \rightarrow Y$ be semi*-continuous surjection and X be semi*-connected. Then Y is connected.

Proof: Let $f: X \rightarrow Y$ be semi*-continuous surjection and X be semi*-connected. Let V be a clopen subset of Y . By Definition 2.14(i) and by Theorem 2.15(i), $f^{-1}(V)$ is semi*-regular in X . Since X is semi*-connected, $f^{-1}(V) = \emptyset$ or X . Hence $V = \emptyset$ or Y . This proves that Y is connected.

Theorem 3.10: Let $f: X \rightarrow Y$ be a semi*-irresolute surjection. If X is semi*-connected, so is Y .

Proof: Let $f: X \rightarrow Y$ be a semi*-irresolute surjection and let X be semi*-connected. Let V be a subset of Y that is semi*-regular in Y . By Definition 2.14(ii) and by Theorem 2.15(ii), $f^{-1}(V)$ is semi*-regular in X . Since X is semi*-connected, $f^{-1}(V) = \emptyset$ or X . Hence $V = \emptyset$ or Y . This proves that Y is semi*-connected.

Theorem 3.11: Let $f: X \rightarrow Y$ be a pre-semi*-open and pre-semi*-closed injection. If Y is semi*-connected, so is X .

Proof: Let A be subset of X that is semi*-regular in X . Since f is both pre-semi*-open and pre-semi*-closed, $f(A)$ is semi*-regular in Y . Since Y is semi*-connected, $f(A) = \emptyset$ or Y . Hence $A = \emptyset$ or X . Therefore X is semi*-connected.

Theorem 3.12: If $f: X \rightarrow Y$ is a semi*-open and semi*-closed injection and Y is semi*-connected, then X is connected.

Proof: Let A be a clopen subset of X . Then $f(A)$ is semi*-regular in Y . Since Y is semi*-connected, $f(A) = \emptyset$ or Y . Hence $A = \emptyset$ or X . By Theorem 2.10, X is connected.

Theorem 3.13: If there is a semi*-totally-continuous function from a connected space X onto Y , then Y has the indiscrete topology.

Proof: Let f be a semi*-totally-continuous function from a connected space X onto Y . Let V be an open set in Y . Then by Theorem 2.5(i), V is semi*-open in Y . Since f is semi*-totally-continuous, $f^{-1}(V)$ is clopen in X . Since X is connected, by Theorem 2.10, $f^{-1}(V) = \emptyset$ or X . This implies $V = \emptyset$ or Y . Hence Y has the indiscrete topology.

Theorem 3.14: If there is a totally semi*-continuous function from a semi*-connected space X onto Y , then Y has the indiscrete topology.

Proof: Let f be a totally semi*-continuous function from a semi*-connected space X onto Y . Let V be an open set in Y . Since f is totally semi*-continuous, $f^{-1}(V)$ is semi*-regular in X . Since X is semi*-connected, $f^{-1}(V) = \emptyset$ or X . This implies $V = \emptyset$ or Y . Thus Y has the indiscrete topology.

Theorem 3.15: If $f: X \rightarrow Y$ is a strongly semi*-continuous bijection and Y is a space with at least two points, then X is not semi*-connected.

Proof: Let $y \in Y$. Then $f^{-1}(\{y\})$ is a non-empty proper subset that is semi*-regular in X . Hence by Theorem 3.6, X is not semi*-connected.

Theorem 3.16: Let $f: X \rightarrow Y$ be contra-semi*-continuous surjection and X be semi*-connected. Then Y is connected.

Proof: Let $f: X \rightarrow Y$ be contra-semi*-continuous surjection and X be semi*-connected. Let V be a clopen subset of Y . By Definition 2.14(viii) and Theorem 2.15(iii), $f^{-1}(V)$ is semi*-regular in X . Since X is semi*-connected, $f^{-1}(V) = \emptyset$ or X . Hence $V = \emptyset$ or Y . This proves that Y is connected.

Theorem 3.17: Let $f: X \rightarrow Y$ be a contra-semi*-irresolute surjection. If X is semi*-connected, so is Y .

Proof: Let $f: X \rightarrow Y$ be a semi*-irresolute surjection and let X be semi*-connected. Let V be a subset of Y that is semi*-regular in Y . By Definition 2.14(ix) and Theorem 2.15(iv), $f^{-1}(V)$ is semi*-regular in X . Since X is semi*-connected, $f^{-1}(V) = \emptyset$ or X . Hence $V = \emptyset$ or Y . This proves that Y is semi*-connected.

Theorem 3.18: Let X be a locally indiscrete space. Then the following are equivalent:

- (i) X is connected.
- (ii) X is semi*-connected.
- (iii) X is semi-connected.

Proof: Follows from Remark 2.16.

IV. Semi*-Compact and Semi*-Lindelöf Spaces

In this section we introduce semi*-compact spaces and semi*-Lindelöf spaces and study their properties.

Definition 4.1: A collection \mathcal{A} of semi*-open sets in X is called a *semi*-open cover* of $B \subseteq X$ if $B \subseteq \bigcup \{U_\alpha : U_\alpha \in \mathcal{A}\}$ holds.

Definition 4.2: A space X is said to be *semi*-compact* if every semi*-open cover of X has a finite subcover.

Definition 4.3: A subset B of X is said to be *semi*-compact relative to X* if for every semi*-open cover \mathcal{A} of B , there is a finite subcollection of \mathcal{A} that covers B .

Definition 4.4: A space X is said to be *semi*-Lindelöf* if every cover of X by semi*-open sets contains a countable subcover.

Remark 4.5: Every finite space is semi*-compact and every countable space is semi*-Lindelöf.

Theorem 4.6: (i) Every semi*-compact space is semi*-compact.

- (ii) Every semi*-compact space is compact.
- (iii) Every semi*-Lindelöf space is semi*-Lindelöf.
- (iv) Every semi*-Lindelöf space is Lindelöf.
- (v) Every semi*-compact space is semi*-Lindelöf.

Proof: (i), (ii), (iii) and (iv) follow from Theorem 2.5. (v) follows from Definition 2.12, Definition 2.13, Definition 4.2 and Definition 4.4.

Theorem 4.7: Every semi*-closed subset of a semi*-compact space X is semi*-compact relative to X .

Proof: Let A be a semi*-closed subset of a semi*-compact space X . Let B be semi*-open cover of A . Then $B \cup \{X \setminus A\}$ is a semi*-open cover of X . Since X is semi*-compact, this cover contains a finite subcover of X , namely $\{B_1, B_2, \dots, B_n, X \setminus A\}$. Then $\{B_1, B_2, \dots, B_n\}$ is a finite subcollection of B that covers A . This proves that A is semi*-compact relative to X .

Theorem 4.8: A space X is semi*-compact if and only if every family of semi*-closed sets in X with empty intersection has a finite subfamily with empty intersection.

Proof: Suppose X is compact and $\{F_\alpha : \alpha \in \Delta\}$ is a family of semi*-closed sets in X such that $\bigcap \{F_\alpha : \alpha \in \Delta\} = \emptyset$. Then $\bigcup \{X \setminus F_\alpha : \alpha \in \Delta\}$ is a semi*-open cover for X . Since X is semi*-compact, this cover has a finite subcover, say

$\{X \setminus F_{\alpha_1}, X \setminus F_{\alpha_2}, \dots, X \setminus F_{\alpha_n}\}$ for X . That is $X = \bigcup \{X \setminus F_{\alpha_i} : i = 1, 2, \dots, n\}$. This implies that $\bigcap_{i=1}^n F_{\alpha_i} = \emptyset$. Conversely,

suppose that every family of semi*-closed sets in X which has empty intersection has a finite subfamily with empty intersection. Let $\{U_\alpha : \alpha \in \Delta\}$ be a semi*-open cover for X . Then $\bigcup \{U_\alpha : \alpha \in \Delta\} = X$. Taking the complements, we get $\bigcap \{X \setminus U_\alpha : \alpha \in \Delta\} = \emptyset$. Since $X \setminus U_\alpha$ is semi*-closed for each $\alpha \in \Delta$, by the assumption, there is a finite subfamily, $\{X \setminus U_{\alpha_1}, X \setminus U_{\alpha_2}, \dots,$

$X \setminus U_{\alpha_n}\}$ with empty intersection. That is $\bigcap_{i=1}^n (X \setminus U_{\alpha_i}) = \emptyset$. Taking the complements on both sides, we get $\bigcup_{i=1}^n U_{\alpha_i} = X$.

Hence X is semi*-compact.

Theorem 4.9: Let X be a semi*- T_2 space in which $S^*O(X)$ is closed under finite intersection. If A is a semi*-compact subset of X , then A is semi*-closed.

Proof: Suppose X is a semi*- T_2 space in which $S^*O(X)$ is closed under finite intersection. Let A be a semi*-compact subset of X . Let $x \in X \setminus A$. Since X is semi*- T_2 , for each $a \in A$, there are disjoint semi*-open sets U_a and V_a containing x and a respectively. $\{V_a : a \in A\}$ is a semi*-open cover for A . Since A is semi*-compact, this cover has a finite subcover say, $\{V_{a_1},$

$V_{a_2}, \dots, V_{a_n}\}$. Let $U_x = \bigcap_{i=1}^n U_{a_i}$. Then by assumption, U_x is a semi*-open set containing x . Also $U_x \cap A = \emptyset$ and hence $U_x \subseteq X \setminus A$.

Then by Theorem 2.17, $X \setminus A$ is semi*-open and hence A is semi*-closed.

Theorem 4.10: Let $f : X \rightarrow Y$ be a semi*-irresolute surjection and X be semi*-compact. Then Y is semi*-compact.

Proof: Let $f : X \rightarrow Y$ be a semi*-irresolute surjection and X be semi*-compact. Let $\{V_\alpha\}$ be a semi*-open cover for Y . Then $\{f^{-1}(V_\alpha)\}$ is a cover of X by semi*-open sets. Since X is semi*-compact, $\{f^{-1}(V_\alpha)\}$ contains a finite subcover, namely $\{f^{-1}(V_{\alpha_1}), f^{-1}(V_{\alpha_2}), \dots, f^{-1}(V_{\alpha_n})\}$. Then $\{V_{\alpha_1}, V_{\alpha_2}, \dots, V_{\alpha_n}\}$ is a finite subcover for Y . Thus Y is semi*-compact.

Theorem 4.11: If $f : X \rightarrow Y$ is a pre-semi*-open function and Y is semi*-compact, then X is semi*-compact.

Proof: Let $\{V_\alpha\}$ be a semi*-open cover for X . Then $\{f(V_\alpha)\}$ is a cover of Y by semi*-open sets. Since Y is semi*-compact, $\{f(V_\alpha)\}$ contains a finite subcover, namely $\{f(V_{\alpha_1}), f(V_{\alpha_2}), \dots, f(V_{\alpha_n})\}$. Then $\{V_{\alpha_1}, V_{\alpha_2}, \dots, V_{\alpha_n}\}$ is a finite subcover for X .

Thus X is semi*-compact.

Theorem 4.12: If $f : X \rightarrow Y$ is a semi*-open function and Y is semi*-compact, then X is compact.

Proof: Let $\{V_\alpha\}$ be an open cover for X . Then $\{f(V_\alpha)\}$ is a cover of Y by semi*-open sets.

Since Y is semi*-compact, $\{f(V_\alpha)\}$ contains a finite subcover, namely $\{f(V_{\alpha_1}), f(V_{\alpha_2}), \dots, f(V_{\alpha_n})\}$.

Then $\{V_{\alpha_1}, V_{\alpha_2}, \dots, V_{\alpha_n}\}$ is a finite subcover for X . Thus X is compact.

Theorem 4.13: Let $f : X \rightarrow Y$ be a semi*-continuous surjection and X be semi*-compact.

Then Y is compact.

Proof: Let $f : X \rightarrow Y$ be a semi*-continuous surjection and X be semi*-compact. Let $\{V_\alpha\}$ be an open cover for Y . Then $\{f^{-1}(V_\alpha)\}$ is a cover of X by semi*-open sets. Since X is semi*-compact, $\{f^{-1}(V_\alpha)\}$ contains a finite subcover, namely $\{f^{-1}(V_{\alpha_1}), f^{-1}(V_{\alpha_2}), \dots, f^{-1}(V_{\alpha_n})\}$. Then $\{V_{\alpha_1}, V_{\alpha_2}, \dots, V_{\alpha_n}\}$ is a cover for Y . Thus Y is compact.

Theorem 4.14: A space X is semi*-Lindelöf if and only if every family of semi*-closed sets in X with empty intersection has a countable subfamily with empty intersection.

Proof: Suppose X is compact and $\{F_\alpha : \alpha \in \Delta\}$ is a family of semi*-closed sets in X such that $\bigcap \{F_\alpha : \alpha \in \Delta\} = \emptyset$. Then $\bigcup \{X \setminus F_\alpha : \alpha \in \Delta\}$ is a semi*-open cover for X . Since X is semi*-Lindelöf, this cover has a countable subcover, say

$\{X \setminus F_{\alpha_i} : i = 1, 2, \dots\}$ for X . That is $X = \bigcup \{X \setminus F_{\alpha_i} : i = 1, 2, \dots\}$. This implies that $\bigcap_i (X \setminus F_{\alpha_i}) = \emptyset$. Conversely, suppose

that every family of semi*-closed sets in X which has empty intersection has a countable subfamily with empty intersection. Let $\{U_\alpha : \alpha \in \Delta\}$ be a semi*-open cover for X . Then $\bigcup \{U_\alpha : \alpha \in \Delta\} = X$. Taking the complements, we get $\bigcap \{X \setminus U_\alpha : \alpha \in \Delta\} = \emptyset$.

Since $X \setminus U_\alpha$ is semi*-closed for each $\alpha \in \Delta$, by the assumption, there is a countable sub family, $\{X \setminus U_{\alpha_i} : i=1, 2, \dots\}$ with empty intersection. That is $\bigcap_i (X \setminus U_{\alpha_i}) = \emptyset$. Taking the complements we get $\bigcup_i U_{\alpha_i} = X$. Hence X is semi*-Lindelöf.

Theorem 4.15: Let $f: X \rightarrow Y$ be a semi*-continuous surjection and X be semi*-Lindelöf. Then Y is Lindelöf.

Proof: Let $f: X \rightarrow Y$ be a semi*-continuous surjection and X be semi*-Lindelöf. Let $\{V_\alpha\}$ be an open cover for Y. Then $\{f^{-1}(V_\alpha)\}$ is a cover of X by semi*-open sets. Since X is semi*-Lindelöf, $\{f^{-1}(V_\alpha)\}$ contains a countable subcover, namely $\{f^{-1}(V_{\alpha_n})\}$. Then $\{V_{\alpha_n}\}$ is a countable subcover for Y. Thus Y is Lindelöf.

Theorem 4.16: Let $f: X \rightarrow Y$ be a semi*-irresolute surjection and X be semi*-Lindelöf. Then Y is semi*-Lindelöf.

Proof: Let $f: X \rightarrow Y$ be a semi*-irresolute surjection and X be semi*-Lindelöf. Let $\{V_\alpha\}$ be a semi*-open cover for Y. Then $\{f^{-1}(V_\alpha)\}$ is a cover of X by semi*-open sets. Since X is semi*-Lindelöf, $\{f^{-1}(V_\alpha)\}$ contains a countable subcover, namely $\{f^{-1}(V_{\alpha_n})\}$. Then $\{V_{\alpha_n}\}$ is a countable subcover for Y. Thus Y is semi*-Lindelöf.

Theorem 4.17: If $f: X \rightarrow Y$ is a pre-semi*-open function and Y is semi*-Lindelöf, then X is semi*-Lindelöf.

Proof: Let $\{V_\alpha\}$ be a semi*-open cover for X. Then $\{f(V_\alpha)\}$ is a cover of Y by semi*-open sets.

Since Y is semi*-Lindelöf, $\{f(V_\alpha)\}$ contains a countable subcover, namely $\{f(V_{\alpha_n})\}$. Then $\{V_{\alpha_n}\}$ is a countable subcover for X. Thus X is semi*-Lindelöf.

Theorem 4.18: If $f: X \rightarrow Y$ is a semi*-open function and Y is semi*-Lindelöf, then X is Lindelöf.

Proof: Let $\{V_\alpha\}$ be an open cover for X. Then $\{f(V_\alpha)\}$ is a cover of Y by semi*-open sets. Since Y is semi*-Lindelöf, $\{f(V_\alpha)\}$ contains a countable subcover, namely $\{f(V_{\alpha_n})\}$. Then $\{V_{\alpha_n}\}$ is a countable subcover for X. Thus X is Lindelöf.

Performance Comparison of Three Different Classifiers for Hci Using Hand Gestures

Anand.H.Kulkarni¹, Sachin.A.Urabinahatti²

Department of Computer Science and Engineering
Goite Institute Of Technology, Belgaum, Karnataka, India

Abstract: With the ever-increasing diffusion of computers into the society, the present popular mode of interactions with computers (mouse and keyboard) will become a bottleneck in the effective utilization of information flow between the computers and the human. The use of hand gestures provides an attractive alternative to cumbersome interface for human-computer interaction (HCI). The hand can be used to communicate, with much more information by itself compared to computer mouse, joysticks, etc. allowing a greater number of possibilities for computer interaction. Developing new techniques for human-computer interaction is very challenging, in order to use hands for interaction, it is necessary to be able to recognize them in images. In this paper, a robust hand gesture recognition system is presented for recognizing static gestures based on Zernike moments (ZMs) using Three Classifiers K-nearest Neighbour(KNN), Support Vector Machine (SVM) and Artificial Neural Network (ANN). The proposed system is able to recognize the gesture irrespective of the angles in which the hand gesture image is captured, which makes the system more flexible, and a comparative study is carried out to show which classifier works better in reorganisation of gestures.

Keywords: Hand Gesture Recognition, Human Computer Interaction, KNN, SVM, ANN, Zernike Moments.

I. INTRODUCTION

The way humans interact with computers is constantly evolving, with the general purpose of being to increase the efficiency and effectiveness by which interactive tasks are completed. The purpose of this review is to introduce the field of gesture recognition as a mechanism for interaction with computers. Gestures are expressive, meaningful body motions involving physical movements of the fingers, hands, arms, head, face, or body with the intent of:

- 1) Conveying meaningful information or
- 2) Interacting with the environment [2].

Gestures can be static or dynamic some gestures also have both static and dynamic elements, as in sign languages. A hand gesture is defined as a dynamic movement referring to a sequence of hand postures connected by continuous motions over a short time span, such as waving good-bye; hand posture is a static hand pose without involvement of movements. Hand gesture recognition finds applications in varied domains including virtual environments, smart surveillance, sign language translation, medical systems etc. Hand gesture is used to control an event like navigation of slides in Power Point Presentation i.e., during a presentation, the presenter does not have to move back and forth between computer and

screen to select the next slide. Hand Gestures can be used for remote controls for television sets, stereos and room lights. Household robots could be controlled with hand gestures. In Human Computer interaction, to operate computer with hand gestures no accessories like gloves are needed. The approaches to implement Human-Computer Interaction using Hand Gestures are based on k-Nearest Neighbour (KNN), Support Vector Machines (SVM) and Artificial Neural Network (ANN) Methods.

II. METHODOLOGY

The methodological analysis of the present work has been presented pictorially in Figure 1. The work commence with capturing Hand gesture images using cameras or scanners. These images are made to undergo pre-processing steps like filtering and segmentation. Then different texture and colour features are extracted from the processed image. Finally, the feature values are fed as input to the classifier (KNN, ANN, SVM) to classify the given image.

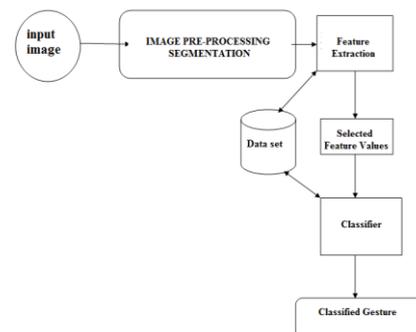

Fig 1: Block Diagram

- Input Image:** The first step in the proposed approach is to capture the video from the digital camera and extract the video frames. The video is captured from the digital camera and the captured frames are then stored in the image database.
- Image Database:** The next point in the project is creation of the image database with all the images that would be used for training and testing. The construction of an image database is clearly dependent on the application. The image database in the proposed approach consists of 200 image samples; where 40 image samples for each gesture 1, gesture 2, gesture 3, gesture 4 and gesture 5. The image database itself is responsible for the better efficiency of the classifier as it is that which decides the robustness of the algorithm.

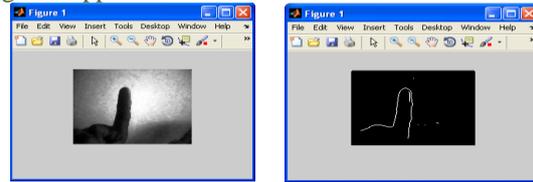

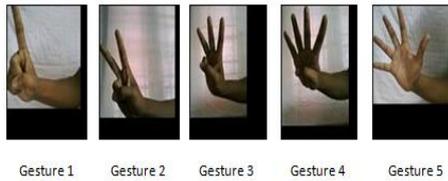

Fig 2a: Before segmentation Fig 2b: After segmentation

C. **Image Pre-processing:** Image pre-processing is the name for operations on images at the lowest level of abstraction whose aim is an improvement of the image data that suppress undesired distortions or enhances some image features important for further processing and analysis task. It does not increase image information content. Its methods use the considerable redundancy in images. Neighbouring pixels corresponding to one real object have the same or similar brightness value. If a distorted pixel can be picked out from the image, it can be restored as an average value of neighbouring pixels. In the proposed approach image pre-processing methods are applied to the frames extracted from the video captured and which are stored in image database. The image processing method i.e., median filtering is used in order to remove noise and preserve the edges in the image, Edge detection for segmentation i.e., to extract the region of interest (hand part) from the image.

i. Median Filtering

The median filter is a nonlinear digital filtering technique, often used to remove noise. Such noise reduction is a typical pre-processing step to improve the results of later processing (for example, edge detection on an image). Median filtering is a nonlinear operation often used in image processing to reduce "salt and pepper" noise. Median filtering is a non-linear smoothing method that reduces the blurring of edges and significantly eliminates impulse noise. It suppresses image noise without reducing the image sharpness and can be applied iteratively.

ii. Segmentation

Image segmentation is process i.e., used to simplify and/or change the representation of an image into something that is more meaningful and easier to analyze. As the premise of feature extraction and pattern recognition, image segmentation is one of the fundamental approaches of digital image processing. Image Segmentation is the process that is used to distinguish object of interest from background. The proposed approach uses edge as a factor to extract the region of interest from the given image. Edges are pixels where the intensity image function changes abruptly. Edge detectors are collection of local image pre-processing methods used to locate changes in the brightness function. Edges are the sign of lack of continuity, and ending. EDGE function finds edges in intensity image. EDGE function takes image as its input, and returns a binary image of the same size, with 1's where the function finds edges in image and 0's elsewhere. The figure 2 shows the filtered image and the edges in the segmented image that is detected using EDGE function.

D. **Feature Extraction**

The aim of this phase is to find and extract features that can be used to determine the meaning of a given gesture. Shift and rotation invariant features lead to a better recognition of hand gestures even if the hand gesture is captured in a different angle.

Hence Zernike moments are used to calculate feature set. The proposed approach considers 11 order of moments to extract the feature from the segmented image.

Zernike moments (ZM)

Objects are generally recognized with the help of their shapes and most of the real time objects have irregular shapes. Hence they cannot be properly described with the help of regular shape descriptors like circularity, linearity and so on. Hence we adopt Zernike moments. The moments are higher space feature vector and are generally of order N. The more order of moments are considered, the better the recognition probability. If any image is assumed to be an object, its descriptors are known as feature vectors.

The Zernike polynomials are a set of complex, orthogonal polynomials defined over the interior of a unit circle $x^2 + y^2 = 1$

Zernike moment of order n and repetition m is defined as:

$$Z_{nm} = \frac{1}{\pi} \int_{x^2+y^2 \leq 1} V_{nm}(\rho, \theta) f(x, y) dx dy \quad (1)$$

Where:

$f(x,y)$ is the image intensity at (x,y) in Cartesian coordinates,

n is a non-negative integer, m is an integer such that $n-|m|$ is even positive integer

and $|m| \leq n, \geq x^2+y^2$

θ is the angle between vector ρ and the x -axis in a counter clockwise direction.

The form of orthogonal Zernike basis polynomials, $V_{nm}(\rho, \theta)$

$V_{nm}(\rho, \theta)$ is a complex conjugate of $V_{nm}(\rho, \theta) = R_{nm}(\rho)e^{-jm\theta}$ in polar coordinates

(ρ, θ) and $j = \sqrt{-1}$

The polar coordinates polar coordinates (ρ, θ) in the image domain are related to Cartesian coordinates (x,y) as $x = \rho \cos(\theta)$ and $y = \rho \sin(\theta)$.

$R_{nm}(\rho)$ is a radial defined as follows:

$$R_{nm}(\rho) = \sum_{s=0}^{n-m/2} \frac{(-1)^s [(n-s)! \rho^{n-2s}]}{s!(n+\frac{|m|-s}{2})(n-\frac{|m|-s}{2})} \quad (2)$$

To calculate the Zernike moments of an image $f(x,y)$, the image is first mapped onto the unit disk using polar coordinates, where the center of the image is the origin of the unit disk. Pixels falling outside the unit disk are not used in the calculation. Because Z_{mn} is complex, we use the Zernike moments modules Z_{mn} as the features of shape in the recognition of patterns. The magnitude of Zernike moments has rotational invariance property. An

image can be better described by a small set of its Zernike moments than any other type of moments such as geometric moments, Legendre moments, and complex moments in terms of mean-square error. Zernike moments do not have the properties of translation invariance and scaling invariance. The way to achieve such invariance is image translation and image normalization before calculation of Zernike moments [10].

D. Gesture Recognition & Classification:

The recognition process consists of two phases, training and classification. Classification of gestures is done using KNN (k-Nearest Neighbor), ANN (Artificial Neural Network) and SVM (Support Vector Machine) classifiers.

i. K-Nearest Neighbour

KNN stands for “k-nearest neighbour algorithm”, it is one of the simplest but widely used machine learning algorithm. An object is classified by the “distance” from its neighbours, with the object being assigned to the class most common among its k distance-nearest neighbours. If k = 1, the algorithm simply becomes nearest neighbour algorithm and the object is classified to the class of its nearest neighbour [11][12].

ii. Artificial Neural Network

An Artificial Neural Network (ANN) is an information processing paradigm that is inspired by the way biological nervous systems, such as the brain, process the information. The key element of this paradigm is the novel structure of the information processing system. It is composed of a large number of highly interconnected processing elements (neurons) working in unison to solve specific problems. ANNs, like people, learn by example. An ANN is configured for a specific application, such as pattern recognition or data classification, through a learning process. A trained neural network can be thought of as an "expert" in the category of information it has been given to analyze [9][13].

iii. Support Vector Machine

SVMs are currently a hot topic in the machine learning community, creating a similar enthusiasm at the moment as Artificial Neural Networks used to do before. Far being, SVMs yet represent a powerful technique for general (nonlinear) classification, regression and outlier detection with an intuitive model representation. Support vector machines are a set of related supervised learning methods used for classification and regression. Given a set of training examples, each marked as belonging to one of two categories, an SVM training algorithm builds a model that predicts whether a new example falls into one category or the other [14][15][16].

IV. CONCLUSION

In this project work the area of hand-gesture recognition is introduced. The system developed here is a real time hand gesture recognition, main problem of gesture recognition lies in the complexity of the classification algorithms, especially when using high dimensional feature vectors which become necessary in order to be able to distinguish several hundreds of gestures. Thus, the development of good classification methods & precise features is very important in order to run such systems in real-time. The Proposed approach is based on Zernike moments for feature extraction because ZM's are direction and scaling invariant. Therefore proposed approach got better results with 11 Zernike moments and achieved the recognition rate of the KNN up to 77.5%, ANN up to 82.5% and SVM up to 91% for the gesture image with uniform background in light environment with minimum distance of 1 or 2 feet. The results show a significant accuracy in real time recognition. So by this we can conclude this system works with better efficiency considering SVM as a classifier either then ANN or KNN classifier.

Abstract : This paper describes design and analysis of Spur gear. In the present work, it is proposed to substitute the metallic gear of sugarcane juice machine with plastic gears to reduce the weight and noise. For the purpose of two different types of plastic materials were considered namely Nylon and Polycarbonate and their viability are checked with their counterpart metallic gear (Cast iron). Based on the static analysis, the best plastic material is recommended for the purpose. Static analysis of a 3-D model has been performed using ANSYS 10.0. Compared to Cast iron spur gears Nylon gears are suitable for the application of sugarcane juice machine application under limited load conditions.

Keywords: Cast iron spur gears, Static analysis, Nylon Spur gears, and Polycarbonate spur gears.

I. Introduction

According to the position of axes of the shafts the following are the different kinds of gears.

a. Parallel

- Spur gear
- Helical gear
- Rack and pinion

b. Intersecting

- Bevel gears

c. Non – Intersecting and Non parallel

- Worm gears

The gear materials used for the manufacture of gears depend upon the strength and service conditions like wear and noise etc. The gears maybe manufactured from metallic or non – metallic materials. The cast iron is widely used for the manufacture of gears due to its good wearing properties, excellent machine ability and ease of producing complicated shapes by casting method. The non – metallic materials like wood, rawhide, compressed paper and plastics like Nylon, Acrylic and Polycarbonate etc are used for gears, especially for reducing weight and noise.

Weight reduction can be achieved primarily by the introduction of better material, design optimization and better manufacturing processes. The plastic materials have corrosion resistance, low electrical and thermal conductivity, easily formed into complex shapes, wide choices of appearance, colors and transparencies. The introduction of plastic materials was made it possible to reduce the weight of the spur gear without any reduction on load carrying capacity and stiffness.

The Nylon materials have high strength, good mechanical

and abrasion resistance property, excellent wear resistance, resistant to most chemicals and self-lubricant. Polycarbonate materials have, high impact strength, good dimension stability and heat resistance. Since, Nylon and Poly carbonate have good properties as stated above the cast iron spur gears of sugarcane juice machine are being replaced by plastic spur gears. The plastic material offer opportunities for substantial weight saving but not always are cost-effective over their cast iron counter parts.

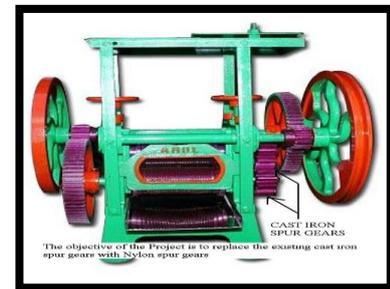

Fig. No. 1 Schematic diagram of a sugarcane juice machine.

II. Literature Review:

The review mainly focuses on replacement of Cast iron spur gears with the Nylon spur gear in the application of sugarcane juice machine.

R. Yakut, H. Düzçükoğlu*, M.T. Demirci et al

[1] In this study, load carrying capacity and occurring damages of gears which are made of PC/ABS blends were investigated. PC is hard material and ABS is soft material. The usage of materials limits these drawbacks. However PC and ABS polymers combine each other, the PC/ABS blends have suitable mechanical properties for gear applications in the industrial areas. In this study, usability of PC/ABS composite plastic materials as spur gear was investigated. PC/ABS gears were tested by applying three different loading at two different numbers of revolutions on the FZG experiment set.

J.L. Moya, A.S. Machado, J.A.Velásquez, R. oytisolo, A.E.Hernández, J.E. Fernández, and J.M. Sierra et al [2] In this study they have performed a theoretical analysis of a procedure to determine the Lewis Factor and also performed the contact analysis of spur gears to find the stress distribution between gear tooth.

Alexandre Luís Gasparin^I; Leandro Luís Corso^I; Eduardo Kirinus Tentardini^{II}; Regina Célia Reis Nunes^{III}; Maria Madalena de Camargo Forte^{IV}; Ricardo Vinicius Bof de Oliveira, et al [3] The focus of this paper is to establish a characterisation method for seven polyamide (PA) grades to determine the major material to manufacture an automotive

worm gear. The composite properties were measured according to the worm gear loadings: tensile strength, Young's modulus, abrasion and impact resistance. They were also correlated to the PA moisture absorption and its glass fibre (GF) reinforcement. The data from mechanical tests were applied in the finite element analysis (FEA) using the von Mises stress criterion. Before the rig tests of the PA worm gears, the injection process was evaluated, through the capillary rheometry. A higher difficulty to process PA 6/6 30% GF was found, due to its lower apparent viscosity. In the end, the influence of moisture absorption was as decisive to the gear's material selection as the GF to the pinion. Thus, the PAs with the best performance were: PA 6 with 30% GF (gear) and with PA 60% GF (pinion).

III. Specification Of The Problem

In this project work it is proposed to substitute the metallic gear of sugarcane juice machine with plastic gears to reduce the weight and noise. For the purpose of two different types of plastic materials were considered namely Nylon and Polycarbonate and their viability are checked with their counterpart metallic gear (Cast iron). Based on the static analysis, the best plastic material is recommended for the purpose. A virtual model of spur gear was created in Pro-E. Model is imported in ANSYS 10.0 for analysis by applying normal load conditions. After analysis a comparison is made among existing Cast iron spur gear. Based on the deflections and stresses from the analysis we choose the best one between the Nylon and Polycarbonate spur gears.

IV. GEARS

Gear is nothing but a toothed wheel which is useful to transmit power from one shaft to another shaft. They are suitable when two machine parts are nearer to each other. They give exact ratio of transmission of motion, slip cannot take place between gears, they are useful for high torque transmission.

In spur gear teeth is parallel to axis of rotation. Spur gear transmit power from one shaft to another parallel shaft.

4.1 Materials for Gears :

The gear materials used for the manufacture of gears depend upon the strength and service conditions like wear and noise etc. The gears maybe manufactured from metallic or non – metallic materials. The cast iron is widely used for the manufacture of gears due to its good wearing properties, excellent machine ability and ease of producing complicated shapes by casting method. The non – metallic materials like wood, rawhide, compressed paper and plastics like Nylon, Acrylic and Polycarbonate etc are used for gears, especially for reducing weight and noise.

4.2 Theoretical calculations of conventional Cast iron Spur gear:

In the present analysis the maximum torque, allowable stress and tangential load of the spur gear are calculated based on the desired sugarcane juice machine motor specifications and are as following below:

4.3 Specifications of sugarcane juice machine motor:

Power (P) = 1.5 kW = 1500 watt

Speed (N) = 1400 RPM

$$\text{Power (P)} = 2 * \pi * N * T / 60$$

$$1500 = (2 * \pi * 1400 * T) / 60$$

$$\text{Torque (T)} = (1500 * 60) / (2 * \pi * 1400)$$

$$T = 10.2313 \text{ N-m}$$

$$T = 102313 \text{ N-mm}$$

$$T = F * (d/2)$$

$$F = T / (d/2)$$

$$F = 10231 / 90$$

$$F = 113.677 \text{ N}$$

Where 'F' is the Tangential load

Using Lewis equation

$$\text{Tangential load } F = \sigma_b * y * P_c * b$$

$$113.677 = \sigma_b * 0.1034 * (\pi * 10) * 54$$

$$\sigma_b = 113.677 / (0.1034 * (\pi * 10) * 54)$$

$$\sigma_b = 0.648 \text{ N/mm}^2$$

Where 'σ_b' is the allowable stress

'y' is the Lewis form factor

'P_c' (Circular pitch) = π * module

'b' is the face width of the gear

'd' is the pitch circle diameter of the gear

The Maximum allowable stress as per the design of the desired spur gear, σ_b = 0.648 N/mm²

Allowable stress of Cast iron (high grade) =

$$= \text{Ultimate tensile strength} / 3$$

$$= 320 / 3 = 106.67 \text{ N/mm}^2 > 0.648 \text{ N/mm}^2$$

Allowable stress of Nylon =

$$= \text{Ultimate tensile strength} / 3$$

$$= 69 / 3 = 23 \text{ N/mm}^2 > 0.648 \text{ N/mm}^2$$

Allowable stress of Polycarbonate =

$$= \text{Ultimate tensile strength} / 3$$

$$= 62 / 3 = 20.67 \text{ N/mm}^2 > 0.648 \text{ N/mm}^2$$

SO the design is safe

Page no 8.21)

V. Geometric details of desired spur gear:

- Module (m) = 10 mm
- Addendum = 1 module
- Dedendum = 1.157 * module
- Pressure angle (α) = 20 degrees
- Tooth thickness(t) = 1.571 * module
- Whole depth = 2.25 * module
- Face width(b) = 5.4 * module
- Fillet radius = 3.9 * module
- No of teeth(z) = 18

5.1 Calculation of gear tooth proportions:

- Pitch circle diameter (p.c.d) = z * m
= 18 * 10 = 180 mm
- Base circle diameter (D_b) = D Cos α
= 180 Cos 20 = 169.145 mm
- Out circle diameter = (Z+2) * m
= (18+2) * 10 = 200 mm
- Clearance = Circular pitch / 20
= 31.4 / 20 = 1.57 mm
- Dedendum =
= Addendum + clearance = 10 + 1.57
= 11.57 mm.

• Module = D/z = 180/18 = 10mm.

• Dedendum circle diameter = p.c.d - 2 * dedendum = 80 - 2 * 11.57 = 156.86 mm.

• Fillet radius = circular pitch/8 = 31.4/8 = 3.9 mm

• Pitch circle diameter (Pc) = m * z = 10 * 18 = 180mm

• Hole depth = 2.25 * m = 2.25 * 10 = 22.5mm

• Thick ness of the tooth = 1.571 * 10 = 15.71mm

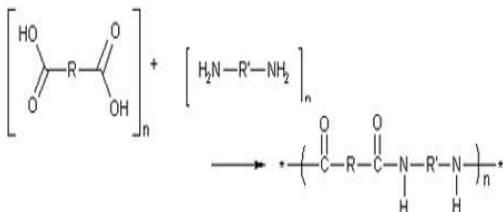

• Face width (b) = Ψ * a = 0.3 * 180 = 54 mm
 Where 'a' is the centre distance between two gears = (180 + 180 / 2) 180 mm and assume Ψ = 0.3
 Diametral pitch = Number of teeth/ P.C.D = 18 / 180 = 0.1 mm

VI. Specification Of Existing Cast Iron Gear:

The typical chemical composition of the cast iron material : Carbon - 2.5 to 3.7%, Silicon - 1.0 to 3.0%, Manganese - 0.5 to 1.0%, Phosphorus - 0.1 to 0.9% and Sulphur - 0.07 to 0.10%

6.1 SPECIFICATIONS OF NYLON AND POLYCARBONATE PLASTIC MATERIALS:

Chemical composition of Nylon:

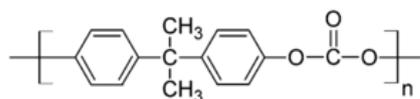

Its properties are determined by the R and R' groups in the monomers. In nylon 6, 6, R' = 6C and R = 4C alkanes, but one also has to include the two carboxyl carbons in the diacid to get the number it donates to the chain.

The majorities of nylons tends to be semi-crystalline and are generally very tough materials with good thermal and chemical resistance. The different types give a wide range of properties with specific gravity, melting point and moisture content tending to reduce as the nylon number increases. Nylons can be used in high temperature environments. Heat stabilized systems allow sustained performance at temperatures up to 185oC.

Chemical composition of Polycarbonate:

The main polycarbonate material is produced by the reaction of bisphenol A and phosgene COCl₂. The overall reaction can be written as follows:

Polycarbonates received their name because they are polymers containing carbonate groups (-O-(C=O)-O-). Most polycarbonates of commercial interest are derived from rigid monomers. A balance of useful features including temperature resistance, impact resistance and

optical properties position polycarbonates between commodity plastics and engineering plastics

Table: 1 Material properties of cast iron, Nylon and Polycarbonate:

Material Property	Cast Iron	Nylon	Polycarbonate
Young's Modulus (N/mm ²)	1.65e5	2.1e5	2.75e5
Poisson's ratio	0.25	0.39	0.38
Density (Kg/mm ³)	7.2e-6	1.13e-6	1.1e-6
Co-efficient of friction	1.1	0.15-0.25	0.31
Ultimate Tensile strength (Mpa)	320-350	55-83	55-70

VII. Finite Element Analysis Of Spur Gear :

Finite element modeling is described as the representation of the geometric model in terms of a finite number of element and nodes. It is actually a numerical method employed for the solution of structures or a complex region defining a continuum. Solutions obtained by this method are rarely exact. However, errors in the approximate solution can be minimized by increasing the number of equations till the desired accuracy obtained. This is an alternative to analytical methods that are used for getting exact solution of analysis problems. The solution of general problem by finite element method always follows an orderly step-by-step process. for analysis in ANSYS 10.0. The loading conditions are assumed to be static. The element choosen is solid Brick 8 node45.

VIII. Results Obtained From Ansys:

From the static analysis using ansys the deflections and vonmisse stress and strain values for the cast iron, Nylon and polycarbonate are obtained as following below tables.

For Cast Iron Spur gear:

Pressure (N/mm ²)	Vonmisse Stress (N/mm ²)	Deflection (mm)	Strain
1	3.832	0.002905	2.21e-4
2	7.665	0.005811	4.41e-4
3	11.497	0.008716	6.62e-4
4	15.33	0.011622	8.82e-4
5	19.078	0.014488	1.14e-3

For Nylon Spur gear:

Pressure (N/mm ²)	Vonmisse Stress (N/mm ²)	Deflection (mm)	Strain
1	3.582	0.002381	2.19e-4
2	7.163	0.004762	4.37e-4
3	10.745	0.007143	6.56e-4
4	14.327	0.009524	8.74e-4
5	17.82	0.011867	1.29e-3

For Polycarbonate Spur gear:

Pressure (N/mm ²)	Vonmisse Stress (N/mm ²)	Deflection (mm)	Strain
1	3.615	0.001817	2.20e-4
2	7.863	0.003635	4.45e-4
3	10.846	0.005452	6.61e-4
4	14.462	0.007274	8.82e-4
5	17.989	0.009059	1.38e-3

stresses and deflection values of the spur gear were increased. And the minimum stress values are obtained for Nylon spur gear compared with Cast iron and Polycarbonate. According to the study, analysis, results and graphs we recommend the best plastic material is Nylon and Nylon gears are suitable for the application of sugar cane juice machine under limited load conditions.

Graphs:

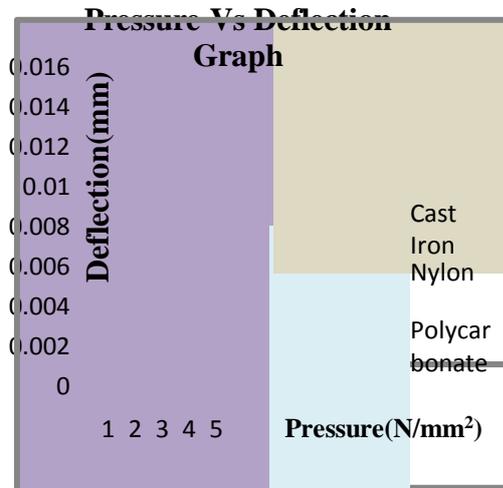

Fig 1: Pressure Vs Deflection graph

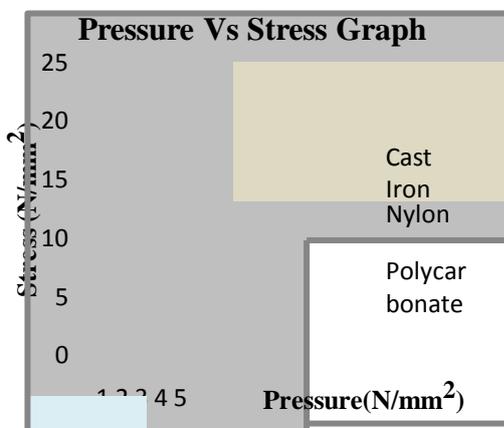

Fig 2: Pressure Vs Stress graph

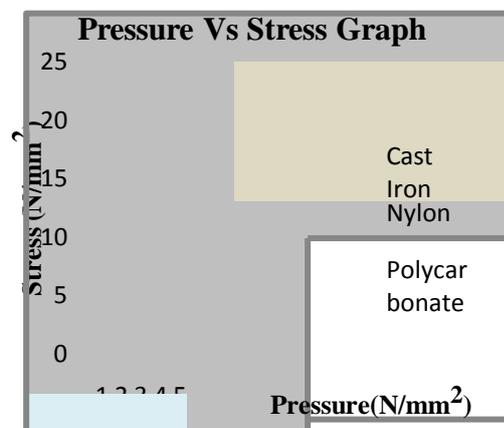

Fig 3: Stress Vs Strain graph

Results and discussion

From the static analysis by increasing the pressure on the tooth flank surface we observed that the vonmisse

IX. CONCLUSIONS:

To find the suitable design gears with less weight and less cost, corrosion resistance, frictionless also. To design and manufacture a sugarcane juice for a common people including women. With less cost, self lubricating neat and clean hygienic juice. With more material removal of deflection and stress are increased. So for safe operation of my design is more appropriate under limited load conditions for Nylon gear.

Abstract : In this paper, necessary modules have been implemented to make architecture to insert into motion estimation. The significant function of motion estimation (ME) in a video coder, testing such a module is of priority concern. While focusing on the testing of ME in a video coding system, this work presents an error detection and data recovery (EDDR) design, based on the residue-and quotient (RQ) code, to embed into ME for video coding testing applications. An error in processing elements (PEs), i.e. key components of a ME, can be detected and recovered effectively by using the proposed EDDR design. Experimental results indicate that the modules required for proposed EDDR design for ME testing can detect errors and recover data with an acceptable area overhead and timing penalty. Importantly, the proposed EDDR design performs satisfactorily in terms of throughput and reliability for ME testing applications.

Keywords – Motion Estimation, SAD Tree, Error detection and recover circuits.

I. INTRODUCTION

Methodologies

Coding approaches such as parity code, Berger code, and residue code have been considered for design applications to detect circuit errors. Residue code is generally separable arithmetic codes by estimating a residue for data and appending it to data. Error detection logic for operations is typically derived by a separate residue code, making the detection logic is simple and easily implemented. For instance, assume that N denotes an integer, N1 and N2 represent data words, and m refers to the modulus. A separate residue code of interest is one in which N is coded as a pair. $N \cdot m$ is the residue N of m modulo . Error detection logic for operations is typically derived using a separate residue code such that detection logic is simply and easily implemented. However, only a bit error can be detected based on the residue code. Additionally, an error can not be recovered effectively by using the residue codes. Therefore, this work presents a quotient code, which is derived from the residue code, to assist the residue code in detecting multiple errors and recovering errors. In order to simplify the complexity of circuit design, the implementation of the module is generally dependent on the addition operation. Additionally, based on the concept of residue code, the following definitions shown can be applied to generate the RQ code for circuit design. the corresponding circuit design of the RQCG is easily realized by using the simple adders (ADDs). Namely, the

RQ code can be generated with a low complexity and little hardware cost.

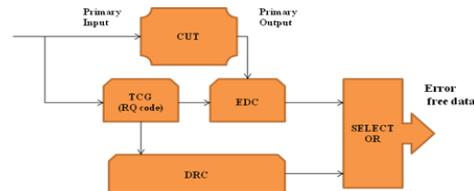

Fig 1: Circuit Diagram

Sum Of Absolute Difference Calculation

By utilizing PEs, SAD shown in as follows, in a macro block with size N X N of can be evaluated:

$$\begin{aligned}
 SAD &= \sum_{i=0}^{N-1} \sum_{j=0}^{N-1} |X_{ij} - Y_{ij}| \\
 &= \sum_{i=0}^{N-1} \sum_{j=0}^{N-1} |(q_{xij} \cdot m + r_{xij}) - (q_{yij} \cdot m + r_{yij})|
 \end{aligned}$$

Where $r_{xi,j}$, $q_{xi,j}$ and $r_{yi,j}$, $q_{yi,j}$ denote the corresponding RQ code of $X_{i,j}$, $Y_{i,j}$ and modulo M. Importantly, and represent the luminance pixel value of Cur_pixel and Ref_pixel, respectively.

PIXEL VALUES

	0	1	2	3
0	128	128	64	255
1	128	64	255	64
2	64	255	64	128
3	255	64	128	128
	Cur_pixel			

	0	1	2	3
0	1	1	2	3
1	1	2	3	4
2	2	3	4	5
3	3	4	5	5
	Ref_pixel			

Fig 2: Circuit Diagram

NUMERIC CALCULATION

A numerical example of the 16 pixels for a 4X 4 macroblock in a specific PEi of a ME is described . We presents an example of pixel values of the Cur_pixel and Ref_pixel. Based on, the SAD value of the 4X 4 macroblock is

$$\begin{aligned}
 SAD &= \sum_{i=0}^3 \sum_{j=0}^3 |X_{ij} - Y_{ij}| \\
 &= X_{00} - Y_{00} + |X_{01} - Y_{01}| + \dots + X_{33} - Y_{33} \\
 &= (128 - 1) + (128 - 1) + \dots + (128 - 5) \\
 &= 2124.
 \end{aligned}$$

According to describe about RQ Code for modulo operation is assumed $M=2^6-1=63$ RQ code for SAD value $RT=RPEi=|2124|63=45$ and $QT=QPEi=|2124/63|=33$.

II. MAIN MODULE'S:

1. SAD TREE
2. RQ CODE GENERATION
3. ERROR DETECTION CIRCUIT
4. DATA RECOVERY CIRCUIT

MODULE DESCRIPTION:

2.1 SAD TREE

We propose a 2-D intra-level architecture called the Propagate Partial SAD The architecture is composed of PE arrays with a 1-D adder tree in the vertical direction. Current pixels are stored in each PE, and two sets of continuous reference pixels in a row are broadcasted to PE arrays at the same time. In each PE array with a 1-D adder tree, distortions are computed and summed by a 1-D adder tree to generate one-row SAD. The row SADs are accumulated and propagated with propagation registers in the vertical direction. The reference data of searching candidates in the even and odd columns are inputted by Ref. Pixels 0 and Ref Pixels 1, respectively. After initial cycles, the SAD of the first searching candidate in the zero th column is generated, and the SADs of the other searching candidates are sequentially generated in the following cycles. When computing the last searching candidates in each column, the reference data of searching candidates in the next columns begin to be inputted through another reference input. In Propagate Partial SAD, by broadcasting reference pixel rows and propagating partial-row SADs in the vertical direction, it provides the advantages of fewer reference pixel registers and a shorter critical path. Since $Rt(Q_t)$ is equal to RPE_i (QPE_i) EDC is enabled and a signal "0" is generated to describe a situation in which the specific PE_i is error-free. Conversely, if SA1 and SA0 errors occur in bits 1 and 12 of a specific PE_i i.e. the pixel values of $PE_i = 2124$. for video coding systems, motion estimation (ME) can remove most of temporal redundancy, so a high compression ratio can be achieved. Among various ME algorithms, a full-search block matching algorithm (FSBMA) is usually adopted because of its good quality and regular computation. In FSBMA, the current frame is partitioned into many small macroblocks (MBs) of size For each MB in the current frame (current MB), one reference block that is the most similar to current MB is sought in the searching range of size in the reference frame. The most common used criterion of the similarity is the sum of absolute differences (SAD).

$$SAD = \sum_{i=0}^{N-1} \sum_{j=0}^{N-1} |X_{i,j} - Y_{i,j}|$$

$$= \sum_{i=0}^{N-1} \sum_{j=0}^{N-1} |(q_{xij} \cdot m + r_{xij}) - (q_{yij} \cdot m + r_{yij})|$$

where cur and ref are pixel values in the current MB (current pixel) and reference block (reference pixel), respectively, is one searching candidate in the search range, Distortion is the difference between the current pixel and the reference pixel, and SAD is the total distortion of this searching candidate. The row (column) SAD is the summation of distortions in a row (column). After all searching candidates are examined, the searching candidate that has the smallest SAD is selected as the motion vector of the current MB. Although FSBMA provides the

best quality among various ME algorithms, it consumes the largest computation power. In general, the computation complexity of ME varies from maximum of a typical video coding system. Hence, a hardware accelerator of ME is required. Variable block-size motion estimation (VBSME) is a new coding technique and provides more accurate predictions compared to traditional fixed block-size motion estimation (FBSME). With FBSME, if an MB consists of two objects with different motion directions, the coding performance of this MB is worse. On the other hand, for the same condition, the MB can be divided into smaller blocks in order to fit the different motion directions with VBSME. Hence, the coding performance is improved. VBSME has been adopted in the latest video coding standards, including H.263, MPEG-4, WMV9.0, and H.264/AVC. For instance, in H.264/AVC, an MB with a variable block size can be divided into seven kinds of blocks including 4x4, 4x8, 8x4, 8x8, 8x16, 16x8, and 16x16. Although VBSME can achieve a higher compression ratio, it not only requires huge computation complexity but also increases the difficulty of hardware implementation for ME. Traditional ME hardware architectures are designed for FBSME, and they can be classified into two categories.

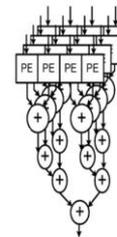

Fig3: Partial SAD tree

One is an inter-level architecture, where each processing element (PE) is responsible for one SAD of a specific searching candidate and the other is an intra-level architecture, where each PE is responsible for the distortion of a specific current pixel.

The concept of the proposed SADTree architecture. The proposed SAD Tree is a 2-D intra-level architecture and consists of a 2-D PE array and one 2-D adder tree with propagation registers. Current pixels are stored in each PE, and reference pixels are stored in propagation registers for data reuse. In each cycle, current and reference pixels in a row are inputted into propagation registers to update reference pixels. In propagation registers, reference pixels are propagated in the vertical direction row by row. In SAD Tree architecture, all distortions of a searching candidate are generated in the same cycle, and by an adder tree, distortions are accumulated to derive the SAD in one cycle. In order to provide a high utilization and data reuse, the snake scan is adopted and reconfigurable data path propagation registers are developed in the proposed SAD Tree, which consists of five basic steps from A to E. The first step, A, fetches pixels in a row and the shift direction of propagation registers is downward. When calculating the last candidates in a column, one extra reference pixel is required to be inputted, that is, step B. When finishing the computation of one column, the reference pixels in the propagation registers

are shifted left in step C. Because the reference data have already been stored in the propagation registers, the SAD can be directly calculated. The next two steps, D and E, are the same as steps A and B except that the shift direction is upward. After finishing the computation of one column in the search range, we execute step C and then go back to step A. This procedure will iterate until all searching candidates in the search range have been calculated. the data reuse between two successive searching candidates can be maximized

SUB MODULES'S

- ADDER TREE
- HALF ADDER
- FULL ADDER
- RIPPLE CARRY ADDER

2.1.1 PROCESSING ELEMENT

A ME (Motion Estimation) consists of many PEs incorporated in a 1-D or 2-D array for video encoding applications. A PE generally consists of two ADDs (i.e. an 8-b ADD and a 12-b ADD) and an accumulator (ACC). Next, the 8-b ADD (a pixel has 8-b data) is used to estimate the addition of the current pixel (Cur pixel) and reference pixel (Ref_pixel). Additionally, a 12-b ADD and an ACC are required to accumulate the results from the 8-b ADD in order to determine the sum of absolute difference (SAD) value for video encoding applications. Notably, some registers and latches may exist in ME to complete the data shift and storage. encoding applications. Notably, some registers and latches may exist in ME to complete the data shift and storage. The PEs are essential building blocks and are connected regularly to construct a ME. Generally, PEs are surrounded by sets of ADDs and accumulators that determine how data flows through them. PEs can thus be considered the class of circuits called ILAs, whose testing assignment can be easily achieved by using the fault model, cell fault model (CFM). Using CFM has received considerable interest due to accelerated growth in the use of high-level synthesis, as well as the parallel increase in complexity and density of integration circuits (ICs). Using CFM makes the tests independent of the adopted synthesis tool and vendor library. Arithmetic modules, like ADDs (the primary element in a PE), due to their regularity, are designed in an extremely dense configuration. A ME generally consists of PEs with a size of 4 x 4. However, accelerating the computation speed depends on a large PE array, especially in high-resolution devices with a large search range such as HDTV. Additionally, the visual quality and peak signal-to-noise ratio (PSNR) at a given bit rate are influenced if an error occurred in ME process. A testable design is thus increasingly important to ensure the reliability of numerous PEs in a ME. Moreover, although the advance of VLSI technologies facilitate the integration of a large number of PEs of a ME into a chip, the logic-per-pin ratio is subsequently increased, thus decreasing significantly the efficiency of logic testing on the chip. As a commercial chip, it is absolutely necessary for the ME to introduce design for testability (DFT). Motion estimation is the process of determining motion vectors that describe the transformation from one 2D image to another; usually from adjacent frames in a video sequence. It is an ill-posed problem as the motion is in three dimensions but the images

are a projection of the 3D scene onto a 2D plane. The motion vectors may relate to the whole image (global motion estimation) or specific parts, such as rectangular blocks, arbitrary shaped patches or even per pixel. The motion vectors may be represented by a translational model or many other models that can approximate the motion of a real video camera, such as rotation and translation in all three dimensions and zoom. Closely related to motion estimation is optical flow, where the vectors correspond to the perceived movement of pixels. In motion estimation an exact 1:1 correspondence of pixel positions is not a requirement. Applying the motion vectors to an image to synthesize the transformation to the next image is called motion compensation. The combination of motion estimation and motion compensation is a key part of video compression as used by MPEG 1, 2 and 4 as well as many other video codec's.

2.1.2 ADDER TREE

In this module Half Adder is a digital combinational circuit that is used for the addition of two bits and provides an output in the form of a sum bit and a carry bit. The logical functional equations that relate the outputs S and C of a half adder circuit to the input bits are given below
 $Sum(S) = A \text{ ex-OR } B$
 $Carry(C) = A.B$

Thus a half adder circuit can easily be synthesized by using 1 ex-OR gate and 1 AND gate. Since a half adder circuit can only be used to add two bits, it becomes obsolete in case of multi-bit addition in practical applications.

Fig5: Truth Table

APPLICATIONS:

- In electronics, an adder or summer is a digital circuit that performs addition of numbers. In many computers and other kinds of processors, adders are used not only in the arithmetic logic unit(s), but also in other parts of the processor, where they are used to calculate addresses, table indices, and similar.
- Although adders can be constructed for many numerical representations, such as binary-coded decimal or excess-3, the most common adders operate on binary numbers.
- In cases where two's complement or ones' complement is being used to represent negative numbers, it is trivial to modify an adder into an adder-subtractor. Other signed number representations require a more complex adder.

2.1.3 FULL ADDER:

In this module describe about full adder operation. The limitation of a half-adder is that it cannot accept a carry-in bit. the carry-in bit represents the carry-out of the previous low-order bit position. Thus a half-adder can be used only for the two least significant digits when adding two multi bit binary numbers, since there can be no possibility of a propagated carry to this stage. In multi bit addition, a carry bit from a previous stage must be taken into account, which gives rise to the necessity for designing a full adder. A full adder can accept two operands bits, a_i and b_i , and a carry-in bit c_i from previous stage; it produces a sum bit s_i and a carry-out bit c_o . sum bit s_i is 1 if there is an odd number of 1's at the inputs of the full adder, whereas the carry-out c_o is 1 if there are two or more 1's at the inputs. The sum and carry out bits will be 0 otherwise. In ripple carry adder, the carry signals must ripple through all the full adders before the outputs stabilize to the correct values; hence such an adder is often called a ripple adder. addition is to be performed the carry-out generated from the least significant stage of the adder propagates through the successive stages and produces a carry-in into the most significant stage of the adder. The time required to perform addition in a ripple adder depends on the time needed for the propagation of carry signals through the individual stages of the adder. Thus ripple carry addition is not instantaneous. The greater the number of stages in a ripple carry adder the longer is the carry propagation time, and consequently the slower the adder.

APPLICATIONS:

1. Addition is an essential function in fundamental arithmetic operations.
2. It is also the most copiously used operation in application-specific processors and digital signal processing application (DSP).
3. Full-adder has been introduced by integrating the full-adder into a multiplier-less finite impulse response (FIR) filter that is commonly used in the multi rate filter bank for biomedical applications.

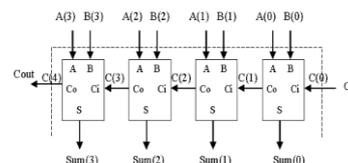

2.1.4 RIPPLE CARRY ADDER

A standard 8-bit ripple-carry adder built as a cascade from eight 1-bit full-adders. Click the input switches or use the following bind keys: ('c') for carry-in, for A0..A7 and ('1','2', ..., '8') for B0..B7. To demonstrate the typical behavior of the ripple-carry adder, very large gate-delays are used for the gates inside the 1-bit adders - resulting in an addition

time of about 0.6 seconds per adder. Note that each stage of the adder has to wait until the previous stage has calculated and propagates its carry output signal. Obviously, the longest delay results for operands like $A = 0b0000000$, $B=0b11111111$ or $A=0b01010101$ and $B=0b10101010$ (select these, and then switch carry-in to both 0 and 1, and watch the circuit to settle). Therefore, the total delay of a ripple-carry adder is proportional to the number of bits.

Faster adders are often required for bit widths of 16 or greater. A carry-look ahead adder (CLA) is a type of adder used in digital logic. A carry-look ahead adder improves speed by reducing the amount of time required to determine carry bits. It can be contrasted with the simpler, but usually slower, ripple carry adder for which the carry bit is calculated alongside the sum bit, and each bit must wait until the previous carry has been calculated to begin calculating its own result and carry bits (see adder for detail on ripple carry adders). The carry-look ahead adder calculates one or more carry bits before the sum, which reduces the wait time to calculate the result of the larger value bits. The Kogge-Stone adder and Brent-Kung adder are examples of this type of adder. Arithmetic operations like addition, subtraction, multiplication, division are basic operations to be implemented in digital computers using basic gates like AND, OR, NOR, NAND etc. Among all the arithmetic operations if we can implement addition then it is easy to perform multiplication (by repeated addition), subtraction (by negating one operand) or division (repeated subtraction). Half Adders can be used to add two one bit binary numbers. It is also possible to create a logical circuit using multiple full adders to add N-bit binary numbers. Each full adder inputs a **Cin**, which is the **Cout** of the previous adder. This kind of adder is a **Ripple Carry Adder**, since each carry bit "ripples" to the next full adder. The first (and only the first) full adder may be replaced by a half adder. The block diagram of 4-bit Ripple Carry Adder is shown here below. The layout of the ripple carry adder is simple, which allows for fast design time; however, the ripple carry adder is relatively slow, since each full adder must wait for the carry bit to be calculated from the previous full adder. The gate delay can easily be calculated by inspection of the full adder circuit. Each full adder requires three levels of logic. In a 32-bit [ripple carry] adder, there are 32 full adders, so the critical path (worst case) delay is $31 * 2(\text{for carry propagation}) + 3(\text{for sum}) = 65$ gate delays. Arithmetic Module Generator (AMG) supports various hardware algorithms for two-operand adders and multi-operand adders. These hardware algorithms are also used to generate multipliers, constant-coefficient multipliers and multiply accumulators. In the following, we briefly describe the hardware algorithms that can be handled by AMG.

4 Bit Ripple Carry Adder

Want to write a VHDL model for a 4 bit ripple carry adder.

```

Logic equation for each full adder is:
sum <= a xor b xor ci;
co <= (a and b) or (ci and (a or b));
    
```

Fig8: Ripple Carry Adder

The most straightforward implementation of a final stage adder for two n-bit operands is a ripple carry adder, which requires n full adders (FAs). The carry-out of the ith FA is connected to the carry-in of the (i+1)th FA. Figure shows a ripple carry adder for n-bit operands, producing n-bit sum outputs and a carry out.

III. RQ CODE GENERATION

Coding approaches such as parity code, Berger code, and residue code have been considered for design applications to detect circuit errors. Residue code is generally separable arithmetic codes by estimating a residue for data and appending it to data. Error detection logic for operations is typically derived by a separate residue code, making the detection logic is simple and easily implemented. The basic problem we have to resolve is that memory and communications technology isn't totally reliable; we have to expect and be ready to deal with errors in the hardware. This document will describe two very different technologies for detecting, and maybe correcting, errors that may occur in data storage and transmission. The first approach to be described is more appropriate for environments like memory: a relatively small amount of data is fetched in parallel. This approach, called "error detecting and correcting codes," is based on defining a distance between two bit strings in terms of the number of bits that have to change to get from the first string to the second. Extra bits are added to each string, which are set so that some minimum number of bits must change to get from one valid string to another. If the received string isn't valid, it is assumed that the correct string is the one "closest" to the received string. The second approach is more appropriate to environments in which relatively large amounts of data are to be transferred, but they are transferred serially. In this approach a "signature" is appended to the data string; the number of bits in the signature is much less than the number of bits that would be required to do an error correcting code. This approach will lead to adding checksums or cyclic redundancy checks to the string. R. W. Hamming wrote the paper that both opened and closed this field in 1950. His interest was in providing a means of self-checking in computers, which were just being developed at the time he wrote this. the paper appeared in the *Bell System Technical Journal*, April, 1950. Definitely worth tracking down in the library and reading The Hamming distance between two bit strings is the number of bits you have to change to convert one to the other: this is the same as the number of edges you have to traverse in a binary hypercube to get from one of the vertices to the other. The basic idea of an error correcting code is to use extra bits to increase the dimensionality of the hypercube, and make sure the Hamming distance between any two valid points is greater than one.

- If the Hamming distance between valid strings is only one, a single-bit error results in another valid string. This means we can't detect an error.
- If it's two, then changing one bit results in an invalid string, and can be detected as an error.

Unfortunately, changing just one more bit can result in another valid string, which means we can't know which bit was wrong: so we can detect an error but not correct it.

3.1 CONCURRENT ERROR DETECTION (CED)

While the extended BIST schemes generally focus on memory circuit, testing-related issues of video coding have seldom been addressed. Thus, exploring the feasibility of an embedded testing approach to detect errors and recover data of a ME is of worthwhile interest. Additionally, the reliability issue of numerous PEs in a ME can be improved by enhancing the capabilities of concurrent error detection (CED). The CED approach can detect errors through conflicting and undesired results generated from operations on the same operands. CED can also test the circuit at full operating speed without interrupting a system. Thus, based on the CED concept, this work develops a novel EDDR architecture based on the RQ code to detect errors and recovery data in PEs of a ME and, in doing so, further guarantee the excellent reliability for video coding testing applications. Error detection logic for operations is typically derived using a separate residue code such that detection logic is simply and easily implemented. However, only a bit error can be detected based on the residue code. Additionally, an error can't be recovered effectively by using the residue codes. Therefore, this work presents a quotient code, which is derived from the residue code, to assist the residue code in detecting multiple errors and recovering errors. the corresponding circuit design of the RQCG is easily realized by using the simple adders (ADDs). Namely, the RQ code can be generated with a low complexity and little hardware cost. Concurrent test methods enable integrated circuits to verify the correctness of their results during normal operation. While this ability is highly desirable, especially in high safety applications, designing a cost-effective concurrently testable circuit is a challenging task. Quality assessment of concurrent test methods relies on several parameters, including the model of detectable faults or errors, the worst-case detection latency, and the incurred area overhead. Additionally, an important consideration is whether a concurrent test method is intrusive or non-intrusive, i.e. whether the original circuit is modified or left intact, respectively. The importance of concurrent test in only accentuated by the plethora and variety of previous research efforts in this area. Several low-cost, non-intrusive, concurrent fault detection (CFD) methods have been proposed for stuck-at faults in combinational circuits. C-BIST employs input monitoring to perform concurrent self-test. While hardware overhead is very low, the method relies on an ordered appearance of all possible input vectors before a signature indicating circuit correctness can be calculated, resulting in very long detection latency. This problem is alleviated in R-CBIST, where the requirement for a uniquely ordered appearance of all input combinations is relaxed at the cost of a small RAM. Alternatively, latency is reduced through the comparison-based method which uses additional logic to predict the circuit responses for a complete test set. Towards the high-cost end, several concurrent error detection (CED) zero-latency methods have been proposed for both combinational and sequential circuits. Reducing the area overhead below the cost of duplication typically requires redesign of the original circuit, thus leading to intrusive methodologies. In more and more applications, cryptographic operations are performed on embedded processors. Some of the most important applications in this context are payment, identification, access control, digital rights management and

IP protection. In order to guarantee the security of these applications, it is necessary to implement countermeasures against physical attacks on the embedded processors. During the last 15 years numerous physical attacks have been published that allow the extraction of secret information based on the observation or manipulation of an embedded device and its environment. Typical examples of physical attacks are timing attacks, power analysis attacks and fault attacks. While timing and power analysis attacks have received much attention already immediately after their publication, not so much attention has been paid on fault attacks so far. However, fault attacks become increasingly important. Meanwhile there exist several publications that discuss methods to induce faults in order to reveal secret information. In general there are two types of fault attacks.

SUBMODULES

- COMPARATOR
- PRIORITY ENCODER
- MULTIPLEXER
- SUBTRACTOR
- QUASI BLOCK

3.1.1 COMPARATOR

A digital comparator or magnitude comparator is a hardware electronic device that takes two numbers as input in binary form and determines whether one number is greater than, less than or equal to the other number. Comparators are used in a central processing units (CPU) and microcontrollers. Examples of digital comparator include the CMOS 4063 and 4585 and the TTL 7485 and 74682-'89. The analog equivalent of digital comparator is the voltage comparator. Many microcontrollers have analog comparators on some of their inputs that can be read or trigger an interrupt. A digital comparator is an electronic circuit or device capable of accepting two binary signals and performing tests on those signals to determine their equivalence to each other. The simplest form of a digital comparator compares two binary signals, known in computer processing as bits, and uses a series of logical gates to determine if the two bits are equal or if one is greater than the other based on binary logic in which each signal is given the value of either zero or one. Most digital comparator circuits are designed to accept multiple bits for comparison, where in many applications the bits are combined by external software or hardware into actual numbers. At the heart of most central processing units (CPUs) in computers and other digital devices, a comparator performs a large portion of the logical operations that allow a computer function. Outside of computers, digital comparators also are used in some devices in which analog input is converted into digital information that is measured or monitored, such as in some testing meters. The way a digital comparator functions starts with the input of information. The comparator can only handle binary data, meaning that whatever the input mechanism is, the signal coming into the circuit can only have two states, which commonly are referred to as zero and one. When a bit is compared to another bit, it can be tested in one of three ways by the digital comparator. The first is equivalency, meaning the result of comparing one bit to another will result in a positive, or true, result if both of the bits equal one or if both of the bits equal zero. Individual bits also can be checked to see if one is greater than or less than another.

For a sequence of bits, however, comparisons to determine which set has a higher or lower value need to check each bit to see which set has a more highly placed most significant bit, because this determines the actual numerical value of the bit set. Beyond computer processors, a digital comparator can be used in some devices that contrast visual images with digital images, as can be the case in engineering that relies on computer-aided drafting (CAD) programs to check if the physically manufactured products match specifications. They also can be employed to convert analog signals into digital patterns. A digital comparator also can be used in conjunction with a number of other devices to act as a monitor in an industrial setting to see accurate digital information about the state of a machine.

Inputs		Outputs		
B	A	A > B	A = B	A < B
0	0	0	1	0
0	1	1	0	0
1	0	0	0	1
1	1	0	1	0

Table 1:1-bit Comparator

This is useful if we want to compare two variables and want to produce an output when any of the above three conditions are achieved. For example, produce an output from a counter when a certain count number is reached. Consider the simple 1-bit comparator above.

3.1.2 PRIORITY ENCODER

Here we applied input width is 5 bit and output width is 3 bit by using priority encoder. A priority encoder is a circuit or algorithm that compresses multiple binary inputs into a smaller number of outputs. The output of a priority encoder is the binary representation of the ordinal number starting from zero of the most significant input bit. They are often used to control interrupt requests by acting on the highest priority request. If two or more inputs are given at the same time, the input having the highest priority will take precedence. An example of a single bit 4 to 2 encoder is shown, where highest-priority inputs are to the left and "x" indicates an irrelevant value - i.e. any input value there yields the same output since it is superseded by higher-priority input. The output V indicates if the input is valid. Priority encoders can be easily connected in arrays to make larger encoders, such as one 16-to-4 encoder made from six 4-to-2 priority encoders - four 4-to-2 encoders having the signal source connected to their inputs, and the two remaining encoders take the output of the first four as input. The priority encoder is an improvement on simple encoder circuit in terms of all handling possible input configurations.

3.1.3 MULTIPLEXER

In this module will generate reminder code according to selection line. We applied three input signal as mux_in and m. we obtain the output (specific signal) from given input signal.

If A greater than B is equal to 1 will get mux_in signal. If A lesser than B we get m signal. Otherwise we get 0(8 bit signal). A data selector, more commonly called a **Multiplexer**, shortened to "Mux" or "MPX", are

combinational logic switching devices that operate like a very fast acting multiple position rotary switch. They connect or control, multiple input lines called "channels" consisting of either 2, 4, 8 or 16 individual inputs, one at a time to an output. Then the job of a multiplexer is to allow multiple signals to *share* a single common output. For example, a single 8-channel multiplexer would connect one of its eight inputs to the single data output. Multiplexers are used as one method of reducing the number of logic gates required in a circuit or when a single data line is required to carry two or more different digital signals.

3.1.4 SUBTRACTOR

Here we calculate the difference between input signal and specific constant value with help of subtraction. This model converts two rotations A and B into their difference A-B. This is useful for various applications. For instance, when you build a treaded vehicle such as a construction bulldozer, you'd like one motor to control total motion, and the other the turning. This construction does that: connect the treads to the (A+B) and (A-B) axles, and the motors to A and B. Now motor A makes the vehicle go forward or backward, and B turns it left or right. Of course you can also run them simultaneously. The great advantage is that you can now guarantee that the two sides of the treaded vehicle run at the same speed that does not happen with 2 motors, they always have a slight power difference. So it is more likely that it goes straight when you want it to.

3.1.5 QUASI BLOCK

This block will generate quotient value according to given input. Here we applied 3 bit input then generate 8 bit signal as output. Coding approaches such as parity code, Berger code, and residue code have been considered for design applications to detect circuit errors. Residue code is generally separable arithmetic codes by estimating a residue for data and appending it to data. Error detection logic for operations is typically derived by a separate residue code, making the detection logic is simple and easily implemented.

3.1.6 ACCUMULATOR

In this module consists flip-flop act as a accumulator. We can store a bit of data. Flip-flop" is the common name given to two-state devices which offer basic memory for sequential logic operations. Flip-flops are heavily used for digital data storage and transfer and are commonly used in banks called "registers" for the storage of binary numerical data. There are some circuits that are not quite as straight forward as the gate circuits we have discussed in earlier lessons. However, you still need to learn about circuits that can store and remember information. They're the kind of circuits that are used in computers to store program information RAM memory.

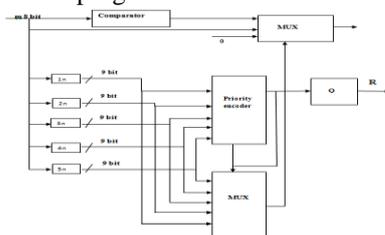

FIG 9: M MOD N OPERATION

IV. ERROR DETECTION CIRCUIT

In this module indicates that the operations of error detection in a specific PE_i is achieved by using EDC, which is utilized to compare the outputs between TCG and in order to determine whether errors have occurred. The EDC output is then used to generate a 0/1 signal to indicate that the tested PE_i is error-free/errancy. Using XOR operation can be identify the error if any variation in terms of residue and quotient value. Because a fault only affects the logic in the fanout cone from the fault site, the good circuit and faulty circuits typically only differ in a small region. Concurrent fault simulation exploits this fact and simulates only the differential parts of the whole circuit. Concurrent fault simulation is essentially an event-driven simulation with the fault-free circuit and faulty circuits simulated altogether. In concurrent fault simulation, every gate has a concurrent fault list, which consists of a set of bad gates. A bad gate of gate x represents an imaginary copy of gate x in the presence of a fault. Every bad gate contains a fault index and the associated gate I/O values in the presence of the corresponding fault. Initially, the concurrent fault list of gate x contains local faults of gate x. The local faults of gate x are faults on the inputs or outputs of gate x. As the simulation proceeds, the concurrent fault list contains not only local faults but also faults propagated from previous stages. Local faults of gate x remain in the concurrent fault list of gate x until they are detected. As we move to the nanometer age, we have begun to see nanometer designs that contain hundreds of millions of transistors.

V. DATA RECOVERY CIRCUIT

In this module will be generate error free output by quotient multiply with constant value (64) and add with remainder code. During data recovery, the circuit DRC plays a significant role in recovering RQ code from TCG.

Notably, the proposed EDDR design executes the error detection and data recovery operations simultaneously. Additionally, error-free data from the tested PE_i or data recovery that results from DRC is selected by a multiplexer (MUX) to pass to the next specific PE_{i+1} for subsequent testing. Error concealment in video is intended to recover the loss due to channel noise, e.g., bit-errors in a noisy channel and cell- loss in an ATM network, by utilizing available picture information. The error concealment techniques can be categorized into two classes according to the roles that the encoder and the decoder play in the underlying approaches. Forward error concealment includes methods that add redundancy in the source to enhance error resilience of the coded bit streams. For example, I-picture motion vectors were introduced in MPEG-4 to improve the error concealment. However, a syntax change is required in this scheme. In contrast to this approach, error concealment by post-processing refers to operations at the decoder to recover the damaged images based on image and video characteristics. In this way, no syntax is needed to support the recovery of missing data. we have only discussed the case in which one frame has been damaged and we wish to recover damaged blocks using information that is already contained in the bit-stream.

The temporal domain techniques that we have considered rely on information in the previous frame to perform the reconstruction. However, if the previous frame is heavily damaged, the prediction of the next frame may

also be affected. For this reason, we must consider making the prediction before the errors have occurred. Obviously, if one frame has been heavily damaged, but the frame before that has not been damaged, it makes sense to investigate how the motion vectors can be extrapolated to obtain a reasonable prediction from a past reference frame. Following this notion, we have essentially divided the problem of error concealment into two parts. The first part assumes that the previous frames are intact or are close to intact. This will always be the case for low BER and short error bursts.

Furthermore, a localized solution such as the techniques presented in the previous subsection will usually perform well. However, if the BER is high and/or the burst length is long, the impact of a damaged frame can propagate, hence the problem is more global and seems to require a more advanced solution, i.e., one which considers the impact over multiple frames. In the following, we propose an approach that considers making predictions from a past reference frame, which has not been damaged. The estimated motion information which differs from the actual one may be recovered from that of neighbor blocks. Because a moving object in an image sequence is larger than the block size of a minimal block in many occasions, motion information of neighbor blocks are usually the same as, or approximate to, current blocks. The concept of global motion is discussed in many researches on motion estimation or related interests. In method which reconstructs the frame with the aid of neighbor motion vector is successfully applied to motion estimation. Thus, an error signal "1" is generated from EDC and sent to mux in order to select the recovery results from DRC.

VII. CONCLUSION

This paper presents an FPGA implementation of efficient architecture to make an application embedding into video code testing applications. The required modules have been taken and theoretical analysis have done and numerical calculations were calculated and verified. Combinational circuits are taken and simulation results have obtained which are required to built an architecture are explained and necessary types of codes which are generated to make errors to be detected and recovered.

Design of Stabilizing Controllers for the Nonlinear Power Systems

Rekha¹, A. K. Singh²

¹*Asst. Professor, Electrical & Electronics Engg. Dept., NIT Jamshedpur, India*

²*Professor, Electrical & Electronics Engg. Dept., NIT Jamshedpur, India*

Abstract: The objective here is the development of mathematical model of the non-linear power system which can be utilized for implementing the different class of controller. The controller designed here is to fulfill the stability requirement of the system as well as to make the system transiently stable. The linearization of the power system is done using direct feedback linearization technique and the model thus obtained has parameters which can be used as controller input. The linear LQ optimal control theory is applied to the model to design an optimal feedback control law, $v_f(t)$.

Keywords: Stabilizer, FLC (fuzzy logic controller), DFL (direct feedback linearization).

I. Introduction

We consider here nonlinear control theory to design controllers for power systems to improve the transient stability and to achieve voltage regulation. The problem of designing controller to prevent an electric power system losing synchronism after a large sudden fault is of great importance in power system design.

In recent years, most of the non-linear excitation controllers have been developed based on the classical third order dynamic generator model. The simulation results showed that such a simplification has very little effect on the performances of the designed controllers. Establishing a global control structure for general non-linear control systems is preferred, as control of complex system over a wide range of operating conditions can be achieved for a set of control objective. A general global control structure is based on the qualitative analysis of the dynamical systems. Local controllers are designed based on local models and local performance requirements and co-ordination rules are employed to combine the local elements control.

II. Non-Linear Systems

The topic of non-linear control has attracted particular attention during the past few decades as virtually all physical systems are non-linear in nature. Non-linear control analysis and design provides a sharper understanding of real world. For real world systems, large ranges of operation cannot be avoided, and demanding specifications are required by modern technology such as high performance robotics and aircraft which typically involve non-linear dynamics. Therefore use of non-linear control is crucial.

With the development of powerful microprocessor and low cost dedicated digital signal processors, non-linear controllers are becoming easier to implement reliably.

There are numerous examples of large dynamical systems that provide great challenges to control engineers. For example Electrical power systems, aerospace system, process control system in chemical and petroleum industries all require non-linear control.

III. Linear Model Of Synchronous Machine

When system is subjected to a small load change, it tends to acquire a new operating state. During the transition between the initial state and the new state the system behavior is oscillatory. If two states are such that all state variables change only slightly (i.e. x_i changes from x_{i0} to $x_{i0} + x_{i\Delta}$ where $x_{i\Delta}$ is small change in x_i), the system is operating near the initial state. The initial state may be considered as a quiescent operating condition for the system. The behavior of the system when it is perturbed such that the new and old equilibrium states are nearly equal, the system equations are linearized about the Q operating condition. First order approximations are made for system equations. The new linear equations thus derived are assumed to be valid in the region near the Q-condition. The dynamic response of a linear system is determined by its characteristic equation.

IV. PID Controllers

Classical and modern methodologies in linear and non-linear control provide powerful design tools for systems modeled by ordinary differential equation. However, linear methods are valid for a small operating region, and many non-linear methods are only effective within a certain operating region due to the non-existence of global geometric structures.

Multiple controllers are widely used in practice where controllers adapt themselves to different operating conditions and are able to co-ordinate various control requirements. Control of a complex system over a wide range of operating conditions to achieve a set of control objectives is called global control.

To achieve the goals of global control, multiple controllers are needed. They are derived from the design method of local control and operate over different operating points during different time periods to fulfill the corresponding primary control requirements. Therefore how to co-ordinate the controllers is the major issue of global control.

A plant model of a physical system that is to be controlled is usually very complex and difficult. Adaptive control is a model-free controller that can be used to control non-linear systems. Most of the adaptive controllers involve certain types of function approximator from input/output

experiments. The basic objective of adaptive control is to maintain consistent performance of a control system in the presence of the designed parameters. Traditional adaptive controllers cannot make use of human experience, which is usually expressed in linguistic terms.

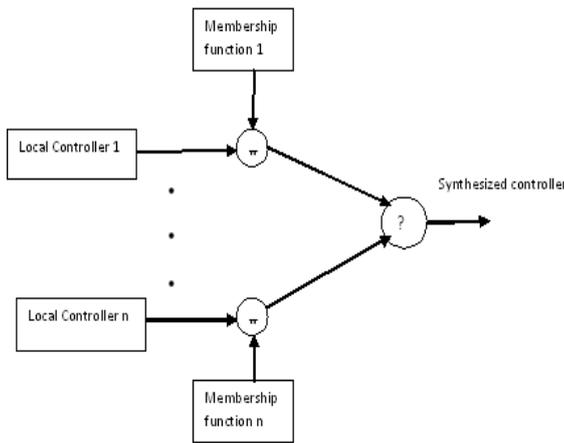

Figure 1. Heterogeneous control law

V. Controller Design Techniques

Since power system are highly non-linear and the operating conditions can vary over a wide range, the conventional PSS (CPSS) performance is degraded when the operating point changes from one to another because of fixed parameters of stabilizers.

Metaheuristic optimization technique like GA, Tabu search, simulated annealing, bacteria foraging, particle swarm optimization.

A. Power system damping controller structure

Power System Stabilizer model consists of:

1. Gain block
2. Washout block
3. Phase compensation block

The input to PSS is rotor speed deviation, output is auxiliary excitation signal given to the generator excitation system.

$$\left[\frac{\Delta U}{\Delta w} \right] = K_s \left[\frac{(1 + sT_1)}{(1 + sT_2)} \right] \left[\frac{(sT_w)}{(1 + sT_w)} \right]$$

K_s - PSS gain

T_1, T_2 – PSS time constant

Signal washout function is a high pass filter which removes DC signals. The washout time is in the range of 1-20 sec

Eg. $T_w = 15$ sec

Eigen value based objective function

$$[J] = \text{Max}\{\text{Re}[\lambda_i]\}, (\lambda_i) \in (\lambda\tau)$$

Where (λ_i) belongs to the group of electromechanical mode Eigen values $(\lambda\tau)$.

B. Fuzzy controller based design

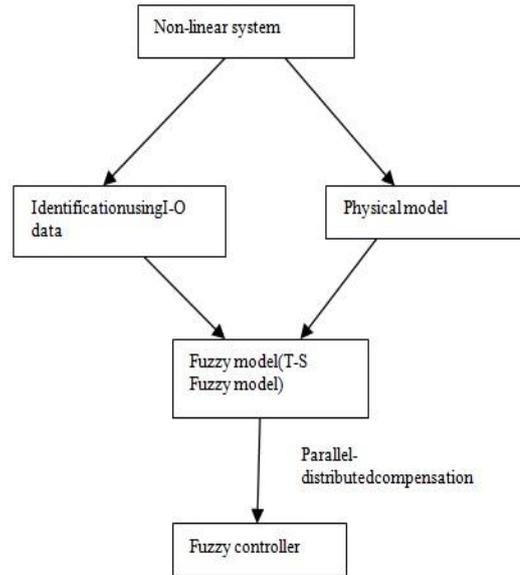

Figure.2 Fuzzy model-based fuzzy control designs

Table 1. Comparisons of different control designs

	Work Range	Simple	Stability
Linear	$\left(-\frac{\pi}{4}, \frac{\pi}{4}\right)$	Yes	Local
Non-linear	$\left(-\frac{\pi}{2}, \frac{\pi}{2}\right)$	No	Non-local
Fuzzy PDC	$(-\pi, \pi)$	No	Non-local

A properly designed voltage regulating system can increase the steady state stability limit of a synchronous machine by a considerable amount. Fast regulator and exciter action and low transient reactance are desirable. The amplification factor of the regulating system must be co-ordinated properly with the machine and system constants are made as large as possible amortisseur windings have little effect on the possible gain in power limit. For maximum gain in power limit, a regulator with broad regulation and rapid response should be used.

C. FLC based on GA

The design employs Sugeno type fuzzy controllers as parameters can be manipulated using GA. Single and two inputs fuzzy controllers are used. The GA manipulates all parameters of the fuzzy controller to find the optimum solution.

Genetic Algorithm (GA) are global, parallel, stochastic search methods founded on Darwinian evolutionary principles. During the last decade GA's have been applied in a variety of areas, with varying degrees of success within each. GA exhibit considerable robustness in problem domain that is not conducive to formal, rigorous, classical analysis. The computational complexity of the GA has proved to be the chief obstruction to real time applications. Hence majority of the applications that use GA's are by nature off-line.

Commonly GA's have been used to optimize both structure and parameter values for both controllers and plant models. Normally Takagi-Sugeno (TS) fuzzy system are employed for control based on GA trying to optimize the parameters of the fuzzy controller. Inputs of the GA will be encoded then cross-over and mutation will be carried out on the population to finally change the centers and variances of the Gaussian membership functions of Sugeno fuzzy controller. The resulting controller will be capable of guiding the system to the desired characteristic with permissible value of error.

After fuzzy controller has been designed, its parameters should be manipulated by G.A, this algorithm should be able to optimize centers, variances and coefficients.

D. Robust controller design

When the parameters in the power system are known, we can design a DFL control law to linearize the plant. But when large sudden fault occurs the reactance of the transmission line x_L changes a lot. These changes are treated as parametric uncertainty. Hinfinity control is closely associated with many robustness problems such as sensitivity minimization and stabilization of uncertain systems. However when there is parameter uncertainty in plant modeling, no robust behavior on Hinfinity performance along with stability can be guaranteed by standard H_∞ control method.

VI. Mathematical Modelling Of The System

The following abbreviations are used while designing the model:

$$\Delta\delta(t) = \delta(t) - \delta_0$$

$\delta(t)$ = power angle of the generator

δ_0 = power angle of the generator at the operating point;

$\omega(t)$ = the relative speed of the generator

$$\Delta P_e = P_e(t) - P_m$$

P_m = mechanical input power

P_e = active electric power delivered by the generator;

ω_0 = synchronous machine speed; $\omega_0 = 2\pi f_0$

D = per unit damping constant

H = per unit inertia constant

$E_q'(t)$ = the transient emf in the quadrature axis

$E_f(t)$ = the equivalent emf in the excitation coil;

Tdo = the direct axis transient short circuit time;

$Q_e(t)$ = the reactive power

If(t) = the excitation current

Iq(t) = the quadrature axis current;

Vt(t) = the generator terminal voltage;

Kc = the gain of the excitation amplifier;

Uf(t) = the input of the SCR amplifier of the generator

$$x_{ds} = x_T + \frac{1}{2}x_L + x_d;$$

$$x_{ds}' = x_T + \frac{1}{2}x_L + x_d';$$

x_T = reactance of the transformer

x_d = direct axis reactance

x_L = the reactance of transmission line;

$$x_s = x_T + \frac{1}{2}x_L$$

x_{ed} = the mutual reactance between the excitation coil and the stator coil;

V_s = the infinite bus voltage;

Mechanical equation:

$$\Delta\dot{\delta}(t) = \omega(t) \quad (1)$$

$$\omega\dot{(t)} = \frac{-D}{H}\omega(t) - \frac{\omega_0}{H}\Delta P_e(t) \quad (2)$$

Generator Electrical Dynamics:

$$\dot{E}'_q(t) = \frac{1}{T_{do}}(E_f(t) - E_q(t)) \quad (3)$$

Electrical Equations:

$$E_q(t) = \frac{x_{ds}}{x_{ds}'}E'_q(t) - \frac{x_d - x_d'}{x'_{ds}}V_s \cos\delta(t) \quad (4)$$

$$E_f(t) = K_c u_f(t) \quad (5)$$

$$P_e(t) = \frac{V_s E_q(t)}{x_{ds}} \sin\delta(t) \quad (6)$$

$$I_q(t) = \frac{V_s}{x_{ds}} \sin\delta(t) = \frac{P_e(t)}{x_{ad} I_f(t)} \quad (7)$$

$$Q_e(t) = \frac{V_s}{x_{ds}} E_q(t) \cos\delta(t) - \frac{V_s^2}{x_{ds}} \quad (8)$$

$$E_q(t) = x_{ad} I_f(t) \quad (9)$$

$$V(t) = \frac{1}{x_{ds}} \left\{ x_s^2 E_q^2(t) + V_s^2 x_d^2 + 2x_s x_d x_{ds} P_e(t) \cot\delta(t) \right\}^{1/2} \quad (10)$$

A. Non-linear controller design for the power system

The DFL technique [8] is very useful method for power system non-linear controller design. By employing a non-linear feedback compensating law, a non-linear system can be directly transformed to a system whose closed loop dynamics are linear over a very wide range.

To design a non-linear controller for the power system, since $E'_q(t)$ is physically un-measurable, we eliminate $E'_q(t)$ by differentiating equation (6) and using (1) to (6)

Equation (6) is

$$P_e(t) = \frac{V_s E_q(t)}{x_{ds}} \sin\delta(t)$$

$$\frac{dP_e(t)}{dt} = \frac{V_s}{x_{ds}} E_q(t) \cos\delta(t) \dot{\delta}(t) + \frac{V_s}{x_{ds}} \dot{E}'_q(t) \sin\delta(t)$$

$$= \frac{V_s}{x_{ds}} E_q(t) \cos\delta(t) \omega(t)$$

$$+ \frac{V_s}{x_{ds}} \sin\delta(t) \left[\frac{x_{ds}}{x'_{ds}} \dot{E}'_q(t) + \frac{x_d - x_d'}{x'_{ds}} V_s \sin\delta(t) \omega(t) \right]$$

$$= \frac{V_s}{x_{ds}} E_q(t) \cos\delta(t) \omega(t)$$

$$+ \frac{V_s}{x_{ds}} \sin\delta(t) \left[\frac{x_{ds}}{x'_{ds}} \frac{1}{T_{do}} (E_f(t) - E_q(t)) + \frac{x_d - x_d'}{x'_{ds}} V_s \sin\delta(t) \omega(t) \right]$$

We have $T'_{do} = \frac{x_{ds}}{x_{ds}} T_{do}$

$$= -\frac{1}{T'_{do}} P_e(t) + \frac{1}{T'_{do}} \left\{ \frac{V_s}{x_{ds}} \sin\delta(t) [K_c u_f(t) + T_{do} (x_d - x'_d) \frac{V_s}{x_{ds}} \sin\delta(t) \omega(t)] + T'_{do} \frac{V_s}{x_{ds}} E_q(t) \cos\delta(t) \omega(t) \right\}$$

$$= -\frac{1}{T'_{do}} \Delta P_e(t) + \frac{1}{T'_{do}} \left\{ \frac{V_s}{x_{ds}} \sin\delta(t) [K_c u_f(t) + T_{do} (x_d - x'_d) \frac{V_s}{x_{ds}} \sin\delta(t) \omega(t)] + T'_{do} \frac{V_s E_q(t)}{x_{ds}} \cos\delta(t) \omega(t) - P_m \right\},$$

As $\Delta P_e(t) = P_e(t) - P_m$

Therefore

$$\Delta P_e(t) = -\frac{1}{T'_{do}} \Delta P_e(t) + \frac{1}{T'_{do}} v_f(t)$$

Where

$$v_f = \frac{V_s \sin\delta(t)}{x_{ds}} [K_c u_f(t) + T_{do} (x_d - x'_d) \frac{V_s}{x_{ds}} \sin\delta(t) \omega(t)] + T'_{do} \frac{V_s E_q(t)}{x_{ds}} \cos\delta(t) \omega(t) - P_m$$

or,

$$v_f(t) = I_q(t) [K_c u_f(t) + T_{do} (x_d - x'_d) \frac{V_s}{x_{ds}} \sin\delta(t) \omega(t)] + T'_{do} [Q_e(t) + \frac{V_s^2}{x_{ds}}] \omega(t) - P_m$$

The model (1) to (3) is therefore linearized,

The linearized model is

$$\Delta \dot{\delta}(t) = \omega(t) \tag{11}$$

$$\omega(t) = \frac{-D}{H} \omega(t) - \frac{\omega_0}{H} \Delta P_e(t) \tag{12}$$

$$\Delta \dot{P}_e(t) = -\frac{1}{T'_{do}} \Delta P_e(t) + \frac{1}{T'_{do}} v_f(t) \tag{13}$$

where $v_f(t)$ is the new input.

After linearization, we can employ linear control theory, such as LQ-optimal control theory, to design a feedback law

$$v_f(t) = f(\delta(t), \omega(t), P_e(t)) \tag{14}$$

To give the desired stability and performance properties, $v_f(t)$ and $P_e(t)$ are the control inputs.

The DFL-LQ optimal controller [10] and the DFL voltage regulator can be obtained by use of DFL techniques and linear optimal control theory.

VII. Simulation Results

The variables $V_i(t)$, $w(t)$ and $P_e(t)$ are to be tracked to their prefault steady values after a fault occurs. An effective feedback control law employed here is

$$v_f(t) = 19.3(\delta(t) - \delta_0) + 6.43(\omega(t)) - 47.6(P_e(t) - P_{m0}) + P_{m0} \tag{15}$$

By employing the control law (15) on the DFL compensated system, the simulation results were obtained for power angle and terminal voltage.

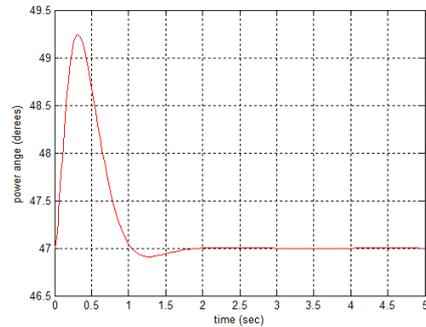

Figure 3a. DFL-LQ optimal controller (Power angle)

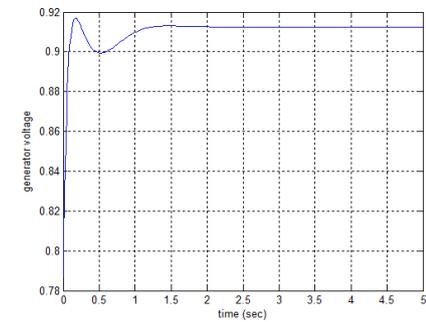

Figure 3b. DFL-LQ optimal controller (voltage response)

An electric power plant described in [10], is taken with operating points:

$$\delta_0 = 47^\circ, P_{m0} = 0.45 \text{ p.u. and } V_{t0} = 1.0 \text{ p.u.}$$

The fault considered here is permanent fault, which occurs at 0.1 sec and the fault is removed by opening the breaker of the faulted line at 0.25 sec. The simulation results show that using only DFL-LQ optimal controller or DFL voltage regulator, we cannot achieve both good transient response and good post-fault performances. If we can combine both types of controller then better result is expected. This could be done by the design of DFL co-ordinated controller.

VIII. Conclusion

The linearized mathematical model is obtained for the power system. This model can be utilized for designing different types of controllers for stabilizing the parameters of the power system. Here in this paper, the approach of direct feedback linearization (DFL) is used and the simulation results were obtained for DFL-LQ optimal controller. The new DFL coordinated controller can achieve better transient stability results than the excitation controller irrespective of the operating point of the system and the fault sequence.

Development of the A Three-Dimensional Magnetic-Field-Independent Absorbing Boundary Condition (Mfiabc) For Cold Magnetoplasma

Mohammad pourbagher¹, Javad nourinia¹ and Nader pourmahmud²

1(Department of Electrical Engineering, Urmia university, IRAN)

2(Department of Mechanical Engineering, Urmia university, IRAN)

Abstract: A Three-Dimensional Cartesian-coordinate magnetized cold plasma algorithm has the capability to simulate wave behaviors in cold plasma under applied magnetic fields of arbitrary direction and magnitude. Plasma effects contributed by electrons, positive, and negative ions may all be included by this algorithm. A magnetic-field-independent absorbing boundary condition (ABC) is then proposed to truncate the computational domains that employ the cold plasma algorithm. To terminate the computational domain of the magnetized cold plasma FDTD algorithm an appropriate absorbing boundary condition (ABC) is required in order to model local regions of the Earth, or to model unbounded problems in the radial (vertical direction) on a global scale.

Keywords: Cold plasma, FDTD method, Boundary condition, PML, Ionosphere

I. Introduction

In FDTD modeling, it is not possible to handle an open region problem directly since the data storage in a computer is limited by the size of memory. To mitigate this problem, an accurate and computationally efficient absorbing boundary condition (ABC) is needed to truncate the computational domain to suppress spurious reflections of the outgoing waves to an acceptable level. Its original split-field formulation introduced by Berenger [1] and various later reformulations, such as the uniaxial PML (UPML) [2], the convolutional PML (CPML) [3], and the NPML [4] provide orders-of-magnitude lower reflections and other advantages over previous versions of ABCs. However, the application of the standard PMLs has been limited to situations wherein the group and phase velocities of the incident wave are aligned in the same direction. When this is not the case, the PMLs cease to attenuate the field and can in fact act as an amplifier [5-7], which causes the algorithm to become analytically unstable. Becache et al. [6] confirms this instability with a theoretical analysis of PMLs for anisotropic media, for acoustic waves in elastic materials, and for EM waves. Cummer [7] has discussed the PML amplification phenomenon for the negative index materials (NIMs) in which the NIM materials exhibit both positive and negative refractive indexes over a range of frequencies. More recently, Chevalier et al. [8] encountered the same instability problem when modeling the antenna performance in a magnetized plasma for whistler waves. As pointed out in [7], this instability problem is inherent in the PMLs and is not implementation-specific. This poses a problem for modeling wave propagation in anisotropic media, such as whistler waves in magnetized cold plasma.

To address this issue, Cummer [7] has derived a modified PML solution for the negative index material (NIM) referred to as the NIMPML which is an adaptation of the previous NPML [4]. However, this method requires the simulated material to have a homogeneous permittivity and permeability ($\epsilon_r = \mu_r$), which is hardly the case for the ionospheric plasma medium that varies with both altitude and spatial position around the Earth. More recently, Chevalier et al. [5] presented in 2006 a new PML formulation referred to as the KPML which explicitly utilizes information on the k -vector direction of incident waves. Numerical tests in [5] demonstrate that KPML does not perform as well as the traditional CPML in open free-space problems, but it is stable and attenuates outgoing waves well for a case of whistler wave propagation in magnetized plasma media. However, the KPML can only be used as an effective ABC for dense magnetized plasma when the electron cyclotron frequency is much smaller than the plasma frequency. This is not the case for the lower region of the ionosphere. Moreover, the KPML algorithm is based on a single orientation of the background magnetic-field relative to each side of the FDTD grid and as such is not suitable for simulations involving spatially-varying magnetic-field directions such as for global modeling of the Earth-ionosphere system.

Considering these issues relating to the application of PMLs to magnetized plasma, we next consider Mur's ABC [9] as an alternative. Unfortunately, it is known that the original Mur's ABC exhibit an early-time instability for certain modeling scenarios. J. N. Hwang and F. C. Chen [10] have reported that the Mur's first-order ABC will cause instability problem for ADI-FDTD method. Zhang Yusheng and Wang Wenbing [11] have also confirmed that the second-order Mur's ABC combined with FDTD method to solve 3-D scattering problems is unstable. We encountered the same instability problem when applying the second-order Mur's ABC to the magnetized cold plasma algorithm. To solve this issue, Zhang and Wang [10] presented a new discretization scheme of the Engquist and Majda's second-order ABC equations [12] different from the scheme of Mur's ABC [9], which they claim is stable. However, we find through longer numerical tests that the early-time instability of Mur's ABC is simply replaced by a late-time instability in Zhang and Wang's scheme. In this article, the feasibility of a variation of Zhang and Wang's scheme is investigated to serve as an effective ABC for the 3-D FDTD magnetized cold plasma formulation. We choose this scheme despite its inherent late-time instability because it has the potential to provide an acceptable level of error regardless of the direction of the background magnetic-field, a capability

not provided by KPML. We then present a simple but very effective way to further delay the late-time instability of this magnetized plasma ABC.

II. Formulations

In 1977, Engquist and Majda [12] derived a theory of one-way wave equations suitable for analytical ABCs in FDTD simulations. The second-order approximations of these formulations at outer boundaries of a 3-D Cartesian space lattice can be expressed as follows.

$$x=1 \rightarrow \frac{\partial^2 U}{\partial x \partial t} - \frac{1}{v} \frac{\partial^2 U}{\partial t^2} + \frac{v}{2} \frac{\partial^2 U}{\partial y^2} + \frac{v}{2} \frac{\partial^2 U}{\partial z^2} = 0 \quad (1)$$

$$x=h \rightarrow \frac{\partial^2 U}{\partial x \partial t} + \frac{1}{v} \frac{\partial^2 U}{\partial t^2} - \frac{v}{2} \frac{\partial^2 U}{\partial y^2} - \frac{v}{2} \frac{\partial^2 U}{\partial z^2} = 0 \quad (2)$$

$$y=1 \rightarrow \frac{\partial^2 U}{\partial y \partial t} - \frac{1}{v} \frac{\partial^2 U}{\partial t^2} + \frac{v}{2} \frac{\partial^2 U}{\partial x^2} + \frac{v}{2} \frac{\partial^2 U}{\partial z^2} = 0 \quad (3)$$

$$y=m \rightarrow \frac{\partial^2 U}{\partial y \partial t} + \frac{1}{v} \frac{\partial^2 U}{\partial t^2} - \frac{v}{2} \frac{\partial^2 U}{\partial x^2} - \frac{v}{2} \frac{\partial^2 U}{\partial z^2} = 0 \quad (4)$$

$$z=1 \rightarrow \frac{\partial^2 U}{\partial z \partial t} - \frac{1}{v} \frac{\partial^2 U}{\partial t^2} + \frac{v}{2} \frac{\partial^2 U}{\partial x^2} + \frac{v}{2} \frac{\partial^2 U}{\partial y^2} = 0 \quad (5)$$

$$z=p \rightarrow \frac{\partial^2 U}{\partial z \partial t} + \frac{1}{v} \frac{\partial^2 U}{\partial t^2} - \frac{v}{2} \frac{\partial^2 U}{\partial x^2} - \frac{v}{2} \frac{\partial^2 U}{\partial y^2} = 0 \quad (6)$$

where U denotes the scalar field components located at outer boundaries and v is the wave phase velocity, which is initially set to c , the velocity in free space. By central-differentiating the partial and second-order time and spatial derivatives of Equations (1)-(6) at time step n and at spatial locations half grid cell inside each boundary, one can obtain the well-known second-order Mur's ABC. In this article, by utilizing a different discretization scheme of Equations (1) - (6) than that utilized in Zhang and Wang's scheme [11], we derive our ABC expressions detailed as below. Our different approach from the so-called upwind-difference scheme of Zhang and Wang's ABC results in the same final form of the formulations as in Zhang and Wang's ABC. Here, we take Equation (1) as an example a derivation of the ABC expression for the $x = 1$ boundary. First, U around time step n and spatial location $(i+1, j, k)$ can be Taylor-expanded as

$$U_{i+1,j,k}^n = U_{i,j,k}^n + \left(\frac{\partial U}{\partial x} \Big|_{i,j,k}^n \right) \cdot \Delta x + O(\Delta x^2) \quad (7)$$

From Equation (7), the first-order finite-difference approximation of the space derivative can then be obtained as

$$\frac{\partial U}{\partial x} \Big|_{i,j,k}^n = \frac{U_{i+1,j,k}^n - U_{i,j,k}^n}{\Delta x} \quad (8)$$

Applying Approximation (8) to both the spatial and time derivatives for the first term of Equation (1), we obtain the following:

$$\frac{\partial^2 U}{\partial x \partial t} \Big|_{i,j,k}^n = \frac{1}{\Delta t} \left(\frac{\partial U}{\partial x} \Big|_{i,j,k}^n - \frac{\partial U}{\partial x} \Big|_{i,j,k}^{n-1} \right) = \frac{1}{\Delta t} \left(\frac{U_{i+1,j,k}^n - U_{i,j,k}^n}{\Delta x} - \frac{U_{i+1,j,k}^{n-1} - U_{i,j,k}^{n-1}}{\Delta x} \right) = \frac{1}{\Delta t \Delta x} (U_{i+1,j,k}^{n-1} - U_{i,j,k}^{n-1}) - \frac{1}{\Delta t \Delta x} (U_{i+1,j,k}^n - U_{i,j,k}^n) \quad (9)$$

Next, the central-difference scheme is applied to the last three second-order time and spatial derivatives of Equation (1) at time step n and the $x = 1$ plane. Equation (1) can now be expressed as

$$\frac{U_{i+1,j,k}^{n-1} - U_{i,j,k}^{n-1}}{\Delta t \Delta x} - \frac{U_{i,j,k}^n - U_{i,j,k}^{n-1}}{\Delta t \Delta x} - \frac{U_{i,j,k}^{n+1} - 2U_{i,j,k}^n + U_{i,j,k}^{n-1}}{v \Delta t^2} + \frac{v(U_{i,j,k+1}^n - 2U_{i,j,k}^n + U_{i,j,k-1}^n)}{2 \Delta y^2} + \frac{v(U_{i,j,k+1}^{n-1} - 2U_{i,j,k}^{n-1} + U_{i,j,k-1}^{n-1})}{2 \Delta z^2} = 0 \quad (10)$$

By moving the field components of time step n and $n-1$ to the right-hand side, Equation (10) is rewritten as Equation (11):

$$U_{i,j,k}^{n+1} = 2U_{i,j,k}^n - U_{i,j,k}^{n-1} - \frac{v \Delta t}{\Delta x} (U_{i,j,k}^n - U_{i,j,k}^{n-1}) + \frac{v \Delta t}{\Delta x} (U_{i,j,k}^{n-1} - U_{i,j,k}^{n-2}) + \frac{1}{2} \left(\frac{v \Delta t}{\Delta y} \right)^2 \cdot (U_{i,j,k+1}^n - 2U_{i,j,k}^n + U_{i,j,k-1}^n) + \frac{1}{2} \left(\frac{v \Delta t}{\Delta z} \right)^2 \cdot (U_{i,j,k+1}^{n-1} - 2U_{i,j,k}^{n-1} + U_{i,j,k-1}^{n-1}) \quad (11)$$

As mentioned earlier, this ABC formulation exhibits a late-time instability that is improved over the early-time instability of the traditional Mur's ABC for magnetized plasma. Thus, to further delay the start of this late-time instability, we intentionally multiply the newly updated field components along the ABC boundaries each time step by a stability control factor s slightly less than 1.0. Then, Equation (11) above is reexpressed as Equation (12) below (wherein $s = 1.0$ yields the original ABC Equation (11)). It is expected that this multiplication factor will increase the level of reflection from the boundary, but it will further improve the stability (in the extreme case, $s = 0.0$ yields a PEC boundary wherein all the wave are fully reflected, but the algorithm is completely stable). Equation (113) is the final ABC expression for $x = 1$ boundary. It is used to terminate the magnetized cold plasma algorithm developed. Similarly, the ABC expressions for all other outer boundaries can also be derived in a same manner and the resulting formulations are shown as Equations (13) - (17).

$$x = 1 \rightarrow U_{i,j,k}^{n+1} = s \cdot \left\{ 2 \cdot U_{i,j,k}^n - U_{i,j,k}^{n-1} - \frac{v \Delta t}{\Delta x} (U_{i,j,k}^n - U_{i,j,k}^{n-1}) + \frac{v \Delta t}{\Delta x} (U_{i,j,k}^{n-1} - U_{i,j,k}^{n-2}) + \frac{1}{2} \left(\frac{v \Delta t}{\Delta y} \right)^2 \cdot (U_{i,j,k+1}^n - 2 \cdot U_{i,j,k}^n + U_{i,j,k-1}^n) + \frac{1}{2} \left(\frac{v \Delta t}{\Delta z} \right)^2 \cdot (U_{i,j,k+1}^{n-1} - 2 \cdot U_{i,j,k}^{n-1} + U_{i,j,k-1}^{n-1}) \right\} \quad (12)$$

$$x = h \rightarrow U|_{h,j,k}^{n+1} = s \cdot \left\{ 2 \cdot U|_{h,j,k}^n - U|_{h,j,k}^{n-1} - \frac{v\Delta t}{\Delta x} (U|_{h,j,k}^n - U|_{h-1,j,k}^n) + \frac{v\Delta t}{\Delta x} (U|_{h,j,k}^{n-1} - U|_{h-1,j,k}^{n-1}) + \frac{1}{2} \left(\frac{v\Delta t}{\Delta y} \right)^2 \cdot (U|_{h,j+1,k}^n - 2 \cdot U|_{h,j,kn} + U|_{h,j-1,kn}) + 12 (v\Delta t \Delta z)^2 \cdot (U|_{h,j,k+1n} - 2 \cdot U|_{h,j,kn} + U|_{h,j,k-1n}) \right\} \quad (13)$$

$$y = 1 \rightarrow U|_{i,1,k}^{n+1} = s \cdot \left\{ 2 \cdot U|_{i,1,k}^n - U|_{i,1,k}^{n-1} - \frac{v\Delta t}{\Delta y} (U|_{i,1,k}^n - U|_{i,2,k}^n) + \frac{v\Delta t}{\Delta y} (U|_{i,1,k}^{n-1} - U|_{i,2,k}^{n-1}) + \frac{1}{2} \left(\frac{v\Delta t}{\Delta x} \right)^2 \cdot (U|_{i+1,1,k}^n - 2 \cdot U|_{i,1,kn} + U|_{i-1,1,kn}) + 12 (v\Delta t \Delta z)^2 \cdot (U|_{i,1,k+1n} - 2 \cdot U|_{i,1,kn} + U|_{i,1,k-1n}) \right\} \quad (14)$$

$$y = m \rightarrow U|_{i,m,k}^{n+1} = s \cdot \left\{ 2 \cdot U|_{i,m,k}^n - U|_{i,m,k}^{n-1} - \frac{v\Delta t}{\Delta y} (U|_{i,m,k}^n - U|_{i,m-1,k}^n) + \frac{v\Delta t}{\Delta y} (U|_{i,m,k}^{n-1} - U|_{i,m-1,k}^{n-1}) + \frac{1}{2} \left(\frac{v\Delta t}{\Delta x} \right)^2 \cdot (U|_{i+1,m,k}^n - 2 \cdot U|_{i,m,kn} + U|_{i-1,m,kn}) + 12 (v\Delta t \Delta z)^2 \cdot (U|_{i,m,k+1n} - 2 \cdot U|_{i,m,kn} + U|_{i,m,k-1n}) \right\} \quad (15)$$

$$z = 1 \rightarrow U|_{i,j,1}^{n+1} = s \cdot \left\{ 2 \cdot U|_{i,j,1}^n - U|_{i,j,1}^{n-1} - \frac{v\Delta t}{\Delta z} (U|_{i,j,1}^n - U|_{i,j,2}^n) + \frac{v\Delta t}{\Delta z} (U|_{i,j,1}^{n-1} - U|_{i,j,2}^{n-1}) + \frac{1}{2} \left(\frac{v\Delta t}{\Delta x} \right)^2 \cdot (U|_{i+1,j,1}^n - 2 \cdot U|_{i,j,1n} + U|_{i-1,j,1n}) + 12 (v\Delta t \Delta y)^2 \cdot (U|_{1,j+1,1n} - 2 \cdot U|_{i,j,1n} + U|_{i,j-1,1n}) \right\} \quad (16)$$

$$z = p \rightarrow U|_{i,j,p}^{n+1} = s \cdot \left\{ 2 \cdot U|_{i,j,p}^n - U|_{i,j,p}^{n-1} - \frac{v\Delta t}{\Delta z} (U|_{i,j,p}^n - U|_{i,j,p-1}^n) + \frac{v\Delta t}{\Delta z} (U|_{i,j,p}^{n-1} - U|_{i,j,p-1}^{n-1}) + \frac{1}{2} \left(\frac{v\Delta t}{\Delta x} \right)^2 \cdot (U|_{i+1,j,p}^n - 2 \cdot U|_{i,j,pn} + U|_{i,j-1,pn}) + 12 (v\Delta t \Delta y)^2 \cdot (U|_{1,j+1,pn} - 2 \cdot U|_{i,j,pn} + U|_{i,j-1,pn}) \right\} \quad (17)$$

III. Numerical Experiments

1.1. Accuracy studies

The performance of our ABC scheme is first evaluated by testing the reflection error in a $100 \times 100 \times 100$ -cell FDTD grid having an x -directed electric dipole source at its center with a Gaussian modulated sinusoidal waveform as

$$E_x = \exp\left[-\left(\frac{t-t_0}{t_w}\right)^2\right] \cdot \sin(2\pi f_c t) \quad (18)$$

where $t_w = 2.93 \mu s$, $t_0 = 2.2t_w$ and $f_c = 4.0 \text{ MHz}$ is the center frequency of the source. The lattice space increments in each Cartesian direction of the FDTD grid are $\Delta x = \Delta y = \Delta z = 5m$, the time step Δt is 0.97 times the Courant limit and the stability control factor is $s = 1$. The plasma medium has an electron density N_e of $1.86 \times 10^8 m^{-3}$, which corresponds to the ionosphere at an altitude of about 90 km. A static background magnetic field of 1.0×10^{-5} Tesla of various orientations is applied to the plasma to approximately mimic the magnetic field of the Earth. Without loss of generality, the E_x field component is probed at a point in the same xy -plane as the source and 3 cells from the outer y -boundary. The relative reflection error $Error|_{i,j,k}^n$ of the ABC at time-step n and grid location (i, j, k) is then calculated by the method detailed in [10] and defined as

$$Error|_{1,j,k}^n = \frac{|E|_{i,j,k}^n - E_{ref}|_{i,j,k}^n|}{|E_{ref,max}|_{i,j,k}^n|} \quad (19)$$

where $E|_{i,j,k}^n$ is the electric field value recorded at the probing point, and the reference solution $E_{ref}|_{i,j,k}^n$ is obtained from a sufficiently large benchmark grid having no reflected signals from grid boundaries at the probing point over the time-stepping span of interest. The maximum amplitude of the reference fields over all time steps at grid location (i, j, k) is denoted as $E_{ref,max}|_{i,j,k}^n$.

Figure 1(a)-(c) illustrate the numerical results of the relative errors for different applied magnetic field directions. For Figure 1(a), a z -directed magnetic field is applied to the plasma ($B_z = -1.0 \times 10^{-5}$ T and $B_x = B_y = 0$ T). For Figure 1(b), an x -directed magnetic field is applied to the plasma in the upper half of the grid ($z \geq z_{max}/2$, $B_x = 1.0 \times 10^{-5}$ and $B_y = B_z = 0$ T) and a z -directed magnetic field is applied to the plasma in the lower half of the grid ($z < z_{max}/2$, $B_z = -1.0 \times 10^{-5}$ and $B_x = B_y = 0$ T), where z_{max} is the maximum number of grid cells in the z -direction. For Figure 1(c), a magnetic field with 45 degree codip and Azimuth angles is applied to the plasma ($B_x = B_y = 0.5 \times 10^{-5}$ and $B_z = -0.707 \times 10^{-5}$). For all the cases depicted in Figure 1(a)-(c), the reflection errors are seen to be less than $\sim 5\%$, clearly demonstrating the ABC's capability to provide the same approximate level of error regardless of the applied magnetic field direction.

To further evaluate the newly-derived ABC's performance compared to the original Mur's ABC, the same simulation parameters of Figure 1(c) are repeated with the original Mur's ABC. Figure 1(d) shows that the maximum reflection error for the case of the original Mur's ABC is also around 5%, as for the ABC of this chapter.

Next, the same numerical experiments have also been repeated without ABC (PEC in place of the ABC) to compare its performance with a PEC boundary. The result with a simulation condition as in the case of Figure 1(c) is shown in Figure 2. In this test, the ABC is simply removed and replaced by a PEC boundary and the recorded electric field variation at the probing point is then compared to those obtained from the grid with ABCs and from the large reference grid. One can see

that the PEC boundary is obviously introducing much larger reflection signals compared to the ABC and the large reference grid cases.

3.2. Evaluation of the ABC's performance in dense plasma

In Section 3.1, we performed accuracy studies of the ABC at a relatively low altitude (~ 90km) of the ionosphere (therefore a relatively low density plasma). To study the ABC's performance at higher altitudes (more dense plasma), the same simulation of Figure 1(a) is repeated for progressively larger electron densities N_e . We find through a series of tests that the maximum reflection error remains at the same level as for Figure 1(a) until the electron density N_e is increased to a level such that the center frequency f_c of the source becomes near to the critical cutoff frequencies of the plasma.

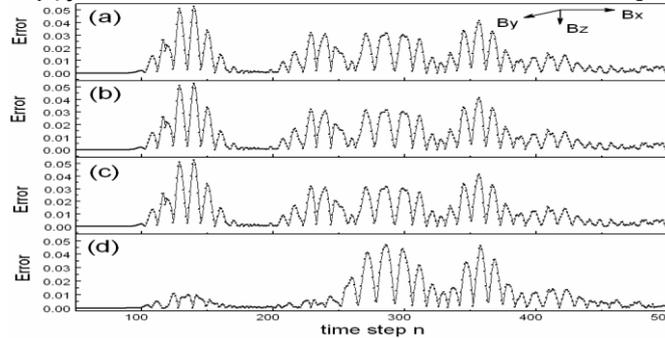

Figure.1. Reflection errors for different magnetic field directions applied to the plasma (a) $B_x=B_y=0$ T, $B_z=-1.0 \times 10^{-5}$ T (b) $B_x=1.0 \times 10^{-5}$ and $B_y=B_z=0$ T for $z \geq z_{max} / 2$, and $B_z = -1.0 \times 10^{-5}$ and $B_x = B_y = 0$ T for $z < z_{max} / 2$ (c) $B_x=B_y=0.5 \times 10^{-5}$ and $B_z=-0.707 \times 10^{-5}$ (d) same magnetic field as in (c) applied to Mur's ABC.

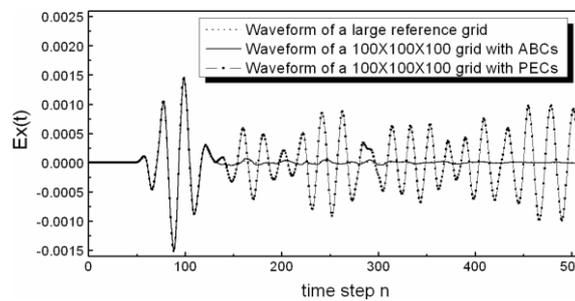

Figure.2. Time-domain electric field variations recorded at the probing point.

For example, Figure 3(c) illustrates the source spectrum employed in all of the numerical experiments. Figure 3(a) shows the dispersion diagram (wavenumber v.s. wave frequency) for the case of Figure 1(a) (a low-density plasma with $N_e = 1.86 \times 10^8 \text{ m}^{-3}$ corresponding to an altitude of ~ 90km), and Figure 3(b) shows the dispersion diagram for a higher density plasma with $N_e = 4.85 \times 10^{10} \text{ m}^{-3}$ (corresponding to an altitude of ~ 400km). The dotted lines of Figure 3(a) and Figure 3(b) represent the dispersion relation of the LHC-wave and the solid lines represent the dispersion diagram of the RHC-wave. We note that according to Figure.3, as N_e is increased from $1.86 \times 10^8 \text{ m}^{-3}$ to $4.85 \times 10^{10} \text{ m}^{-3}$ the source begins to have substantial spectrum below the cutoff frequencies of the LHC- and RHC-waves. This causes the portion of the source spectrum below ~ 2.1 MHz to change from propagating modes as for the case of Figure 3(a) to non-propagating modes as for the case of Figure 3(b). More importantly, though, closer to the cutoff frequencies, the phase velocity is increased. As a result, because a velocity of c corresponding to free space has been assumed for the ABC, the reflection error increases from ~ 5 % as for Figure.1(a) to ~ 6 % as shown in Figure.4(a) for the same scenario except for having an increased N_e . To improve the accuracy, instead of using the free-space speed c for v in equations (1) - (6), the phase velocity v in the plasma at the source center frequency f_c is utilized, resulting in a value of ~ 1.13c. Figure 4(b) presents the results using $v = 1.13 c$, and as expected, the maximum reflection error is now reduced to ~ 4.5 % from ~ 6 % of Figure 4(a).

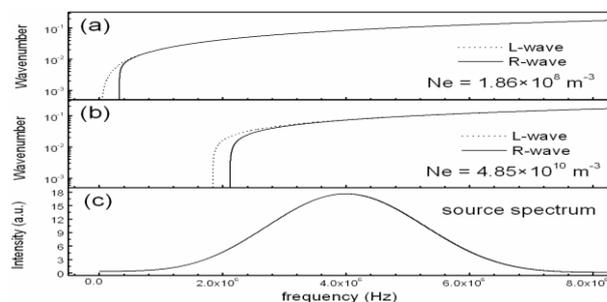

Figure.3. (a) dispersion diagram for a low-density plasma ($N_e = 1.86 \times 10^8 \text{ m}^{-3}$) (b) dispersion diagram for a high-density plasma ($N_e = 4.85 \times 10^{10} \text{ m}^{-3}$) (c) source wave spectrum

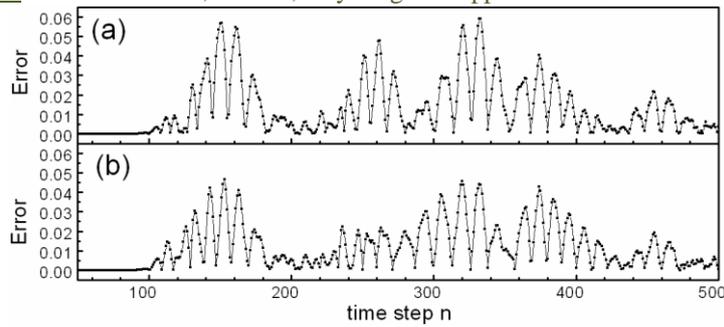

Figure.4. Reflection errors for a dense plasma ($N_e = 4.85 \times 10^{10} \text{ m}^{-3}$) (a) phase velocity v of the ABC assumed as free-space speed c (b) $v=1.13c$

IV. Conclusion

We find through longer numerical tests that the early-time instability of Mur's ABC is simply replaced by a late-time instability in Zhang and Wang's scheme. In this article, the feasibility of a variation of Zhang and Wang's scheme is investigated to serve as an effective ABC for the 3-D FDTD magnetized cold plasma formulation. We choose this scheme despite its inherent late-time instability because it has the potential to provide an acceptable level of error regardless of the direction of the background magnetic-field, a capability not provided by KPML. We then presented a simple but very effective way to 60 further delay the late-time instability of this magnetized plasma ABC. In Section 2, the formulation of the ABC scheme is first derived. Next, in Section 3, the newly-developed ABC scheme is rigorously tested by evaluating its reflection errors for different cases.

Radiation Properties of the Array Pattern Synthesis Using Fibonacci and Normalized Modified Binomial (Nmb) Polynomials

Abdolkhalegh Mohammadi and Mohammad Pourbagher, Javad Nourinia

Microelectronics Research Laboratory, Urmia university, IRAN

Abstract: This paper presents radiation property of the array antenna pattern synthesis using new polynomial. Fibonacci and Smooth Normalized Modified Binomial (SNMB) are two polynomials which the property of their pattern are investigated. Fibonacci have a good side lobe level but the lobes are smooth and no tapering is observed. SNMB array type can be accomplished to have tapered minor lobe which is suitable for Radar and low-noise systems.

Keywords- polynomials, array, minor lobe, first null, side lobe level (SLL)

I. Introduction:

Antenna array radiation pattern synthesis has taken major interest since the beginning of the array antenna era. The problem is generally to synthesize the optimum complex excitation coefficients for a given array geometry that will yield an array factor which is – in some sense– close to a desired array factor. Especially when it comes to the subject of shaped pattern synthesis, optimization techniques with iterative procedures are used. Genetic algorithms (GA) [1] are the most widely used methods in pattern synthesis, which can almost deal with all the synthesizing problems. Particle swarm optimization (PSO) [2] and simulated annealing (SA) [3] have already been used in array synthesis for different requirements too. Immune algorithm (IA) [4] is also a new heuristic optimization algorithm which has powerful function of global search. Although some studies like [5] focus on the problem with a different point of view, i.e., attempting to find the optimum geometry under the existence of prescribed excitation coefficients, most of the literature deals with the problem of obtaining the optimum coefficients for one dimensional linear arrays, possibly due to its practical use. Various methods have been applied for the solution of the problem. Among these are non-iterative methods such as Fourier Transform Method, Woodward-Lawson Method, and Taylor Line Source Synthesis Method.

Currently, development of wireless application such as radar and communication with low noise becomes rapidly. The antenna plays an important role as the key device in transmitting and receiving the signal. Generally it is desired to antenna to provide maximum directivity, narrow beamwidth and low side lobe level especially far out minor lobes in order to reduce the noise entering through those minor lobes. The antenna array is one of the most suitable candidates that can fulfill these requirements. In most cases, the elements of an array are identical. The total field of the array is determined by the vector addition of the fields radiated by the individual elements. This is usually not the case depends on the separation between the elements. To provide very directive patterns, it is necessary

that the field from the elements of the array interfere constructively (add) in the desired directions and interfere destructively (cancel each other) in the remaining space. In an array with identical elements, there are at least five parameters that can control the shape of the overall pattern of the antenna [6]. Excitation amplitude of the individual elements is one of the features that help us to control the pattern of the array antenna. In N-element linear array with uniform spacing and nonuniform amplitude there are three famous distributions: uniform, binomial and Tschebyscheff. An uniform amplitude array yields the smallest half-power beamwidth. It is followed, in order, by the Dolph-Tschebyscheff and binomial arrays. In contrast, binomial arrays usually possess the smallest side lobes followed, in order, by the Dolph-Tschebyscheff and uniform arrays. As a matter of fact, binomial arrays with element spacing equal or less than $\lambda/2$ have no side lobes. It is apparent that the designer must compromise between side lobe level and beamwidth. a criterion that can be used to judge the relative beamwidth and side lobe level of one design to another is the amplitude distribution (tapering) along the source. It has been shown analytically that for a given side lobe level the Dolph-Tschebyscheff array produces the smallest beamwidth between the first nulls. Conversely, for a given beamwidth between the first nulls, the Dolph-Tschebyscheff design leads to the smallest possible side lobe level. Uniform arrays usually possess the largest directivity.

For some applications, such as radar and low-noise systems, it is desirable to sacrifice some beamwidth and low inner minor lobes to have all the minor lobes decay as the angle increases on either side of the main beam [7]. In these applications the side lobes should be tapered. In this paper radiation properties of array pattern synthesis using some new special polynomials is discussed

II. Array pattern synthesis using Fibonacci polynomials

In this part the design procedures of the array pattern synthesis using modified Fibonacci polynomials will be illustrated. The issue refers to compute the radiation pattern and half power beamwidth (HPBW) and directivity of N-element linear array with uniform spacing and nonuniform amplitude which are excited by Fibonacci polynomials. In the following The Fibonacci polynomials will be introduced. The formula of Fibonacci polynomials is

$$F_n = F_{n-1} + F_{n-2} \quad (1)$$

$$F_0 = 0$$

$$F_1 = 1$$

The generated polynomial will be 0,1,1,2,3,5,8,13,21,34,55,89,...

To use this polynomial for excitation of N-elements we write the Fibonacci polynomial with $n=N+1$ term, after that

we again write these n terms in a degradation form, now if N be even, the same terms will be repeated in a degradation form without any change. Also if N be odd, the maximum term will be omitted from the degradation form terms. Let N=4, the Fibonacci polynomial will be 0,1,1,2,3,5

N is even so we write this polynomial in a degradation form directly after initial terms

0,1,1,2,3,5,5,3,2,1,1,0

Now we omit the additional terms from both sides until the number of terms be equal to number of elements (4 elements).

~~0,1,1,2,3,5,5,3,2,1,1,0~~

So the amplitude of excitation coefficients for 4-elements array will be

3,5,5,3

Again for a 5-elements array the Fibonacci polynomial will be

0,1,1,2,3,5,8

Now these terms will come with degradation form and the maximum term will be omitted.

0,1,1,2,3,5,8,5,3,2,1,1,0

Now we omit the additional terms from both sides until the number of terms be equal to number of elements (five elements). The answer is: 3,5,8,5,3

The polynomials of Fibonacci for different N are brought here:

N=1		1		
N=2		2	2	
N=3	2	3	2	
N=4	3	5	5	3

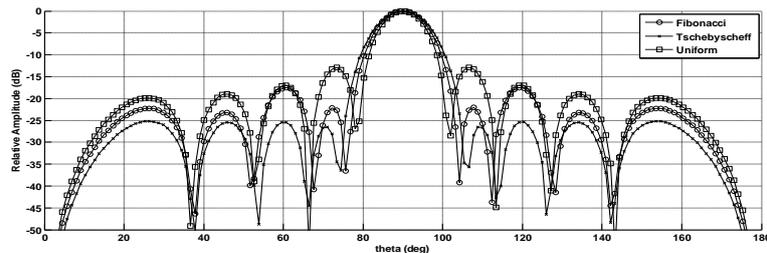

Fig. 1. Comparison of Fibonacci, Uniform and Tschebyscheff

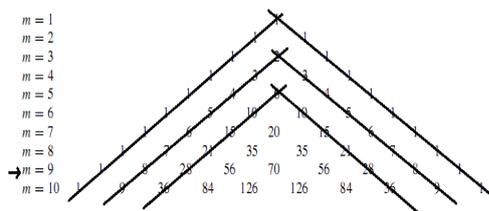

Fig. 2. Deleted sides of pascal's triangle

After that the excitation coefficients are normalized to the big one. In fig. 2 this method is shown completely.

For formulizing the above steps we start with binomial expansion:

$$(1 + x)^{N-1} = \binom{N-1}{0} + \binom{N-1}{1}x + \binom{N-1}{2}x^2 + \dots + \binom{N-1}{N-1}x^{N-1} \quad (2)$$

N is the number of elements. So the excitation coefficients are:

$$\binom{N-1}{0}, \binom{N-1}{1}, \binom{N-1}{2}, \dots, \binom{N-1}{N-1} \quad (3)$$

N=5	3	5	8	5	3			
N=6	5	8	13	13	8	5		
N=7	5	8	13	21	13	8	5	
N=8	8	13	21	34	34	21	13	8

Now if we use some changes to these polynomials the features of radiation will be better.

For example we can add the difference between the smallest and the greatest excitation coefficient to all elements, so the directivity will be better. Now we compare the radiation pattern, HPBW and Directivity of an array with 10 elements which excited by Fibonacci, uniform, binomial and Tschebyscheff. In Fig. 1 We observe that the pattern of fibonacci is between the Uniform and Tschebycheff. It shows that the directivity of fibonacci is better than Tschebycheff but not as well as Uniform. Tschebycheff pattern has the smallest first minor lobe. We do not observe any good tapering from Tschebycheff and fibonacci patterns. But Uniform array has tapered.

III. Normalized Modified Binomial (NMB) :

Using the binomial method for excitation of arrays has some problems. For example the differences between excitation coefficients are very much and it makes some practical problems. In modified binomial polynomial this problem has been solved by keeping other features. In this method we omit two sides of pascal's triangle for several times according to number of element. After that we use the new triangle and by the knowledge of number of element the appropriate row of triangle is chosen. For example for a three element array we delete the sides for three times. Then the third row of new triangle is chosen.

From Posteriori reasoning we will find out that the Nth row of new triangle is the 3*Nth of the Pascal's triangle which some coefficient are omitted. For finding the excitation coefficient by new triangle we can trace the following:

$$\binom{N^{old}-1}{N^{new}}, \binom{N^{old}-1}{N^{new}+1}, \dots, \binom{N^{old}-1}{N^{old}-N^{new}} \quad (4)$$

For example for a five-element array the results is:

$$N^{new}=5$$

$$N^{old}=3*5=15$$

$$\binom{15-1}{5}, \binom{15-1}{6}, \binom{15-1}{7}, \binom{15-1}{8}, \binom{15-1}{9}$$

The coefficients are:
2002,3003,3432,3003,2002

Now we normalize coefficients to the bigger one.
0.58, 0.87, 1, 0.87, 0.58

The new triangle for excitation coefficient is:

N=1		1	
N=2		1	1
N=3	0.8	1	0.8

N=4	0.71	1	1	0.71				
.	0.58	0.87	1	0.87	0.58			
.	0.5	0.8	1	1	0.8	0.5		
.	0.41	0.68	0.9	1	0.9	0.68	0.41	
.	0.36	0.68	0.84	1	1	0.84	0.68	0.36

N=1	1							
N=2	1	1						
N=3	1	1.2	1					
N=4	1	1.29	1.29	1				
N=5	1	1.29	1.42	1.29	1			
N=6	1	1.3	1.5	1.5	1.3	1		
N=7	1	1.27	1.49	1.59	1.49	1.27	1	
N=8	1	1.24	1.48	1.64	1.64	1.48	1.24	1

Now if we use some changes to this triangle the features of radiation will be better.

For example if the difference between the smallest and the greatest excitation coefficient be added to all elements, the directivity will be better. The excitation coefficient will be:

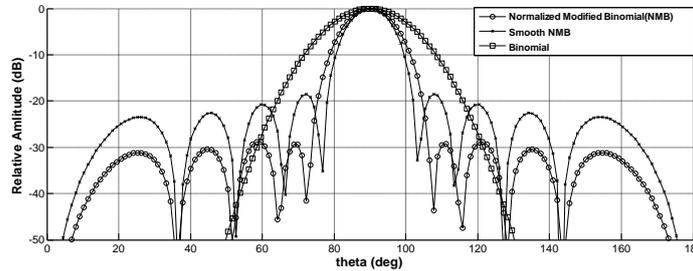

Fig. 3. Comparison between Normalized Modified Binomials, smooth NMB and Binomial

We call this polynomial Smooth Normalized Modified Binomials (SNMB). Now we compare this new polynomial with binomial and other special polynomials. At first in fig. 3 We observe the effect of changes to polynomials. By adding the difference of smallest and largest coefficient to all excitation coefficients, the amplitudes will be more smooth and it help us to have a directivity better than NMB.

The most important part of Fig. 3 is the tapering of smooth NMB polynomial pattern. As in this figure is observed, the NMB and Binomial (which has no side lobe) has no tapering.

In fig. 4 the pattern of Smooth NMB and Tschebycheff are compared. The directivity of smooth NMB is better than Tschebycheff, although the side lobe level is worse. Tschebycheff has no tapering in minor lobes but the tapering in Smooth NMB is evident. As mentioned above this property is suitable for some application like Radar and low-noise system.

There are other polynomials which have this property (tapering). Hermite polynomials and A continuous line-source distribution that yields decaying minor lobes and, in addition, controls the amplitude of the sidelobe is that introduced by Taylor [8] in an unpublished classic

memorandum. It is referred to as the Taylor (one-parameter) design.

Both polynomials have some disadvantages, for example Hermite in spite of having tapered minor lobe is sacrifices directivity. Totally the disadvantage of designing an array with decaying minor lobes as compared to a design with equal minor lobe level (Dolph-Tschebyscheff), it yields about 12 to 15% greater half-power beamwidth. Also Taylor designing methods are more applicable for large arrays [3].

As it is observed in fig. 4 the Smooth NMB has a better directivity than Tschebycheff. It has tapered minor lobe without sacrificing the directivity.

The advantage of Tschebycheff and Taylor designing methods is their capability in controlling the side lobe level, in other words for a given side lobe level, the smallest possible first-null beamwidth (or the smallest possible sidelobe level for a given first-null beamwidth) is achieved by Dolph-Tschebyscheff array design. If this property of Dolph-Tschebyscheff design be combined by Smooth NMB tapering property the best answer will occur. Then a trade-off between side lobe level and tapering ratio could be made.

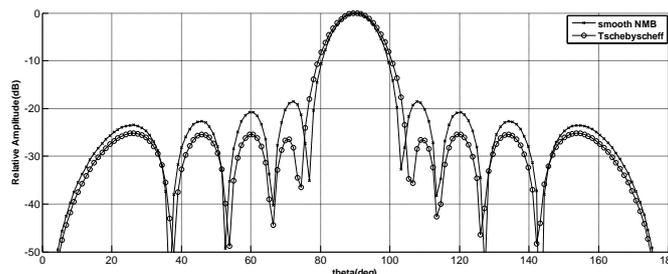

Fig. 4. Comparison between Tschebycheff and smooth NMB

IV. Conclusion:

In this paper radiation properties of array pattern synthesis using some special polynomials is discussed. In Radar and low noise systems it is desirable to sacrifice

some beamwidth and low inner minor lobes to have all the minor lobes decay as the angle increases on either side of the main beam. In radar applications this is preferable because interfering or spurious signals would be reduced

further when they try to enter through the decaying minor lobes. Thus any significant contributions from interfering signals would be through the pattern in the vicinity of the major lobe. The best polynomial that gives this property is Hermite polynomial. In spite of giving this tapered minor lobes Hermite polynomials reduces directivity. In this paper the end was to excite the amplitude by some new polynomials to give us a tapered lobe by keeping Directivity constant. Smooth NMB do this, by keeping directivity it has a good tapered minor lobes.

Variable Step Variable Weights Lms (Vsvwlms) Algorithm By Modified Leaky Lms

Mohammad purbagher, Abdolkhalegh Mohammadi, Javad Nourinia,
Changiz ghobadi

Department of Electrical Engineering, Urmia university, IRAN

Abstract: This paper proposes a modified leaky least-mean-square (LLMS) algorithm by variable step and variable weight factor (VSVWLMS) that used magnification of error signal. This algorithm uses a variant rate of convergence (ROF) and a variant weight factor for searching in performance surface. In each step the algorithm chooses a new rate of convergence for searching and run computations according to this new rate of convergence. This algorithm at the beginning of convergence uses large value of rate of convergence for increasing speed of convergence. After that by approaching to optimum point the algorithm uses small rate of convergence to give a more accurate response. Also the algorithm uses variant parameter to multiply to the weight vector and new method of varying this parameter in each step. Here the gist of matter refers to using the features of two algorithm, Variable Step Least-Mean-Square (VSLMS) and Leaky LMS which helps to increase the speed of convergence and combining these feature.

Keywords: adaptive filter , Leaky LMS, rate of convergence , VSLMS

I. Introduction

In recent years a growing field of research in adaptive systems has resulted in a variety of adaptive automats whose characteristics in limited ways resemble certain characteristics of living systems and biological adaptive processes [1].

The essential and principal property of the adaptive system is its time-varying self-adjusting performance. In many instances, however, the complete range of input conditions may not be known exactly, or even statistically; or the condition changes from time to time. In such circumstances, an adaptive system that continually seeks the optimum within an allowed class of possibilities, using an orderly search process, would give superior performance compared with a system of fixed design.

We begin by representing the performance feedback process In the Fig.1. where the input $x_k \in \mathcal{R}^N$ is a stationary zero-mean vector random process with autocorrelation matrix $R \triangleq E [x_k x_k^T]$ for all k, the desired output d_k is a stationary zero-mean scalar random process, $W_k \in \mathcal{R}^N$ is the weight vector, and k is the time index. The system output at time k is given by $y_k = W_k^T x_k$, and the error ϵ_k is computed via $\epsilon_k = d_k - y_k$.

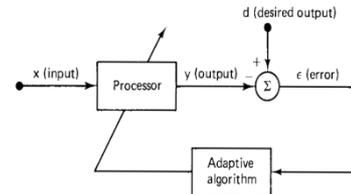

Figure.1 Block diagram of an adaptive filter.

Assume that x_k and d_k are jointly stationary with crosscorrelation vector $P \triangleq E [d_k x_k]$ for all k. Define a convex cost function

$$\zeta \triangleq E [\epsilon_k^2] = E [d_k^2] - 2P^T W + W^T R W \quad (1)$$

This cost function is the mean square error (MSE). It can easily be shown that, if R is full rank, the unique optimal fixed weight vector which minimizes ζ is given by

$$W^* = R^{-1} P \quad (2)$$

This is called the Wiener solution [2].

It is clear from this expression that the mean square error ζ is precisely a quadratic function of the component of the weight vector W when the input component and desired response input are stationary stochastic variables. A portion of a typical two-dimensional mean square error function is illustrated in Fig. 2.

The vertical axis represent the mean square error and the horizontal axes the value of the two weights. The bowl-shaped quadratic error function, or performance surface for in this manner is a paraboloid.

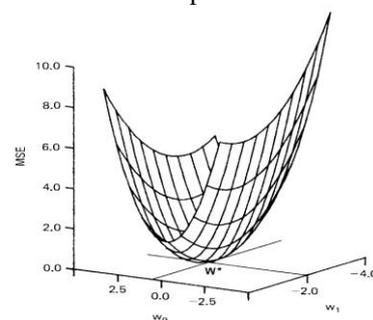

Figure.2 portion of a two dimensional quadratic performance surface. the mean square error is plotted vertically, and the optimum weights vector is $W^* = (0.65, -2.10)$. the minimum MSE is 0.0 in this example.

1.2. Gradient and minimum mean-square error

Many useful adaptive process that cause the weight vector to seek the minimum of the performance surface so by gradient method [1]. The gradient of the mean square error surface, designated $\nabla(\zeta)$ or simply ∇ , can be obtained by differentiating (1) to obtain the column vector

$$\nabla \triangleq \frac{\partial \zeta}{\partial W} = \left[\frac{\partial \zeta}{\partial w_0} \quad \frac{\partial \zeta}{\partial w_1} \quad \dots \quad \frac{\partial \zeta}{\partial w_L} \right]^T = 2RW - 2P \quad (3)$$

where R is autocorrelation and P is crosscorrelation. To obtain the minimum square error the weight vector W is set at its optimum value W^* , where the gradient is zero :

$$\nabla = 0 = 2RW^* - 2P \tag{4}$$

Assuming that R is nonsingular, the optimum weight vector W^* , sometimes called the wiener weight vector, is found from (9) to be [3-5]

$$W^* = R^{-1}P$$

II. VSVWLMS algorithm

In fact a filter consists of an electrical circuit or software program that chooses the desired signal from unwanted noise and signals. In an adaptive filter (self-improved filter), the filter modified itself after a while (a few iteration) and learn how to optimize weights to achieve the optimum response called wiener response. Leaky LMS algorithm is one of the algorithms used in adaptive filters

$$W(k+1) = \beta W(k) + 2\mu\epsilon(k)X(k) \tag{5}$$

where β is a small number near one and $W(k)$ is weight vector in n th iteration. $\epsilon(n)$ is the error signal and $x(n)$ is the input signal and μ is rate of convergence.

What is discussed in this algorithm represents a new method according to Leaky LMS and VSLMS algorithm to accelerating the speed of the convergence. In this algorithm β and μ are variant and defined like below

$$W(k+1) = \beta(k)W(k) + 2\mu(k)\epsilon'(k)X(k) \tag{6}$$

$$\beta(k) = e^{-\left(\frac{k}{k+1}\right)} \tag{7}$$

$$\mu(k) = \mu(k-1) + 0.01^k (A(k)A(k-1)) \tag{8}$$

$$A(k) = \epsilon'(k)X(k) \tag{9}$$

where ϵ' is the magnificated error signal, i.e.

$$\epsilon'(k) = 5\epsilon(k) \tag{10}$$

$$y(k) = X^T(k)W(k) \tag{11}$$

III. Convergence proof

This section examines the process of mathematical algorithms and its convergence explains. After that by transforming coordinate system to principle coordinate, convergence condition is examined. In the following gradient estimate convergence examined.

$$E[\nabla'(k)] = E[-2\epsilon'(k)X(k)] \\ = -10 E [d(k) X(k) - X(k) X^T(k) W(k)]$$

$$= 10 (RW - p) = 5 \nabla(k) \tag{12}$$

now the convergence of the weights to the optimum weight is discussed.

$$E[w(k+1)] = E[\beta(k)w(k)] + 10\mu E[\epsilon(k)X(k)]$$

$$E[w(k+1)] = e^{-\left(\frac{k}{k+1}\right)} E[w(k)] + 10\mu E[\epsilon(k)X(k)] \tag{13}$$

by substituting $\epsilon(n)$ in the above equation and considering $W^* = R^{-1}P$ it will be

$$E[w(k+1)] = (\beta(k) - 10\mu R)E[w(k)] + 10\mu R w^* \tag{14}$$

by transforming the coordinates to the principle coordinate and using eigen value matrix Λ it will be

$$\Lambda = \begin{pmatrix} \lambda_0 & \dots & 0 \\ \vdots & \ddots & \vdots \\ 0 & \dots & \lambda_L \end{pmatrix} \tag{15}$$

$$E[v'] = (\beta(k) - 10\mu\Lambda)^k v'_0 \tag{16}$$

$r = \text{geometric ratio} = \beta(k) - 10\mu\Lambda$

v'_0 is the initial weight vector in the principle-axis system. we also note that [4-7]

where v' is the weight vector, W , in the principle-axis system, Λ is the diagonal eigenvalue matrix of R , and

$$r \approx e^{-\frac{1}{\tau}} = 1 - \frac{1}{\tau} + \frac{1}{2\tau^2} - \dots \tag{17}$$

we have

$$\beta(k) - 10\mu\lambda_k \approx 1 - \frac{1}{\tau}$$

therefore

$$\tau_k = \frac{1}{10\mu(k)\left(\lambda_k + \frac{1-\beta(k)}{10\mu(k)}\right)} \tag{18}$$

The geometric ratio of the learning curve, on the other hand [8], [10]

$$r_{mse} = r^2 \tag{19}$$

$$\exp\left(-\frac{1}{\tau_{mse}}\right) = \exp\left(-\frac{2}{\tau}\right) = r^2 = r_{mse} \tag{20}$$

$$\tau_{mse} = \frac{\tau}{2} \tag{21}$$

and know that

$$M = \frac{\text{excess MSE}}{\zeta_{min}} \approx \mu \text{tr}[R] \tag{22}$$

$$\text{tr}[R] = \sum_{n=0}^L \lambda_n \\ = \frac{1}{4\mu} \sum_{n=0}^L \frac{1}{\tau_{mse}} = \frac{L+1}{4\mu} \left(\frac{1}{\tau_{mse}}\right)_{av}$$

$$M \approx \frac{L+1}{4\tau_{mse}} \tag{23}$$

where $L+1$ is the total weights, Therefore misadjustment in the VSVWLMS is

$$M \approx (L+1)(5\mu(k))\left(\lambda_k + \frac{1-\beta(k)}{10\mu(k)}\right) \tag{24}$$

We also note that λ_{max} cannot be greater than the trace of R , which is the sum of the diagonal elements of R , that is [1], [8-12]

$$\lambda_{max} \leq \text{tr}[\Lambda] = \sum(\text{diagonal elements of } \Lambda) = \sum(\text{diagonal elements of } R) = \text{tr}[R] \tag{25}$$

here the condition of convergence is bellow

$$|r| < 1 \text{ which yields below equation}$$

$$\frac{\beta(k)-1}{10\lambda_{min}} < \mu < \frac{\beta(k)+1}{10\lambda_{max}}$$

This disparity increases as the eigenvalue spread $\lambda_{max}/\lambda_{min}$ increases – corresponding to an equivalent increase in the eccentricity of the elliptical contours of constant MSE [13-18]. Thus, the key step in improving the transient performance of LMS lies in decreasing the input eigenvalue spread.

IV. Simulation results

In this section an example which compares the proposed algorithm with the Leaky LMS and VSLMS algorithm is represented. The block diagram of the example is shown

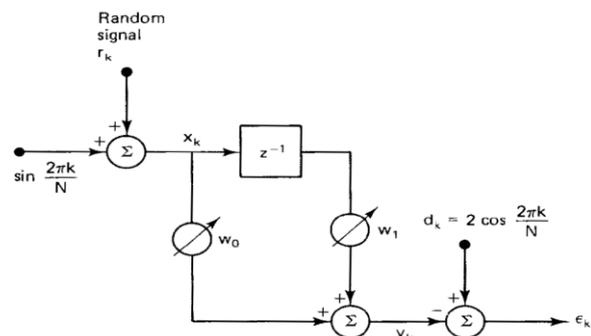

Figure.3 Block diagram for a filter with two weights.

The simulation result of this example for the same starting point and the identical stage (250 iteration) for the proposed algorithm, Leaky LMS and VSLMS algorithm and the comparison between them is presented in Fig. 4 and Fig. 5.

In Fig. 6 it is shown that the suggested algorithm converge to the optimum point with a bigger stage. It shows that the convergence occur faster. In Fig. 7 which enlarge the last point of the convergence, it is shown that with the same iteration, the response of the proposed algorithm is closer than to the optimum point. In this figure the last point of VSLMS is (5.263, -4.860) and the last point of suggested algorithm is (5.227, -4.829) in the same iteration while the optimum point is (4.828, -5.226).

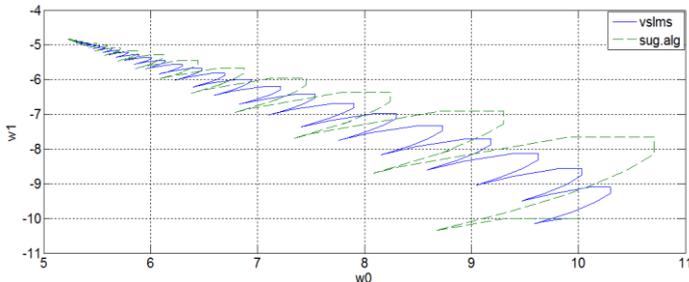

Figure.4 suggested algorithm versus VSLMS.

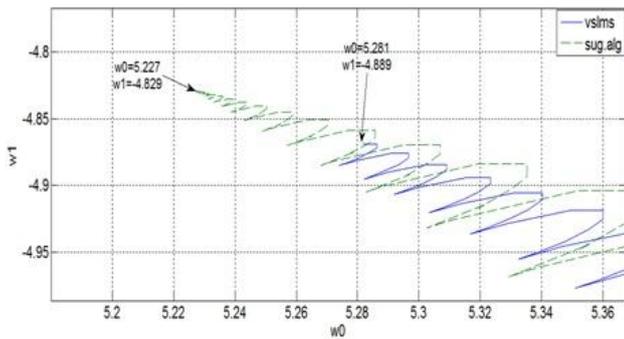

Figure.5 Comparison between the suggested algorithm and the VSLMS in seeking the optimum point with the same iteration

In Fig. 4 it is shown that the suggested algorithm converge to the optimum point with a large steps. It shows that the convergence occur faster. In Fig. 5 which enlarge the last point of the convergence, shown with the same iteration, the response of the proposed algorithm is closer than to the optimum point. In this figure the last point of Leaky LMS is (5.281, -4.889) and the last point of suggested algorithm is (5.227, -4.829) in the same iteration while the optimum point is (4.828, -5.226).

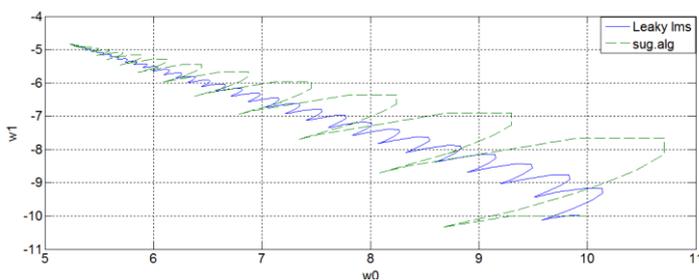

Figure.6 Suggested algorithm versus Leaky LMS.

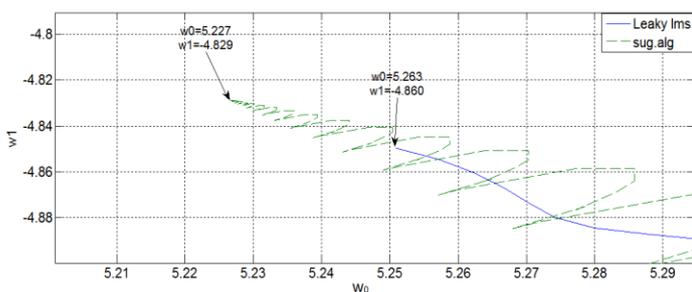

Figure.7 Comparison between the suggested algorithm and the Leaky LMS in seeking the optimum point with the same iteration.

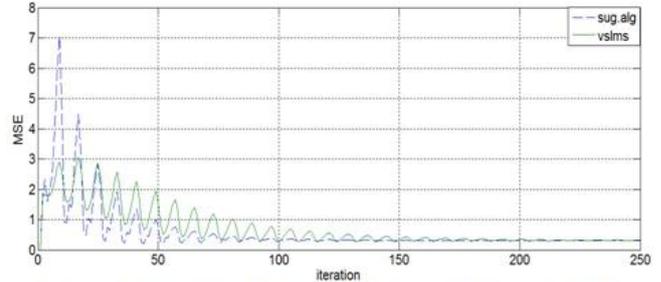

Figure.8 Comparison between the learning curves of the suggested algorithm and VSLMS.

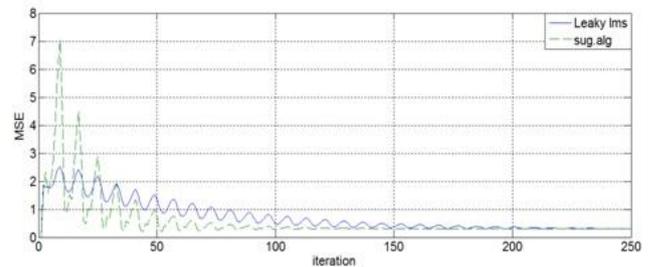

Figure.9 Comparison between learning curves of suggested algorithm and Leaky LMS

In the Figures 8 and 9 the mean-square-error (MSE) versus iteration are illustrated. It is clear that the suggested algorithm at first has a bigger MSE, but after some iteration it will be lower than Leaky LMS and VSLMS algorithm's MSE. It shows that the algorithm in fewer iteration reaches to the desirable accuracy and give us a better response.

V. Conclusion

In this paper a new algorithm for adaptive filter has been introduced which was called VSVWLMS. This algorithm uses the features of Leaky LMS and VSLMS and combined them to accelerate the speed of convergence. In the simulation result it has been observed that in the same iteration VSVWLMS algorithm converge to the optimum point with more speed.

Robust Information Clustering on MDI

Mr. S. M. Krishna Ganesh¹, Dr. S. Venkatesan Jaya Kumar²

¹(Department of Computer Science and Engineering, St. Joseph College of Engineering and Technology, India)

²(Department of General Engineering St. Joseph College of Engineering and Technology, India)

Abstract : We propose a robust framework for determining a natural clustering of a given dataset, based on the minimum description length (MDL) principle. The proposed framework, robust information-theoretic clustering (RIC), is orthogonal to any known clustering algorithm. Given a preliminary clustering, RIC purifies these clusters from noise, and adjusts the clustering's such that it simultaneously determines the most natural amount and shape of the clusters. RIC, for refining a clustering and discovering a most natural clustering of a dataset. In particular, we propose a novel criterion, volume after compression (VAC), for determining the goodness of a cluster, and propose algorithms for robust estimation of the correlation structure of a cluster in the presence of noise, identification and separation of noise using VAC, and construction of natural correlation clusters by a merging procedure guided by VAC. It is fully automatic, that is, no difficult or sensitive parameters must be selected by the user. Our RIC method can be combined with any clustering technique ranging from K-means and K-medoids to advanced methods such as spectral clustering. The various performance related graphs shows that our algorithm is computationally and performance wise better than other clustering algorithms.

Keywords - Clustering techniques, Minimum description Length, Volume after compression

I. INTRODUCTION

In General, Clustering mean the assignment of objects into groups so that objects from the same cluster are more similar to each other than objects from different clusters.

Clustering is a common technique for statistical data analysis, which is used in many fields, including machine learning, data mining, pattern recognition, image analysis and bioinformatics. Clustering techniques fall into a group of undirected data mining tools. The goal of undirected data mining is to discover structure in the data as a whole. There is no target variable to be predicted, thus no distinction is being made between independent and dependent variables. Depending on the clustering technique, clusters can be expressed in different ways identified clusters may be exclusive, so that any example belongs to only one cluster. They may be overlapping; an example may belong to several clusters. they may be probabilistic, whereby an example belongs to each cluster with a certain probability. clusters might have hierarchical structure, having crude division of examples at highest level of hierarchy, which is then refined to sub-clusters at lower levels. The problem of clustering has attracted a huge volume of attention for

several Decades, with multiple books (Hartigan, Van-Rijsbergen), surveys (Murtagh) and papers (X-means (Pelleg and Moore), G-means (Hamerly and Elkan), CLARANS (Ng and Han), CURE (Guha), CLIQUE (Agrawal), BIRCH (Zhang), DBSCAN (Ester)). Recent interest in clustering has been on finding clusters that have non-Gaussian correlations in subspaces of the attributes, for example, the work of Bohm, Tung and Aggarwal and Yu. Finding correlation clusters has diverse applications ranging from spatial databases to bioinformatics. The hard part of clustering is to decide what is a good group of clusters, and which data points to label as outliers and thus ignore for clustering. We show a fictitious set of points in 2D. Shows a grouping of points that most humans would agree is good a Gaussian like Cluster at the left, a line-like cluster at the right, and a few noise points (outliers) scattered throughout. However, typical clustering algorithms like How can we quantify the goodness of a grouping? We would like a function that will give a good score to the grouping of and a bad one to that of diagram. How can we write an algorithm that will produce good groupings efficiently and without getting distracted by outliers..

II. MOTIVATION

Clustering has attracted a huge volume of interest. Recently, there have been several papers focusing on scalable clustering algorithms, such as, CURE [Guha et al. 1998], CLIQUE [Agrawal et al. 1998], BIRCH [Zhang et al. 1996], DBSCAN [Ester et al. 1996], and OPTICS [Ankerst et al. 1999]. There are also parameter-free algorithms like X-means [Pelleg and Moore 2000], and G-means [Hamerly and Elkan 2003]. However, they all suffer from one or more of the following drawbacks: They focus on spherical or Gaussian clusters, and/or are sensitive to outliers, and/or need user-defined thresholds and parameters. Most algorithms are geared towards Gaussian or plain spherical clusters; for example, the well-known K-means algorithm, BIRCH [Zhang et al. 1996] (which is suitable for spherical clusters), X-means [Pelleg and Moore 2000], and G-means [Hamerly and Elkan 2003]. These algorithms tend to be sensitive to outliers because they try to optimize the log-likelihood of a Gaussian, which is equivalent to the Euclidean (or Mahalanobis) distance—either way, an outlier has high impact on the clustering.

Density-based clustering methods, such as DBSCAN and OPTICS, can detect clusters of arbitrary shape and data distribution and are robust against noise. For DBSCAN the user has to select a density threshold, and for OPTICS to derive clusters from the reachability plot. K-harmonic means [Zhang et al. 2000] avoids the problem of outliers, but still needs k . Spectral

clustering algorithms [Ng et al. 2001] perform K-means or similar algorithms after decomposing the $n \times n$ gram matrix of the data (typically using PCA). Clusters of arbitrary shape in the original space correspond to Gaussian clusters in the transformed space. Here also k needs to be selected by the user. Recent interest in clustering has been on finding clusters that have non-Gaussian correlations in subspaces of the attributes [Böhme et al. 2004; Tung et al. 2005; Aggarwal and Yu 2000]. Finding correlation clusters has diverse applications ranging from spatial databases to bioinformatics. The information bottleneck method [Tishby et al. 2000], which is used by Slonim and Tishby for clustering terms and documents [Slonim and Tishby 2000], and the work of Still and Bialek [2004]. Based on information theory they derive a suitable distance function for coclustering, but the number of clusters still needs to be specified in advance by the user. Clustering is important for many applications such as Library, city planning. There are several motivations for robust clustering, but the basic requirement is to remove the noise. Previously used techniques do not able to cluster the group in efficient manner because does not contains sufficient information to cluster, cannot able to activate in fast manner, cannot able to group the given data in efficient manner and computations are performed in a tough manner.

III. PROPOSED ALGORITHM RIT

The following illustrates the proposed algorithm for Robust Information Theoretical Clustering

Input: Dataset as input

Output: To Identified & analysis the best pair with minimal cost as output.

Step1: Give the input dataset.

Step2: The input dataset is filtered by using noise removal method, then purify the cluster dataset by removing noise.

Step3: After purifying, merge the dataset.

Step4: Find the best pair of clusters to merge.

Step 5: Identify and analyze the best pair with minimal cost of dataset.

IV. PURIFICATION OF NOISE

The first step of purifying a cluster of points is to identify the proper decorrelation matrix. We generate several estimates (called candidates) of the covariance matrix, using various estimation methods, and pick the one with the best overall VAC value. In our experiments, the candidates include the matrix $_C$ from the conventional method using arithmetic average, and matrix $_R$ from the robust method described earlier. We also determine a conventional and a robust candidate, matrices $_C$, 50 and $_R$, 50, respectively, by considering only a certain percentage (e.g., 50%) of points in the cluster being closest to the robustly estimated center $_iR$. In addition, we always have the identity matrix I as one candidate decorrelation matrix. Among

these matrices, our algorithm selects the matrix giving the best (lowest) overall VAC.

The next step is to detect noise points in the cluster. By now, we have computed the robust center $_iR$, and have chosen a candidate covariance matrix which we call $_*$ (the corresponding decorrelation matrix is V^*). The goal is to partition the set of points in cluster C into two new sets: C_{core} (for core points) and C_{out} (outliers). First, our method orders the points of C according to the Mahalanobis distance defined by the candidate covariance matrix $_*$. Initially, we define all points to be outliers ($C_{out} = C$, $C_{core} = \{\}$). Then, we iteratively remove points $_x$ from C_{out} (according to Mahalanobis sort order starting with the point closest to the center) and insert them into C_{core} , and compute the coding costs before and after moving the point $_x$.

V. MERGING FROM NOISE

Our RIC framework is designed to refine the result of any clustering algorithm. Due to imperfection of the clusters given by an algorithm, our cluster purifying algorithm may lead to redundant clusters containing noise objects that fit well to other neighboring noise clusters. Our algorithm corrects the wrong partitions by merging clusters that share common characteristics, taking into account the subspace orientation and data distribution. We use the proposed VAC value to evaluate how well two clusters fit together.

The idea is to check whether the merging of a pair of clusters could decrease the corresponding VAC values. Our proposed merging process is an iterative procedure. Our algorithm merges those two clusters which have the maximum $savedCost$ (,) value, resulting in a greedy search toward a clustering that has the minimum overall cost. To deter this greedy algorithm from getting stuck in a local minimum, we do not stop immediately, even when no savings of $savedCost$ (,) value can be achieved by merging pairs of clusters. In other words, we do not stop when $savedCost(,) = 0$. Instead, the algorithm continues for another t iterations, continuing to merge cluster pairs (C_i, C_j) with the maximum $savedCost(C_i, C_j)$ value, even though now the $savedCost(C_i, C_j)$ value is negative and merging C_i and C_j will increase the VAC value of the overall dataset. Whenever a new minimum is reached the counter is reset to zero.

VI. EXPERIMENTAL RESULTS

We proposed to compare the noise cluster, purified cluster and merged cluster with Optimization values and maximal cost values. When compared purified cluster is better than other clusters. In the figure 1, We compared noise cluster, purified cluster and emerging cluster with optimization values. Then we Compare best pair of merging cluster with purified cluster.

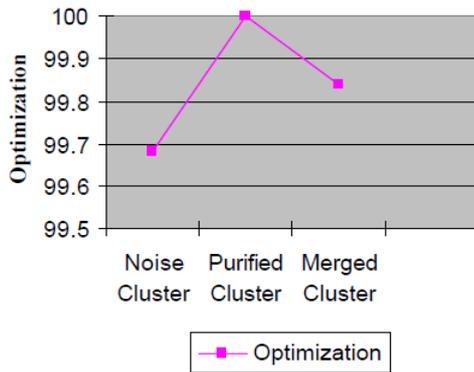

Figure 1. Compare best pair of merging cluster

In the figure 2, we compared noise cluster, purified cluster and merging cluster with maximal cost values. Compare best pair of merging cluster with the purified cluster

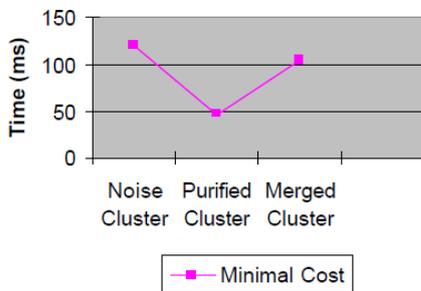

Figure 2. Compare the best pair of merging cluster with maximal cost

Type	Optimization	Maximal Cost (ms)
Noise Cluster	99.68531	120
Purified Cluster	100	47
Merged Cluster	99.840	104

Table: Values of Optimization and Maximal cost in Noise cluster, purifies cluster and merged clusters

VII. CONCLUSION

In this paper, RIC framework is designed. We have input dataset filtered to those data by using noise removal method, then purify clusters dataset by removing noise. After data set TyA is purified merge with the dataset. Find the best pair of clusters to merge. To identify and analysis the best pair with minimal cost of dataset. Previous work clustering methods, such as DBSCAN and OPTICS, can detect clusters of arbitrary shape and data distribution and are robust against noise. For DBSCAN the user has to select a density threshold, and for OPTICS o derive clusters from the reachability plot. K-harmonic means avoids the problem of outliers, but still needs k. There are several motivations for robust clustering, but the basic requirement is to remove the noise. Previously used techniques does not able to cluster the group in efficient manner because it does not contains sufficient information to cluster, unable to activate in fast manner

and unable to group the given data in efficient manner and computations are performed in this method

VIII. ACKNOWLEDGMENT

We would like to thank the anonymous reviewers for their insightful remarks and valuable suggestions, which were very helpful in improving the article. We thank our respected Rev.Fr.Dr.Arulraj Founder, DMI Group of institutions, East Africa and India, Dr.T.X.A.Ananth, Director, Mr. Ignatius Herman, Director (Academic), Dr. V.Krishnan Ph.D, Principal, DMI.St.Joseph College of Engg & Technology, Tanzania. for their encouragement and support. Also we thank our parents, friends and colleagues for their support and encouragement.

2_(Department of Mechanical Engineering, Urmia university, IRAN)

Abstract : *In this article the wave equation of an inhomogeneous plasma has been numerically solved by the use of Bessel function. Applying this mathematical approach produced the capability in comparison among other well known method such as WKB and Airy Function Method (AFM). The result which presented in this research shows that the Bessel Function Method (BFM) has reasonable agreement with the standard analytical solutions like AFM. Although there are some discrepancies between two methods, but in many ranges they can attain to common point of view. WKB method because of its simplicity and superabundant approximation could not satisfy the expected result especially at cutoff range, therefore is taken as a primary means to solve the mentioned problem.*

Keywords: Airy function, cutoff, inhomogeneous, Debye sphere

I. Introduction

The plasma state is a characterization of matter where long range electromagnetic interactions dominate the short range inter atomic or intermolecular forces among a large number of particles. Plasmas are generally high temperature entities, and some of the properties of a plasma are connected with thermal effects, and among the wave types we shall discuss are sound waves. Unmagnetized plasmas are generally the first to be studied because they are isotropic, i.e. the properties are the same in all directions. The waves that such a plasma will support are either high frequency electromagnetic waves which see the plasma as a simple dielectric due to the response of the electrons to the wave (by comparison the ions are generally immobile), or sound-type waves. We define the thermal speed to be the most probable speed in a Maxwellian distribution.

$$v_j = \sqrt{\frac{2kT_j}{m_j}} \quad j=e, i \quad (1)$$

for electrons or ions. In addition to the thermal speeds for electrons and ions, however, there are two other fundamental parameters which characterize a plasma in the absence of a magnetic field, and these are the plasma frequency and the Debye length. The plasma frequency is the oscillation frequency of a simple unmagnetized plasma when the charge distribution is locally perturbed from its equilibrium, and is given for electrons by

$$\omega_{pe} = \sqrt{\frac{n_e e^2}{m_e \epsilon_0}} \quad (2)$$

The Debye length is the distance a thermal particle travels during a plasma period. Its definition is

$$\lambda_{De} = \sqrt{\frac{\epsilon_0 k T_e}{n_e e^2}} = \frac{v_e}{\sqrt{2} \omega_{pe}} \quad (3)$$

In fact, unless an assembly of charged particles is large enough that it is many Debye lengths in size, and of such a density that there are many particles in a Debye sphere, we do not call the assembly a plasma. It is thus apparent that

plasma waves are fundamental to the very definition of a plasma [1]. In a cold plasma, these latter waves become a simple oscillation at the plasma frequency, below which the electromagnetic waves do not propagate. In a thermal plasma, however, there are sound-like waves near this frequency, and in a plasma with disparate electron and ion temperatures with $T_e \gg T_i$, there is even a kind of hybrid sound wave that depends on the electron temperature and the ion mass. These waves even perturbed from its equilibrium, and is given for electrons by process. While these several kinds of behavior are already much more complicated than waves in ordinary fluids, they are very simple compared to the complexities added by a magnetic field. Even the kinds of nonlinearities in this simple plasma damp through a nondissipative are richer in both diversity and complexity than in fluid dynamics where only averages over the velocity distribution are analyzed. Compared to ordinary fluids, plasmas even have an additional kind of turbulence, called microturbulence, which has many kinds of sources.

The addition of magnetic field effects to the subject of plasma waves adds a host of new phenomena, among which are: anisotropy, since there is now a preferred direction; new kinds of transverse waves existing only in magnetized plasmas, which we call Alfvén waves; finite Larmor orbit effects due to thermal motions about the magnetic field lines; and many other kinds of waves which are either totally new or greatly modified. Because of the anisotropy, the description of these effects is inevitably complicated algebraically, and this tends sometimes to obscure the physics. Even in a cold plasma where thermal effects are absent, the number of wave types added by the inclusion of the magnetic field is large, and wave types vary greatly with the angle of propagation with respect to the magnetic field. We find waves which are guided by the magnetic field in certain frequency ranges, and cases where the phase and group velocities are nearly normal to one another [2].

Whereas in a cold unmagnetized plasma, the only parameter that may lead to inhomogeneities is the plasma

density, the magnetic field not only adds a possible new source of inhomogeneity, but the gradients may appear in different directions.

When thermal effects are added to the cold plasma effects, the new phenomena can be grouped into two general categories: acoustic wave phenomena due to various kinds of sound waves; and kinetic phenomena due to the fact that in a thermal or near thermal distribution, there are some particles moving at or near the phase velocity. These particles have resonant interactions with the waves due to their long interaction time with the wave. These interactions can lead to either collisionless wave damping or to instabilities and wave growth. When coupled with magnetic field effects, finite Larmor orbit effects lead to even more new wave types and instabilities. The uniform plasmas of the previous chapters are idealizations which are rarely realized, although in some bounded regions, the approximation may be very good. We can generally assume a plasma is uniform if the plasma parameters vary little over a wavelength. In most laboratory plasmas, however, and over the vast regions of space, densities and magnetic fields vary to such an extent that it is sometimes difficult to estimate from uniform plasma theory where the wave energy will go and whether it will reach specified regions [3-5]. In many instances, these various effects can be separated and dealt with one at a time, but there are important cases where a combination of effects occur, several of which are simultaneously important, and each individual technique breaks down.

II. WKB method for one dimensional inhomogeneities

As an illustration of the method used in treating one-dimensional inhomogeneities, we consider an unmagnetized plasma with only a density variation. The wave equation,

$$\nabla(\nabla \cdot E) - \nabla^2 E + \frac{1}{c^2} \frac{\partial^2 E}{\partial t^2} = -\mu_0 \frac{\partial j}{\partial t} \quad (4)$$

depends only on variations in the plasma density through the plasma current, so we let $n_0 = n_0(x)$. Since all equilibrium quantities are independent of y and z , we can Fourier transform in those directions and assume harmonic time dependence. Then

$$\nabla \rightarrow \hat{e}_x \frac{d}{dx} + \hat{e}_y ik_y + \hat{e}_z ik_z \quad \frac{\partial}{\partial t} \rightarrow -i\omega$$

but another simplification is possible since the plasma is isotropic, since then one can rotate the coordinate system about the x -axis until the wave has no k_z component. Then the current may be derived from the equations of motion for ions and electrons

$$m_j \frac{\partial v_j}{\partial t} = q_j E \quad j=i,e \quad (5)$$

$$j = en_0(x)(v_i - v_e) \quad (6)$$

with the result that

$$j \approx \frac{in_0(x)e^2}{\omega m_e} E = \frac{ie_0}{\omega} \omega_{pe}^2(x) E \quad (7)$$

Then the z -component of equation (4), which is not coupled the other component, is

$$-\left(\frac{d^2}{dx^2} - k_y^2\right)E_z + \left[\frac{\omega_{pe}^2(x)}{c^2}\right]E_z = 0 \quad (8)$$

This can then be cast into the WKB form

$$\frac{d^2 y}{dx^2} + k^2(x)y = 0 \quad (9)$$

where $y(x) = E_z(x)$ and

$$k^2(x) \triangleq \frac{\omega^2 - \omega_{pe}^2(x)}{c^2} - k_y^2 \quad (10)$$

For $k(x) = \text{constant}$, the solution is trivial and of the form

$$y = A_1 e^{ikx} + A_2 e^{-ikx} \quad (11)$$

and represents waves traveling to the left and to the right. Looking for solutions which are similar to the uniform result, we assume an eikonal solution of the form

$$y(x) = A(x)e^{i\psi(x)} \quad (12)$$

where $A(x)$ is assumed to be a slowly varying amplitude and $\psi(x)$ is the eikonal, a rapidly varying phase such that $\psi'(x) = \pm k(x)$. In order to determine the limits of validity of this method, we choose the upper sign and insert equation (12) into equation (9), first noting the derivatives

$$y' = ikAe^{i\psi} + A'e^{i\psi}$$

$$y'' = -k^2 A e^{i\psi} + 2ikA'e^{i\psi} + ik'Ae^{i\psi} + A''e^{i\psi} \quad (13)$$

so that equation (9) becomes

$$A'' + 2ikA' + ik'A = 0 \quad (14)$$

If A'' is assumed small, then to lowest order, $A(x) = \frac{1}{\sqrt{k(x)}}$, and the complete solution is written (for either sign) as

$$y(x) = \frac{A_0}{\sqrt{k(x)}} \exp\left[\pm i \int k(x) dx\right] \quad (15)$$

Taking this as the zero order result, we assume the solution is modified by the correction term,

$$A(x) = \frac{[1+\eta(x)]}{\sqrt{k(x)}} \quad (16)$$

where again we assume that η is slowly varying so that we neglect η'' when this is inserted into equation (14). The result may be expressed as

$$\frac{\eta'}{1+\eta} = \frac{1}{4i} \frac{\frac{k''}{k^2} - \frac{3k''}{2k^3}}{1 + \frac{1}{2i} \frac{k'}{k^2}}$$

$$\eta \approx \frac{1}{4i} \frac{k'}{k^2} \quad (17)$$

The condition for validity may thus be written as $|\eta| \ll 1$ or as

$$\left|\frac{1}{k} \frac{dk}{dx}\right| \ll k \quad (18)$$

which means that the change of wavelength over a wavelength should be small. This approximation fails when $k \rightarrow 0$ or when $k' \rightarrow \infty$, or whenever the wave approaches either a cutoff or a resonance. In figure.1 equation (15) which is the answer of problem is plotted with estimated values. In this figure $y(x)$ is considered to have linear variation. It is shown that the answer is increased at first and after that it coming down. It is because of inhomogeneity in plasma and variety of density.

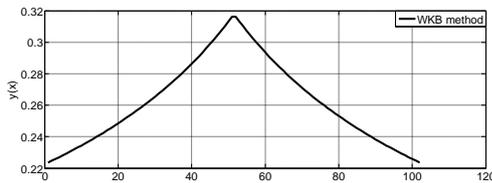

figure.1 $y(x)$ which here is $E_z(x)$ versus x

III. Airy Function Method

The behavior near a cutoff is important enough to justify further analysis, and was analyzed so long ago that it is considered by many to be part of the WKB formalism rather than restricted to the condition of equation (18). In the neighborhood of the cutoff, we expand $k^2(x)$ about the cutoff,

$$k^2(x) = k^2(x_0) + \frac{d}{dx}k^2(x)|_{x_0}(x - x_0) + O(x - x_0)^2 \quad (19)$$

where $k^2(x_0) = 0$ defines x_0 and we define the coefficient such that $k^2(x) = \beta^2(x-x_0)$. Then the result of equation (15) valid whenever $|x-x_0| \gg \beta^{-2/3}$. The behavior near the cutoff must come from the solution of the differential equation [4-8], however, since the approximations always fail sufficiently close to cutoff. The differential equation may be written as

$$\frac{d^2y}{dx^2} + \beta^2(x - x_0)y = 0 \quad (20)$$

which by means of the variable change $z \triangleq \beta^{2/3}(x - x_0)$ can be written

$$y'' - zy = 0 \quad (21)$$

which is the Airy equation. The solutions of the Airy equation are well known [8] and may be represented by the two independent solutions

$$y(z) = c_1 Ai(z) + c_2 Bi(z) \quad (22)$$

which have the asymptotic forms

$$Ai(z) = \frac{1}{2\sqrt{\pi z^{1/4}}} e^{-\zeta}$$

$$Ai(-z) = \frac{1}{\sqrt{\pi z^{1/4}}} \left[\sin\left(\zeta + \frac{\pi}{4}\right) - \cos\left(\zeta + \frac{\pi}{4}\right) \right]$$

$$Bi(z) = \frac{1}{\sqrt{\pi z^{1/4}}} e^{\zeta}$$

$$Bi(-z) = \frac{1}{\sqrt{\pi z^{1/4}}} \left[\sin\left(\zeta + \frac{\pi}{4}\right) + \cos\left(\zeta + \frac{\pi}{4}\right) \right]$$

(23)

where $\zeta = \frac{2}{3}z^{3/2}$. These asymptotic solutions must be matched to the approximate eikonal solutions which represent incoming and outgoing waves, which given by equation (15)

$$y(x) = \frac{A_1}{(x-x_0)^{1/4}} e^{i\frac{2}{3}\beta(x-x_0)^{3/2}} + \frac{A_2}{(x-x_0)^{1/4}} e^{-i\frac{2}{3}\beta(x-x_0)^{3/2}} \quad x > x_0$$

$$y(x) = \frac{B_1}{|x-x_0|^{1/4}} e^{i\frac{2}{3}\beta|x-x_0|^{3/2}} + \frac{B_2}{|x-x_0|^{1/4}} e^{-i\frac{2}{3}\beta|x-x_0|^{3/2}} \quad x < x_0$$

(24)

In figure.2 the solution of problem is plotted. In this figure $y(x)$ increases at first because of inhomogeneity and decrease later. It is observed that there is a sharp peak at the cutoff region.

IV. solution with Bessel function

The matching implied here between the asymptotic forms of the Airy function solutions and the WKB solutions requires that there be a finite region of overlap where both approximations are simultaneously valid. The conditions for validity are shown in figure.3. When the exact expression for $k^2(x)$ is linear, the overlapping region is unbounded of course, but for any other variation, there is some limit when the linear approximation fails. If the real variation of $k^2(x)$ deviates substantially from linear before the WKB expressions are valid, then there may be no overlap, so that accurate possible.

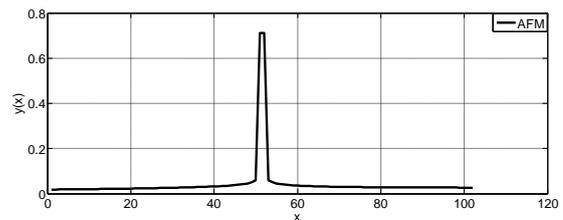

Figure. 2 $y(x)$ which is (x) versus x in Airy function method

In this paper a solution of problem with Modified Bessel function is presented. By considering an equations by the following form

$$x^2 y'' + x(a + 2bx^p) y' + (c + dx^{2q} + b(a + p - 1)x^p + b^2 x^{2p}) y = 0 \quad (25)$$

which $(1 - a)^2 \geq 4c$ and d, p, q are not zero. The total solution of the equation above is

$$Y = x^\alpha e^{-\beta x^p} \{c_1 J_\mu(\lambda x^q) + c_2 Y_\mu(\lambda x^q)\} \quad (26)$$

In this answer $\alpha = \frac{1-a}{2}$, $\beta = \frac{b}{p}$, $\lambda = \frac{\sqrt{|d|}}{q}$ and $\mu = \frac{\sqrt{(1-a)^2 - 4c}}{2q}$. If assume that a and b be zero from the equation (25) it is resulted

$$x^2 y'' + (c + dx^{2q}) y = 0 \quad (27)$$

Which $c \leq 1/4$ and d, p, q are not zero. By dividing the both side of the equation (27) to x^2 equation (28) will be resulted

$$y'' + (cx^{-2} + dx^{2(q-1)}) y = 0 \quad (28)$$

By putting equation (20) and (28) equivalent and supposing $X = x - x_0$, it can be written

$$Cx^{-2} + dx^{2(q-1)} \triangleq \beta^2(X) \quad (29)$$

The above equation shows that for putting both side of equation equivalent, C must be zero, $d = \beta^2$, and $q = \frac{3}{2}$, by these value $\alpha = \frac{1}{2}$, $\beta = 0$, $\lambda = \frac{2\beta}{3}$, $\mu = \frac{1}{3}$ which the

relation of them is expressed above. So by these values the solution of equation will be

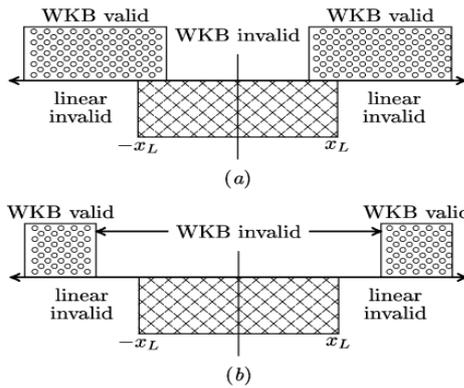

Figure.3 Validity conditions for matching the asymptotic forms of the inner functions and the outer WKB approximants. (a) Finite overlap case, so the matching is valid. (b) No overlap case, so the matching is inaccurate.

$$y = x^{\frac{1}{2}} \left\{ c_1 J_{\frac{1}{3}} \left(\frac{2\beta}{3} x^{\frac{2}{3}} \right) + c_2 Y_{\mu} \left(\frac{2\beta}{3} x^{\frac{2}{3}} \right) \right\} \quad (30)$$

This answer is plotted in figure .4 and it is observed that reaching to the peak which occurs at cutoff, is more monotonically. To compare solutions to each other different answer is plotted in figure.5 with each other. Of course the values of parameters in formulas are estimated and in this figure the peaks of each solution is not the same.

V. Conclusion

The numerical result of presented research has focused to attain with the well known WKB analytical method. The result which presented in this research shows that the Bessel Function Method (BFM) has reasonable agreement with the standard analytical solutions like AFM. This investigation was an attempt to explore the complete behaviors of wave in inhomogeneous plasma media. Although the use of mathematical method [7-10], Bessel function method, could not match completely to others method, WKB and AFM, but its behavior near cutoff point had good conformity. There are some discrepancies between two methods, but in many ranges they can attain to common point of view. In this paper the matter has been examined for one dimension and for future investigations it can be generalized for three dimensions. There are some estimation in this article to reduce the difficulty of explanation and computation, for example in part 3. We neglect higher order of $K(x)$, Because the condition is for one dimension. these simplifications does not affect the main results.

Abstract: Vibration qualification testing of propellant actuated devices or power cartridges used in fighter aircraft pose a challenge for the design and fabrication of the vibration test fixture for multi-direction. The vibration test fixture is made for CDBU type of cartridge among the various cartridges. Fixture for vibration testing is of cylindrical structure having maximum diameter of 235mm and of 36 mm thickness. The weight of the fixture is restricted up to the 5 kg.

This structure has analyzed and experimentally evaluated. The design of fixture has its certain advantages like; it can accommodate 16 cartridges in multi-directions at a time and can be tested, it uses all the fixing points of the shaker table. Fixture is designed with Aluminum 6061-T6 Alloy adhering to the general principles of vibration fixture design avoiding resonance in the frequency range of test. Theoretical analysis for the natural frequency calculations is based on advanced theory of plate bending. Computer Aided Design software Pro-E Wildfire 4.0 is used for modeling and drafting work of the fixture. Finite element software ANSYS is used for the modal and random response analysis. Experimental trial was conducted for the two axis for 6 hrs. Control and monitoring accelerometers are bonded at critical locations to get the best results.

Experimental investigations suggested good correlation between computed and experimentally determined values and plots.

Index Terms: Power Cartridges, Vibration Testing, PAD's Test fixture, Governing equilibrium equations, FE modal Analysis, Experimental results.

I. INTRODUCTION

Today's all the modern fighter aircraft has most essential integral part with it is power cartridges. Power cartridges are low cost explosive actuated devices. They are essential parts of any military aircraft. The importance of the power cartridges can be gauged from the fact that no military aircraft, otherwise flight worthy, is allowed to take off without installing the essential power cartridges. Some of the important functions of power cartridges are to operate auxiliary systems and sub-systems of aircraft, Effective release of weapon with high degree of reliability and for giving distress signaling.

The purpose of installing power cartridges is to save the precious life of pilot from the endangered aircraft in emergency within shortest possible time. Such cartridges are also known as Propellant Actuated Devices (PAD). PAD's are used to give certain specified performance in actual system or subsystem where they are installed in the aircraft. The most important and valuable inventory of air force is its combat aircraft. The time, efforts and cost to groom a pilot to

the required efficiency are enormous. Their life is extremely precious for the services and is required to be protected against all conditions and adverse circumstances. All military aircrafts are fitted with ejection seat for escape of the pilot from endangered aircraft in emergency. Various types of power cartridges are provided in the seat ejection system to perform different functions during the ejection process. In addition to the seat ejection, power cartridges are employed for other operational requirements also.

Power cartridges are categorized on the means of initiation are, mechanical types and electrical types.

Consumers expect and demand products of high quality and reliability. To fulfill these requirements the system after design should undergo various qualification tests. In these qualification tests vibration is one of the stringent test in which the product should undergo. However, vibration is very ramified topic. During this vibration tests, poor mechanical design will cause mechanical failure and customer dissatisfaction. This also causes increase in product cost and loss of credibility.

In order to prove the acceptability of the indigenous cartridges the various tests like Impact Test, Sealing Test, Vibration Test, Salt Mist Test, Life Assessment Test etc are carried out as per JSG 0102 Standard. Out of these Vibration Qualification Test is considered here.

Vibration tests are performed for the following reasons, Develop materiel to function in and withstand the vibration exposures of a life cycle including synergistic effects of other environmental factors, materiel duty cycle, and maintenance.

This method is limited to consideration of one mechanical degree-of-freedom at a time.

Verify that materiel will function in and withstand the vibration exposures of a life cycle.

Vibration results in dynamic deflections of and within materiel. These dynamic deflections and associated velocities and accelerations may cause or contribute to structural fatigue and mechanical wear of structures, assemblies, and parts. In addition, dynamic deflections may result in impacting of elements and/or disruption of function.

This paper briefly describes the fixture design methodology, facility augmentation to the testing, analysis carried out and evaluation methods adopted for the fixture experimentally.

II. FIXTURE DESIGN METHODOLOGY

An ideal fixture is a structure having infinite stiffness at all frequencies with zero mass. Since this is not achievable in practice, it is always a trade-off between the stiffness and mass relationships [13]. Hence, the fixture has to weigh less and at the same time not modify the dynamic characteristics of the UUT. It is also recommended that the

designer understands the manufacturing process and the time and cost involved in producing a fixture.

A vibration fixture is a device that typically interfaces the vibration shaker / shock machine and the test item. The basic idea with any fixture is that it should convey all possible forces produced by the shaker to the test object. Generally it is not possible to fix a test object directly to the shaker table itself. For that fixture acts as a transition piece between the two.

The objective of making fixture is, to take vibration test of Power Cartridges by fixing it on the fixture. The purpose of vibration test is to check proper functioning of Cartridges under vibrant conditions.

2.1 Basic Fixture Design:

The knowledge of the dynamic behavior of structures is often of primary importance in many applications, particularly in the field of aerospace and mechanical design. Prediction of modal parameters such as resonance frequencies and mode-shapes is an essential step of design. For this purpose, numerical techniques based on finite element model are commonly used.

Unfortunately, uncertainties on mechanical properties, tolerances in fabrication and assembly processes may cause discrepancies between numerical predictions and experimental results. To ensure that the mechanical component will survive the dynamic environment in which it is operating; vibration qualification testing is required according to international standards or manufacturer specifications.

Understanding of the dynamic behavior of the power cartridges is important during the operating condition. Therefore, it is necessary to carry-out vibration qualification testing to international standards (or as per user's requirements) to ensure that the structures survive the service or operating environment. Vibration testing generally requires a fixture which is an intermediary structure to interface with the specimen (often called DUT, Device Under Test / UUT, Unit under test) and the vibration generating equipment (vibration shakers). A fixture is designed to take care of different shapes and sizes of the specimens and the attachment points. The design methodology proposed is based on topological optimization tools.

An ideal fixture is a structure having infinite stiffness at all frequencies with zero mass. Since this is not achievable in practice, it is always a trade-off between the stiffness and mass relationships.

Also the acceleration level possible with the shaker is inversely proportional to the total moving mass it has to drive. Hence, the fixture has to weigh less and at the same time not modify the dynamic characteristics of the UUT. A bad fixture results in isolation at attachment points and a good fixture transmits the input with fidelity. A good fixture has resonances above the frequency range of interest. Location of center of gravity of the shaker, slip table with the UUT has to be as close as possible to mitigate overturning moment concerns.

Rigs and Fixtures are used to primarily to connect a test specimen to a shaker table. The specimen is often referred to as the Unit Under Test (UUT). As the UUT rarely couples directly to the shaker, an interface is required to

convert the hole pattern of the attachment points to the hole pattern of the shaker inserts. The main objective of the Fixture is to couple the UUT as directly as possible without adding or subtracting energy from the applied test.

The vibration fixture will require a design that when loaded with the specimen and connected to the shaker, will have no resonances within the specified frequency range.

This is rarely achievable but our design can assist in keeping the fixture resonances low in Q so that our controller can apply some compensation during testing.

Materials generally considered for vibration fixtures like Stainless Steel, Aluminum, Magnesium have similar E/ρ ratio (ratio of Young's modulus to density) not affecting the natural frequency of the fixture. However, when the shakers are operating at their full performance level, like in the present case, weight of the fixture dominates the selection of the material. Composite materials though are ideal for fixture to test large and heavy specimen, fabrication of the same is highly difficult.

Though Magnesium is a lighter metal, fabricability issues and availability of indigenous fabrication techniques have compelled to choose Aluminum alloy as the candidate material.

To design a test fixture that can be used for many different test pieces is extremely difficult and the usual practice is to treat each UUT separately. An interface plate can be designed to support each of these test items and is therefore required to be of a high standard. Individual test fixtures may not require the same build standard as the interface plate and this can affect the choice of material. When choosing the material it needs to be consider the test frequency range, the overall mass and the cost.

A low level vibration test that requires a frequency range from 20 Hz to 100 Hz may find that a wooden or plastic fixture is adequate. Whereas high level high frequencies test (typically above 500Hz) will require a much stiffer material. Often the fixture has a mass many times greater than the UUT and this will impact upon the Force capability of the shaker. This too will influence the material used as certain materials have a very good stiffness-to-mass ratio such as duralumin, magnesium or aluminum. Another characteristic of a material is its damping properties, e.g. the hysteretic damping of aluminum is approximately four times greater than that for steel. It is advisable to avoid steel for the above reasons i.e. it is heavy, it rings, it is difficult to work with, the resonances are of high Q and it is expensive.

Considerations for the fixture material are,
Mass - The material should be as low in mass as possible without detriment to the stiffness. As $F = M \times A$ the material mass will have an influence on the shakers thrust ability. Often a fixture will be sculptured and material removed to reduce the mass. The dynamics of the fixture remain unchanged but the stiffness and strength may be compromised and should be considered.

Stiffness - The stiffer the fixture the higher any resonant frequencies. If the first resonant can be kept above the test frequency range the quality of test will be improved. The fixture must be stiff enough not to influence the test or change during a test.

Strength - The Fixture will see high stress levels from the applied vibration or the UUT response and must be strong

enough to transmit the forces and survive the tests.

Natural Frequencies- The natural or first resonant frequency should be measured during a rig assessment and will preferably be higher than the test requirements upper frequency.

Damping - For fixtures with high 'Q' resonances, the control method will require some investigation. If possible it is preferable to use damping at the fixtures points of influence to reduce the 'Q'. For example a hollow tube will be damped by filling it with foam and often clamping or additional supports will prevent a high 'Q' response.

Attachment - The fixture should hold the UUT in multi-direction at a time. The UUT is held in a manner in which it is used in service and the brackets, isolation supports or other in service fittings should be attached to the fixture to represent an in service configuration. The UUT is rigidly held in a manner that ensures a known test specification is applied with out loss or compromise from the fixture.

Dynamic response - The UUT has its own response to a vibration test specification. The fixture should not modify the natural dynamics of the UUT or the test will be compromised. A dynamically inert fixture is not possible but its influence can be kept to a minimum by following the step by step guidelines above.

Fatigue - A fixture needs to be significantly stronger than the UUT so that it does not fatigue during use. Avoid thin brackets, small bolts, sharp corners, overhanging areas and weak areas that will fatigue quickly.

This system is designed to have high stiffness at right angles to the vibration axis. If high overturning moments are applied to the armature then the suspension guide will be compromised. This cross axis force applied during vibration needs to be understood and kept low so as not to damage the bearings and armature.

Designing all fixtures to be light and stiff will assist in preventing unwanted cross axial motion. The Centre of Gravity (C of G) should be precisely calculated and each rig or fixture should be rigidly coupled to the armature or slip table. If the C of G of the payload is kept low and aligns with the armature centre then cross axial stress will be minimized. However if the payload C of G is high or offset, then a turning moment is introduced during vibration. The easiest and cheapest fixture for this size of shaker is that made of welded aluminum plate.

The mating surfaces of the fixture is machined as flat as possible.

Attachment of bolts from fixture to shaker table is of counter-sunk type so that the stressed length of the bolt is twice the diameter.

The objective is to design and evaluate the vibration fixture to qualify the power cartridge to the specifications generated to simulate flight vibration conditions. Prediction of modal parameters such as resonance frequencies and mode-shapes is an essential step of design. A fixture is designed to take care of different shapes and sizes of the specimens and the attachment points. Also the acceleration level possible with the shaker is inversely proportional to the total moving mass it has to drive. Location of center of gravity of the shaker, slip table with the UUT has to be as close as possible to mitigate overturning moment concerns. As the UUT rarely couples directly to the shaker, an

interface is required to convert the hole pattern of the attachment points to the hole pattern of the shaker inserts. .

The fixture is well designed and not too large. Overhanging the shaker table is avoided. Its first resonant mode occurs well above the highest test frequency. Consider the mounting method for each axis of motion.

There are many fixture types that can be used to support the UUT. The main considerations that influence a design are dictated by the UUT itself. These are the physical shape, the mass, the size, the test requirement frequency range and severity, the number of axis to be tested, the attachment points, the quantity of units per test, the centre of gravity, off load moments etc.

With the target weight of < 6 kg, number of design configurations with different parameters, shapes are studied. Finally, the fixture is configured as a cylindrical structure and fabricated with AA-6061 T-6 alloy. By considering all these factors and according to the bolt size pattern holes on shaker table, 'M10 standard bolts' are used here to bolt a fixture with shaker table. While in the fixture assembly 'M4 bolts' are used here for bolting. The basic dimensions of the fixture are, maximum diameter of the fixture is ϕ 235 mm with the thickness of plate 36 mm. Centre of gravity of the fixture is maintained with the centre of gravity of shaker machine table. Fig. (1) gives the details of the fixture.

Fig (1). Details of fixture.

2.2 Governing equilibrium equations:

The theoretical work produces very practical benefits because it allows the prediction of the modal response of a structure. By finding and addressing potential problems early in the design process, manufacturers save money and improve product quality.

In the advanced theory of plate bending, theory of circular plate bending coincides with natural frequency calculation of our circular fixture (adapter plate). So equations are derived from the advanced theory of plate bending [8]. It is also observed that formulas mentioned [4] coincides with our derived formula for calculation of first natural frequency.

Derivations:

Equilibrium equations for small-displacement theory of flat plate,

$$\frac{\partial}{\partial x} \left\{ \frac{1}{\alpha} \left[\frac{\partial}{\partial x} (\beta M_{xx}) + \frac{\partial}{\partial y} (\alpha M_{xy}) + (\alpha_y M_{xy}) - (\beta_x M_{yy}) + \alpha \beta R_y \right] \right\} + \frac{\partial}{\partial y} \left\{ \frac{1}{\beta} \left[\frac{\partial}{\partial x} (\beta M_{xx}) + \frac{\partial}{\partial y} (\alpha M_{yy}) - (\alpha_y M_{xx}) + (\beta_x M_{yy}) - \alpha \beta R_x \right] \right\} + h \alpha \beta B_z + \alpha \beta P_z = 0 \quad \dots\dots\dots(1)$$

For rectangular axes, $\alpha = \beta = 1$ and equation (1) reduces to,

$$\frac{\partial^2 M_{xx}}{\partial x^2} + 2 \frac{\partial^2 M_{xy}}{\partial x \partial y} + \frac{\partial^2 M_{yy}}{\partial y^2} + hB_z + P_z = 0 \dots\dots(2)$$

Where, M_{xx} , M_{yy} is bending moment and $M_{xy} = M_{yx}$ is twisting moment. α and β are constants. H = plate thickness.

Stress-Strain-Temperature relations for isotropic elastic plates:

Let σ_{xx} , σ_{yy} & σ_{zz} are plane stresses of plate. Whereas ϵ_{xx} , ϵ_{yy} & ϵ_{zz} are strains of plate.

For linearly elastic isotropic materials and plane stress relative to (x, y) plane stress-strain-temperature relations are,

$$\begin{aligned} \sigma_{xx} &= \frac{E}{1-\nu^2} (\epsilon_{xx} + \nu \epsilon_{yy}) - \frac{EkT}{1-\nu} \\ \sigma_{yy} &= \frac{E}{1-\nu^2} (\nu \epsilon_{xx} + \epsilon_{yy}) - \frac{EkT}{1-\nu} \\ \sigma_{xy} &= 2G\epsilon_{xy} = G\gamma_{xy} \dots\dots\dots(3) \end{aligned}$$

Where, E = Young's Modulus.
 ν = Poisson's Ratio.
 k = Coefficient of Linear Thermal Expansion.
 G = Shear Modulus.
 T = Temperature Measured above an arbitrary zero.

By Kirchhoff's theory of Kinematics strain-displacement relations for plates,

Solve for equation (2) and then substitution of it into stress resultant equations of flat plate [4],

Then moment equations we get are,

$$\left. \begin{aligned} M_{xx} &= -D \left(\frac{k_{xx}}{\alpha^2} + \frac{\nu k_{yy}}{\beta^2} + T^1 \right) \\ M_{yy} &= -D \left(\nu \frac{k_{xx}}{\alpha^2} + \frac{k_{yy}}{\beta^2} + T^1 \right) \\ M_{xy} &= -D \frac{(1-\nu)}{\alpha\beta} k_{xy} \end{aligned} \right\} \dots\dots\dots(4)$$

Where, $D = \frac{Eh^3}{12(1-\nu^2)}$ (5)

The quantity D = Flexural rigidity of the plate. Considering strain energy and boundary conditions of the plate

On substitution for M_{xx} , M_{xy} , M_{yy} in terms of 'w' in equation (2) with $B_z = 0$ and $P_z = P$

$$\nabla^2 \nabla^2 w = \frac{P}{D} \dots\dots\dots (6)$$

Where, $\nabla^2 \nabla^2 w = w_{xxxx} + 2w_{xxyy} + w_{yyyy}$

$\nabla^2 \nabla^2 =$ Invariant vector operator.

p = Lateral Pressure.

w = Lateral Displacement.

Solutions of $\nabla^2 \nabla^2 w = \frac{P}{D}$ for circular plates,

For the circular plates with radius 'a' and thickness 'h' employing polar coordinate with the origin 'a' the center of the plate, equation (6) may be written as,

$$\nabla^2 \nabla^2 w = \left(\frac{\partial^2}{\partial r^2} + \frac{1}{r} \frac{\partial}{\partial r} + \frac{1}{r^2} \frac{\partial^2}{\partial \theta^2} \right) \left(\frac{\partial^2 w}{\partial r^2} + \frac{1}{r} \frac{\partial w}{\partial r} + \frac{1}{r^2} \frac{\partial^2 w}{\partial \theta^2} \right) = \frac{p}{D} \dots\dots\dots(7)$$

Here as per our requirement considering only axial symmetric case, in which plate is loaded and supported symmetrically. Then equation (7) reduces to,

$$\left(\frac{\partial^2}{\partial r^2} + \frac{1}{r} \frac{\partial}{\partial r} \right) \left(\frac{\partial^2 w}{\partial r^2} + \frac{1}{r} \frac{\partial w}{\partial r} \right) = \frac{p}{D} \dots\dots\dots (8)$$

Solution of above equation with p = p0 = constant is,

$$w = \frac{p_0 r^4}{64D} + A_1 + A_2 \ln r + B_1 r^2 + B_2 r^2 \ln r$$

or

$$\delta = \frac{p_0 r^4}{64D} + A_1 + A_2 \ln r + B_1 r^2 + B_2 r^2 \ln r$$

Where, δ = Deflection.

A1, A2, B1, B2 = Constants of integration

These constants of integration are determined by boundary conditions at r = a.

Therefore Circular Plate with Fixed Edges.

$$\delta(a) = A_1 + B_1 r^2 + \frac{p_0 r^4}{64D} = 0$$

After solution for A1 and B1

$$\delta = \frac{p_0 r^4}{64D} \left[1 - \left(\frac{r}{a} \right)^2 \right]^2$$

Or

$$\delta = \frac{qa^4}{64D} \left[1 - \left(\frac{r}{a} \right)^2 \right]^2 \dots\dots\dots(9)$$

Where, q = Intensity of Load(N / mm²)

Therefore as per the data of the fixture, the numerical value of the first natural frequency obtained after solution of equation (7) is **7925.85 Hz**.

III. ANALYSIS

Modal analysis is a powerful tool for understanding the vibration characteristics of mechanical structures. It simplifies the vibration response of a complex structure by reducing the data to a set of modal parameters that can be analyzed with relative ease. This application note discusses the concept of modal analysis, applications where modal analysis is useful, and techniques for the acquisition and visualization of modal data. In this project modal analysis of the vibration fixture is to be performed and after

experimental trials response analysis is to be shown.

Analysis of the fixture is carried out by geometric modeling in Pro/E, meshing in ANSYS and applying boundary conditions. Modal analysis is a process of describing a structure in terms of its natural characteristics which are the frequency, damping and mode shapes its dynamic properties. The modal testing has become an effective means for identifying, understanding, and simulating dynamic behavior and responses of structures.

Analysis yields a 1st natural frequency mode of **8543.4 Hz**. The random vibration analysis is carried out for the response with constant value of $0.03 \text{ g}^2/\text{Hz}$. The FE analysis by ANSYS indicates that there is no resonance observed in the required range of frequency. In random analysis controlled value of rms is equal to the demanded value of rms which shows uniformity in the structure. Theoretical estimated weight of the fixture is considered for the analysis. The fixture designed meets the mass and frequency requirements.

Fig (2) gives few representative plots of analysis.

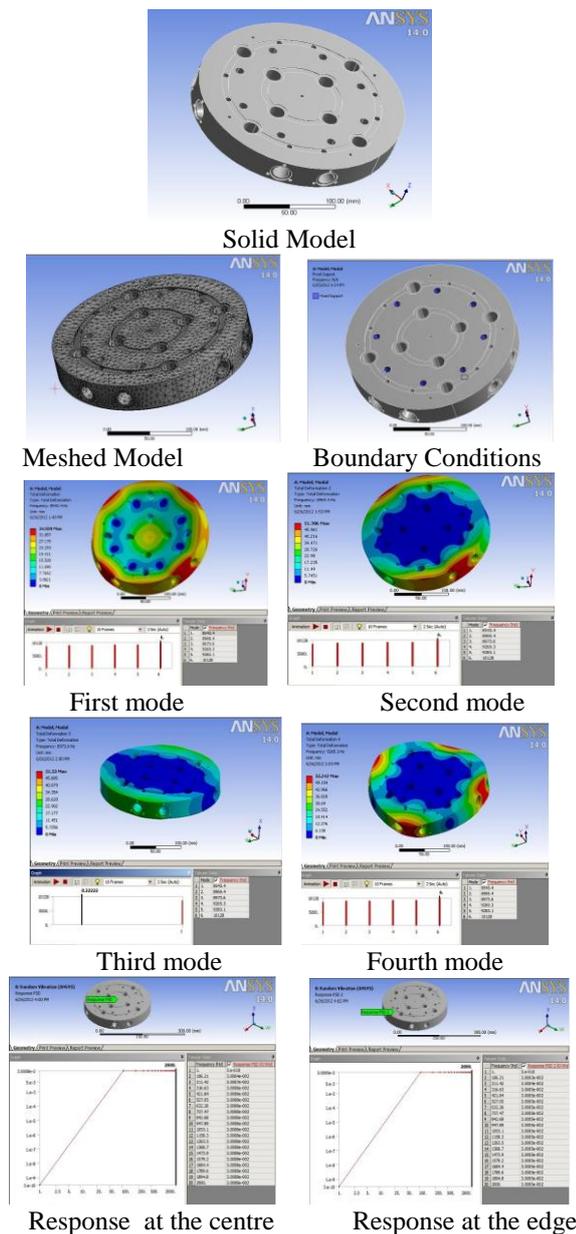

Fig (2).Representative plots of analysis

IV. FIXTURE EVALUATION

Certain augmentation to the facility is carried out before evaluating the fixture to facilitate testing of the power cartridges.

Subsequent to the design, analysis & fabrication the fixture is evaluated. Weight of the fixture after fabrication is 5 kg as compared to die theoretically predicted value of 3.7 kg. Main purpose of evaluating a fixture is to investigate the fixture natural frequencies, transmissibility, cross-axial response. Resonance search, Sine and Random vibration tests are carried out to evaluate the fixture. A low vibration level resonance search followed by sine, random search is carried out.

Sine and Random vibration tests to the test specification are carried out with two control accelerometers on the fixture top as shown in fig (2). Table (1) gives sequence of test conducted.

Table1. Sequence of test conducted.

Sine / Random	Specifications
Sine vibration test	5-11 Hz - 12mm DA. 11-2000 Hz – 3G Sweep rate – 1 Oct / Min.
Random vibration test	70-2000 Hz – 0.03 g ² / Hz

Fig.(3) gives test set-up in Z-axis.

Fig(3) Fixture Evaluation in Z-axis.

2.3 Discussions:

Resonance survey is conducted before and after the vibration tests. Lowest acceptance level based on facility limitation is employed.

The sine resonance survey conducted before and after tests from UUT in between frequency range of 5-2000 Hz. The plot of the sine vibration test is as shown in fig.(4) The machine was not tripped during test which indicates good design of fixture without any potential weakness. This indicates the uniformity in vibration level in the fixture and damping is good in structure.

Fig.(5) shows plotted result of the random vibration test of the fixture. Results shows control rms value is very close to the demanding rms value which indicates uniform structure of the fixture. There was no any peak or resonance observed within the range of vibration i.e. up to 2000 Hz. This indicates that fixture resonance is greater than UUT resonance.

The vibration fixture is ideally designed so that it gives unit transmissibility in the frequency range of test. Cross axial response is not observed within the frequency range is observed.

Control accelerometers provided on the top of the fixture with maximal control options yielded smooth control.

After correlation of the theoretical, simulated and experimental results observation shows that all the results are very close.

Prof. Mrs. R.S. Bindu Dr. D.Y. Patil College of Engineering, Pune, India, for their continual guidance.

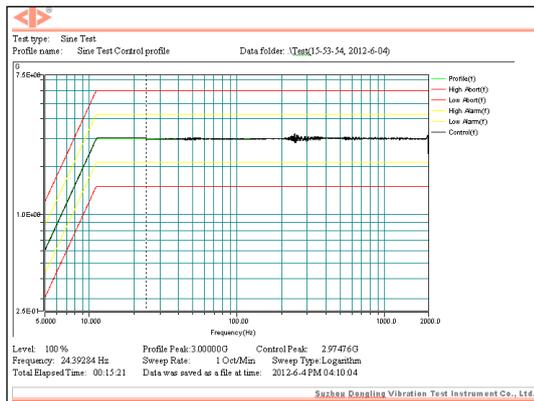

Fig (4) Sine vibration test

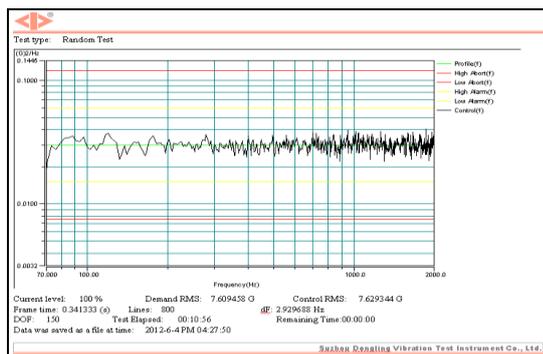

Fig (4) Random vibration test

V. CONCLUSION

An aluminum vibration fixture with AA6061-T6 alloy for power cartridges is designed, analyzed and evaluated. For vibration test of a single small test object, designing a vibration fixture is trivial task. However, it becomes complicated one while vibrating many of such test objects in a single fixture in multiple directions. A good vibration fixture avoids under-test or over-test of the test items. This has its implications on timely completion of test program and further development activity as a whole.

Various configurations are conceived before arriving at the present configuration. FE analysis is carried out using ANSYS tool. Evaluation is carried out using 4t duel shaker system. The control mechanism of vibration shaker works best for properly designed vibration fixtures.

The first natural frequency of the fixture from FE analysis is 8543.4 Hz. From the test the natural frequency observed is above the frequency limits. This is in close correlation with the prediction. All the accelerometers response at the top of the fixture are similar indicating a good design.

The fixture is suitable for vibration testing of cartridges used here and of future upcoming cartridges of similar types.

VI. ACKNOWLEDGMENT

The author wishes to acknowledge the ARDE design team for rendering a helping hand in the design, analysis and test facilities for carrying out the vibration tests. The author also wishes to acknowledge the Project Guide

Experimental Based Selection of Best Sorting Algorithm

¹ D.T.V Dharmajee Rao, ²B.Ramesh

¹ Professor & HOD, Dept. of Computer Science and Engineering, AITAM College of Engineering, JNTUK

² Dept. of Computer Science and Engineering, AITAM College of Engineering, JNTUK

Abstract: Sorting algorithm is one of the most basic research fields in computer science. Sorting refers to the operation of arranging data in some given order such as increasing or decreasing, with numerical data, or alphabetically, with character data.

There are many sorting algorithms. All sorting algorithms are problem specific. The particular Algorithm one chooses depends on the properties of the data and operations one may perform on data. Accordingly, we will want to know the complexity of each algorithm; that is, to know the running time $f(n)$ of each algorithm as a function of the number n of input elements and to analyse the space and time requirements of our algorithms. Selection of best sorting algorithm for a particular problem depends upon problem definition. Comparisons of sorting algorithms are based on different scenario. This work experimentally analyzes the performance of various sorting algorithms by calculating the execution time.

Keywords: Sort-Algorithm, Sorting, Quick sort, Merge sort, Radix sort, Bubble sort, Gnome sort, Cocktail sort, Counting sort.

I. Introduction

Sort is an important operation in computer programming. For any sequence of records or data, sort is an ordering procedure by a type of keyword. The sorted sequence is benefit for record searching, insertion and deletion. Thus enhance the efficiency of these operations.

Two categories of sort algorithms were classified according to the records whether stored in the main memory or auxiliary memory. One category is the internal sort which stores the records in the main memory. Another is the external sort which stores the records in the hard disk because of the records' large space occupation. In fact, by utilizing the splitting and merging, the external sort could be converted to internal sort. Therefore, only internal sort algorithms such as Bubble, Select, Insertion, Merge, Shell, Gnome, Cocktail, Counting, Radix and Quick Sort were discussed bellow.

For the convenience, we make two assumptions bellow. One is the sequence order, ascending is default. Another is all the records of the sequence were stored in the continuous address memory cells. In this situation, the order of records was determined by the position which stored in the memory. The sort is the move operation of records.

The two classes of sorting algorithms are $O(n^2)$ (which includes the bubble, insertion, selection, gnome, cocktail and shell sorts) and $O(n \log n)$ (which includes the heap, merge, and quick sort)

1.1 Theoretical Time Complexity of Various Sorting Algorithms

Time Complexity of Various Sorting Algorithms

Name	Best	Average	Worst
Insertion sort	n	n^*n	n^*n
Selection Sort	n^*n	n^*n	n^*n
Bubble Sort	n	n^*n	n^*n
Shell Sort	n	$n (\log n)^2$	$n (\log n)^2$
Gnome Sort	n	n^*n	n^*n
Quick Sort	$n \log n$	$n \log n$	n^*n
Merge Sort	$n \log n$	$n \log n$	$n \log n$
Cocktail Sort	n	n^*n	n^*n
Counting Sort	-	$n+ r$	$n+ r$
Radix Sort	-	$n(k/d)$	$n(k/d)$
Heap Sort	$n \log n$	$n \log n$	$n \log n$

II. Fundamental Sorting Algorithms

A. Insertion Sort

Insertion sort algorithm used in the experiments below was described by C language as:

Algorithm

1. For I=2 to N
2. A[I]=item ,J=I-1
3. WHILE j>0 and item<A[J]
4. A[J+1]=A[J]
5. J=J-1
6. A[J+1]=item

Pseudo Code

```
void insertion_sort(int b[],int N11)
{
int i,j,Temp,A[20000];
double starttime,endtime,difftime;
starttime=omp_get_wtime();
for(i=0;i<N11;i++)
A[i]=b[i];
for(i=1; i<N11; i++)
{Temp = A[i];
j = i-1;
while(Temp<A[j] && j>=0)
{A[j+1] = A[j];
j = j-1;}
A[j+1] = Temp;
}
```

B. Bubble Sort

Bubble sort algorithm used in the experiments below was described by C language as:

Algorithm

1. for I=1 to N-1 (for pass)
2. for k=1 to N-I (for comparison)
3. if $A[K] > A[K+1]$
4. swap $[A(k), A(k+1)]$

Pseudo Code

```
void bubble(int a[],int n)
{
int i,j,t;
for(i=n-2;i>=0;i--)
{ for(j=0;j<=i;j++)
{ if(a[j]>a[j+1])
{ t=a[j];a[j]=a[j+1];a[j+1]=t;}}
}
```

C. Selection Sort

Selection sort algorithm used in the experiments below was described by C language as:

Algorithm

1. for I=1 to N-1
2. min=A [I]
3. for K=I+1 to N
4. if (min>A [K])
5. min=A [K], Loc=K
6. Swap (A [Loc],A[I])
7. Exit

Pseudo Code

```
void selesort(int b[],int n)
{
int i, j,a[20000],min,index;
double starttime,endtime,difftime;
for(i=0;i<n;i++)
a[i]=b[i];
for(i=0;i<n-1;i++)
{ min=a[i]; index=i;
for(j=i+1;j<n;j++)
if(a[j]<min)
{ min=a[j];index=j;
}
a[index]=a[i];
a[i]=min;
}
```

D. Quick Sort

Quick sort algorithm used in the experiments below was described by C language as:

Algorithm

Quick sort (A, p, r)

1. If $p < r$
2. Then $q \leftarrow$ partition (A, p, r)
3. Quick sort (A, p, q-1)
4. Quick sort (A ,q+1 ,r)

To sort an entire array A, the initial call is Quick sort (A, 1, length [A]).

Partition the array

The key to the algorithm is the PARTITION procedure, which rearranges the sub array A [p...r] in place.

Partition (A, p, r)

1. $x \leftarrow A[r]$
2. $i \leftarrow p-1$
3. For $j \leftarrow p$ to r-1

4. Do if $A[j] \leq x$
5. Then $i \leftarrow i+1$
6. Exchange $A[i] \leftrightarrow A[j]$
7. Exchange $A[i+1] \leftrightarrow A[r]$
8. Return i+1

Pseudo Code

```
void quick_sort(int arr[], int low, int high) {
int i = low;
int j = high;
int y = 0;
int z = arr[(low + high) / 2];
do {
while(arr[i] < z) i++;
while(arr[j] > z) j--;
if(i <= j)
{ y = arr[i];arr[i] = arr[j]; arr[j] = y;
i++;j--;}
} while(i <= j);
if(low < j)
quick_sort(arr, low, j);
if(i < high)
quick_sort(arr, i, high);
}
```

E. Counting Sort

Counting sort algorithm used in the experiments below was described by C language as:

Algorithm

1. for I=0 to K
2. $C[I]=0$
3. For j=1 to length [A]
4. $C[A(J)]=C[A(J)]+1$
5. For I=1 to K
6. $C[I]=C[I]+C[I-1]$
7. For J=length(A) down to 1
8. $B[C(A(J))]=A[J]$
9. $C[A(J)]=C[A(J)]-1$

Pseudo Code

```
void countingsort(int *a, int n)
{
int i, min, max,array[20000];
for(i=0;i<n;i++)
array[i]=a[i];
min = max = array[0];
for(i=0; i < n; i++)
{ if ( array[i] < min )
{ min = array[i];}
else if( array[i] > max )
{ max = array[i];}
}
```

F. Shell Sort

Shell sort algorithm used in the experiments below was described by C language as:

Algorithm

1. for I=n to i/2 (for pass)
2. for i=h to n
3. for j=1 to j=j-h upto $j \geq h$ && $k < a[j-h]$
4. assign $a[j-h]$ to $a[j]$

Pseudo Code

```
void shell_sort(int a[],int n)
{
int j,i,m,mid;
for(m = n/2;m>0;m/=2)
```

```

{for(j = m;j< n;j++)
{for(i=j-m;i>=0;i-=m)
if(a[i+m]>=a[i])
break;
else
{mid = a[i];a[i] = a[i+m];a[i+m] = mid;}}}
}
} while(swapped);

```

III. Problem Statement

The problem of sorting is a problem that arises frequently in computer programming. Many different sorting algorithms have been developed and improved to make sorting fast. As a measure of performance mainly the average number of operations or the average execution times of these algorithms have been investigated and compared.

G. Gnome Sort

Gnome sort algorithm used in the experiments below was described by C language as:

Algorithm

1. for I=1 to n (for pass)
2. if i=0 and a[i-1] < a[i] then i++
3. else swap(a[i-1],a[i])
4. return a

Pseudo Code

```

void gnomeSort(int a[], int n)
{
    int i = 1, j = 2;
    int temp;
    while(i < n)
    {if(a[i-1] <= a[i])
        {i = j;j++;}
        else
        {temp = a[i];a[i] = a[i-1];a[i-1] = temp;
            i--;
            if(i == 0)
            {
                i = j;
                j++;
            }
        }
    }
}

```

H. Cocktail Sort

Cocktail sort algorithm used in the experiments below was described by C language as:

Algorithm

1. for i=1 to n (for pass)
2. for i=n-1 to 1
3. while !i
4. swap(a[i-1],a[i])

Pseudo Code

```

void cocktasort(int a[], int l)
{
    int swapped = 0;
    int i,a[20000];
    do {
        for(i=0; i < (l-1); i++) {
            if ( a[i] > a[i+1] ) {
                temp = a[i];
                a[i] = a[i+1];
                a[i+1] = temp;
                swapped = 1;
            }
        }
        if ( ! swapped ) break;
        swapped = 0;
        for(i= l - 2; i >= 0; i--) {
            if ( a[i] > a[i+1] ) {
                int temp = a[i];
                a[i] = a[i+1];
                a[i+1] = temp;
                swapped = 1;
            }
        }
    }
}

```

3.1 Problem statement

All sorting algorithms are nearly problem specific. How one can predict a suitable sorting algorithm for a particular problem? What makes good sorting algorithms? Speed is probably the top consideration, but other factors of interest include versatility in handling various data types, consistency of performance, memory requirements, length and complexity of code, and stability factor (preserving the original order of records that have equal keys).

For example, sorting a database which is so big that cannot fit into memory all at once is quite different from sorting an array of 100 integers. Not only will the implementation of the algorithm be quite different, naturally, but it may even be that the same algorithm which is fast in one case is slow in the other. Also sorting an array may be different from sorting a linked list.

3.2 Justification

In order to judge suitability of a sorting algorithm to a particular problem we need to see, are the data that application needs to sort tending to have some pre existing order?

- What are properties of data being sorted?
- Do we need stable sort?

Generally the more we know about the properties of data to be sorted, the faster we can sort them. As we already mentioned the size of key space is one of the most important factors (sort algorithms that use the size of key space can sort any sequence for time $O(n \log k)$).

3.3 Explanation

Many different sorting algorithms have been invented so far. Why are there so many sorting methods? For computer science, this is a special case of question, "why there are so many x methods?", where x ranges over the set of problem; and the answer is that each method has its own advantages and disadvantages, so that it outperforms the others on the same configurations of data and hardware. Unfortunately, there is no known "best" way to sort; there are many best methods, depending on what is to be sorted on what machine and for what purpose. There are many fundamental and advance sorting algorithms. All sorting algorithm are problem specific means they work well on some specific problem, not all the problems. All sorting algorithm apply to specific kind of problems. Some sorting algorithm apply to small number of elements, some sorting algorithm suitable for floating point numbers, some are fit for specific range like (0 1].some sorting algorithm

are used for large number of data, some are used for data with duplicate values.

It is not always possible to say that one algorithm is better than another, as relative performance can vary depending on the type of data being sorted. In some situations, most of the data are in the correct order, with only a few items needing to be sorted; In other situations the data are completely mixed up in a random order and in others the data will tend to be in reverse order. Different algorithms will perform differently according to the data being sorted.

IV. Experimental Study

In order to compare the performance of the various Sorting algorithms above, we use a desktop computer (Intel Dual Core Processor @ 2.4GHz, 2GB RAM, Windows 7 operating system) to do a serial experiments. Under VS2008, using C language, the programs test the performances of various algorithms from input scale size by utilizing random function call and time function call.

4.1 Experiments and Results

When the input sequence is produced by a random function, input sequence is positive, and the input scale varied from 1024 (1K) to 101376(99K), various sort algorithms time costs were demonstrated by table 4.1.1 and figure 4.1.1

4.1.1 Sort Algorithms Time Cost Under Positive Input Sequence

Data Size	Insert Sort	Selec Sort	Bubble Sort	Shell Sort	Gnome Sort	Quick Sort	Merge Sort	Cocktail Sort	Countin Sort	Radix Sort
1K	0.0022	0.0037	0.0112	0.0009	0.0054	0.0003	0.0294	0.0036	0.0001	0.0002

30K	1.0330	1.5091	4.7020	0.0222	2.2820	0.0057	1.2182	3.3793	0.0008	0.0064
40K	1.8413	2.6861	8.3657	0.0475	3.9973	0.0077	1.1318	5.7960	0.0010	0.0085
50K	2.8438	4.0942	12.8560	0.0379	6.1155	0.0097	1.1465	8.9410	0.0012	0.0114
60K	4.0802	5.9034	18.6282	0.0561	8.9355	0.0127	1.7485	13.1773	0.0014	0.0127
70K	5.5719	8.0406	25.6148	0.0541	12.7165	0.0139	2.9771	18.6538	0.0016	0.0150
80K	7.5296	11.3767	34.5813	0.1189	16.3145	0.0156	3.2230	24.1683	0.0027	0.0225
90K	9.1565	13.1304	42.1701	0.0713	21.0288	0.0177	3.6278	31.0652	0.0028	0.0245
99K	11.4789	16.7561	52.3442	0.0675	24.7972	0.0194	2.7245	36.7319	0.0023	0.0214

From the table and the figure above, we got when the scale of input sequence was small, the difference of time cost between these algorithms was small. But with the scale of input sequence becoming larger and larger, the difference became larger and larger. Among these algorithms, the radix sort, counting sort, quick sort, shell and merge was the best, then all other traditional sorts. Whatever, the time cost curve of radix sort, counting sort, quick sort, shell sort was almost a line. It's the slowest changing with the input scale increasing.

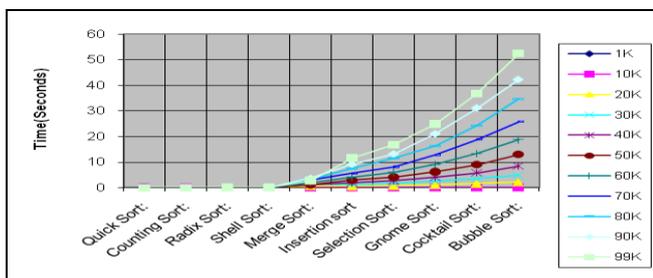

Figure 4.1.1 Time cost Comparison of various sorting algorithms with positive input sequence

When the input sequence is produced by a random function, input sequence is negative and the input scale varied from 1024 (1K) to 101376(99K), various sort algorithms time costs were demonstrated by table 4.1.2 and figure 4.1.2

4.1.2 Sort Algorithms Time Cost Under Negative Input Sequence

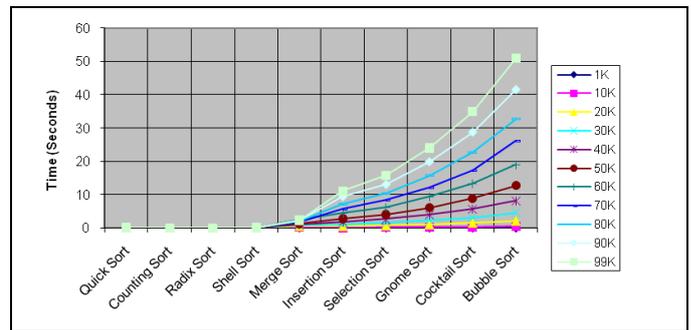

Figure 4.1.2 Time cost Comparison of various Sorting algorithms with Negative input sequence

4.2 Performances Evaluations

Two criteria to evaluate the sort algorithms: time and space. The time related to the comparison operations and move operations of records in the algorithms. The space may dependent or independent to the input sequence scale. If the additional space needed in the algorithm is independent to the input, its space complexity is O(1) . Otherwise, its space complexity is O(n) .

Let N denote the number of input records, in which there are n elements were ordered. Then we could define K, called ordered factor

$$K = (n/N)$$

$K \in [0, 1]$ reflects the sort degree of random sequence. K is bigger, more ordered exists in the sequence. Otherwise, K is smaller, more random exists in the sequence. Let RCN represent the number of comparison operation, and RCN represent the number of remove operation, T(n) and S(n) represent the algorithm time complexity and space complexity respectively. When $K \rightarrow 1$, then RCN $\rightarrow 0$ and T(n) become lesser. When $K \rightarrow 0$, then RCN and T(n) become bigger. According to S (n) whether independent or dependent to the input scale, its value is O (1) or O (n).

V. Conclusion

Every sorting algorithm has some advantages and disadvantages. In the following table we are tried to show

the strengths and weakness of some sorting algorithms according to their order, memory used, stability, data type and complexity. To determine the good sorting algorithm, speed is the top consideration but other factor include handling various data type, consistency of performance, length and complexity of code, and the prosperity of stability.

Sort	Order	Worst Case	Memory	stability	Data Type	Complexity
Quick	$n \log n$	n^2	$nk+np+stack$	no	all	High
Merge	$n \log n$	$n \log n$	$nk+np+stack$	yes	all	Medium
Shell	$n(\log n)^2$	n	$nk+np$	no	all	Low
Insertion	n^2	n^2	$nk+np$	yes	all	very low
Selection	n^2	n^2	$nk+np$	yes	all	very low
Bubble	n^2	n^2	$nk+np$	yes	all	very low
Counting	n	n	$nk+np$	yes	all	very low
Gnome	n	n^2	$nk+np$	yes	all	very low
Cocktail	n	n^2	$nk+np$	yes	all	very low

Table 5.1: Strength and Weakness of various sorting algorithm

From the average time algorithms cost, the radix sort, counting sort, quick sort, shell and merge sort are superior to other algorithms. But in the worst time situation, the quick sort cost too much time than the merge sort.

When the input scale isn't big, time cost of algorithms has not an obvious difference. But with the input scale increasing, the Radix sort has certainly on advantage over other algorithms.

For the space occupation, the quick sort and merge sort cost too much than others, their space complexity is $O(\log n)$ and $O(n)$, the space occupation of the radix and counting sort is $O(nk)$ and $O(n+k)$, dependent to the input scale. Other algorithms cost little, their space complexity is $O(1)$, independent to the input scale.

For the application, appropriate sort algorithm is selected according to the attributes of input sequence. If the input scale is small, any traditional algorithm is a good choice. But when the input scale is large Radix Sort, Counting sort, Shell Sort, Quick sort and Merge sort is the necessary choice essentially.

Remote Radar Data Acquisition and Control Using Cdma RF Link

Rohit N Singh*, M.Chennakesavulu**

^{1,2}(Department of E.C.E, RGM CET, Nandyal

Abstract : Radar Seeker is used in missile system for detection and tracking a target. It will be integrated in the nose cone of the missile. During testing and launching of the missile all necessary important parameters and status of the seeker are collected for analysis to ascertain the health of the Seeker. Similarly the configuration and control of the seeker is to ensure the proper mode of operation of seeker.

During launch campaign the technicians and engineers cannot go near the missile and the seeker Health, but the knowledge of seeker health is very much necessary for the launch campaign, so a remote Control and data acquisition system should be there to confirm the health of the seeker either through wired serial communication link or using RF Link.

The Aim of this project is to Design and Develop a "Remote Radar Data Acquisition and Control using CDMA RF Link " and to Test with an existing radar seeker.

Keywords : RADAR SEEKER, QPSK, CORTEX –M3 (ARM Processor), SPZB260 (ZIGBEE Module), Costas loop.

I. INTRODUCTION

Radar (RADio Detection And Ranging) is an object-detection system which uses radio waves to determine the range, altitude, direction, or speed of objects. It can be used to detect aircraft, ships, spacecraft, guided missiles, motor vehicles, weather_ formations, and terrain. The **seeker** is a homing system perceives the target with its own radar , extracts tracking data from the received signal, and computes its own steering commands. As it closes on the target, a fixed angular error at the missile results in a decreasing linear error, providing the higher accuracy characteristic of homing guidance. An **active radar seeker** is basically a tracking Radar whose antenna is mounted on a stabilized platform so as to provide necessary isolation of the antenna from the body motion of the missile. Enabling the antenna to keep tracking the target and generating signals which are used in terminal guidance of the missile.

CDMA (Code Division Multiple Access) is a spread spectrum multiple access technique. Spread spectrum modulation was originally developed for military applications, where resistance to jamming is of major concern. A spread spectrum technique spreads the bandwidth of the data uniformly for the same transmitted power[1]. A spreading code is a pseudo-random code. These are studied and performance expressions are derived and confirmed by computational simulation using MALAB SIMULINK. The spread spectrum technique which is present in SPZB260 Zigbee module, is used in order to establish RF communication and it is controlled by ARM Cortex M3 Processor(LPC1768).

Section2 provides a brief description of Spread Spectrum Modulation scheme using QPSK, SPZB260 and ARM Cortex M3. Section 3 gives block diagram of

Transmitter and Receiver. The procedure to implement transmitter and receiver using Simulink are explained in this section. Section 4 provides simulation results of transmitter-receiver, which are supporting the theory provided in the earlier sections in Simulink. Finally the work is concluded in section 5 and the scope for future work is explained.

II. General Structure Of The System

A. Definition of Spread Spectrum

Spread spectrum is a means of transmission in which the data sequence occupies a bandwidth in excess of the minimum bandwidth necessary to send it. The spectrum spreading is accomplished before transmission through the use of a code that is independent of data sequence. The same code is used in the receiver to despread the received signal so that the original data sequence may be recovered[1][2].

B. Working of DSSS

A conceptual diagram of DSSS system is given in fig 1. At the transmitter the digital binary information or data $d(t)$ having a source bit rate of $f_b = 1/T_b$ (Where f_b is bit rate and T_b is the bit duration) is XORed with spreading signal $c(t)$ is a pseudonoise (PN) signal having chip rate of $f_c = 1/T_c$ (f_c is chip rate and T_c is the pulse duration)[2]. Where $f_c \gg f_b$

The data stream entering the modulator is converted by a serial to parallel converter into two separate data streams.

One stream, $I(t)$ is in the phase and other $Q(t)$, is quadrature phase . After obtaining the inphase and Quadrature signals ,we need to do modulation for the transmission of the signal. The inphase signal is multiplied by a carrier cosine wave and Quadrature signal is multiplied by sin signal. The both $I(t)$ and $Q(t)$ signal are summed to produce the transmitting signal with four phase signal.

In the Receiver the received signal or the modulated signal is first demodulated and then despread. So, for demodulation we use Costas loop. Costas loop is used to track the carrier signal and phase of modulated signal. It produces two output one is Inphase and the other quadrature phase. This two signal are passed through the parallel to serial convertor to obtain spreading signal. By using matched filter as despread we can obtain required binary data.

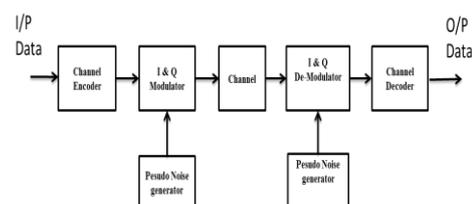

Figure 1: Block diagram of Spread Spectrum Communication system

C. Pseudo Noise Sequence

The types of spreading sequences are Gold sequences, maximum-length sequences, kasami sequences or walsh sequences. pseudo noise code generators are periodic in that the sequence that is produced repeats itself after some period of time. Such a periodic sequence is portrayed in fig 2. The Best known , best described PN sequences are maximal length. The generator contains type D flip-flops and is connected so that each data input except D0 is the input of the preceding flip-flop. Not all Q flip flop outputs need be connected to parity generator . the number of flip flop L and selection of which flip flop outputs are connected to parity generator determines the length and characteristics of the generated PN sequences. When the code is generated by maximum-length sequence , the value is $2^n - 1$, where n is the number of stages in the code generator[2].

$$L = 2^n - 1$$

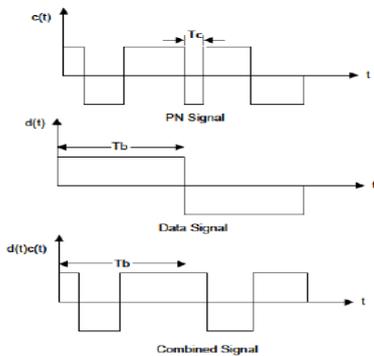

Figure 2: Wave form of Pseudo Random generator

Autocorrelation:

Te auto correlation function for the periodic wave is defined as number of agreements less number of disagreements in a term by term comparison over one full period of sequence with cyclic shift (position τ) of the sequence itself:

$$Ra(\tau) = \int_{-\infty}^{\infty} f(t) \cdot f(t - \tau) \cdot dt$$

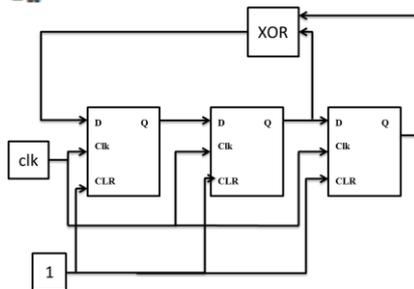

Figure 3: Block diagram of Pseudo Random generator

D. Direct Sequence QPSK

In QPSK, the data stream Inphase and Quadrature phase , with each stream having a symbol rate equal to half that of the incoming bit . Both I and Q are separately applied to multipliers. The Inphase multiplier is the carrier signal $\sin\omega t$ and Quadrature multiplier is the carrier signal $\cos\omega t$. The I multiplier output signal has phase 90 and 270 degrees and Q multiplier output signal has phase 0 and 180 degrees. Figure 4 shows a typical QPSK waveform in the time domain[4].

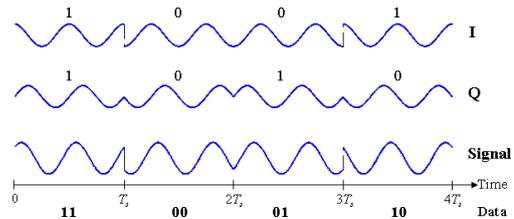

Figure 4: Wave form In phase and quadrature of QPSK modulation

E. Costas Loop

Costas loop is use for carrier recovery and phase detection which is used as demodulation circuit.

In Costas Loop the incoming signal is mixed with the output of the VCO, both before its phase is shifted and after its phase is shifted by 90 degrees. These two outputs are then filtered, multiplied together, filtered again and to control the frequency of the voltage controlled oscillator. The decoded spreading data stream can be taken from the output of the mixer output[1].

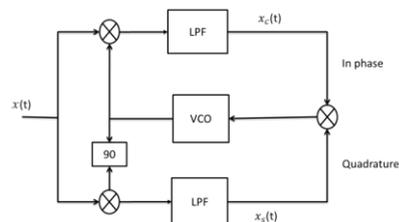

Figure 5: Block diagram of Costas Loop Carrier and phase recovery

$$x_c(t) = A \cos \psi(t) + n_c(t)$$

$$x_s(t) = A \cos \psi(t) + n_s(t)$$

When these two outputs are multiplied together, the product is

$$x_c(t)x_s(t) = \frac{A^2}{2} \sin \psi(t) + n_{eq}(t)$$

F. Hardware Requirement

Here we use the Arm Cortex M3 Processor to Control the Spread Spectrum Module (i.e SPBZB260) via SPI mode Here, we use two SPB260 and two LPC1768.

The first pair is connected to seeker via serial communication (UART) via LPC1768 which acts as client and other pair is connected to the system . were command and data sent and receive using GUI via serial communication(UART). Which is also called basestation. The following fig 6 show the the CDMA communication between the seeker and user.

i) SPBZB260

he SPBZB260 integrates a 2.4 GHz, IEEE802.15.4-compliant transceiver. SPBZB260 exposes access to the

while waiting for a Response. To determine when a Response is ready, use one of two methods: Clock the SPI until the SPZB260 transmits a byte other than 0xFF. Interrupt on the falling edge of nHOST_INT.

The first method, clocking the SPI, is recommended due to simplicity in implementing. During the Wait section, the SPZB260 will transmit only 0xFF and will ignore all incoming data until the Response is ready. When the SPZB260 transmits a byte other than 0xFF, the transaction has officially moved into the Response section.

c) Response Section

When the SPZB260 transmits a byte other than 0xFF, the transaction has officially moved into the Response section. The data format is the same format used in the Command section. The response can be of any length from 2 to 128 bytes and will not begin with 0xFF. Depending on the actual response, the length of the response is known from the first or second byte and this length should be used by the Host to clock out exactly the correct number of bytes. Once all bytes have been clocked, it is allowable for the LPC1768 to deassert chip select. Since the LPC1768 is in control of clocking the SPI, there are no ACKs or similar signals needed back from the Host because the SPZB260 will assume the LPC1768 could accept the bytes being clocked on the SPI[7].

SOFTWARES USED

1. Keil uVision4 software for embedded C programming.
2. Flash Magic software programmer for dumping code into ARM-cortex M3 LPC 1768 Microcontroller
3. Debugger used is CoCoX CoIDE
4. Visual Basic for GUI which used to send command to LPC1768 via serial port.

III. Implementation Of Transceiver Model In Matlab/Simulink

A. CDMA Transmitter in Simulink

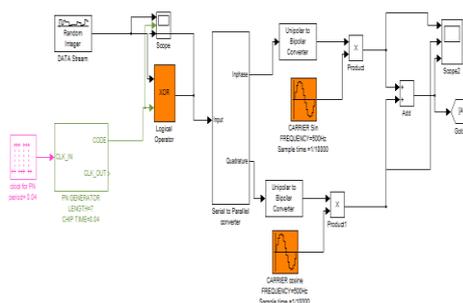

Figure 10: Implementation of CDMA Transmitter in Simulink:

i. Generating binary data stream: By using *Random integer generator block* in the communication tool box, we can generate binary data stream of 250Kbps. By adjusting the parameters like M-ary number, initial seed, sample time and output data type, we can achieve the fixed binary stream. In a real time scenario, this data stream is supplied by application that will generate information to be transmitted.

ii. Generating PN sequence: PN code is generated using D-flip-flop. we can generate 7 bit- PN sequence chip rate of 0.04ms by using 3 D- flip-flop and a XOR gate to generate 7 bit PN code.

iii. Serial to parallel converter implementation: By using flip-flops in Simulink extras tool box, we can get the parallel data from the serial data. The necessary instruments are one clock, one JK flip flop and two D flipflops. The initial conditions of the flip-flops using is zero and the period of the clock was decided by the input data stream. By this way we can easily generate the parallel data technically called as inphase and Quadrature data. Here necessary one bit offset delay is provided by the D flip flop itself. multiplied to get a Direct spread spectrum signal.

iv. Performing Modulation: After obtaining the inphase and Quadrature signals we need to do modulation for the transmission of the signal. Generally we do this with the help of high frequency(500HZ and sample time of 1/10000) sinusoidal carrier. By using sine wave block in Signal Processing Tool Box, sine wave can be generated by adjusting the parameters like amplitude, frequency, sample time, phase and sine type. Now the inphase signal after half sine pulse shaping is multiplied by a sine wave and Quadrature is multiplied by its cosine signal which is nothing but 90 degree phase shift of original sinusoidal carrier.

V. Output of the Transmitter: Addition of both inphase and Quadrature signals after modulation, generates the required transmitter output. The required output signal is generated by using sum block in commonly used blocks. There will be no phase transitions in the output, which is an advantageous property[8].

B. CDMA Receiver in Simulink

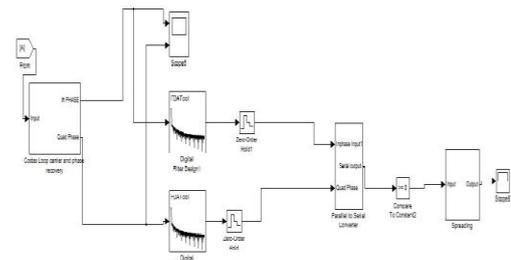

Figure 11: Implementation of CDMA Receiver in Simulink:

i. Multiplying with RF carrier: By using Costas loop is use for carrier recovery and phase detection which is used as demodulation circuit. In Costas Loop the incoming signal is mixed with the output of the VCO, both before its phase is shifted and after its phase is shifted by 90 degrees. These two outputs are then filtered, multiplied together, filtered again and to control the frequency of the voltage controlled oscillator. The decoded spreading data stream can be taken from the output of the mixer output.

ii. Sampling and Thresholding :

a. Sampling: By using the zero order hold circuit in the Simulink discrete menu, a sample and hold circuit was

generated. It samples the signal for every T time period. By setting the sample time in this block, adjust the time period T in zero order hold circuit.

b. **Thresholding:** By using compare to constant block in the Simulink logic and bit operations menu. By setting operator, constant value and output data type parameters, we can get the comparator circuit, which compares the sampled data with the predefined threshold value and detects whether the transmitted data is „1“ or „0“.

iii. **Parallel to serial conversion:** By using switch block in the Simulink signal routing menu, convert the parallel data into serial data. By setting the threshold value and the criterion for parallel to serial conversion, convert parallel data into serial data

iv. **Despreading:** The resulting data coming after serial to parallel conversion is multiplied with the delayed PN sequence. So that original is recovered data with small amount of delay. The incoming bit stream and the resultant output both are same but with a small amount of delay.

IV. Simulation Results

A. At the transmitter end

The following figures demonstrate simulation results for CDMA transmission system. The results are displayed in the form of snapshots of scope signals.

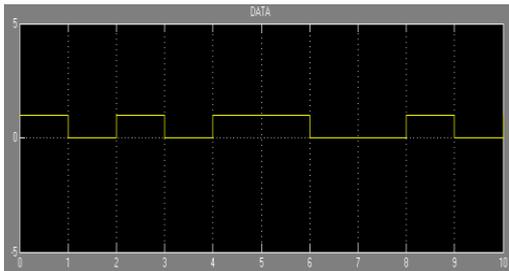

Figure 12: Binary data generated by Random integer Generator

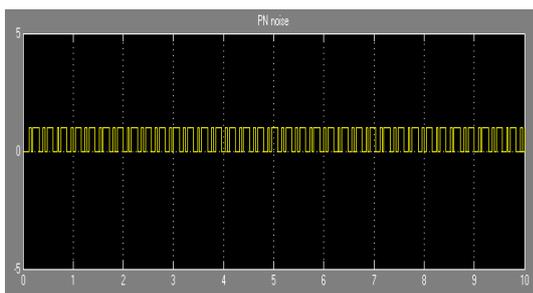

Figure 13: PN Generator

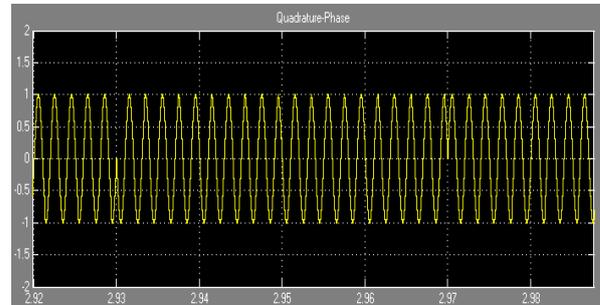

Figure 16: Quadrature phase modulation signal

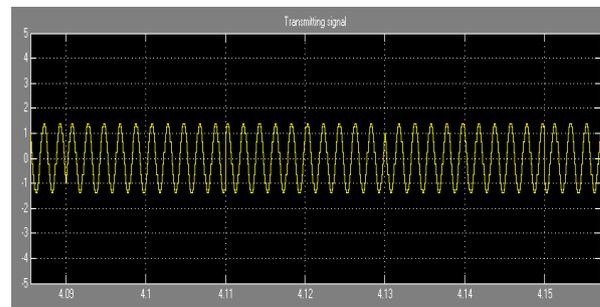

Figure 17: DSSS signal to transmit

B. At the receiver end

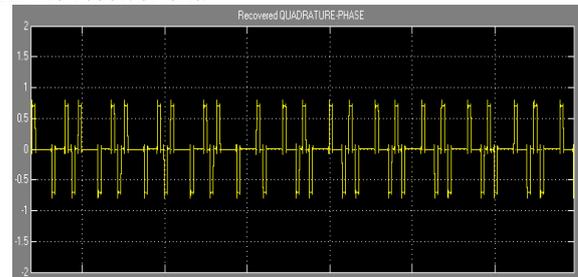

Figure 18: Recovered In phase stream using costas loop

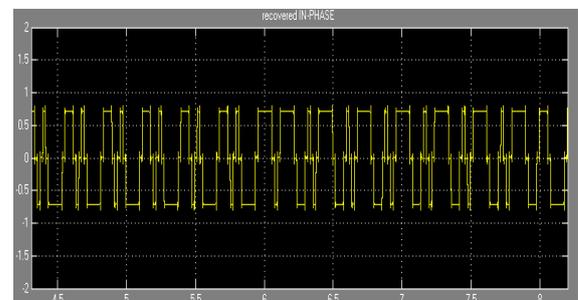

Figure 19: Recovered Quad phase stream using costas loop

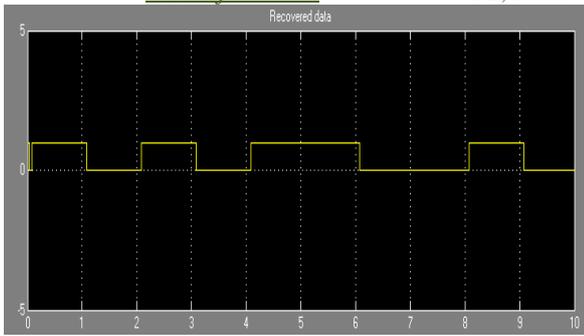

Figure 20: Recovered Data stream with small delay

V. CONCLUSION

CDMA RF link is used for achieving the communication between transmitters and receivers. Simulation results were plotted. Hard ware implementation is to be done using cortexM3 processor and SPZB260 Zigbee module for RF communications. In future, we aspire to improve the design with many (2 to 3) client to control the other system of the missile.

Thermal Analysis And Optimization Of I.C. Engine Piston Using finite Element Method

A. R. Bhagat¹, Y. M. Jibhakate²

¹M.Tech Student Heat Power Engineering, Mechanical Engineering Department, KITS College of Engineering Nagpur,
²Asso. Professor, Mechanical Engineering Department, KITS College of Engineering Nagpur, India.

Abstract: This paper describes the stress distribution of the seizure on piston four stroke engine by using FEA. The finite element analysis is performed by using computer aided design (CAD) software. The main objectives is to investigate and analyze the thermal stress distribution of piston at the real engine condition during combustion process. The paper describes the mesh optimization with using finite element analysis technique to predict the higher stress and critical region on the component. The optimization is carried out to reduce the stress concentration on the upper end of the piston i.e (piston head/crown and piston skirt and sleeve). With using computer aided design(CAD), Pro/ENGINEER software the structural model of a piston will be developed. Furthermore, the finite element analysis performed with using software ANSYS.

Keywords : Ansys, Piston crown, Piston skirt, ProE, stress concentration, Thermal analysis etc.

I. Introduction

A piston is a component of reciprocating IC-engines. It is the moving component that is contained by a cylinder and is made gas-tight by piston rings. In an engine, its purpose is to transfer force from expanding gas in the cylinder to the crankshaft via a piston rod and/or connecting rod. As an important part in an engine, piston endures the cyclic gas pressure and the inertial forces at work, and this working condition may cause the fatigue damage of piston, such as piston side wear, piston head/crown cracks and so on. The investigations indicate that the greatest stress appears on the upper end of the piston and stress concentration is one of the mainly reason for fatigue failure. On the other hand piston overheating-seizure can only occur when something burns or scrapes away the oil film that exists between the piston and the cylinder wall. Understanding this, it's not hard to see why oils with exceptionally high film strengths are very desirable. Good quality oils can provide a film that stands up to the most intense heat and the pressure loads of a modern high output engine. Thermal analysis is a branch of materials science where the properties of materials are studied as they change with temperature. FEM method are commonly used for thermal Analysis. Due to the complicated working environment for the piston; on one hand, the FEA for the piston became more difficult, on the other hand, though there have many methods which are put forward to apply optimal design, the optimal parameters is not easy to determine. In this study, the piston is used in low idle and rated speed gas engine. In order to enhance the engine dynamic and economic, it is necessary for the piston to implement optimization. The mathematical model of optimization is established firstly, and the FEA is carried out by using the ANSYS software. Based on the analysis of

optimal result, the stress concentrates on the upper end of piston has become evaluate, which provides a better reference for redesign of piston.

II. The Fea Of The Piston

2.1. Theoretical Foundation

In engine, transfer of heat takes place due to difference in temperature and from higher temperature to lower temperature. Thus, there is heat transfer to the gases during intakes stroke and the first part of the compression stroke, but the during combustion and expansion processes the heat transfer take place from the gases to the walls.

So the piston crown/head, piston ring and the piston skirt should have enough stiffness which can endure the pressure and the friction between contacting surfaces. In addition, as an important part in engine, the working condition of piston is directly related to the reliability and durability of engine. So it is important for the piston skirt and the piston ring to carry out structural and optimal analysis which can provide reference for design of piston.

So the mean effective pressure on the piston crown, piston top ring and the piston skirt should be restricted at low idle (850rpm) and at rated speed (2700rpm). The formula can be expressed as,

$$IHP = \frac{P_m \times L \times A \times N/2}{60 \times 10^3} \dots\dots\dots (1)$$

Where,

- P_m Mean Effective Pressure (bar) ;
- L- stroke length(mm) ; A –Area(mm²) ;
- N-speed (rpm) ;
- IHP- indicated horse power (watt)

Thus for low idle speed (850RPM) P_m=74.18 bar and for rated speed (2700RPM) P_m= 23.33bar So, Calculation purpose Mean Effective Pressure, P_m = 23.33 bar taken.

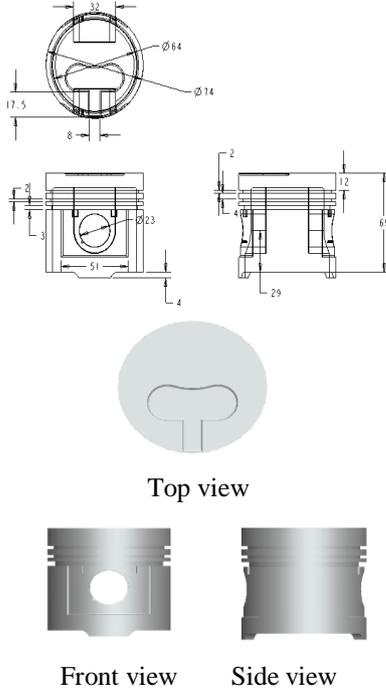

2.2. The Finite Element Analysis

In this work, due to the symmetry of structure, model of piston has been made in the Pro/E software, and then the FEM is established using ANSYS software. The 3-D 20-node solid element SOLID95 is applied to mesh the whole structure, and 27374 nodes and 14129 elements are obtained. In addition, in order to obtain the better result, the contact pair which is important to carry out the research should be established between the piston crown, piston ring and piston skirt. The contact is highly non-linear and need more computing power. In order to compute effectively, it is important to know the physical property and establish the reasonable model. In this study, the surface-surface contact is applied to the model. The FEA of piston is carried out by using the ANSYS software. The equivalent stress and the deformation of the piston are obtained respectively, as shown in the Fig. (1 and 2). As shown in the Fig., the maximum stress appears at the centre and at edge of piston

sleeve and the value of the stress is 228N/mm². As shown in the Fig. (1), the maximum deformation occurs on piston and the value of deformation is 0.760mm. The analysis of contact is carried out by using ANSYS workbench software, and the result is shown in the Figures It is correspond with the truth.

III. Piston Design

The design data for designing of I.C engine Piston with the help of pro-E is collected from TATA MOTORS for Diesel engine vehicle.

IV. Thermal Analysis Of Piston Using Fea Approach

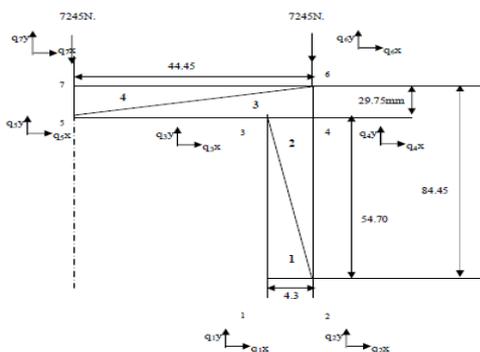

Figure 9.1: Piston Design

$E = 72.5 \times 10^3 \text{ N/mm}^2$
 $\mu = 0.334$

4.1 Force Vector Matrix, F Radius of Centroid,

$$r_1 = \frac{(x_1 + x_2 + x_3)}{3}$$

$$r_1 = \frac{(40.15 + 44.15 + 40.15)}{3}$$

$r_1 = 41.583 \text{ mm}$

and

$|J_1| = 235.21$

$A_1 = \frac{|J_1|}{2} = 117.5 \text{ mm}^2$

Strain Displacement Matrix, B₁

$B_1 = \frac{1}{|J_1|}$

Material Property Matrix, D₁

$D_1 = \frac{E(1-\mu)}{(1+\mu)(1-2\mu)}$

Stiffness Matrix K₁

$K_1 = t_1 \times A_1 \times B T_1 \times D_1 \times B_1$

$K_1 = (2 \times \pi \times r_1) \times A_1 \times B T_1 \times D_1 \times B_1$

Material Property Matrix, D₁=D₂=D₃=D₄

Similarly for element 2,3,4. Force Vector Matrix, F Piston is treated as Axis-symmetrical object about the centre axis of the piston q_{1x},q_{1y}, q_{2x},q_{2y}, q_{3x},q_{3y}, q_{4x},q_{4y}, q_{5x},q_{5y}, q_{6x},q_{6y}, q_{7x},q_{7y} are the nodes position from 1 to 7 along x and y directions. Each 7245 N force acting vertical down word at node no 6 and node no 7 respectively.

4.2 Temperature load Vector Matrix,

$\theta_1 = 1 = 2 \times \pi \times r_1 \times A_1 \times B T_1 \times D_1 \times \epsilon_{01}$

$\alpha_{All} = 23 \times 10^{-6} \text{ W/}^\circ\text{C}$

$\Delta T = \text{Element Temp} - \text{Room Temp} = 150 - 40 = 110^\circ\text{C}$

Similarly for element 2,3,4.

Global Temperature Load Vector Matrix

$\theta^G = 1 \times 10^6 [\theta]_{1 \times 14}$

Assembled Global Force Vector Matrix, FG=F+ θ^G

$[F^G]_{14 \times 1} = [K^G]_{14 \times 14} = [U]_{14 \times 1}$

Where ‘U’ is Displacement Matrix. By solving the above equations, we get, displacement at various nodes.

Nodes	Analytical values of deformation	Ansys values of deformation
U2X	0.0216	0.805
U4X	0.0538	0.785
U6X	0.4241	0.760
U6Y	0.4366	0.724
U7X	-0.0024	0.077
U7Y	0.4198	0.434

V. Optimization Analysis With Steel

Modern engines with variable valve train or different direct injection concepts require pistons with complex crown shapes which would often lead to a higher piston weight. Therefore in every new piston development, the piston geometry is optimized in particular in the ring belt/piston skirt area. Intensive application of numerical simulation methods enables significant weight reductions while increasing at the same time the load-bearing capacity. Newly developed alloys with better castability, but also higher fatigue resistance in the critical temperature and stress region, allow the realization of thinner wall structures. Improved casting methods enable large recesses for the ring belt and hence a considerable reduction in the piston weight. But also the use of steel pistons in i. c engines is discussed again and again. The advantages of steel pistons such as reduced installation clearances, low fuel consumption figures and long service life would have to be evaluated against customer demands such as low emission levels,

lightweight, efficient cooling and a competitive price. But up to now, there are no definite indications that steel pistons would be a viable concept for mass production. The analysis is done in ANSYS Workbench for two materials aluminium alloy which is existing material and suggested material with different material properties. Following result are obtained as shown in figure.

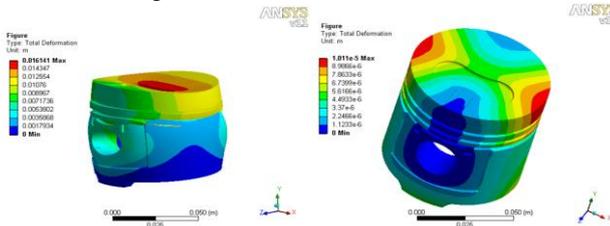

Figure1: Comparison between total deformation

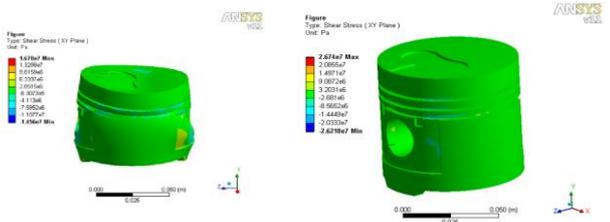

Figure2: Comparison between Shear Stress

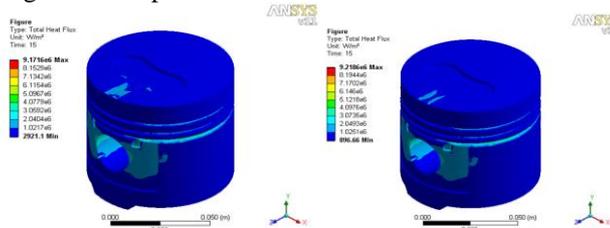

Figure3: Comparison between total heat flux

VI. Conclusion

Piston skirt may appear deformation at work, which usually causes crack on the upper end of piston head. Due to the deformation, the greatest stress concentration is caused on the upper end of piston, the situation becomes more serious when the stiffness of the piston is not enough, and the crack generally appeared at the point A which may gradually extend and even cause splitting along the piston vertical. The stress distribution on the piston mainly depends on the deformation of piston. Therefore, in order to reduce the stress concentration, the piston crown should have enough stiffness to reduce the deformation.

1. The optimal mathematical model which includes deformation of piston crown and quality of piston and piston skirt.
2. The FEA is carried out for standard piston model used in diesel engine and the result of analysis indicate that the maximum stress has changed from 228 Mpa. To 89 Mpa. And biggest deformation has been reduced from 0.419 mm to 0.434 mm.

Abstract : This paper presents an approach towards VLSI implementation of the Discrete cosine Transform for image compression. Modules required for the corresponding circuit. The design follows the JPEG standard and can be used for both lossy and lossless compression. In Discrete cosine transform, the filter implementation plays the key role. The poly phase structure is proposed for the filter implementation, which uses the Distributive Arithmetic (DA) technique. The implementation of DA based DCT IP core in ASIC (Application Specific Integrated Circuit). Which is popular in FPGA (Field Programmable Gate Array) implementations. To exploit the available resources on FPGAs, a new technique, which incorporates pipelining and parallel processing of the input samples, is proposed, with this architecture the speed (throughput) of the design increases. The intermediate coefficients obtained are efficiently stored in a memory and accessed for efficient memory utilization on FPGAs. The design is targeted on Xilinx spartan3, and the ASIC design of the same is carried out.

Keywords: DCT, Distributed Arithmetic.

I. Introduction

Recently, multimedia applications are used widely in many embedded and portable systems, such as mobile phones, MP3 player and PDA, which require area efficient within high performance constraints. Therefore, area efficient design becomes a more important objective in Very Large Scale Integration (VLSI) designs. Moreover; the multiplication unit always lies on the critical path and ultimately determines the performance and area efficient of arithmetic computing systems. To achieve high-performance and lengthen the battery lifetime, it is crucial to develop a compression with high-speed. In multimedia and digital signal processing (DSP) applications, many area efficient approaches have been presented. An efficient technique for calculation of sum of products or vector dot product or inner product or multiply and accumulate (MAC) MAC operation is very common in all Digital Signal Processing hardware designs. In a constant word length multiplier, the extra bits in the partial sums as well as the final product are truncated and no of binary adders required for accumulating 2 partial products equal to the wordlength W. This causes truncation errors whose value not only depend on multiplicand and multiplier but also on arrangement of partial product accumulation. In general, the truncation part (TP) is usually truncated to reduce hardware costs in parallel shifting and addition operations, known as the direct truncation (Direct-T) method. Thus, a large truncation error occurs due to the neglecting of carry

propagation from the TP to Main Part (MP). Distributed arithmetic is a bit level rearrangement of a multiply accumulate to hide the multiplications. It is a powerful technique for reducing the size of a parallel hardware multiply-accumulate that is well suited to FPGA designs. It can also be extended to other sum functions such as complex multiplies, fourier transforms and so on. Look at my Radar on a chip paper for an application example of distributed arithmetic. In most of the multiply accumulate applications in signal processing, one of the multiplicands for each product is a constant. Usually each multiplication uses a different constant. Using our most compact multiplier, the scaling accumulator, we can construct a multiple product term parallel multiply-accumulate function in a relatively small space if we are willing to accept a serial input. In this case, we feed four parallel scaling accumulators with unique serialized data. Each multiplies that data by a possibly unique constant, and the resulting products are summed in an adder tree. If we stop to consider that the scaling accumulator multiplier is really just a sum of vectors, then it becomes obvious that we can rearrange the circuit. Here, the adder tree combines the 1 bit partial products before they are accumulated by the scaling accumulator. All we have done is rearranged the order in which the 1xN partial products are summed. Now instead of individually accumulating each partial product and then summing the results, we postpone the accumulate function until after we've summed all the 1xN partials at a particular bit time. This simple rearrangement of the order of the adds has effectively replaced N multiplies followed by an N input add with a series of N input adds followed by a multiply. This arithmetic manipulation directly eliminates N-1 Adders in an N product term multiply-accumulate function. For larger numbers of product terms, the savings becomes significant. Further hardware savings are available when the coefficients C_n are constants. If that is true, then the adder tree shown above becomes a Boolean logic function of the 4 serial inputs. The combined 1xN products and adder tree is reduced to a four input look up table. The sixteen entries in the table are sums of the constant coefficients for all the possible serial input combinations. The table is made wide enough to accommodate the largest sum without overflow. Negative table values are sign extended to the width of the table, and the input to the scaling accumulator should be sign extended to maintain negative sums. Obviously the serial inputs limit the performance of such a circuit. As with most hardware applications, we can obtain more performance by using more hardware. In this case, more than one bit sum can be computed at a time by duplicating the LUT and adder tree as shown here. The second bit computed will have a different weight than the first, so some shifting is required

before the bit sums are combined. In this 2 bit at a time implementation, the odd bits are fed to one LUT and adder tree, while the even bits are simultaneously fed to an identical tree. The odd bit partials are left shifted to properly weight the result and added to the even partials before accumulating the aggregate. Since two bits are taken at a time, the scaling accumulator has to shift the feedback by 2 places. This paralleling scheme can be extended to compute more than two bits at a time. In the extreme case, all input bits can be computed in parallel and then combined in a shifting adder tree. No scaling accumulator is needed in this case, since the output from the adder tree is the entire sum of products. This fully parallel implementation has a data rate that matches the serial clock, which can be greater than 100 MS/S in today's FPGAs. The Discrete cosine transform (DCT) is widely used in digital image processing, especially in image transform coding, as it performs much like the optimal Karhunen-Loeve transform (KLT) under a variety of criteria. Many algorithms for the computation of the DCT have been proposed since the introduction of the DCT by Ahmed, Natarajan, and Rao in 1974. However, though most of them are good software solutions to the realization of DCT, only a few of them are really suitable for VLSI implementation. Cyclic convolution plays an important role in digital signal processing due to its nature of easy implementation. Specifically, there exists a number of well-developed convolution algorithms and it can be easily realized through modular and structural hardware such as distributed arithmetic and systolic array. The way of data movement forms a significant part in the determination of the efficiency of the realization of a transform using the distributed arithmetic. The realization of a cyclic convolution with the distributed arithmetic requires only simple table look-up technique and some simple rotations of the corresponding data set. Hence, the cyclic convolution structure can be considered as the simplest form that is most suitable to be realized with the distributed arithmetic. It is because of this reason, one may consider that the basic criterion for the realization of a transform using the distributed arithmetic relies on the possibility of having an efficient way to convert the transform into the cyclic convolution form. If we could be able to convert a transform into the cyclic convolution form with the minimum number of operations, it would imply an optimal approach for the realization of the transform using the distributed arithmetic. Some basic formulations have been suggested for the realization of the DCT using the distributed arithmetic. In their formulations, they either still required some extra multiplications for their formulations or have to use cyclic convolutions of different lengths. The former case has the major problem that it violates the major advantage of the distributed arithmetic which replaces multiplications by additions. The latter case requires relatively complicated circuitry to allow the realization of cyclic convolutions of variable lengths. Different from the above approaches, one may also convert the DCT into the Discrete Fourier Transform (DFT) and make use of the famous algorithms to convert the corresponding DFT into cyclic convolution form. Indeed, this is a possible approach; however, it turns a real transform into a transform with complex numbers. The realization could still be complicated even if some simplification techniques are to be applied.

The field of computer science is growing at the fastest pace since it started back in the early 20th century. We didn't have the actual computing machines until the mid of the 20th century but the algorithms for computing were already being developed from the beginning of the century. The advancement of the computing field has affected every imaginable field in the human lives. These fields include engineering, medicine, geology, meteorology, movies, and pictures etc. The high speed of digital computer has contributed to significant progress in the field of optics. Image processing by far has benefited significantly from the high speed digital computers. Since the day the very first successful picture was taken in June of 1827, the quality and style of images have improved significantly. Niepce took this picture by using material that hardened on exposure to light. There were many different ways to taking these images before the camera that we know today was created. The main problem with all of the images taken was the fact that with every picture that was taken a lot of redundant and useless information was also stored. The problems range from faded, blurry and noisy pictures. All these useless data stored with the images is termed as Noise. Noise, in technical terms is defined as the irrelevant or meaningless data. Image restoration is one of the many branches of image processing. It is defined as a process that removes all the noise and irrelevant data from the images to make them clearer and better visible. The tools and techniques used in image processing are imported from signal processing. The main difference, however, between signal processing and image processing is that when binary data is compressed, it is essential that we get the same data back when it is decompressed. With the images, on the other hand, it is not required. When an image is decompressed it is in most cases enough to get a replica of the image as long as the mean square error is within certain set limits and tolerable. As mentioned above, there are a number of factors that can adversely affect the image quality. There have been a number of techniques introduced and being researched to enhance the image as well as to improve the usefulness of the data. Enhancement programs make the information more visible. One of the most popular enhancement techniques is the Histogram equalization. This technique redistributes the intensities of the image equally to the entire gray level range of the image. Convolution is an image processing technique which is essentially a sequence mask operating on pixel neighborhood. Convolution involves High Pass and Low pass filters. Other image processing techniques include noise filters, trend removing filters, edge detection, and image analysis tools etc. One of the important aspects of image processing is the reduction of the coded description of the image while keeping all the pertinent information. Data compression methods with zero information loss have been used on image data for some time. GIF, JPEG, MPEG etc are all examples of the tools used for data compression without the loss of the information. There are various techniques used these days to capture and store the images in a compressed format to reduce their storage sizes and use a smaller space. There are basically two categories of compression techniques; lossless and lossy. The main difference between these two categories is that in lossy compression the quality of the image is reduced in order to achieve higher compression ratio. On the other hand, in a lossless

compression the quality of the image is given a higher preference than the compression ratio. So it can be said that there is an apparent trade off between quality of the image and the compression ratio whenever we talk about the image compression. Lossy techniques include Transform Coding such as DCT, Wavelets and Gabor, Vector quantization, Segmentation and Approximation methods, Spline approximation methods i.e. Bilinear Interpolation/Regularization, Fractal coding which includes Texture synthesis, Iterative functions systems (IFS) and Recursive iterative functions systems (RIFS). Lossless compression techniques, on the other hand, includes Run length Encoding, Huffman Encoding, Entropy Coding (Lempel/Ziv) and Area coding . Discrete cosine transform (DCT) has become the most popular technique for image compression over the past several years. One of the major reasons for its popularity is its selection as the standard for JPEG. DCTs are most commonly used for non-analytical applications such as image processing and signal-processing DSP applications such as video conferencing, fax systems, video disks, and HDTV. DCTs can be used on a matrix of practically any dimension. Mapping an image space into a frequency space is the most common use of DCTs. For example, video is usually processed for compression/decompression as 8 x 8 blocks of pixels. Large and small features in a video picture are represented by low and high frequencies. An advantage of the DCT process is that image features do not normally change quickly, so many DCT coefficients are either zero or very small and require less data during compression algorithms. DCTs are fast and, like FFTs, require calculation of coefficients. The entire standards employ block based DCT coding to give a higher compression ratio. Various different techniques and algorithms employed for DCT will be discussed in detail in section 3 where DCT will be explored. As the topic of my thesis suggests, I will be exploring the possibilities of discrete cosine transforms for multi-resolution analysis. The aim here is to see if we can get the same results in compression using DCT as we can get by using the wavelets. The word multi-resolution refers to the simultaneous presence of different resolutions. The notion of multi-resolution was introduced by Mallat and Meyer in the years 1988-89. Multi-resolution analysis provides a convenient framework for developing the analysis and synthesis filters . DCTs have been in used for compression for quite some time and have been very popular. As I mentioned earlier the main reason for DCTs popularity is the fact that it's been used as a standard in JPEGs. Wavelets are considered better than DCT when it comes to getting better results in compression. The supporters of MPEGs and JPEGs claim that DCT provides very good results as far as the compression is concerned. If this claim is in fact true then the question is that why are so many people interested in Internet protocol streaming. The reason IP streaming is really good that there are algorithms that provide a lot more compression with the same video quality as MPEG-2 does. We can take a wavelet algorithm and keep the same video quality and use 1 Mbps for a very nice high quality movie that would take us 3 Mbps with normal MPEGs with DCT . The previous paragraph is good argument for choosing wavelets over DCT, however, the previous paragraph has been erroneous in the sense that researches use DCT and JPEG interchangeably. The arguments made in previous

paragraph against DCT are in fact against the standard JPEG and not DCT. JPEG uses just a small part of DCT and should not be taken as standard DCT algorithms in comparisons with wavelet. The basic difference between DCT and wavelets is that in wavelets rather than creating 8 X 8 blocks to compress, wavelets decompose the original signal into sub-bands. Wavelets are basically an optimizing algorithm for 5 representing a lot of change in the pictures. With DCT algorithm, the 8 X 8 blocks can lose their crisp edges, whereas, with wavelets the edges are very well defined. I don't really want to go in detail with the differences between wavelets and DCT but I just want to mention it to prove my case for the proposal of DCT for multi-resolution analysis. There is another compression method being developed call Fractals which is based on quadratic equations. This method is very well suitable with images which have patterns or a lot of repetitions. Now, if the wavelets produce much better results than DCT then why do we need to try DCT for multi-resolution? The reason is that there are certain drawbacks to wavelets specially in terms of computation time required. For the highest compression rates, it takes a longer time to encode. The other reason is that MPEG is already a standard using DCTs and computer hardware comes with MPEGs built in. There is hardly any hardware available in the market these days which comes with wavelets as a built in standard.

II. METHODOLOGIES

It is the process of analyzing the design of Discrete Cosine Transform (DCT) core with Error Compensated Adder Tree based on distributed arithmetic. An efficient technique for calculation of sum of products or vector dot product or inner product or multiply and accumulate (MAC) MAC operation is very common in all Digital Signal Processing hardware designs. An old technique that has been revived by the wide spread use of Field Programmable Gate Arrays (FPGAs) for Digital Signal Processing (DSP). DA efficiently implements the MAC using basic building blocks (Look Up Tables) in FPGAs .The "basic" DA technique is bit-serial in nature. DA is basically a bit-level rearrangement of the multiply and accumulate operation DA hides the explicit multiplications by without ROM look-ups an efficient technique to implement on Field Programmable Gate Arrays (FPGAs). The speed in the critical path is limited by the width of the carry propagation Speed can be improved upon by using techniques to limit the carry propagation. An increasing number of services and the growing popularity of high definition TV require higher coding efficiency. As the ongoing demand increases, for better compression performance of the latest video coding standard, the H.264/AVC (Advanced Video Coding) is formulated .The H.264/AVC is also known as MPEG-4 Part 10 (Wiegand,et al., 2003;Sullivan,et al.,2004; Richardson, 2003).An advantage of the H.264/AVC is the simplicity of its transform. Distributed Arithmetic (DA) is an effective method for computing inner products when one of the input vectors is fixed. It uses pre computed look-up tables and accumulators instead of multipliers for calculating inner products and has been widely used in many DSP applications such as DFT, DCT, convolution, and digital filters. In particular, there has been great interest in implementing DCT with parallel distributed arithmetic and

in reducing the ROM size required in the implementations since the DA-based DCT architectures are known to have very regular structures suitable for VLSI implementations. Most DA-based DCT implementations use the original DCT algorithm, or the even-odd frequency decomposition of the DCT algorithm along with some memory reduction techniques such as the partial sum technique and/or the offset binary coding technique. On the other hand, the proposed architecture uses the DA-based DCT algorithm and requires less area than the conventional approaches, regardless of the memory reduction techniques employed in the ROM Accumulators (RACs).

MAIN MODULE'S:

- ERROR COMPENSATION CIRCUIT
- ERROR COMPENSATED ADDER TREE
- 1-D 8-POINT DCT DESIGN

III. MODULE DESCRIPTION:

Error Compensated Circuit:

Multipliers are commonly used components in digital signal processing applications (DSP). The multiplier produces $2n$ -bit output for n bit multiplicand and n bit multiplier input. But for some applications we may only require n bit multiplicand result. We can truncate n least-significant bits and preserve the m most significant bit. Although doing this would cause significant errors the area will be reduced half. To reduce truncation error we propose error compensation methods. In some applications these error could be ignored. The output will obtain MSBs using a rounding operation called post truncation (Post-T), which is used for high-accuracy applications. Hardware cost increases in the VLSI design. In general, the TP is usually truncated to reduce hardware costs in parallel shifting and addition operations, known as the direct truncation (Direct-T) method. Thus, a large truncation error occurs due to the neglecting of carry propagation from the TP to MP.

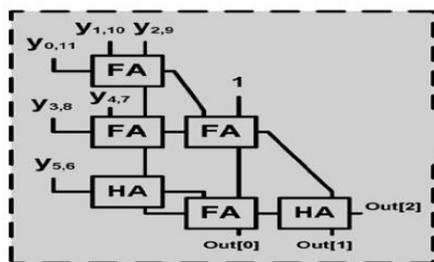

Fig 1: Error Compensation Circuit

In order to alleviate the truncation error effect, several error compensation bias methods have been presented.

All previous works were only applied in the design of a fixed-width multiplier. Because the products in a multiplier have a relationship between the input multiplier and multiplicand, the compensation methods usually use the correlation of inputs to calculate a fixed or an adaptive compensation bias using simulation or statistical analysis. The internal word-length usually uses 12 bits in a DCT design. Consequently, word length $P=12$ is chosen together with different Q values of 3, 6, 9 and 12. The Post-T method provides the most accurate values for fixed-width computation nowadays. In addition, the Direct-T method

has the largest inaccuracies of the errors for low-cost hardware design. The proposed ECAT is more accurate than Direct-T and is close to the performance of the Post-T method using a compensated circuit.

SUB MODULES'S

- HALF ADDER
- FULL ADDER
- ADDITION ELEMENTS

ERROR COMPENSATED ADDER TREE:

In this module consists of error compensated circuit, adder circuit, sign extension, zero extension. FA indicates a full-adder cell with three inputs (a , b , and c) and two outputs, a sum (s) and a carry-out (co). HA indicates half-adder cell with two inputs (a and b) and two outputs, a sum (s) and a carry-out (co). ECAT has the highest accuracy with a moderate area delay product. The shift-and-add method has the smallest area, but the overall computation time is longest. ECAT is suitable for high-speed and low-error applications. authorized doctors can login into the medical. Here also all the details about the doctor are registered by the medical admin. And the medical admin give the authentication details to the particular doctor after getting the authentication details doctor can login to the medical and can start the below processes.

SUBMODULES:

- ERROR COMPENSATED CIRCUIT
- PARTIAL PRODUCT GENERATION

ERROR COMPENSATED CIRCUIT

In this module the shifting and addition computation uses a shift-and-add operator in VLSI implementation in order to reduce hardware cost. However, when the number of the shifting and addition words increases, the computation time will also increase. Therefore, the shift-adder-tree (SAT) presented in operates shifting and addition in parallel by unrolling all the words needed to be computed for high-speed applications. The Q P -bit words operate the shifting and addition in parallel can be divided into two parts: the main part (MP) that includes P most significant bits (MSBs) and the truncation part (TP) that has least significant bits (LSBs).

PARTIAL PRODUCT GENERATION

In this module A truncated multiplier is an $m \times n$ multiplier with m bits output. Partial products can be divided into two subsets. The least significant part (LSP) includes the n less significant columns of the partial product matrix, while the most significant part (MSP) includes the remaining columns. The full-width multiplier output, P is given by $P = SMSP + SLSP$. Where $SMSP$ and $SLSP$ represent the weighted sum of the elements of MSP and LSP respectively. When a n bits output is needed, the most accurate choice is using the full rounded multiplier: it computes all the matrix of partial products, add a constant to the result on $2n$ bits and takes only the first n bits of the sum. The error introduced by the full rounded multiplier is calculated. Unfortunately the full rounded multiplier is the solution with the highest area occupation and power dissipation. A second possibility is using a truncated multiplier in which the partial products of the LSP are

discarded assuming that their contribution to the n most significant bits of the output is negligible. This solution is very advantageous in terms of hardware performances.

the reputation of being a very effective signal analysis tool for many practical applications.

IV. D 8 POINT DCT:

Image data compression has been an active research area for image processing over the last decade and has been used in a variety of applications. This paper investigates the implementation of an image data compression method with VLSI hardware that could be used in practical coding systems to compress JPEG signals. In practical situations, an image is originally defined over a large matrix of picture elements (pixels), with each pixel represented by a 8- or 16-bit gray scale value. This representation could be so large that it is difficult to store or transmit. The purpose of image compression is to reduce the size of the representation and, at the same time, to keep most of the information contained in the original image . DCT based coding and decoding systems play a dominant role in real-time applications. However, the DCT is computationally intensive. In addition, 2D-DCT has been recommended by standard organizations the Joint Photographic Expert Group (JPEG). The standards developed by these groups aid industry manufacturers in developing real-time 2D-DCT chips for use in various image transmission and storage systems. Generally there is a higher degree of correlation between the intensity values of adjacent pixels of an image. image compression can be achieved by removing such a redundant information. The discrete cosine transform (DCT) is widely used in most applications for compression of digital image and video signals. After performing the DCT operation on image or video signals most of energy is found to be concentrated in low frequency region. Recently hardware implementation of video coding standards fall into three main design categories :

1. Video signal processors,
2. Multimedia coprocessors,
3. Dedicated coders and decoders.

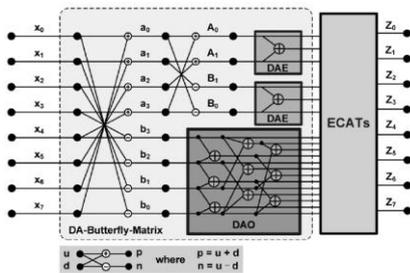

Fig 2: Architecture Of The Proposed 1-D 8-Point DCT

Video signal processors are programmable processors with a digital processing core or reduced instruction set computer core and co-processing unit for compute intensive operations such as motion estimation. Multimedia coprocessors are also programmable. The computation of DCT is on eof process of transforming a block of data from the spatial domain to frequency domain. Inverse process of restoring the spatial domain data from frequency domain is carried out through Inverse DCT (IDCT).The Discrete Cosine Transform (DCT) has gained

DISTRIBUTED ARITHMETIC

Distributed arithmetic is a bit level rearrangement of a multiply accumulate to hide the multiplications. It is a powerful technique for reducing the size of a parallel hardware multiply-accumulate that is well suited to FPGA designs. It can also be extended to other sum functions such as complex multiplies, Fourier transforms and so on. Look at my Radar on a chip paper for an application example of distributed arithmetic. In most of the multiply accumulate applications in signal processing, one of the multiplicands for each product is a constant. Usually each multiplication uses a different constant. Using our most compact multiplier, the scaling accumulator, we can construct a multiple product term parallel multiply-accumulate function in a relatively small space if we are willing to accept a serial input. In this case, we feed four parallel scaling accumulators with unique serialized data.

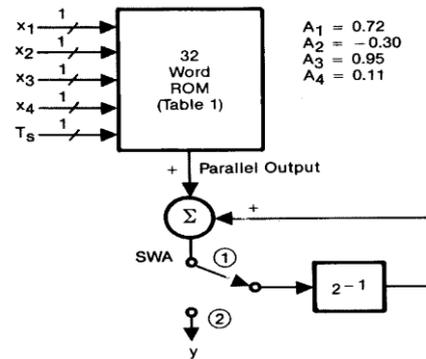

Fig 3: Distributed Arithmetic

Each multiplies that data by a possibly unique constant, and the resulting products are summed in an adder tree .If we stop to consider that the scaling accumulator multiplier is really just a sum of vectors, then it becomes obvious that we can rearrange the circuit. Here, the adder tree combines the 1 bit partial products before they are accumulated by the scaling accumulator. All we have done is rearranged the order in which the 1xN partial products are summed. Now instead of individually accumulating each partial product and then summing the results, we postpone the accumulate function until after we've summed all the 1xN partials at a particular bit time. This simple rearrangement of the order of the adds has effectively replaced N multiplies followed by an N input add with a series of N input adds followed by a multiply. This arithmetic manipulation directly eliminates N-1 Adders in an N product term multiply-accumulate function. For larger numbers of product terms, the savings becomes significant. Further hardware savings are available when the coefficients C_n are constants. If that is true, then the adder tree shown above becomes a Boolean logic function of the 4 serial inputs. The combined 1xN products and adder tree is reduced to a four input look up table. The sixteen entries in the table are sums of the constant coefficients for all the possible serial input combinations. The table is made wide enough to accommodate the largest sum without overflow. Negative table values are sign extended to the width of the table, and the input to the scaling accumulator should be

sign extended to maintain negative sums. Obviously the serial inputs limit the performance of such a circuit. As with most hardware applications, we can obtain more performance by using more hardware. In this case, more than one bit sum can be computed at a time by duplicating the LUT and adder tree as shown here. The second bit computed will have a different weight than the first, so some shifting is required before the bit sums are combined.

DISTRIBUTED ARITHMETIC OPERATION

In this 2 bit at a time implementation, the odd bits are fed to one LUT and adder tree, while the even bits are simultaneously fed to an identical tree. The odd bit partials are left shifted to properly weight the result and added to the even partials before accumulating the aggregate. Since two bits are taken at a time, the scaling accumulator has to shift the feedback by 2 places This paralleling scheme can be extended to compute more than two bits at a time.

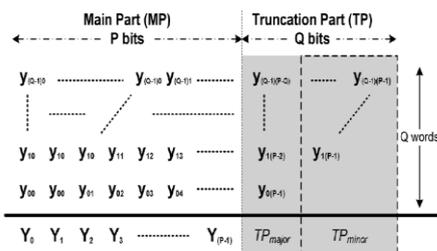

FIG 4: Q , P-bit words shifting and addition operations in parallel

In the extreme case, all input bits can be computed in parallel and then combined in a shifting adder tree. No scaling accumulator is needed in this case, since the output from the adder tree is the entire sum of products. This fully parallel implementation has a data rate that matches the serial clock, which can be greater than 100 MS/S in today's FPGAs. Most often, we have more than 4 product terms to accumulate. Increasing the size of the LUT might look attractive until you consider that the LUT size grows exponentially. Considering the construction of the logic we stuffed into the LUT, it becomes obvious that we can combine the results from the LUTs in an adder tree. The area of the circuit grows by roughly 2n-1 using adder trees to expand it rather than the 2ⁿ growth experienced by increasing LUT size. For FPGAs, the most efficient use of the logic occurs when we use the natural LUT size (usually a 4-LUT, although and 8-LUT would make sense if we were using an 8 input block RAM) for the LUTs and then add the outputs of the LUTs together in an adder tree. The Discrete cosine transform (DCT) is widely used in digital image processing, especially in image transform coding, as it performs much like the optimal Karhunen-Loeve transform (KLT) under a variety of criteria. Many algorithms for the computation of the DCT have been proposed since the introduction of the DCT by Ahmed, Natarajan, and Rao in 1974. However, though most of them are good software solutions to the realization of DCT, only a few of them are really suitable for VLSI implementation. Cyclic convolution plays an important role in digital signal processing due to its nature of easy implementation. Specifically, there exists a number of well-developed convolution algorithms and it can be easily realized through modular and structural hardware such as

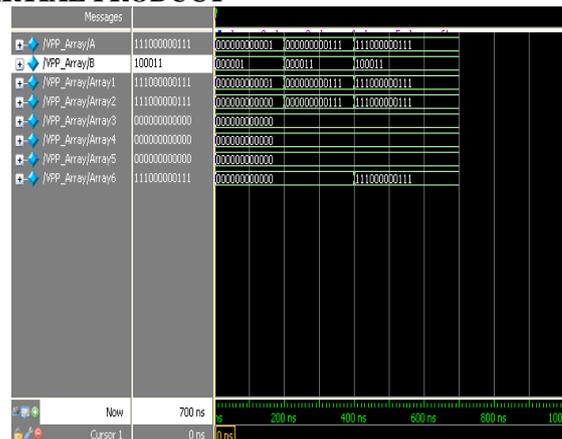

distributed arithmetic and systolic array . The way of data movement forms a significant part in the determination of the efficiency of the realization of a transform using the distributed arithmetic. The realization of a cyclic convolution with the distributed arithmetic requires only simple table look-up technique and some simple rotations of the corresponding data set. Hence, the cyclic convolution structure can be considered as the simplest form that is most suitable to be realized with the distributed arithmetic. It is because of this reason, one may consider that the basic criterion for the realization of a transform using the distributed arithmetic relies on the possibility of having an efficient way to convert the transform into the cyclic convolution form. If we could be able to convert a transform into the cyclic convolution form with the minimum number of operations, it would imply an optimal approach for the realization of the transform using the distributed arithmetic. Some basic formulations have been suggested for the realization of the DCT using the distributed arithmetic. In their formulations, they either still required some extra multiplications for their formulations or have to use cyclic convolutions of different lengths . The former case has the major problem that it violates the major advantage of the distributed arithmetic which replaces multiplications by additions. The latter case requires relatively complicated circuitry to allow the realization of cyclic convolutions of variable lengths. Different from the above approaches, one may also convert the DCT into the Discrete Fourier Transform (DFT) and make use of the famous algorithms to convert the corresponding DFT into cyclic convolution form. Indeed, this is a possible approach; however, it turns a real transform into a transform with complex numbers. The realization could still be complicated even if some simplification techniques are to be applied.

APPLICATIONS

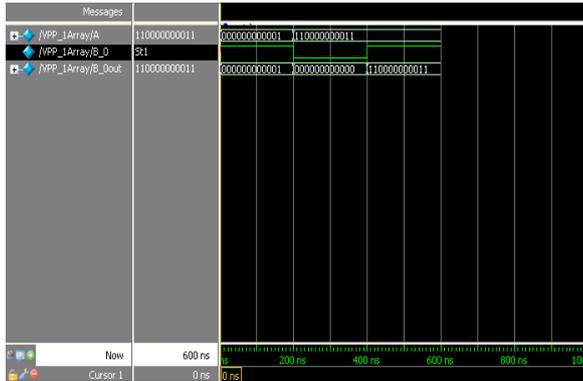

The DCT core can be utilized for a variety of multimedia applications including:

- Office automation equipment (Multifunction printers, digital copiers etc)
- Digital cameras & camcorders
- Video production, video conference
- Surveillance systems

VI. CONCLUSIONS

This paper presents an FPGA implementation of efficient architecture for computing the 2-D DCT with distributed arithmetic. The proposed architecture requires less hardware than conventional architectures which use the original DCT algorithm or the even-odd frequency decomposition method. The modules of the transpose memory and parallel Distributed Arithmetic 2-D DCT architecture were designed and synthesized. The paper contributed with specific simplifications in the multiplier stage, by using shift and adds method, which lead to hardware simplification and speed up over architecture.

Characterization of Fatty Acid Used In Soap Manufacturing In Nigeria: Laundry, Toilet, Medicated and Antiseptic Soap

¹P. Oghome, ²M. U. Eke and ³C.I.O.Kamalu

^{1,3}Department of Chemical Engineering, Federal University of Technology,
P. M. B 1526, Oweeri. ²Quality Control Dept. PZ Cussion, Aba. Coresponding

Abstract: This study characterized the fatty acids in Nigeria made soap ranging from medicated, antiseptic, toilet and laundry soaps. Each sample after preparation was analyzed in a gas chromatography to obtain the chromatogram. The fatty acid distribution in Delta soap showed that palmitic acid (C_{16}) has the highest percentage of 40.48 % approximate followed by oleic acid ($C_{18,1}$), 34.35 % approximate. In Temosol, oleic acid has the highest percentage of 39.35 % approximate and next to it was palmitic acid, 29.11 % approximate. Carex antiseptic soap also contain $C_{18,1}$ and C_{16} as the dominant fatty acid with percentage of 36.06 % and 29.96 % approximate respectively. The dominant fatty acids in Jumbo tab and Truck bar (laundry) are $C_{18,1}$ and C_{16} . Jumbo tab contains 43.47 % C_{16} and 36.20 % $C_{18,1}$ approximate. While Truck bar contains 43.89 % and 31.73 % approximate of oleic and palmitic acids respectively. Lux and Joy soap also contain comparable fatty acids. In Lux, oleic acid is 41.51 %, palmitic acid is 26.70 % approximate. In Joy, oleic acid is 40.60 % and palmitic acid 24.99 % approximate. Other fatty acids present in the soap sample were shown. Eleven different fatty acids were found in the soap analyzed. They are capric, caprylic, lauric, myristic, myristoleic, palmitic, plamitoleic, stearic, oleic, linoleic and linolenic acids.

Keywords: Characterization, fatty acids, fats and oil, soap, chromatography

I. Introduction

Fatty acids are merely carboxylic acids with long hydrocarbon chains. The hydrocarbon chains length may vary from 10-30 carbons (mostly 12-18). The non-polar hydrocarbon alkane chain is an important counterbalance to the polar acid functional group. In acids with only a few carbons, the acid functional group dominates and gives the whole molecule a polar character. However, in fatty acids, the non-polar hydrocarbon chain gives the molecule a non-polar character.

There are two groups of fatty acids: the saturated and the unsaturated. Beef fat contains mainly the saturated fatty acid while olive oil contains the unsaturated fatty acids.

Soap is a function of acids and fatty acids are functions of fats and oil. In the simplest sense, oils that are solid at room temperature are hard whereas those that are liquid at room temperature are soft. The degree of hardness and softness differs according to their sources and other parameters. Oils that are hard contributes to hardness and/or lather in soap. Oils that are soft contribute to conditioning. Oils are made up mainly of a variety of fatty acids. The main conditioning fatty acids are oleic (1 unsaturated bonds), linoleic (2 unsaturated bonds) and linolenic (3 unsaturated bonds). The more unsaturated bonds, the better the conditioning and the more easily it is absorbed by the skin, but the softer the oil is in soap, the more prone to oxidation. Making soap therefore means choosing a combination of oils with different degrees of hard/soft, conditioning and leather, to get the particular product that fits you best. www.soap-making-resource.com/fatty-acids. The aim of this project is to extract and characterize the fatty acid in the finished soaps, thereby identifying their sources; evaluation of fats/oils used in soap manufacturing. Evaluation of blending of fats/oils in soap making, and possible reasons why that blend was adopted. Another objective of this work is to determine the properties of the fatty acids by running a gas chromatography which will

reveal their chain length and based on their chain length, the source could be traced.

Fats and oil as well as their blends are used in the manufacturing of soaps in Nigeria. These fats are of vegetable or animal origin. Their use in soap manufacturing is determined by: Cost, Availability; Easy of handle; Government Policy and functioning of the fatty acids in soap. Therefore, this project becomes important in the sense that the fats/oils, the precursor of fatty acids should be carefully studied so as to know their cost relative to the manufacture, the sources of the soap menu in terms of the fatty acids will be ascertained and the sources that are readily available should be recommended. The functioning of the fatty acids in soap will also be determined by carefully studying their characteristics and properties. By knowing their properties, the handling of the fatty acids and the soap in general in terms of storage, packing, transportation etc will be overcome.

According to Roman Legend, soap was named after mount Sapo, and ancient site of animal sacrifices. After an animal sacrifices, rain would wash the animal fat and ash that collected under the ceremonial alters down the slopes to the banks of the Tiber River. Women washing clothes in the river noticed that if they washed their clothes in certain parts of the river after a heavy rain their clothes were much cleaner (Ahmed) [2]. A soap-like material found in clay cylinders during the excavation of ancient Babylon is evidence that soap making was known as early as 2800 B.C. Inscriptions on the cylinders revealed that fats were boiled with ashes, a soap making method. It is generally agreed that the Hebrew word "borith" which has been translated as soap, is a generic term for any cleaning agent. By the second century A.D, the Greek physician, Galen, recommended soap for both medicinal and cleansing purposes. In other words, it is a substance, that when dissolved in water removed dirt from dirty materials. Scientifically, soap is one of the higher fatty acid or a mixture of such compound. A typical soap contains 80%

mixed oils and 20% coconut oil with about > 0.2% free alkali.

Soaps are water-soluble sodium or potassium salts of fatty acids. Soaps are made from fats and oils or their fatty acids, by treating them chemically with a strong alkali. The fats and oils used in soap making come from animal or plant sources, each fat or oil is made up of a distinctive mixture of several different triglycerides. In a triglyceride molecule, three fatty acid molecules are attached to one molecule of glycerine. There are many types of triglyceride each type consist of its own particular combination of fatty acids. The fatty acids are the components of fats and oils that are used in making soap.

An alkali is a soluble salt of an alkali metal like sodium or potassium, originally, the alkalis used in soap making were obtained from the ashes of plants, but they are now made commercially. The common alkalis used in soap making are sodium hydroxide (NaOH), also called caustic soda and potassium hydroxide (KOH), (Kuye and Okorie) [4]. Saponification of fats and oils is the most widely used soap making process, the process involves heating fats and oils and reacting them with a liquid alkali to produce soap and water (neat soap) plus glycerine. Fats and oils are hydrolyzed (split) with a high pressure steam to yield crude fatty acids and glycerine. The fatty acids are then purified by distillation and neutralized with an alkali to produce soap and water (neat soap). When the alkali is sodium hydroxide sodium soap is formed. Sodium soaps are "hard" soaps. When the alkali is potassium hydroxide, potassium soap is formed. Potassium soaps are softer and are found in some liquid hand soaps and shaving creams. The carboxylate end of the soap molecule is attracted to water. It is called the hydrophilic (water-loving) end. The hydrocarbon chain is attracted to oil and grease and repelled by water. It is known as the hydrophobic (water-hating) end. (www.sdchg.org/cleaning/chemistry/) [5].

In soap making the properties of the fats and oils are important; the fatty acid composition in oil determines its properties (Nwoko) [6]. The acids may be distributed at random in the triglycerides. In the soap making, it's the fatty acid content that matters the most. The chain length (C number) is usually cited and helps describes the molecule's properties in relation to others in its same series. Saturated fatty acids contain no double bonds. They are stiff molecules which tend to increase the melting point of oils.

Saturated fatty acids themselves are solids at room temperature. As they increase in size from lauric to stearic, the melting point of the oil increases. Saturated fatty acids in soap have good cleaning properties and support foam. The longer chains also tend to harden soap. Unsaturated fatty acids are liquids. They tend to have good cleaning power, but lather poorly. These fatty acids also tend to make milder soaps (www.soap-making-resource.com/fatty-acids) [7]

II. Experimental

Apparatus/Reagents

The materials used include methanol, round bottom flask, Condenser, Electro-thermal heater, methanolic HCl; N-heptane; brine, syringes and Gas Chromatography. Four samples of soap: Laundry soap (Jumbo tab and Truck bar), Toilet soap (joy and lux); Medicated soap (Delta and Tetmosol); Antiseptic soap (Carex)

Procedure

0.8 g of each samples was weighed into the round bottom flask, 12 ml of methanol was added and the flask was connected to a condenser and heat applied with the help of electro thermal heater. The setup was allowed to reflux for 30 mins and 2 ml of methanolic HCl (prepared in the ratio 4:1) is added and the sample was allowed to reflux for another 30 min. At this point, the heater was turned off for 3 min in order to allow the sample to cool. 10 and 20 ml of N-heptane and brine were added respectively. The bottom portion (non-volatile) portion of the sample was run off with the help of separating funnel. Finally, the separated volatile portion was transferred into a test tube where 0.5µl was injected into the gas chromatography.

In the chromatography, the carrier gas, nitrogen, carries the sample into the packed column, made of the stationary phase where the fatty acids were adsorbed accordingly. As the sample was continuously introduced, the weakly adsorbed fatty acids was detected by the detector, amplified by the amplifier and was recorded by the recorder. The procedure was repeated for other samples.

III. Results and Discussion

The results obtained are presented in the following Tables.

Table 1: Retention Time, Peak Area and Fatty acid in Medicated Soap (Delta)

Table 8: Fatty acid distribution in different soap

Soaps	Type	Lauric	Palmitic	Stearic	Oleic
Joy	Toilet	10.98	24.99	13.40	40.60
Lux	Toilet	7.27	26.70	12.06	41.51
Jumbo tab	Laundry	1.81	45.47	5.29	36.20
Truck bar	Laundry	0.14	31.73	15.47	43.89
Delta	Medicated	9.27	40.48	2.56	34.95
Tetmosol	Medicated	4.31	29.11	15.64	39.35
Carex	Antiseptic	12.21	26.96	17.12	36.06

Delta and tetmosol soap after the analysis yielded the result shown in Tables 1 and 2. From the result, it was seen that both of them had C₈-C_{18:2} in common but tetmosol had in addition C_{16:1} and C_{18:3}. It was also shown by analysis that the major fatty acids has the highest peak in the chromatogram as shown in Figures 1 and 2 respectively. Of the two soaps, the major fatty acids, oleic and palmitic acid in tetmosol was traced to tallow and palm kernel oil (PKO). Whereas that of Delta soap, was traced to palm oil and palm kernel oil. These fatty acids gave the soaps its characteristics. Hence, delta soap is more active than tetmosol. Their values are for tetmosol palmitic (C₁₆, 29.11%), oleic (C_{18:1}, 39.35%) it also contains the following fatty acids in lesser amounts; caprylic acid (C₈, 0.57%), capric acid (C₁₀, 0.34%), lauric acid (C₁₂, 4.31%), myristic (C₁₄, 4.99%), palmitoleic (C_{16:1}, 1.79%), stearic acid (C₁₈, 15.64%), linoleic (C_{18:2}, 3.74%), linolenic (C_{18:3}, 0.17%), whereas for delta soap, palmitic, 40.48% and oleic, 34.95% dominates, while caprylic (C₈, 0.55%), capric (C₁₀, 0.43%), lauric acid (C₁₂, 9.27%), myristic acid (C₁₄, 3.89%), palmitic acid (C₁₆, 40.48%), oleic acid (C₁₈, 2.56%), linoleic acid (C_{18:1}, 34.95%), linolenic acid (C_{18:2}, 7.86%) are in lesser quantity.

It was found from the chromatogram that carex soap contain 12.21% lauric acid, 26.96% palmitic acid, 17.12% stearic acid, 36.06% oleic acid and 2.96% linoleic acid. Myristic (C₁₄, 3.34%), myristoleic (C_{14:1}, 0.28%), palmitoleic (C_{16:1}, 1.07%) in lesser amount (Table 3). These fatty acids were mainly from tallow.

The fatty acids present in Joy and Lux soap were shown in Tables 4 and 5 respectively. It was seen that Joy soap contains 10.98% lauric acid, 24.995% palmitic acid, 13.4% stearic acid and 40.60 % oleic acid. The lesser quantities are myristic (C₁₄, 2.84%), myristoleic (C_{14:1}, 0.37%), palmitoleic (C_{16:1}, 1.57% and linoleic (C_{18:2},

4.47%). While in Lux, the fatty acids found include 7.3% lauric, 26.70% palmitic, 12.06% stearic and 41.51% oleic acid, others are in lesser quantities caprylic (C₈, 0.22%), capric (C₁₀, 0.58%), myristic (C₁₄, 5.05%), palmitoleic (C_{16:1}, 1.70%) linoleic (C_{18:2}, 4.89%). The Joy fatty acids were mainly from tallow and palm oil while that of Lux was from tallow and PKO. From the analysis, it was clear that there was no much difference between Joy and Lux soap except myristoleic acid present in Joy alone and caprylic and capric present only in Lux. They share similar properties in their cleansing activities.

The analysis of Jumbo and Truck bar soaps were tabulated in Table 6 and 7 respectively. The result showed that palmitic acid present in Jumbo soap is 45.47% and oleic acid 36.20% and others caprylic (C₈ 0.15%), capric (C₁₀, 0.12%), Lauric (C₁₂, 1.81%), myristic (C₁₄, 1.73%), palmitoleic (C_{16:1}, 0.11%), stearic (C₁₈, 5.29%) and linoleic (C_{18:2}, 8.74%) in minor quantities, whereas in Truck bar soap, it is 31.73% palmitic acid, 43.89% oleic acid and 15.47% stearic acid, it also contain the following fatty acids in lesser quantities, lauric acid (C₁₂, 0.14%), myristic (C₁₄, 3.97%), myristoleic (C_{14:1}, 0.28%), palmitoleic (C_{16:1}, 2.17%), linoleic (C_{18:2}, 2.35%). The major source of the Jumbo tab fatty acid is tallow while that of truck bar is tallow and PKO.

It was obvious from the analysis that, every soap whether medicated, antiseptic, toilet, and laundry is a function of palmitic and oleic acid. The soap samples analysed also had fatty acids with carbon atoms in the neighborhood of C₈, C₁₀, C₁₂, and C₁₄ in very little quantities. Although the soaps analyzed had palmitic and oleic acids as their major fatty acid, they were in different percentage composition as shown in Table 8.

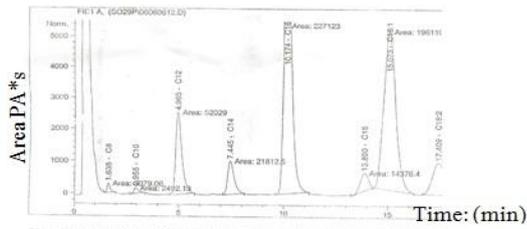

Figure 1: Determination of fatty acid in Delta Soap

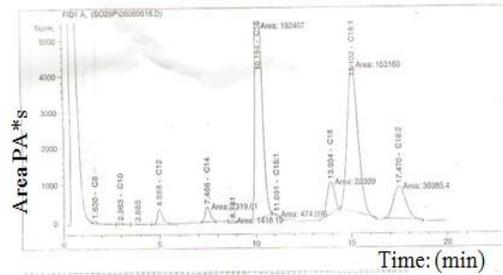

Figure 6: Determination of fatty acid in Jumbo Soap

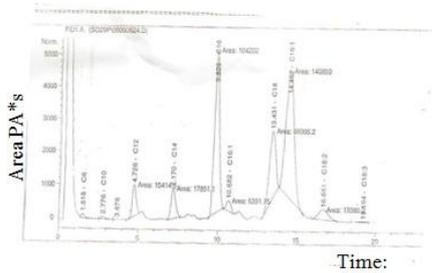

Figure 2: Determination of fatty acid in Tetmosol

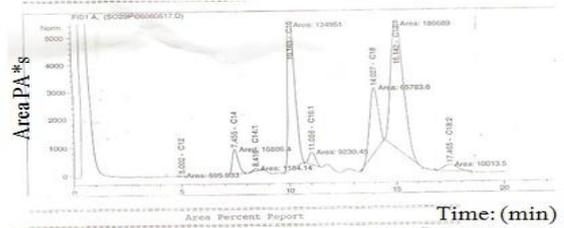

Figure 6: Determination of fatty acid in Truck Soap

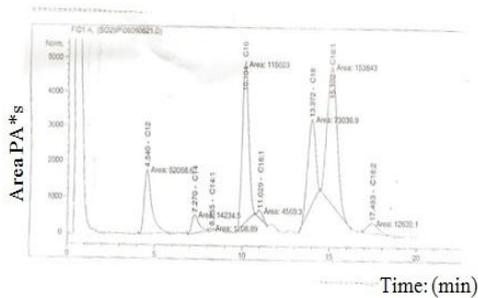

Figure 3: Determination of fatty acid in Carex Soap

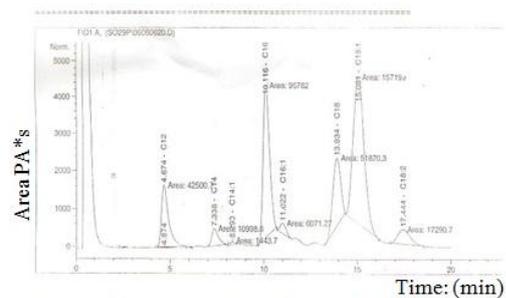

Figure 4: Determination of fatty acid in Joy Soap

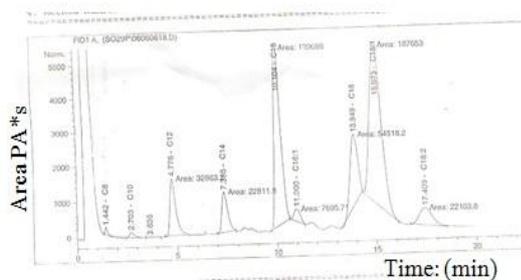

Figure 5: Determination of fatty acid in Lux Soap

IV. Conclusion

The chief fatty acids in soap making are lauric acid, myristic acid, palmitic acid, stearic acid oleic. They are obtained from mutton, tallow, beef tallow (animal fats), palm oil, and palm kernel oil. Joy, Lux, Delta and Carex soap have more percentage of lauric acid. Lauric acid is saturated fatty acids whose single bond helps in soap hardening. It also has good cleansing agent and supports foaming. The percentage of plamitoleic acid is between 0.00-2.20 percent. This acid is unsaturated. It makes soap to be mild, have good cleaning power but foams poorly. It was seen that palmitic acid can be saturated and unsaturated fatty acids, the C₁₆ and C_{16:1} respectively. Stearic acid i.e. the C₁₈ has three members the oleic acid C_{18:1}, the linoleic acid C_{18:2} and the linolenic acid C_{18:3}. The stearic itself is a saturated fatty acid while the other three are unsaturated fatty acids. They help increase mildness in soap.

Compressed Sensing Image Recovery Using Adaptive Nonlinear Filtering

B. Sravanthi¹, Ch. Madhuri Devi²

¹M.tech.Student, Sri Indu College of Engineering & Technology, Hyderabad
²Associate Professor, Sri Indu College of Engineering & Technology, Hyderabad

Abstract: Compressed sensing is a technique that consists providing efficient, stable and fast recovery algorithms which, in a few seconds, evaluate a good approximation of a compressible image from highly incomplete and noisy samples. In this paper, using adaptive nonlinear filtering strategies in an iterative framework can be avoiding the recovery image problem. In this technique has more efficient, stability and low computational cost. The experimental shows that the PSNR, CPU time and recovery image.

Index Terms—Compressed sensing, L_1 -minimization, median filters, nonlinear filters, sparse image recovery, total variation.

I. Introduction

Compressed sensing is a new paradigm for signal recovery and sampling. It states that a relatively small number of linear measurements of a sparse signal can contain most of its salient information and that the signal can be exactly reconstructed from these highly incomplete observations. The major challenge in practical applications of compressed sensing consists in providing efficient, stable and fast recovery algorithms which, in a few seconds, evaluate a good approximation of a compressible image from highly incomplete and noisy samples.

It follows that signals that have a sparse representation in a transform domain can be exactly recovered from these measurements by solving an optimization problem of the form

$$\Phi W^T \alpha = \Phi X \quad (1)$$

Here

Φ is an $M \times N$ measurement matrix and $\alpha = Wu$. The number M of given measurements for which we obtain the perfect recovery depends upon the length and the sparsity level K of the original signal, and on the acquisition matrix [1], [3]. If the unknown x signal has sparse gradient, it has been shown in [2], [3] that it can be recovered by casting problem (1) as

$$\Phi u = \Phi x \quad (2)$$

This formulation is particularly suited to the image recovery problem, since many images can be modeled as piece-wise-smooth functions containing a substantial number of jump discontinuities. Exact measurements are often not possible in real problems, so if the measurements are corrupted with random noise, namely we have

$$Y = \Phi x + e \quad (3)$$

Where e is the error signal and x is the input image. Sparse signals are an idealization that we rarely encounter in applications, but real signals are quite often compressible with respect to an orthogonal basis. This means that, if expressed in that basis, their coefficients exhibit exponential

decay when sorted by magnitude. As a consequence, compressible signals are well approximated by k -sparse signals and the compressed sensing paradigm guarantees that from M linear measurements we can obtain a reconstruction with an error comparable to that of the best possible k -terms approximation within the sparse fying basis [4][2].

In this paper is organized as follows. Proposed method in section II. Section III describes the comparative performance. The simulation results are presented in Section IV. Concluding remarks are made in Section V.

II. Proposed Method

In this paper, we consider an extension of this nonlinear filtering approach to the multi dimensional case. We focus on a recovery problem where the optimal solution, in addition to satisfying the acquisition constraints, has minimal “bounded variation norm,” namely, it minimizes. The optimal reconstruction is evaluated by solving a sequence of total variation regularized unconstrained sub problems, where both isotropic and anisotropic TV estimates have been considered.

The nonlinear filtering strategy has been proposed in the context of a penalized approach to the compressed sensing signal recovery problem. suitable filter is used according to the considered minimization problem and a fast flexible algorithm has been realized for its solution. The procedure of proposed method as shown below

- i) Initialization of parameters
- ii) Updating bound constrains
- iii) Apply constraint non linear filter step
- iv) Convergence test of proposed method
- v) Updating outer iteration

From a theoretical point of view, the non linear adaptive filter is attractive since it can deal with a general class of nonlinear systems while its output is still linear with respect to various higher power system coefficients.

First we initialize the all parameter values then start with the outer iterations. In outer iteration, the image reconstruction problems it is well known that image intensity values have to be not negative and $\leq R, R > 0$. This suggests that we could insert more information in the compressed sensing reconstruction problem by adding a bound constraint as shown below

$$T_s u = y \quad (4)$$

In the case of input data perturbed by additive white Gaussian noise with standard deviation σ

$$Y = S(Tx + e) = Tsx + e_s \quad (5)$$

Where e error value between original image and reconstruction image. After apply the outer iteration then to update the bound constraints as shown below

$$v_{k,i} = u_{k,i} + \beta T_S^T (y - T_S u_{k,i}) \tag{6}$$

Where

T_S is linear operator

$B < \alpha/2$

$V_{k,i}$ is the proximal operator argument

The third step of proposed method is the non linear filter step. The equation of non linear filter as shown below

$$u_{k,i+1} = \arg \min_{u \in C} \left\{ \frac{1}{2} \lambda_{k,i} \beta \|u - v_{k,i}\|_2^2 + F(u) \right\} \tag{7}$$

The fourth step of proposed method is convergence test. In convergence test, The general compressed sensing problem can now be stated using the previous notations. The input data can be represented as

$$Y = T_s x \tag{8}$$

In the case of input data perturbed by additive white Gaussian noise with standard deviation σ in equation (5). If $F(u)$ contains an L-norm the optimization problems can be very difficult to solve directly, due to the nondifferentiability of $F(u)$. To overcome this problem we use the well known penalization approach that considers a sequence of un-constrained minimization sub problems of the form

$$\min_{u \in \mathbb{R}^{N_1 \times N_2}} \left\{ F(u) + \frac{1}{2\lambda_k} \|T_S u - y\|_2^2 \right\} \tag{9}$$

The convergence of the penalization method to the solution of the original constrained problem has been established (under very mild conditions) $\lim \lambda_k = 0$ when. Unfortunately, in general, using very small penalization parameter values makes the unconstrained sub problems very ill-conditioned and difficult to solve. In the present context, we do not have this limitation, since we will approach these problems implicitly, thus, avoiding the need to deal with ill-conditioned linear systems. This is obtained by evaluating an approximation of the solution of (9) iteratively, using an operator splitting strategy (frequently considered in the literature to solve ℓ_1 -regularized problems [5], [6], [7], [8]), and taking advantage of the particular structure of the resulting problems.

III. Comparative Performance

To assess the performance of the proposed filters for removal of noise and to evaluate their comparative performance, different standard performance indices have been used in the thesis. These are defined as follows:

Peak Signal to Noise Ratio (PSNR): It is measured in decibel (dB) and for gray scale image it is defined as:

$$\text{PSNR (dB)} = 10 \log_{10} \left[\frac{\sum_i \sum_j 255^2}{\sum_i \sum_j (S_{i,j} - \hat{S}_{i,j})^2} \right] \tag{8}$$

$S_{i,j}$ and $\hat{S}_{i,j}$ are the input and reconstruction images. The higher the PSNR in the restored image, the better is its quality.

Signal to Noise Ratio Improvement (SNRI): SNRI in dB is defined as the difference between the Signal to Noise

Ratio (SNR) of the restored image in dB and SNR of original image in dB i.e.

SNRI (dB) = SNR of restored image in dB - SNR of noisy image in dB

Where,

SNR of restored image dB =

$$10 \log_{10} \left[\frac{\sum_i \sum_j S_{i,j}^2}{\sum_i \sum_j (S_{i,j} - \hat{S}_{i,j})^2} \right] \tag{9}$$

The higher value of SNRI reflects the better visual and restoration performance.

IV. EXPERIMENTAL RESULTS

V. CONCLUSION

In this paper, avoiding the reconstruction image problem using non linear filter technique and prove the convergence of the resulting two-steps iterative scheme. In this paper, different kinds of measurements and different choices of the function $F(u)$. In fact, since this function plays the role of the penalty function in the variational approach of the image denoising problem, it is possible to exploit the different proposals of the denoising literature in

order to select new filtering strategies and the references therein), perhaps more suited to the different practical recovery problems.

Abstract : This paper represents The algebraic soft-decoding (ASD) of Reed–Solomon (RS) codes provides significant coding gain over hard-decision decoding with polynomial complexity. The low-complexity chase (LCC) algorithm is proposed for reducing the complexity of interpolation, which interpolates over 2^n test vectors, being attractive for VLSI implementation. The interpolation is simplified in LCC decoding by restricting the multiplicity to $m=1$ and replacing the factorization step with Chien's search and Forney's algorithm. In this paper, high-throughput interpolator architecture for soft-decision decoding of Reed–Solomon (RS) codes based on low-complexity chase (LCC) decoding is presented. We have formulated a modified form of the Nielson's interpolation algorithm, using some typical features of LCC decoding. The proposed algorithm works with a different scheduling, takes care of the limited growth of the polynomials, and shares the common interpolation points, for reducing the latency of interpolation. Based on the proposed modified Nielson's algorithm we have derived low-latency architecture to reduce the overall latency of the whole LCC decoder. An efficiency is low, in terms of area-delay product, has been achieved by an LCC decoder, by using the proposed interpolator architecture, over the best of the previously reported architectures for an RS(255,239) code with eight test vectors.

Keyword: RScodes, Guruswami-Sudan algorithm, Registers, Multiplexers, D-flipflop.

I. INTRODUCTION

2. Interpolation

3. Factorization of bivariate polynomials

It's being the interpolation and the most computation-intensive one. Several architectures based on Nielson's algorithm and Lee–O'Sullivan algorithm are found in the literature for the VLSI implementation of interpolation stage. However, their hardware complexity is still high. An interpolation architecture for LCC with $m=3$, called backward interpolation, is proposed in [9], which could be considered as the best of the current approaches. Backward interpolator shares the computation of common points of the test vectors. These points are ordered in such way that a pair of adjacent vectors differ only at one point.

Due to this feature, the backward interpolation architecture involves less area and provides higher speed than its prior ones.

II. REED SOLOMON SOFTWARE PERFORMANCE

The following data details performance numbers for a number of specific RS (n, k) implementations for two general purpose processing architectures and one digital signal processor. Numbers are provided for both decode in the presence of no error, as well as decode in the presence of maximum channel error. Note that correcting errors requires more processing power than simply validating blocks, and that the required processing power increases linearly with the error rate. Typical applications tend to keep the error rate low such that active correction is not required. The two digit hexadecimal number in each column specifies the GF (255) primitive polynomial used to generate the underlying Galois field. In 1960, Irving Reed and Gus Solomon published a paper in the Journal of the Society for Industrial and Applied Mathematics. This paper described a new class of error-correcting codes that are now called Reed-Solomon (R-S) codes. These codes have great power and utility, and are today found in many applications from compact disc players to deep-space applications. This article is an attempt to describe the paramount features of R-S codes and the fundamentals of how they work. Reed-Solomon codes are non-binary cyclic codes with symbols made up of m-bit Sequences, where m is any positive integer having a value greater than 2. R-S (n, k) codes on m-bit symbols exist for all n and k for which $0 < k < n < 2m + 2$

Where k is the number of data symbols being encoded, and n is the total number of code symbols in the encoded block. For the most conventional R-S (n, k) code, $(n, k) = (2m - 1, 2m - 1 - 2t)$

Where t is the symbol-error correcting capability of the code, and $n - k = 2t$ is the number of parity symbols. An extended R-S code can be made up with $n = 2m$ or $n = 2m + 1$, but not any further. Reed-Solomon codes achieve the largest possible code minimum distance for any linear code with the same encoder input and output block lengths. For non-binary codes, the distance between two code words is defined (analogous to Hamming distance) as the number

of symbols in which the sequences differ. For Reed-Solomon codes, the code minimum distance

$$d_{min} = n - k + 1$$

The code is capable of correcting any combination of t or fewer errors, where t can be expressed as

$$T = \lfloor (d_{min}-1) / 2 \rfloor = \lfloor (n-k) / 2 \rfloor$$

where $\lfloor x \rfloor$ means the largest integer not to exceed x . Equation illustrates that for the case of R-S codes, correcting t symbol errors requires no more than $2t$ parity symbols. Equation lends itself to the following intuitive reasoning. One can say that the decoder has $n - k$ redundant symbols to “spend,” which is twice the amount of correctable errors. For each error, one redundant symbol is used to locate the error, and another redundant symbol is used to find its correct value. The erasure-correcting capability, ρ , of the code is

$$\rho = d_{min} - 1 = n - k \quad (5)$$

Simultaneous error-correction and erasure-correction capability can be expressed as follows:

$$2\alpha + \gamma < d_{min} < n - k \quad (6)$$

Where α is the number of symbol-error patterns that can be corrected and γ is the number of symbol erasure patterns that can be corrected. An advantage of non-binary codes such as a Reed-Solomon code can be seen by the following comparison. Consider a binary $(n, k) = (7, 3)$ code. The entire n -tuple space contains $2^n = 2^7 = 128$ n -tuples, of which $2^k = 2^3 = 8$ (or $1/16$ of the n -tuples) are code words. Next, consider a non-binary $(n, k) = (7, 3)$ code where each symbol is composed of $m = 3$ bits. The n -tuple space amounts to $2^{nm} = 2^{21} = 2,097,152$ n -tuples, of which $2^{km} = 2^9 = 512$ (or $1/4096$ of the n -tuples) are code words. When dealing with non-binary symbols, each made up of m bits, only a small fraction (i.e., 2^{km} of the large number 2^{nm}) of possible n -tuples are code words. This fraction decreases with increasing values of m . The important point here is that when a small fraction of the n -tuple space is used for code words, a large d_{min} can be created. Any linear code is capable of correcting $n - k$ symbol erasure patterns if the $n - k$ erased symbols all happen to lie on the parity symbols. However, R-S codes have the remarkable property that they are able to correct any set of $n - k$ symbol erasures within the block. R-S codes can be designed to have any redundancy. However, the complexity of a high-speed implementation increases with Reed-Solomon Codes redundancy. Thus, the most attractive R-S codes have high code rates (low redundancy).

2.1 REED-SOLOMOERROR PROBABILITY

The Reed-Solomon (R-S) codes are particularly useful for burst-error correction; that is, they are effective for channels that have memory. Also, they can be used efficiently on channels where the set of input symbols is large. An interesting feature of the R-S code is that as many as two information symbols can be added to an R-S code of length n without reducing its minimum distance.

For R-S codes, error probability is an exponentially decreasing function of block length, n , and decoding complexity is proportional to a small power of the block length. The R-S codes are sometimes used in a concatenated arrangement. In such a System, an inner convolution decoder first provides some error control by operating on soft-decision demodulator outputs; the convolutional decoder then presents hard-decision data to

the outer Reed-Solomon decoder, which further reduces the probability of error.

2.2 FINITE FIELDS

In order to understand the encoding and decoding principles of non binary codes, such as Reed-Solomon (R-S) codes, it is necessary to venture into the area of finite fields known as Galois Fields (GF). For any prime number, p , there exists a finite field denoted $GF(p)$ that contains p elements. It is possible to extend $GF(p)$ to a field of p^m elements, called an extension field of $GF(p)$, and denoted by $GF(p^m)$, where m is a nonzero positive integer. Note that $GF(p^m)$ contains as a subset the elements of $GF(p)$. Symbols from the extension field $GF(2^m)$ are used in the construction of Reed-Solomon (R-S) codes. The binary field $GF(2)$ is a subfield of the extension field $GF(2^m)$, in much the same way as the real number field is a subfield of the complex number field. Besides the numbers 0 and 1, there are additional unique elements in the extension field that will be represented with a new symbol α . Each nonzero element in $GF(2^m)$ can be represented by a power of α . An infinite set of elements, F , is formed by starting with the elements $\{0, 1, \alpha\}$, and generating additional elements by progressively multiplying the last entry by α , which yields the following:

$$F = \{0, 1, \alpha, \alpha^2, \dots, \alpha^j, \dots\} = \{0, \alpha^0, \alpha^1, \alpha^2, \dots, \alpha^j, \dots\}$$

To obtain the finite set of elements of $GF(2^m)$ from F , a condition must be imposed on F so that it may contain only 2^m elements and is closed under multiplication. The condition that closes the set of field elements under multiplication is characterized by the irreducible polynomial shown below:

$$\alpha^{(2^m-1)} + 1 = 0$$

or equivalently Using this polynomial constraint, any field element that has a power equal to or greater than $2^m - 1$ can be reduced to an element with a power less than $2^m - 1$, as follows:

$$\alpha^{(2^m+n)} = \alpha^{(2^m-1)} \alpha^{n+1} = \alpha^{n+1}$$

2.3 ADDITION IN THE EXTENSION FIELD GF(2M)

Each of the 2^m elements of the finite field, $GF(2^m)$, can be represented as a distinct polynomial of degree $m - 1$ or less. The degree of a polynomial is the value of its highest-order exponent. We denote each of the nonzero elements of $GF(2^m)$ as a polynomial, $a_i(X)$, where at least one of the m coefficients of $a_i(X)$ is nonzero. For $i = 0, 1, 2, \dots, 2^m - 2$,

$$a_i = a_i(X) = a_{i,0} + a_{i,1}X + a_{i,2}X^2 + \dots + a_{i,m-1}X^{m-1}$$

Consider the case of $m = 3$, where the finite field is denoted $GF(2^3)$. the mapping (developed later) of the seven elements $\{a_i\}$ and the zero element, in terms of the basis elements $\{X^0, X^1, X^2\}$ described. Since Equation (10) indicates that $\alpha^0 = \alpha^7$, there are seven nonzero elements or a total of eight elements in this field. Each row in the mapping comprises a sequence of binary values representing the coefficients $a_{i,0}$, $a_{i,1}$, and $a_{i,2}$ in Equation (14). One of the benefits of using extension field elements $\{a_i\}$ in place of binary elements is the compact notation that facilitates the mathematical representation of nonbinary encoding and decoding processes. Addition of two elements of the finite field is then defined as the

modulo-2 sum of each of the polynomial coefficients of like powers,

$$a_i + a_j = (a_i, 0 + a_j, 0) + (a_i, 1 + a_j, 1) X + \dots + (a_i, m - 1 + a_j, m - 1) X^{m-1}$$

2.4 A PRIMITIVE POLYNOMIAL IS USED TO DEFINE THE FINITE FIELD

A class of polynomials called primitive polynomials is of interest because such functions define the finite fields $GF(2^m)$ that in turn are needed to define R-S codes. The following condition is necessary and sufficient to guarantee that a polynomial is primitive. An irreducible polynomial $f(X)$ of degree m is said to be primitive if the smallest positive integer n for which $f(X)$ divides $X^n + 1$ is $n = 2^m - 1$. Note that the statement A divides B means that A divided into B yields a nonzero quotient and a zero remainder. Polynomials will usually be shown low order to high order. Sometimes, it is convenient to follow the reverse format.

2.4.1 ENCODER

The Reed-Solomon encoder reads in k data symbols, computes the $n - k$ parity symbols, and appends the parity symbols to the k data symbols for a total of n symbols. The encoder is essentially a $2t$ tap shift register where each register is m bits wide. The multiplier coefficients are the coefficients of the RS generator polynomial. The general idea is the construction of a polynomial; the coefficients produced will be symbols such that the generator polynomial will exactly divide the data/parity polynomial.

2.4.2 DECODER

The Reed-Solomon decoder tries to correct errors and/or erasures by calculating the syndromes for each codeword. Based upon the syndromes the decoder is able to determine the number of errors in the received block. If there are errors present, the decoder tries to find the locations of the errors using the Berlekamp-Massey algorithm by creating an error locator polynomial. The roots of this polynomial are found using the Chien search algorithm. Using Forney's algorithm, the symbol error values are found and corrected. For an RS (n, k) code where $n - k = 2t$, the decoder can correct up to t symbol errors in the code word. Given that errors may only be corrected in units of single symbols (typically 8 data bits), Reed-Solomon coders work best for correcting burst errors.

2.5 REED-SOLOMON ENCODING

The most conventional form of Reed-Solomon (R-S) codes in terms of the parameters n , k , t , and any positive integer $m > 2$.

$$(n, k) = (2m - 1, 2m - 1 - 2t) \quad (20)$$

where $n - k = 2t$ is the number of parity symbols, and t is the symbol-error correcting capability of the code. The generating polynomial for an R-S code takes the following form:

$$g(X) = g_0 + g_1 X + g_2 X^2 + \dots + g_{2t-1} X^{2t-1} + X^{2t} \quad (21)$$

The degree of the generator polynomial is equal to the number of parity symbols. R-S codes are a subset of the Bose, Chaudhuri, and Hocquenghem (BCH) codes; hence, it should be no surprise that this relationship between the

degree of the generator polynomial and the number of parity symbols holds, just as for BCH codes. Since the generator polynomial is of degree $2t$, there must be precisely $2t$ successive powers of α that are roots of the polynomial. We designate the roots of $g(X)$ as $\alpha, \alpha^2, \dots, \alpha^{2t}$. It is not necessary to start with the root α ; starting with any power of α is possible.

2.6 ENCODING IN SYSTEMATIC FORM

Since R-S codes are cyclic codes, encoding in systematic form is analogous to the binary encoding procedure. We can think of shifting a message polynomial, $m(X)$, into the rightmost k stages of a codeword register and then appending a parity polynomial, $p(X)$, by placing it in the leftmost $n - k$ stages. Therefore we multiply $m(X)$ by X^{n-k} , thereby manipulating the message polynomial algebraically so that it is right-shifted $n - k$ positions. Next, we divide $X^{n-k} m(X)$ by the generator polynomial $g(X)$, which is written in the following form:

$$X^{n-k} m(X) = q(X) g(X) + p(X)$$

where $q(X)$ and $p(X)$ are quotient and remainder polynomials, respectively. As in the binary case, the remainder is the parity. Equation can also be expressed as follows:

$$p(X) = X^{n-k} m(X) \text{ modulo } g(X)$$

The resulting codeword polynomial, $U(X)$ can be written as

$$U(X) = p(X) + X^{n-k} m(X)$$

2.6.1 SYSTEMATIC ENCODING WITH AN $(N-K) -$ STAGE SHIFT REGISTER

Using circuitry to encode a three-symbol sequence in systematic form with the $(7, 3)$ R-S code described by $g(X)$ in the implementation of a linear feedback shift register (LFSR) circuit. It can easily be verified that the multiplier terms taken from left to right, correspond to the coefficients of the polynomial in low order to high order. This encoding process is the non-binary equivalent of cyclic encoding. Here, corresponding to the $(7, 3)$ R-S nonzero code words are made up of $2m - 1 = 7$ symbols, and each symbol is made up of $m = 3$ bits.

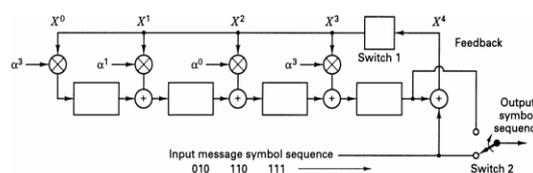

Fig 1: SYSTEMATIC ENCODING WITH LFSR

Here the example is non-binary, so that each stage in the shift register of Figure holds a 3-bit symbol. In the case of binary codes, the coefficients labeled g_1, g_2 , and so on are binary. Therefore, they take on values of 1 or 0, simply dictating the presence or absence of a connection in the LFSR. However in Figure 9, since each coefficient is specified by 3-bits, it can take on one of eight values. The non-binary operation implemented by the encoder of Figure, forming code words in a systematic format, proceeds in the same way as the binary one. The steps can be described as follows:

1. Switch 1 is closed during the first k clock cycles to allow shifting the message symbols into the (n - k)-stage shift register.
2. Switch 2 is in the down position during the first k clock cycles in order to allow simultaneous transfer of the message symbols directly to an output register.
3. After transfer of the kth message symbol to the output register, switch 1 is opened and switch is moved to the up position.
4. The remaining (n - k) clock cycles clear the parity symbols contained in the shift register by moving them to the output register.
5. The total number of clock cycles is equal to n, and the contents of the output register is the codeword polynomial $p(X) + X^{n-k}m(X)$, where $p(X)$ represents the parity symbols and $m(X)$ the message symbols in polynomial form.

2.7 REED-SOLOMON DECODING

Earlier, a test message encoded in systematic form using a (7, 3) R-S code resulted in a codeword polynomial described. Now, assume that during transmission this codeword becomes corrupted so that two symbols are received in error. This number of errors corresponds to the maximum error-correcting capability of the code. For this seven-symbol codeword example, the error pattern, $e(X)$, can be described in polynomial form as follows:

$$e(x) = \sum_{n=0}^6 e_n X^n$$

For this example, let the double-symbol error be such that one parity symbol has been corrupted with a 1-bit error (seen as α^2), and one data symbol has been corrupted with a 3-bit error (seen as α^5). The received corrupted-codeword polynomial, $r(X)$, is then represented by the sum of the transmitted-codeword polynomial and the error-pattern polynomial as follows:

$$r(X) = U(X) + e(X)$$

Following Equation, we add $U(X)$

$$R(x) = (100) + (001)x + (011)x^2 + (100)x^3 + (101)x^4 + (110)x^5 + (111)x^6$$

In this example, there are four unknowns—two error locations and two error values. Notice an important difference between the nonbinary decoding of $r(X)$ that we are faced with in Equation and binary decoding; in binary decoding, the decoder only needs to find the error locations. Knowledge that there is an error at a particular location dictates that the bit must be “flipped” from 1 to 0 or vice versa. But here, the non-binary symbols require that we not only learn the error locations, but also determine the correct symbol values at those locations. Since there are four unknowns in this example, four equations are required for their solution.

2.7.1 ERROR LOCATION

Suppose there are v errors in the codeword at location $X^{j1}, X^{j2}, \dots, X^{jv}$. Then, the error polynomial $e(X)$ shown

$$E(x) = e_{j1}x^{j1} + e_{j2}x^{j2} + \dots + e_{jv}x^{jv}$$

The indices 1, 2, ... v refer to the first, second, ..., vth errors, and the index j refers to the error location. To correct the corrupted codeword, each error value e_{jl} and its location X^{j1} , where $l = 1, 2, \dots, v$, must be determined. We define an error locator number as $j1 \beta = \alpha$. Next, we obtain the $n - k = 2t$ syndrome symbols by substituting α_i into the received polynomial for $i = 1, 2, \dots, 2t$

There are 2t unknowns (t error values and t locations), and 2t simultaneous equations. However, these 2t simultaneous equations cannot be solved in the usual way because they are nonlinear (as some of the unknowns have exponents). Any technique that solves this system of equations is known as a Reed-Solomon decoding algorithm.

III. LOW-COMPLEXITY CHASE DECODING OF RS CODES

Reed Solomon codes are error-correcting codes that have found wide-ranging applications throughout the fields of digital communication and storage. Some of which include:

- Storage Devices (hard disks, compact disks, DVD, barcodes, etc.)
- Wireless Communication (mobile phones, microwave links, etc.)
- Digital Television
- Broadband Modems (ADSL, xDSL, etc.)
- Deep Space and Satellite Communications Networks (CCSDS)

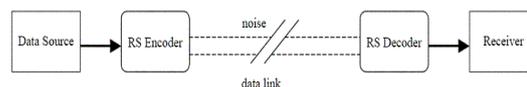

Fig 2: Applications of RS code

RS codes are systematic linear block codes, residing in a subset of the BCH codes called non-binary BCH. It is block because the original message is split into fixed length blocks and each block is split into m bit symbols; linear because each m bit symbol is a valid symbol; and systematic because the transmitted information contains the original data with extra CRC or 'parity' bits appended. These codes are specified as RS (n, k), with m bit symbols. This means that the encoder takes k data symbols of m bits each, appends n - k parity symbols, and produces a code word of n symbols (each of m bits).

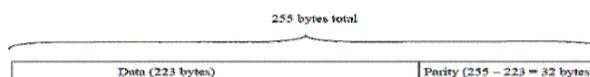

Fig 3: Modified REED SOLMON code

Reed Solomon codes are based on a specialized area of mathematics known as Galois fields (a.k.a. finite fields). These fields are of the form GF (p^m), where p is prime. RS makes use of Galois fields of the form GF (2^m), where elements of the field can be represented by m binary bits. Hence, RS codes of the form RS (2^8) lend themselves well to digital communication. Reed-Solomon codes are powerful error-correcting codes that can be found in a wide variety of digital communications systems, from digital media to wireless communications and deep-space probes. The ubiquitous nature of these codes continues to fuel

research into decoding algorithms some forty years after their introduction. Reed-Solomon codes have been employed in a wide spectrum of digital communications systems because they provide powerful error correction with only a small number of overhead symbols. Reed-Solomon codewords consist of non-binary symbols and therefore the correction of a single symbol could result in the correction of more than one of the constituent bits. For this reason, Reed-Solomon codes are well suited to the correction of burst errors. Classical decoders for Reed-Solomon codes of length n and dimension k can correct up to $t = \lfloor \frac{d_{\min}}{2} \rfloor$ errors where $d_{\min} = (n - k + 1)$ is the minimum distance of the code. Recently, a new class of list decoding algorithms has been introduced that can sometimes correct an even greater number of errors. The list decoding problem is to find the set of codewords at a Hamming distance of t_0 from the received word. If $t_0 > \frac{d_{\min}}{2}$ there might not be a unique codeword so the decoder returns a list of candidate codewords. The Guruswami-Sudan (GS) list decoding algorithm has t_0 as large as $n - p - nk$ errors. To improve the error-correction capability of a decoder even further, the decoder should take advantage of the soft reliability information available from the channel. Soft-decision decoders can provide an asymptotic gain of 2-3 dB on Gaussian channels and 10 dB or more on Rayleigh fading channels. Traditional hard-decision Reed-Solomon decoding algorithms are efficient because they are algebraic; that is, they exploit the underlying algebraic structure of the code to generate a system of equations that is solved using finite field arithmetic. However, an algebraic decoder based on finite field arithmetic does not appear to be compatible with the real-valued, soft information available from the channel and therefore it has been a research challenge to develop an algebraic soft-decision Reed-Solomon decoder. Koetter and Vardy have recently proposed an algebraic soft decision decoding algorithm by extending the list decoder of Guruswami and Sudan to include a method for converting soft information into algebraic conditions. The Koetter-Vardy (KV) algorithm can achieve up to about 4 dB of coding gain at a frame-error-rate (FER) of 10^{-3} on a Gaussian noise channel (with a practical range of 1-1.5 dB) and gains of 2-7 dB on a Rayleigh fading channel. The Koetter-Vardy soft-decision decoding procedure shows a lot of promise from the point of view of error correcting performance. At a first glance, the algorithm seems to be quite computationally complex and not straightforward to implement in VLSI. This paper aims to introduce techniques that reduce the complexity of interpolation-based decoders to the point where an efficient VLSI implementation is possible. A review of the GS and KV list-decoding algorithms. The techniques for significantly reducing the complexity and memory requirements of interpolation-based decoders. A VLSI architecture is then developed that reduces the complexity of evaluating the Hasse derivative, one of the main tasks in interpolation.

IV. INTERPOLATION-BASED LIST DECODING

ALGORITHM

We want to transmit a message f . The bits of the message can be grouped into $\log_2(q)$ -bit symbols chosen from the finite field with q elements, $GF(q)$. An (n, k) Reed-Solomon code over $GF(q)$ represents the k -symbol

message, $f = (f_0, f_1, f_2, \dots, f_{k-1})$ by an n -symbol codeword, $c = (c_0, c_1, c_2, \dots, c_{k-1}, \dots, c_{n-1})$, where $n > k$ and usually $n = q - 1$. The k symbols of the message f can be considered to be the coefficients of the up to degree $(k - 1)$ univariate message polynomial:

$$f(x) = f_0 + f_1x + f_2x^2 + \dots + f_{k-1}x^{k-1}.$$

We use the classical view of Reed-Solomon codes taken from the original definition, with this evaluation map encoding method, a codeword is formed by evaluating the message polynomial $f(x)$ at n elements of $GF(q)$. If the set of evaluation elements is $X = \{x_0, x_1, \dots, x_{n-1}\}$, the codeword c is:

$$c = (f(x_0), f(x_1), \dots, f(x_{n-1})), \quad x_i \in X.$$

We will always assume that $n = q - 1$ and the set of evaluation elements X is the set of nonzero elements of $GF(q)$:

$$X = \{x_0, x_1, x_2, \dots, x_{n-1}\} = \{1, \alpha, \alpha^2, \dots, \alpha^{n-1}\}$$

where α is a primitive n 'th root of unity. The evaluation map encoding method is useful because, it provides insight leading to interpolation-based decoding algorithms.

Guruswami-Sudan algorithm

An interpolation-based decoder takes the point of view that a codeword is a message polynomial evaluated at points in a finite field and uses polynomial interpolation to try to reconstruct that polynomial. The Guruswami-Sudan (GS) algorithm is an interpolation-based list decoder for Reed-Solomon codes. To describe the algorithm, we will first need to review some notation and facts about bivariate polynomials, which are the basic data structures in the algorithm. Consider the bivariate polynomial with coefficients chosen from a finite field:

$$P(x, y) = \sum_{a=0}^{\infty} \sum_{b=0}^{\infty} p_{a,b} x^a y^b \in GF(q)[x, y].$$

Consider the received word $y = c + e$, where e is an error vector with components drawn from $GF(q)$. Since each component of c was generated by evaluating $f(x)$ at a unique value of $x \in X$, a unique x_i can be associated with each received $y_i \in GF(q)$ to form the list of points,

$$L = \{(x_0, y_0), (x_1, y_1), \dots, (x_{n-1}, y_{n-1})\}.$$

If there is no noise ($e = 0$), then $y_i = f(x_i)$, $0 \leq i < n$, and a bivariate polynomial, $P(x, y) = y - f(x)$, passes through all the points in L with a multiplicity of one. This suggests that an interpolation-based approach can be used to decode Reed-Solomon codes. In the presence of noise ($e \neq 0$), the interpolation polynomial will pass through some points that are not part of the codeword. The GS algorithm ensures that under certain conditions, the codeword polynomial "lives inside" the interpolation polynomial [2, 3]. The GS algorithm is an interpolation-based list decoder with two main steps:

1. Interpolation Step: Given the set of points L and a positive integer m , compute $P(x, y)$ of $GF(q)[x, y] \setminus \{0\}$ of minimal $(1, k - 1)$ -weighted degree that passes through all the points in L with multiplicity at least m .

2. Factorization Step: Given the interpolation polynomial $P(x, y)$, identify all the factors of $P(x, y)$ of the form $y - f(x)$ with $\deg f(x) < k$. The output of the algorithm is a list of the code words that correspond to these factors.

A complete factorization of $P(x, y)$ is not necessary since we are just looking for linear y -roots of degree $< k$. An appropriate root-finding algorithm is given. The multiplicity, m , functions as a user-selectable complexity parameter. The error-correcting ability of the GS algorithm increases as the value of m increases. Unfortunately, so does the decoding complexity. Primitive polynomials are of interest here because they are used to define the Galois field.

A popular choice for a primitive polynomial is:

$$p(x) = x^8 + x^7 + x^2 + x^1 + 1$$

This is also known as the 0x87 polynomial, corresponding to the binary representation of the polynomial's coefficients excluding the MSB (i.e. 10000111). This specific polynomial is used in the CCSDS specification for a RS (255, 223). In GF (2⁸) there are 16 possible primitive polynomials.

The VOCAL implementation has the ability to perform all combinations of RS (n, k) [$n = 255$, and $0 < k < n$], for any of the 16 possible Galois fields, including the 0x87 field used by CCSDS. Additionally, the VOCAL RS modules can use any arbitrary generator polynomial for the calculation of the parity symbols.

V. REED SOLOMON IMPLEMENTATIONS

The implementations below can be customized to work with other RS (n, k) codes to yield similar results in performance. Optimized Software Implementation: The pure software implementation is dominated computationally by multiplication over a finite field (Galois Field multiplication). The encoder requires 71,181 cycles per codeword on a MIPS32 processor and the decoder requires 66,045 cycles. Scalar GF Multiply Support: This is the simplest form of VOCAL's hardware acceleration. The Scalar GF Multiply Support extends the capabilities of the MIPS32 processor by taking advantage of MIPS Technologies CorExtend capability to decrease the number of cycles to 23,305 cycles to encode and 9,174 cycles per codeword to decode on the MIPS32 processor. SIMD GF Multiply Support: The SIMD GF Multiply Support requires 128 bytes of local ROM Memory, but increases the performance to 3,918 cycles per megabit to encode and 3,078 cycles per codeword to decode. RS Encode Kernel. The RS Encode Kernel uses 1024 bytes of local ROM memory to encode. The number of cycles to process a codeword on a MIPS32 CPU falls to 2,702 cycles for encoding and decoding only consumes 828 cycles with this implementation.

5.1 METHODOLOGIES

Methodologies are the principles and explanations of High-Throughput Interpolator Architecture for Low-Complexity Chase Decoding of RS Codes. And here we have Five types of modules are used.

MODULES

1. Registers
2. Multiplexers

3. D-flipflop
4. Gf(2⁸) multiplier
5. Gf(2⁸) adder
6. Polynomial Evaluation
7. Polynomial update

MODULE DESCRIPTIONS

5.1.1 REGISTERS

Actual definition of Register is "a combinational of flip-flops". Flip-flops are used as data storage elements. Such data storage can be used for storage of computer science, and such a circuit is described as sequential logic. **Shift Register** is another type of sequential logic circuit that is used for the storage or transfer of data in the form of binary numbers and then "shifts" the data out once every clock cycle, hence the name "shift register". It basically consists of several single bits "D-Type Data Latches", one for each bit (0 or 1) connected together in a serial or daisy-chain arrangement so that the output from one data latch becomes the input of the next latch and so on. The data bits may be fed in or out of the register serially, i.e. one after the other from either the left or the right direction, or in parallel, i.e. all together. The number of individual data latches required to make up a single **Shift Register** is determined by the number of bits to be stored with the most common being 8-bits wide.

The Shift Register is used for data storage or data movement and are used in calculators or computers to store data such as two binary numbers before they are added together, or to convert the data from either a serial to parallel or parallel to serial format. The individual data latches that make up a single shift register are all driven by a common clock signal making them synchronous devices. Generally, shift registers operate in one of four different modes with the basic movement of data through a shift register being:

- **Serial-in to Parallel-out** - In this serial-in to parallel-out, the register is loaded with serial data, one bit at a time, with the stored data being available in parallel form.
- **Serial-in to Serial-out** - In this serial-in to serial-out, the register is loaded with the serial data is shifted serially "IN" and "OUT" of the register, one bit at a time in either a left or right direction under clock control.
- **Parallel-in to Serial-out** - In this parallel-in to serial-out, the register is loaded with the parallel data is loaded into the register simultaneously and is shifted out of the register serially one bit at a time under clock control.
- **Parallel-in to Parallel-out** - In this parallel -in to parallel-out, the register is loaded with the parallel data is loaded simultaneously into the register, and transferred together to their respective outputs by the same clock pulse.
- **Universal shift registers**- Today, high speed bi-directional "universal" type Shift Registers are available as a 4-bit multi-function devices that can be used in either serial-to-serial, left shifting, right shifting, serial-to-parallel, parallel-to-serial, and as a parallel-to-parallel multifunction data register, hence the name "Universal". These devices can perform any combination of parallel and serial input to output

operations but require additional inputs to specify desired function and to pre-load and reset the device.

5.1.2 MULTIPLEXERS

A 2n-to-1 multiplexer sends one of 2n input lines to a single output line. A multiplexer has two sets of inputs: 2n data input lines, n select lines, to pick one of the 2n data inputs. The mux output is a single bit, which is one of the 2n data inputs. A 2n-to-1 multiplexer routes one of 2n input lines to a single output line. Just like decoders, muxes are common enough to be supplied as stand-alone devices for use in modular designs. Muxes can implement arbitrary functions. Smaller muxes can be combined to produce larger ones. It can add active-low or active-high enable inputs. As always, we use truth tables and Boolean algebra to analyze things. Tune in tomorrow as we start to discuss how to build circuits to do arithmetic.

5.1.3 D-FLIP-FLOP

There are some circuits that are not quite as straight forward as the gate circuits. However, we still need to learn about circuits that can store and remember information. They're the kind of circuits that are used in computers to store program information - RAM memory. The combination of two flip-flops constitutes a D-type flip-flop. That's D because the output of the flip-flop is delayed by the time of one clock pulse. Set a value for the data and pulse the clock ON and OFF. We'll find a copy of the data appearing at the output on the trailing edge of the clock pulse. Now, if we consider the combination of two flip-flops as a unit, we have a D flip-flop. It's called a D flip-flop because it delays the signal. The signal appears at the output of the circuit delayed by the time of one clock pulse.

5.1.4 GF (2⁸) MULTIPLIER

Galois Field Theory (GFT) deals with numbers that are binary in nature, have the properties of a mathematical "field," and are finite in scope. Although some Galois computations don't exist in ordinary mathematics, many Galois operations match those of regular math. Addition (Ex-Or) and multiplication are common Galois operations, and logarithms, particularly, are handy for checking multiplication results. For over 40 years, Galois Field multipliers have been used both for coding theory and for cryptography. Both areas are complex, with similar needs, and both deal with fixed symbolic alphabets that neatly fit the extended Galois Field model.

This application note will focus primarily on cryptographic applications of GFT, and will present some practical design solutions that have been synthesized and simulated for ready use. While the basic multiplier structure used by the solutions clearly has its roots in the designs of Berlekamp and Massey from the 1960s, the specific structure used here comes from a more recent paper by Johann Großschädl at IAIK (Graz University of Technology, Austria). This application note does not delve deeply into GFT, although its appendices point out some enlightening tutorial material for interested readers. Its goal instead is to deliver a series of multiplier solutions and verify their correctness and usability. The specific results and tools presented will then be applicable to other multiplier versions of varying lengths. To this end, we

first present a 4-bit multiplier and its verification. We then expand it into an 8-bit multiplier, doing the same, and finally into a 163-bit multiplier. The larger multiplier can eventually be used as part of a solution for Elliptic Curve Cryptography using one of the NIST-recommended curves and the NIST chosen irreducible polynomial. A complete verification of this larger multiplication is an ordeal, but a few examples will be presented to assure readers of its validity.

5.1.5 The Finite Field GF(2⁸).

The case in which n is greater than one is much more difficult to describe. In cryptography, one almost always takes p to be 2 in this case. This section just treats the special case of p = 2 and n = 8, that is, GF(2⁸), because this is the field used by the new U.S. Advanced Encryption Standard (AES). The AES works primarily with bytes (8 bits), represented from the right as:

$b_7b_6b_5b_4b_3b_2b_1b_0$.

The 8-bit elements of the field are regarded as polynomials with coefficients in the field Z_2 :

$$b_7x^7 + b_6x^6 + b_5x^5 + b_4x^4 + b_3x^3 + b_2x^2 + b_1x^1 + b_0.$$

The field elements will be denoted by their sequence of bits, using two hex digits.

5.1.6 Multiplication in GF(2⁸)

Multiplication in this field is much more difficult and harder to understand, but it can be implemented very efficiently in hardware and software. The first step in multiplying two field elements is to multiply their corresponding polynomials just as in beginning algebra (except that the coefficients are only 0 or 1, and $1 + 1 = 0$ makes the calculation easier, since many terms just drop out). The result would be up to a degree 14 polynomial -- too big to fit into one byte. A finite field now makes use of a fixed degree eight irreducible polynomial (a polynomial that cannot be factored into the product of two simpler polynomials). For the AES the polynomial used is the following (other polynomials could have been used):

$$m(x) = x^8 + x^4 + x^3 + x + 1 = 0x11b \text{ (hex)}.$$

The intermediate product of the two polynomials must be divided by $m(x)$. The remainder from this division is the desired product. This sounds hard, but is easier to do by hand than it might seem (though error-prone). To make it easier to write the polynomials down, adopt the convention that instead of $x^8 + x^4 + x^3 + x + 1$ just write the exponents of each non-zero term. (Remember that terms are either zero or have a 1 as coefficient.)

5. GF (2⁸) ADDER

To add two field elements, just add the corresponding polynomial coefficients using addition in Z_2 . Here addition is modulo 2, so that $1 + 1 = 0$, and addition, subtraction and exclusive-or are all the same. The identity element is just zero: 00000000 (in bits) or 0x00 (hex).

VII. CONCLUSION

The modified Nielson’s algorithm, which works with a different scheduling, takes care of the limited growth of the polynomials and shares the common interpolation points, for reducing the latency of interpolation. Based on the proposed modified Nielson’s algorithm, we have derived a low-latency interpolator architecture. An LCC decoder using our low-latency interpolator is found to be at least 39% more efficient in terms of area-delay product over the best of previous works.

Abstract: There is increasing demand for the use of alternate or renewable energy sources to achieve clean and low-cost electricity for agricultural water pumping requirements. The potential for non-thermal onsite power generation also remains enormous in India with increasing investment in small-scale solar and wind power. Promotion of energy production from the combination of sources of energy known as hybrid system is represented by an important objective of meeting the energy demand and justified by environmental protection and increase of energy independence. Design & integration of renewable energy hybrid system also involves the process of selecting the best components and its sizing to provide cheap, efficient, reliable and cost effective renewable energy. During this study a solar and wind hybrid system is optimally designed for a standalone drip irrigation system. It consists of a submersible pump that consumes 2.4 units of electrical energy per day on the average, to drip irrigate 1.5 acres of mango crop. Also, cost optimization of the wind-solar hybrid system is done in this paper to provide useful guidelines for small scale wind-solar hybrid system manufacturers.

Keywords: wind, solar, drip irrigation, cost optimization, solar pumping

I. INTRODUCTION

India possesses a relatively high abundance of sunshine, solar radiation, and moderate wind speeds, hydro, and biomass energy resources. Small scale solar-wind energy systems can make a significant contribution to our nation's energy needs. Indigenous development of small wind power systems up to 25 kW (and hybrids) for stand-alone applications is the objective of new Indian renewable energy act along with the deployment of solar PV Pumps. Drip irrigation system has the potential to solve the problem of food, energy and water security arising from the climate change phenomenon. The merit of drip irrigation technology is that it frees the farmer from the limitations of rain fed farming throughout the year with higher yields while conserving water. Electricity generated from solar-wind hybrid systems can help farmers reduce their electricity costs, an important consideration in the cases of remote farming.

1.1 Definition of hybrid system: - To overcome the drawback of unavailability of power at all times, and to remote places, hybrid systems are developed. In a hybrid

power system, different methods of producing electricity are combined to ensure a continuous power supply. An energy system consisting of two or more generating systems, such as the combination of a wind turbine or diesel generator and a photovoltaic system is termed as a hybrid energy system. Hybrid generation system selected in this design, harnesses both renewable sources of solar power and wind power to form an equivalent of a miniature (or virtual) grid. When the systems are connected together, they will have enhanced reliability, higher efficiency, and lower emissions with an acceptable cost.

1.2 Industry scenario of solar energy generation:-

Complete process of fabrication of a solar panel along with merits and demerits of various solar cells, process techniques and Q/A methodologies have been studied.

Large scale manufacturing of photovoltaic cells, coupled with continued research and development is expected to further make Photovoltaic's within the economic reach of rural areas in India. Cost of multi crystalline solar panel is almost 1\$/Watt now.

II. Configuration Of Hybrid System

The specifications of a hybrid system are derived from a comprehensive understanding of the pumping requirements of the drip irrigation system. Research & development has been carried out to design & develop an integrated and sustainable renewable energy system that supplies electricity to a submersible pump that would cultivate a land of 1.5 acres of mango crop located at Dr.B.V.Raju Institute of Technology, Narsapur, A.P, India. At this area, water depth has been found to be at 120ft below the ground level.

2.1 Water Pumping Requirement:

Submersible pumps are easy to install, have no suction problem, and require no water level guard. Submersible Pump is selected based on the below factors:

- Source of water (well, river, pond, etc.)
- Required pumping flow rate
- Total suction head
- Total dynamic head

To lift this water to the ground levels pump is selected with specifications given in table1:

Table 1. Pumping System Specifications

Total head(meters)	73.1
Discharge(lpm)	90
No of Acres irrigated	1.5
No of liters required/day/acre*	11,100

The Number of liters required/day/acre is calculated by considering the annual average rainfall as zero and also, this value is for the water required for the crop during the dry summer month of May. This value is nearly 1.5 times the annual average requirements of water for the crop.

No. of liters required/day/1.5acre:

$11,100 \times 1.5 = 16,650$ ltrs/day/1.5acre.

No of liters to be pumped/hour : 5,408

Pump running hours/day/1.5acre:

$16,650 / 5,408 = 3.08$ hrs/day/1.5acre.

Table 2. Drip System Specifications

Drippers Capacity(lph)	8
#Drippers	672
Drip system Operation(hrs/day)	3.08

A submersible pump is identified that gives the given Discharge Vs Head requirements.

2.2 Design of Hybrid Energy System:

Reliability and feasibility study of wind-solar hybrid system solution starts with obtaining the meteorological data of the selected place of installation.

2.2.1 Meteorological data required for Solar System:

1. Annual mean daily duration of Sunshine hours
2. Daily Solar Radiation horizontal (KWH/m²/day)

2.2.2 Meteorological data required for Wind System:

1. Mean Annual Hourly Wind Speed (m/sec)
2. Wind Potential in watts that can be harnessed (obtained from Wind map for the location).

The Parameters* that are obtained for the study location are as follows.

*Data obtained from the Indian Meteorological Department (IMD) Hyderabad.

The array factor for circular array is given

Parameter	Design Value
Annual Average Daily Peak Sunshine Hours (ADPS)	9.31
Daily solar Radiation Horizontal(kWh/m ² /day)	3.83
Mean Annual Hourly Wind Speed(m/sec)	3.277

The Various Components of our hybrid system along with their unit specifications are arrived as follows.

Hybrid System Component	Unit Specifications
Sizing of wind generator	700W, 24V DC
Solar Array	240W, 24V DC
Battery sizing	12V, 120Ah
Inverter sizing	3.0kVA

Table 3. Hybrid System Components

2.2.3 Steps to determine Battery Bank Size:

1. Identify total daily use (Calculated from the load list) in Watt-hours (Wh).....(a)
2. Identify Days of Autonomy (backup days); multiply Wh/day by this factor.....(b)
3. Identify Depth of Discharge (DoD) and convert to a decimal value. Divide result of Step (b) by this value.....(c)
4. Divide result from Step (c) by system voltage. Result is the *minimum Amp-hour (Ah) capacity* of your battery bank as per standard operating conditions.

Calculate Battery Bank Size by above approach to give the values below:

Example:

Step 1: Daily Usage (calculated from the load list.) in Watt hours = 2698.08Wh/day.

Load List:

Appliance	Qty	Watts(V*I)	Hrs/day	Wh/day
Electric Motor	1	876	3.08	2698.08

Step 2 : Days of Autonomy (backup days) multiply with Wh/day: $2698.08 \times 1 = 2698.08$ Wh

Step 3 : Depth of Discharge (DoD) 80% and divide step 2 by this value: $2698.08 / 0.80 = 3372.6$ Wh.

Step 4 : Divide result of step 3 by the system voltage (here system voltage is 24V): $3372.6 / 24 = 140.525$ Ah.

Battery Bank Capacity: 24v, 141 Ah.

The recommended battery bank comprises of two LMLA (low maintenance lead acid) batteries of capacity 12v, 150Ah that are connected in series to give a total capacity of 24v, 150Ah.

III. Cost Optimization Of Hybrid Energy System

Solar-wind hybrid energy systems involve a significant initial investment, they can be competitive with conventional energy sources when accounted for a lifetime of reduced or avoided utility costs. The cost of the system itself depends on the system chosen, wind resource on the site, electric costs in the area, and the battery bank required. Cost of the Wind-Solar Hybrid system is to be minimized to provide best value for the customer. So the entire system is analyzed for subsystem costs.

IV. Objective Function And Its Optimization

The power output from a combined solar and wind system, P_{cs} may be expressed as

$$P_{cs} = P_s + P_w$$

Where P_w = Total wind turbine power rating in Watts.

The main goal in designing the hybrid Power Generator is to select the optimum number for N_s (number of solar panels) N_w (number of wind turbines).

Assuming the cost to be a linear function of the size, the total cost of a hybrid system C_{cs} , can be written as

$$C_{CS} = N_s C_s + N_w C_w + N_b C_b$$

Where C_s and C_w represent the cost per unit power potential of individual solar and wind power generators, N_s , N_w , and N_b number of PV panel, wind turbine, and battery respectively.

The optimization problem of combined solar and wind systems is expressed by following equation:

The above Objective function is solved by using an optimization solver of Microsoft Office Excel 2007.

Minimize:

$$C_{CS} = N_s C_s + N_w C_w$$

Subjected to $P_s >= 1;$

$$P_w >= 1;$$

$$P_s + P_w >= 1.18KW$$

The power output from a combined solar and wind system 1.18kw is taken as a constraint as per the requirements given for irrigating 1.5acres of mango crop.

The solution results in optimum numbers of solar panel and wind turbine as $N_s=2$ and $N_w=1$ respectively for the desired energy demand.

Similarly, cost of the system for different power requirements with structure are as follows:

POWER REQUIRE D (KW)	Cost of solar $C_s * 1000$ Rs	# of solar panels N_s	Cost of Wind $C_w * 1000$ Rs	# of Wind turbines N_w	Sub cost $(C_s * N_s + C_w * N_w) * 100$ 0 Rs	# of batterie sN_b	Cost of battery bank $C_b * 1000$ Rs	Total Cost $C_{cs} * 100$ 0 Rs
1.4	43.20	3	76	1	119.2	2	34	153.2
1.18	28.8	2	76	1	104.8	2	34	138.8
2.8	43.2	3	228	3	271.2	4	68	339.2
5.0	14.4	1	532	7	546.4	7	119	665.4
7.5	72	5	684	9	756.0	11	187	943.0
10	14.4	1	1,064	14	1,078.4	14	238	1316.4

Table 4: Cost Analysis of Wind solar hybrid energy System

* Considering the cost of battery bank and inverter is Rs.28/Watt.

V. Results & Discussion

Proposed hybrid system:-

For the given requirement, selected power ratings of solar and wind are: 700watt($1*700W=700W$) and 480($2*240W_p=480W_p$)watt respectively.

The performance and energy generated by the Wind turbine can be estimated through power curve given on fig1.

and the total cost of the system is calculated as **1,38,800/-**.

Hybrid System Component	% of cost
Wind turbine	54.75
Solar PV	20.74
Battery & Inverter	24.50

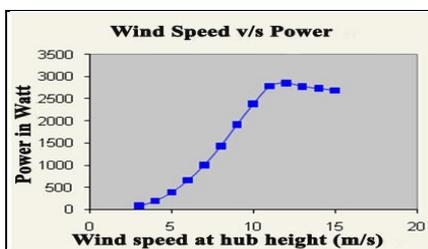

Fig. 1 Power Curve

Drawbacks of independent renewable energy sources are unavailability at all the times and high capital cost, energy availability of rated wind speed requirement. A hybrid energy system helps in overcoming the drawbacks of the renewable energy sources and thus provides continuous supply of electricity.

VI. Conclusions

Solar-Wind Hybrid Systems is the best feasible economic solutions for lowering electricity bills; also they help in avoiding the high costs of extending utility power lines to remote locations, prevent power interruptions, and provide a non-polluting source of electricity. There is a definite need for optimizing the cost of the hybrid Systems based on the various operating and design parameters. In this paper, cost optimization is exercised to minimize the cost of Wind-Solar hybrid system for the given requirement of drip irrigation pumping.

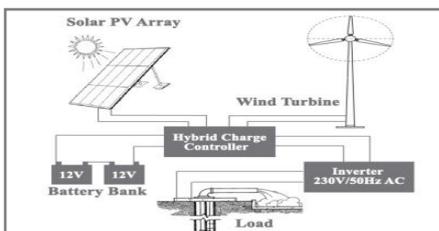

Fig. 2 Hybrid Energy System Model

The optimization problem is solved by using an optimization solver using Matlab. According to the result of the optimization, numbers required for solar panel and wind turbine and battery are computed as 2, 1, and 2 respectively,

The major advantage of wind – solar hybrid energy system is that when used together, the reliability of the system is enhanced. Additionally, the size of battery storage can be reduced. Thus, the analysis performed in this paper will set guidelines to energy consultants or engineers

in designing the hybrid energy system by considering the current industry costs of various subsystem components in order to meet the energy requirement. Remote communities which cannot be reached by electricity grids, except at prohibitive costs, or which do not have easy access to conventional commercial fuels, can easily adopt these hybrid systems for irrigation. This project will there by promote the use of hybrid renewable energy system as a power source for drip irrigation.

Fuzzy Hypothesis Testing Of Anova Model with Fuzzy Data

D. Kalpanapriya and P. Pandian

Department of Mathematics, School of Advanced Sciences, VIT University, Vellore-632 014, INDIA.

Abstract: A new statistical technique for testing the fuzzy hypotheses of one factor ANOVA model using their samples having fuzzy data is proposed without using h-level concept. In the proposed technique, the decision rules that are used to accept or reject the null and alternative hypotheses are provided in which the notions of pessimistic degree and optimistic degree are not used. The idea of the proposed procedure has been clarified by illustrative numerical examples.

Mathematical Subject Classification: 62F03

Keywords: Testing Hypotheses, Fuzzy hypotheses, ANOVA model, Fuzzy data, F-test.

I. Introduction

Analysis of variance (ANOVA) is a statistical technique that will enable us to test the null hypothesis that the three or more populations means are equal against the alternative hypothesis that they are not equal by using their samples information. The ANOVA technique was originally used in the analysis of agricultural research data. Due to the strength and versatility of the technique, the ANOVA technique is now used in all most all research areas especially in Social Science Research and Managerial Decision Making. In traditional statistical testing [7], the observations of sample are crisp and a statistical test leads to the binary decision. However, in the real life, the data sometimes cannot be recorded or collected precisely. The statistical hypotheses testing under fuzzy environments has been studied by many authors using the fuzzy set theory concepts introduced by Zadeh [18]. The application by using fuzzy sets theory to statistics has been widely studied in Manton et al. [8] and Buckley [3] and Viertl [13]. Arnold [2] proposed the fuzzification of usual statistical hypotheses and considered the testing hypotheses under fuzzy constraints on the type I and II errors. Saade [10], Saade and Schwarzlander [11] considered the binary hypotheses testing and discussed the fuzzy likelihood functions in the decision making process by applying a fuzzified version of the Bayes criterion. Grzegorzewski [6] and Watanabe and Imaizumi [14] proposed the fuzzy test for testing hypotheses with vague data, and the fuzzy test gave the acceptability of the null and alternative hypotheses. The statistical hypotheses testing for fuzzy data by proposing the notions of degrees of optimism and pessimism was proposed by Wu [15]. Viertl [12] investigated some methods to construct confidence intervals and statistical tests for fuzzy data. Wu [17] proposed some approaches to construct fuzzy confidence intervals for the unknown fuzzy parameter. Arefi and Taheri [1] developed an approach to test fuzzy hypotheses upon fuzzy test statistic for vague data. A new approach to the problem of testing statistical hypotheses for fuzzy data using the relationship between confidence intervals and testing hypotheses is introduced by Chachi et al.[4]. Mikihiro Konishi et al. [9] proposed the method of ANOVA for the

fuzzy interval data by using the concept of fuzzy sets. Hypothesis testing of one factor ANOVA model for fuzzy data was proposed by Wu [16] using the h-level set and the notions of pessimistic degree and optimistic degree by solving optimization problems.

In this paper, we propose a new statistical fuzzy hypothesis testing of ANOVA model for finding the significance among more than two population means when the data of their samples are fuzzy data. We provide the decision rules which are used to accept or reject the fuzzy null and alternative hypotheses. In the proposed technique, we convert the given fuzzy hypothesis testing of one factor ANOVA model with fuzzy data into two hypothesis testing of one factor ANOVA models with crisp data namely, upper level model and lower level model; then, we test the hypothesis of each of the one factor ANOVA models with crisp data and obtain the results and then, we obtain a decision about the population means on the basis of the proposed decision rules using the results obtained. In the decision rules of the proposed testing technique, we are not using degrees of optimism and pessimism and h-level set which are used in Wu [16]. For better understanding, the proposed fuzzy hypothesis testing technique of ANOVA model for fuzzy data is illustrated with numerical examples.

II. Preliminaries

We need the following results which can be found in [5, 7].

Let $D = \{[a, b], a \leq b \text{ and } a \text{ and } b \text{ are in } \mathbb{R}\}$ the set of all closed bounded intervals on the real line \mathbb{R} .

Result 2.1: Let $A = [a, b]$ and $B = [c, d]$ be in D . Then, $A = B$ if $a = c$ and $b = d$.

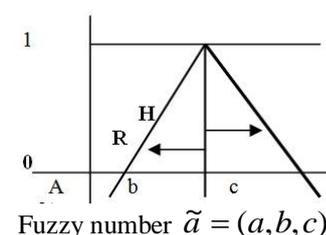

Result 2.2 : If s^2 is the variance of a sample of size n drawn from the population with variance σ^2 , then

$E\left(\frac{ns^2}{n-1}\right) = \sigma^2$, that is, $\frac{ns^2}{n-1}$ is an unbiased estimator of σ^2 .

A triangular fuzzy number $\tilde{a} = (a, b, c)$ can be represented as an interval number form as follows.

$$[\tilde{a}] = [b - (b - a)r, b + (c - b)h];$$

$$0 \leq h, r \leq 1. \tag{1}$$

Note that r is the level of pessimistic and h is the level of optimistic of the fuzzy number $\tilde{a} = (a, b, c)$.

III. One -Factor ANOVA Model

The basic principle of ANOVA technique [7] is to test the difference among the means of populations by studying the amount of variation within each of the samples relative to the amount of variation between the samples. Samples under consideration in ANOVA model are assumed to be drawn from normal populations of equal variances. A one-factor between-subjects ANOVA is used when the analysis involves only one factor with more than two levels and different subjects in each of the experimental conditions.

Consider a sample of size N of a given random variable X drawn from a normal population with variance σ^2 which is subdivided into s classes according to some factor of classification. The main objective is to test the null hypothesis that the factor of classification has no effect on the variables (or) there is no difference between various classes (or) the classes are homogeneous.

Now, let μ_i be the mean of i th population class. The testing hypotheses are given below:

Null hypothesis, $H_0 : \mu_1 = \mu_2 = \dots = \mu_s$ against

Alternative hypothesis, $H_A : \text{not all } \mu_i \text{'s are equal}$

Let x_{ij} be the value of the j th member of the i th class which contains n_i values, \bar{x}_i be the mean value of i th class and \bar{x} be the general mean of all the $N (= \sum_i n_i)$ values.

Now, the total variation, $Q = \sum_i \sum_j (x_{ij} - \bar{x})^2 =$

$$\sum_i \sum_j (x_{ij} - \bar{x}_i)^2 + \sum_i n_i (\bar{x}_i - \bar{x})^2 = Q_2 + Q_1$$

where $Q_1 = \sum_i n_i (\bar{x}_i - \bar{x})^2$ is the variation between

classes and $Q_2 = \sum_i \sum_j (x_{ij} - \bar{x}_i)^2$ is the variation within classes (or) the residual variation.

Now, since i th class is a sample of size n_i from the population with the variance σ^2 , we can conclude that

$M_2 = \frac{Q_2}{N - s}$ is an unbiased estimator of σ^2 with

degrees of freedom $N - s$ and since the entire group is a sample of size N from the population with variance σ^2 ,

we can conclude that $M_1 = \frac{Q_1}{s - 1}$ is an unbiased

estimator of σ^2 with degrees of freedom $s - 1$.

Now, since the population is normal and the estimates M_1 and M_2 are independent, the ratio $\frac{M_1}{M_2}$ or $\frac{M_2}{M_1}$,

whichever is greater than or equal to one, follows a F-distribution with $(s - 1, N - s)$ degrees of freedom in the first case or $(N - s, s - 1)$ degrees of freedom in the later case. Then, we employ the F -test for testing the hypotheses.

The above results are displayed in the form a table, known as the one-factor ANOVA table as given below:

Source of Variation	Sum of Squares	Degrees of freedom	Mean Square	F-value
Between Classes	Q_1	$s - 1$	$M_1 = \frac{Q_1}{s - 1}$	$F = \frac{M_1}{M_2}$
Within Classes	Q_2	$N - s$	$M_2 = \frac{Q_2}{N - s}$	(or) $F = \frac{M_2}{M_1}$

The decision rules in the F-test to accept or reject the null and alternative hypotheses are given below:

(i) If $M_1 < M_2$ and $F = \frac{M_1}{M_2} < F_0$ where F_0 is the

table of F for $(s - 1, N - s)$ degrees of freedom at α level, the null hypothesis is accepted, Otherwise, alternative hypothesis is accepted.

(ii) If $M_2 < M_1$ and $F = \frac{M_2}{M_1} < F_0$ where F_0 is the

table of F for $(N - s, s - 1)$ degrees of freedom at α level, the null hypothesis is accepted, Otherwise, alternative hypothesis is accepted.

Note : For easy computing the values Q , Q_1 and Q_2 , we use the following formulae:

$$Q = \sum_i \sum_j x_{ij}^2 - \frac{T^2}{N} \quad \text{where} \quad T = \sum_i \sum_j x_{ij};$$

$$Q_1 = \sum_i \left(\frac{T_i^2}{n_i} \right) - \frac{T^2}{N} \quad \text{where} \quad T_i = \sum_j x_{ij}$$

and $Q_2 = Q - Q_1$.

IV. Fuzzy One-Factor Anova Model

Suppose that we test the fuzzy hypotheses of one-factor ANOVA model with the data of the given samples are triangular fuzzy numbers. Using the relation (1), we convert the given fuzzy ANOVA model into interval ANOVA model. Construct two crisp ANOVA models from the interval ANOVA model namely, upper level model which is formed using the upper limits of each of

the interval values and lower level model which is formed using the lower limit of each of the interval values. Then, we analyze lower level model and upper level model using the crisp one-factor ANOVA technique.

Let α be the level of significance.

Now, the null hypothesis, $\tilde{H}_0 : \tilde{\mu}_1 = \tilde{\mu}_2 = \dots = \tilde{\mu}_s$ against

the alternative hypothesis, $\tilde{H}_A : \text{not all } \tilde{\mu}_i \text{'s are equal.}$

This implies that the null hypothesis,

$[\tilde{H}_0] : [\tilde{\mu}_1] = [\tilde{\mu}_2] = \dots = [\tilde{\mu}_s]$ against

the alternative hypothesis,

$[\tilde{H}_A] : \text{not all } [\tilde{\mu}_i] \text{'s are equal}$

That is, the null hypothesis,

$[H_0^L, H_0^U] : [\mu_1^L, \mu_1^U] = [\mu_2^L, \mu_2^U] = \dots = [\mu_s^L, \mu_s^U]$

against the alternative hypothesis,

$[H_A^L, H_A^U] : \text{not all } [\mu_i^L, \mu_i^U] \text{'s are equal.}$

This implies the following two sets of hypotheses:

(1) the null hypothesis, $H_0^L : \mu_1^L = \mu_2^L = \dots = \mu_s^L$ against the alternative hypothesis,

$H_A^L : \text{not all } \mu_i^L \text{'s are equal.}$

and

(2) the null hypothesis, $H_0^U : \mu_1^U = \mu_2^U = \dots = \mu_s^U$ against the alternative hypothesis,

$H_A^U : \text{not all } \mu_i^U \text{'s are equal.}$

Note that (1) is the hypotheses of the lower level model and (2) is the hypotheses of the upper level model.

Suppose that if at α level of significance, the null hypothesis of the lower level model is accepted for $0 \leq h \leq h_0$ where $0 \leq h_0 \leq 1$ and the null hypothesis of the upper level model is accepted for $0 \leq r \leq r_0$ where $0 \leq r_0 \leq 1$, then, the fuzzy null hypothesis of the fuzzy

Now, we consider the lower level model. The hypotheses are given below:

Package design (i)	Store j (Observation j)		
	1	2	3
1	11+2h	16+2h	
2	15+4h	15+5h	13+2h
3	18+3h	17+3h	20+3h
4	19+4h	24+3h	

ANOVA model is accepted for $0 \leq h \leq h_0$ and $0 \leq r \leq r_0$ at α level of significance. Otherwise, the fuzzy alternative hypothesis of the fuzzy ANOVA model is accepted at α level of significance.

Remark 4.1. If when $h = 0$ or $r = 0$, that is, center level, the fuzzy null hypothesis of the fuzzy ANOVA model is accepted at α level of significance. Then, only we study about the acceptance levels of null hypothesis in the directions of pessimistic and optimistic.

The proposed statistical technique to test the fuzzy hypothesis of ANOVA model with fuzzy data is illustrated with the following numerical examples.

Example 4.1. A food company wished to test four different package designs for a new product. Ten stores, with approximately equal sales volumes, are selected as the experimental units. Package designs 1 and 4 are assigned to three stores each and package designs 2 and 3 are assigned to two stores each. We cannot record the exact sales volume in a store due to some unexpected situations, but we have the fuzzy data for sales volumes. The fuzzy data are given below:

Package design (i)	Store j (Observation j)		
	1	2	3
1	(9,11,13)	(14,16,18)	
2	(11,15,19)	(10,15,20)	(11,13,15)
3	(15,18,21)	(14,17,20)	(17,20,23)
4	(15,19,23)	(21,24,27)	

We wish to test whether or not the (fuzzy) mean sales are the same for the four designs.

Let $\tilde{\mu}_i$ be the mean sales for the i th design.

Now, the null hypothesis, $\tilde{H}_0 : \tilde{\mu}_1 = \tilde{\mu}_2 = \tilde{\mu}_3 = \tilde{\mu}_4$ against the alternative hypothesis,

$\tilde{H}_A : \text{not all } \tilde{\mu}_i \text{'s are equal.}$

Now, the interval ANOVA model for the given fuzzy ANOVA model is given below:

Package Design (i)	Store j (Observation j)		
	1	2	3
1	[11-2r,11+2h]	[16-2r,16+2h]	
2	[15-4r,15+4h]	[15-5r,15+5h]	[13-2r, 13+2h]
3	[18-3r,18+3h]	[17-3r,17+3h]	[20-3r, 20+3h]
4	[19-4r,19+4h]	[24-3r, 24+3h]	

Now, the upper level model and lower level model for the above interval ANOVA model are given below:

Upper level model: Lower level model:

Package design (i)	Store j (Observation j)		
	1	2	3
1	11-2r	16-2r	
2	15-4r	15-5r	13-2r
3	18-3r	17-3r	20-3r
4	19-4r	24-3r	

the null hypothesis, $H_0^L : \mu_1^L = \mu_2^L = \mu_3^L = \mu_4^L$ and the alternative hypothesis, $H_A^L : \text{not all } \mu_i^L \text{'s are equal.}$

Now, the ANOVA table is given below:

Source of Variation	Sum of Squares	Degree of freedom	Mean square	F-ratio
Between Samples	Q_1^L	3	$M_1^L = \frac{Q_1^L}{3}$	$F_r^L = \frac{M_1^L}{M_2^L}$
Within Samples	Q_2^L	6	$M_2^L = \frac{Q_2^L}{6}$	

where $Q_1^L = 3.73r^2 - 12.73r + 91.26$ and $Q_2^L = 5.17r^2 - 1.6r + 32.34$.

Now, $F_r^L > T$, for all r ; $0 \leq r \leq 0.87$ where $T (= 4.76)$ is the table value of F at 5% level of significance with (3,6) degrees of freedom. Therefore, the null hypothesis H_0^L of the lower level model is rejected for all r ; $0 \leq r \leq 0.87$.

Now, we consider the upper level model. The hypotheses are given below:

the null hypothesis, $H_0^U : \mu_1^U = \mu_2^U = \mu_3^U = \mu_4^U$ and the alternative hypothesis, $H_A^U : \text{not all } \mu_i^U \text{'s are equal.}$

Now, the ANOVA table is given below:

Source of Variation	Sum of Squares	Degree of freedom	Mean square	F-ratio
Between Samples	Q_1^U	3	$M_1^U = \frac{Q_1^U}{3}$	$F_h^U = \frac{M_1^U}{M_2^U}$
Within Samples	Q_2^U	6	$M_2^U = \frac{Q_2^U}{6}$	

where $Q_1^U = 3.73h^2 + 12.73h + 91.26$ and $Q_2^U = 5.17h^2 + 1.6h + 32.34$.

Now, $F_h^U > T$, for all h ; $0 \leq h \leq 1$ where $T (= 4.76)$ is the table value of F at 5% level of significance with (3,6) degrees of freedom. Therefore, the null hypothesis H_0^U of the upper level model is rejected for all h ; $0 \leq h \leq 1$.

Thus, since the null hypotheses H_0^L and H_0^U of the lower level data and upper level data are rejected for all r ; $0 \leq r \leq 0.87$ and h ; $0 \leq h \leq 1$ (note that null hypotheses are not rejected at $r = 0$ and $h = 0$, that is, the centre level), the fuzzy null hypothesis \tilde{H}_0 of the fuzzy ANOVA model is rejected. Therefore, the alternative hypothesis \tilde{H}_A of the fuzzy ANOVA model is accepted. It says that the factor level fuzzy means $\tilde{\mu}_i$ are not equal.

Thus, we conclude that there is a relation between package designs and sales volumes.

Remark 4.2. The decision obtained by the proposed fuzzy hypothesis testing technique for the Example 4.1. is same as in Wu [16].

Example 4.2. Four different machines are used to produce milk pouches of 100 ml each by a city dairy. Before these pouches are dispatched for local distribution, the quality assurance manager selects two samples of pouches from machine1 and machine 4 and three samples of pouches from the machine 2 and the machine3 and determines the number of pouches that does not meet the specifications under the Weights and Measures Act. We cannot record the exact number of pouches in a sample due to some unexpected situations, but we have the fuzzy data for number of pouches. The fuzzy data are given below:

Machine (i)	Sample j		
	1	2	3
1	(8,9,14)	(11,14,18)	
2	(7,11,15)	(8,10,14)	(8,11,14)
3	(12,15,18)	(12,14,19)	(14,17,23)
4	(12,15,19)	(19,21,24)	

Test that there is a significant difference in the performance of the machines.

Let $\tilde{\mu}_i$ be the mean number of non-specifications pouches for the i th machine.

Now, the null hypothesis, $\tilde{H}_0 : \tilde{\mu}_1 = \tilde{\mu}_2 = \tilde{\mu}_3 = \tilde{\mu}_4$ and

the alternative hypothesis, $\tilde{H}_A : \text{not all } \tilde{\mu}_i \text{'s are equal.}$

Now, the interval ANOVA model for the given fuzzy ANOVA model is given below:

Machine (i)	Sample j		
	1	2	3
1	[9-r,9+5h]	[14-3r,14+4h]	
2	[11-4r,11+4h]	[10-2r,10+4h]	[11-3r,11+3h]
3	[15-3r,15+3h]	[14-2r,14+5h]	[17-3r,17+6h]
4	[15-3r,15+4h]	[21-2r,21+3h]	

Now, the upper level model and lower level model for the above interval ANOVA model are given below:

Upper level model: Lower level model:

Machine (i)	Sample j		
	1	2	3
1	9-r	14-3r	
2	11-4r	10-2r	11-3r
3	15-3r	14-2r	17-3r
4	15-3r	21-2r	

Now, we consider the lower level model. The hypotheses are given below:

Machine (i)	Sample j		
	1	2	3
1	9+5h	14+4h	
2	11+4h	10+4h	11+3h
3	15+3h	14+5h	17+6h
4	15+4h	21+3h	

the null hypothesis, $H_0^L : \mu_1^L = \mu_2^L = \mu_3^L = \mu_4^L$ and the alternative hypothesis, $H_A^L : \text{not all } \mu_i^L \text{'s are equal.}$

Now, the ANOVA table is given below:

Source of Variation	Sum of Squares	Degree of freedom	Mean square	F-ratio
Between Samples	Q_1^L	3	$M_1^L = \frac{Q_1^L}{3}$	$F_r^L = \frac{M_1^L}{M_2^L}$
Within Samples	Q_2^L	6	$M_2^L = \frac{Q_2^L}{6}$	

Where $Q_1^L = 1.23r^2 + 3.07r + 82.26$ and $Q_2^L = 5.17r^2 - 8.6r + 35.84$.

Now, $F_r^L < T$, for all $r ; 0 \leq r \leq 0.14$ where T (= 4.76) is the table value of F at 5% level of significance with (3,6) degrees of freedom. Therefore, the null hypothesis H_0^L of the lower level model is accepted for all $r ; 0 \leq r \leq 0.14$.

Now, we consider the upper level model. The hypotheses are given below:

The null hypothesis, $H_0^U : \mu_1^U = \mu_2^U = \mu_3^U = \mu_4^U$ and The alternative hypothesis, $H_A^U : \text{not all } \mu_i^U \text{'s are equal.}$

Now, the ANOVA table is given below:

Source of Variation	Sum of Squares	Degree of freedom	Mean square	F-ratio
Between Samples	Q_1^U	3	$M_1^U = \frac{Q_1^U}{3}$	$F_h^U = \frac{M_1^U}{M_2^U}$
Within Samples	Q_2^U	6	$M_2^U = \frac{Q_2^U}{6}$	

where $Q_1^U = 2.56h^2 - 0.4h + 82.26$ and $Q_2^U = 6.34h^2 - 7h + 35.84$.

Now, $F_h^U < T$, for all $h ; 0 \leq h \leq 0.23$ where T (= 4.76) is the table value of F at 5% level of significance with (3,6) degrees of freedom. Therefore, the null hypothesis H_0^U of the upper level model is accepted for all $h ; 0 \leq h \leq 0.23$.

hypothesis H_0^U of the upper level model is accepted for all $h ; 0 \leq h \leq 0.23$.

Thus, since the null hypotheses H_0^L and H_0^U of the lower level model and upper level model are accepted for all $r ; 0 \leq r \leq 0.14$ and $h ; 0 \leq h \leq 0.23$ (note that null hypotheses are accepted at $r = 0$ and $h = 0$, that is, the centre level), the fuzzy null hypothesis \tilde{H}_0 of the fuzzy ANOVA model is accepted for all $r ; 0 \leq r \leq 0.14$ and $h ; 0 \leq h \leq 0.23$. Thus, we conclude that four machines are equal only if $r ; 0 \leq r \leq 0.14$ and $h ; 0 \leq h \leq 0.23$, that is, the maximum level of pessimistic is 0.14 and the maximum level of optimistic is 0.23.

Remark 4.3. From the Example 4.2., we observe that the acceptance of the fuzzy null hypothesis for not all r and h always, but for some specific levels of r and h , that is, $r ; 0 \leq r \leq 0.14$ and $h ; 0 \leq h \leq 0.23$.

V. Conclusion

In this paper, we propose a new statistical fuzzy hypothesis testing of single-factor ANOVA model with the fuzzy data. In the proposed technique, we transfer the fuzzy ANOVA model into two crisp ANOVA models. Based on the decisions of hypotheses of two crisp ANOVA models, we take a decision on the fuzzy hypothesis of the fuzzy ANOVA model. Since the proposed technique in this paper is mainly based only on the crisp models, the proposed technique can be extended to multi-factor fuzzy ANOVA model and the experimental design analysis having fuzzy data.

Abstract: A detailed investigation is made into the causes, standards, and remedies of the excessive neutral current. A reduced-rating voltage-source converter with a zig-zag transformer for a distribution static compensator is proposed for power-quality improvement in the three-phase four-wire distribution system. The proposed DSTATCOM is employed for the compensation of reactive power, harmonics currents, neutral current, load balancing and the voltage regulation at the point of common coupling. The zig-zag transformer is used for providing a path to the zero-sequence current. The performance of the DSTATCOM is validated through extensive simulations using MATLAB software with its Simulink and power system blockset toolboxes.

Index Terms: Distribution static compensator (DSTATCOM), neutral current compensation, power quality (PQ), zig-zag transformer.

I. INTRODUCTION

Distribution systems are facing severe power-quality (PQ) problems, such as poor voltage regulation, high reactive power and harmonics current burden, load unbalancing, excessive neutral current, etc. The source voltages in the distribution systems are also experiencing PQ problems, such as harmonics, unbalance, flicker, sag, swell, etc. The remedial solutions to the PQ problems are investigated and discussed in the literature and the group of devices is known as custom power devices (CPDs). The distribution static compensator (DSTATCOM) is proposed for compensating PQ problems in the current, and the dynamic voltage restorer (DVR) is used for mitigating the PQ problems in the voltage while the unified power-quality conditioner (UPQC) is proposed for solving current and voltage PQ problems. There are many techniques reported for the elimination of harmonics from the source current as well as the compensation of the neutral current and load balancing. Some neutral current compensation techniques have been patented.

Three-phase four wire distribution systems have been used to supply single-phase low-voltage loads. The typical loads may be computer loads, office automation machines, lighting ballasts, adjustable speeds drives (ASDs) in small air conditioners, fans, refrigerators, and other domestic and commercial appliances, etc., and generally behave as nonlinear loads. These loads may create problems of high input current harmonics and excessive neutral current. The neutral current consists of mainly triplen harmonics currents. The zero-sequence neutral current obtains a path through the neutral conductor. Moreover, the unbalanced

single-phase loads also result in serious zero-sequence fundamental current. The total neutral current is the sum of the zero-sequence harmonic component and the zero-sequence fundamental component of the unbalanced load current, and this may overload the neutral conductor of the three-phase four-wire distribution system.

A number of surveys have been cited about the causes of excessive neutral current in the distribution system. There are different techniques for the mitigation of neutral current in the three-phase four-wire distribution systems. The neutral current compensation using a zig-zag transformer; using a star/delta transformer, using a single-phase active compensator in the neutral path; and using three-phase four-wire active compensators along with source harmonic current compensation are reported in the literature. In this investigation, the causes, standards, and remedial solutions for PQ problems due to the excessive neutral current are analyzed and a technique using a zig-zag transformer along with a reduced rating VSC as a DSTATCOM is designed to mitigate these PQ problems. Moreover, the voltage regulation is also achieved at the point of common coupling (PCC) across the loads.

II. NEUTRAL CURRENT COMPENSATION TECHNIQUES

The major causes of neutral current in three-phase distribution systems are the phase current unbalance, third harmonic currents produced by single-phase rectifier loads, and the third harmonics due to source voltage third harmonics. Even balanced three-phase currents produce excessive neutral current with computer loads in the systems. A study reveals that 22.6% of the sites have a neutral current in excess of 100%. The source voltage distortions in systems with computer loads can cause excessive neutral current. The nonlinear loads are classified into harmonic current source loads and harmonic voltage-source loads.

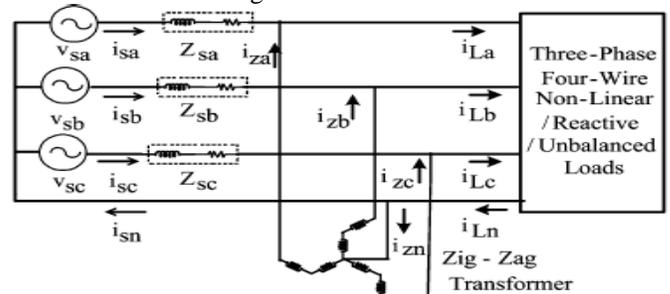

Fig. 1. System configuration with a zig-zag transformer for neutral current compensation.

Various standards are proposed to mitigate PQ problems in the distribution system. The planning for a distribution system, the voltage considerations, calculation of short-circuit capacities, power factor improvement techniques, protective devices, surge protection, and grounding aspects are proposed in IEEE Standard 141-1993. It is a complete guide for an industrial plant power system. The recommended practice for electrical power systems in commercial buildings, the recommendation for harmonic control in power systems, the reference on shunt capacitor design, installation guidelines of improvement of power factor and other applications, the practices for monitoring electrical PQ, and the guide for the application and specification of harmonic filters are available in the literature. In light of the various standards, there are many techniques proposed for the compensation of neutral current in the three-phase four-wire distribution system. These are discussed in the following sections.

A. Zig-Zag Transformer-Based Compensation

The application of a zig-zag transformer for the reduction of neutral current is advantageous due to passive compensation, rugged, and less complex over the active compensation techniques. Fig. 1 shows the connection of a zig-zag transformer in the system and the zig-zag transformer is shown in Fig. 2. A zig-zag transformer is a special connection of three single-phase transformer windings or a three-phase transformer's windings. The zig-zag transformer in the past has been used to create neutral and to convert a three-phase three-wire system into a three-phase four-wire system. The new application of a zig-zag transformer is to connect in parallel to the load for filtering the zero-sequence components of the load currents. The phasor diagram of the zig-zag transformer is shown in Fig. 3. The currents flowing through the utility side of these three transformers are equal. Hence, the zig-zag transformer can be regarded as open-circuit for the positive-sequence and the negative-sequence currents. Then, the current flowing through the zig-zag transformer is only the zero-sequence component.

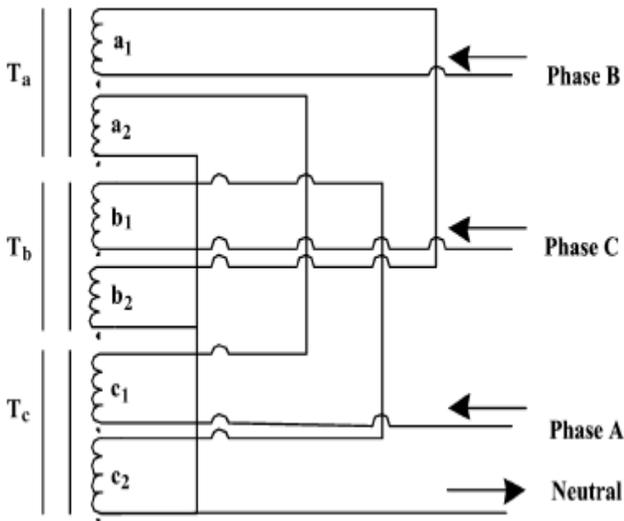

Fig. 2. Zig-zag transformer for neutral current compensation.

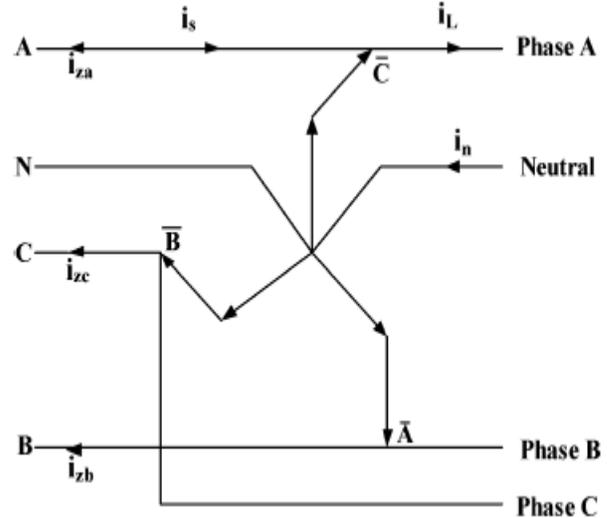

Fig. 3. Diagram showing the flow of currents of zig-zag transformer for neutral current compensation.

An application of a zig-zag transformer alone in a three-phase, four-wire system has the advantages of reduction in load unbalance and reducing the neutral current on the source side. But there are inherent disadvantages such as the performance being dependent on the location of the zig-zag transformer close to the load. Moreover, when the source voltage is distorted or unbalanced, the performance of reducing the neutral current on the source side is affected to an extent.

B. Zig-Zag Transformer With Active Filter-Based Compensation

A hybrid filter consisting of a single-phase VSC and a zig-zag transformer is also efficient in neutral current compensation, and the topology is shown in Fig. 4. A different topology for a single-phase VSC with a self-supporting dc bus and zig-zag transformer-based neutral current compensation system is shown in Fig. 5.

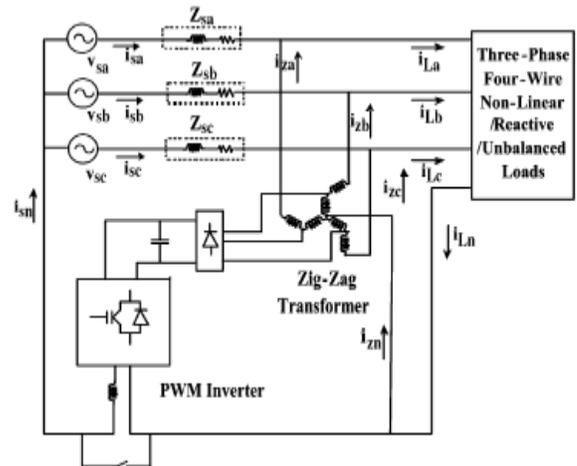

Fig. 4. Reduced rating single-phase inverter with a zig-zag transformer for neutral current compensation.

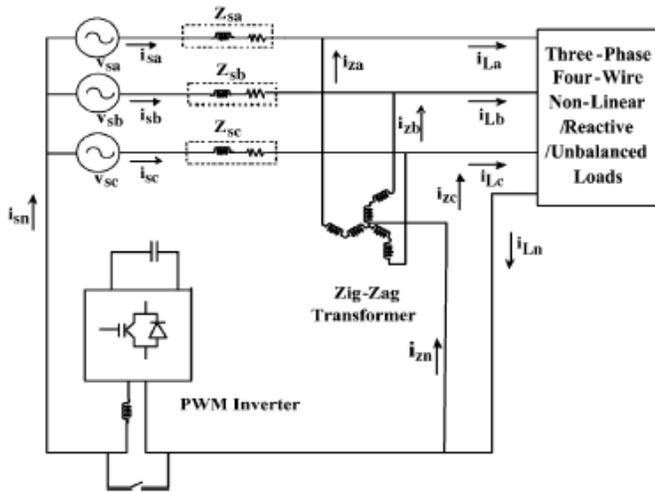

Fig. 5. Hybrid neutral current compensator using a single-phase inverter and zig-zag transformer.

D. Three-Phase Four-Wire Active Compensators

The neutral current along with harmonics, reactive power compensation, and load balancing are achieved using three phase four-wire DSTATCOM-based compensators. Three different topologies for three-phase four-wire DSTATCOMs, such as a voltage-source converter (VSC), with four leg, three single-phase VSC, and three-leg VSC with split capacitors are reported in the literature. Fig. 6 shows a four-leg DSTATCOM, split capacitor-based three-leg DSTATCOM is shown in Fig. 7, shows three single-phase VSC-based DSTATCOMs. Some researchers select the four-leg converter topology as the best alternative compared to others considering the number of switching devices, complexity of control, etc.

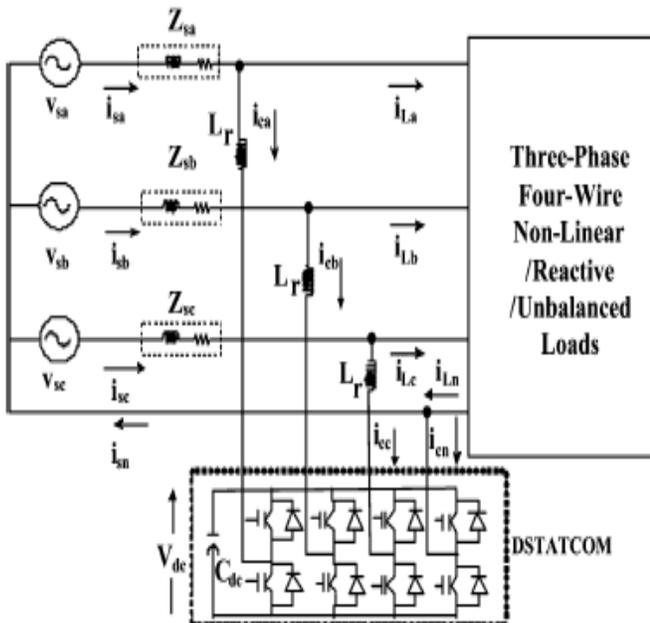

Fig. 6. Three-phase four-leg DSTATCOM for neutral current compensation.

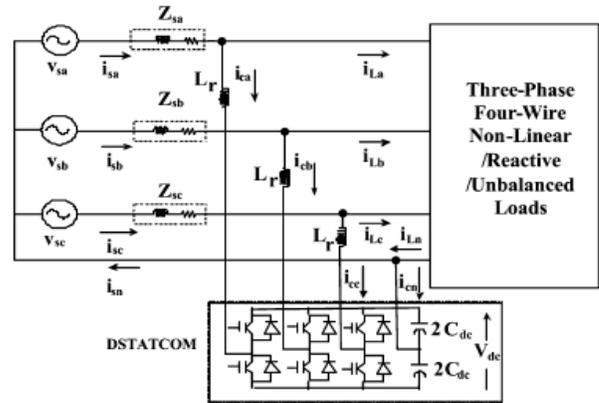

Fig. 7. Three-phase three-leg and split capacitor-based STATCOM for neutral current compensation.

There are different control techniques reported for deriving the reference control signals for the DSTATCOM. The instantaneous reactive power theory (p-q theory), synchronous reference frame (SRF) theory or d-q theory [50], power balance theory, etc., have been proposed to control the DSTATCOM for three-phase four-wire systems. The control of the three-phase four-wire compensation under nonsinusoidal source conditions is verified to be satisfactory in and the method is based on p-q theory. The instantaneous active and reactive powers are calculated after filtering out the harmonics in voltage and the theory is evaluated for a three-phase four-wire four-leg VSC-based system. The three-phase four-wire DSTATCOM-based systems are reported as very effective for the compensation, including neutral current. But this configuration has the disadvantages of a greater number of semiconductor switches, complexity of control, etc. A three-phase three-leg shunt compensator and a zig-zag transformer for neutral current compensation are shown in Fig. 8.

III. PROPOSED REDUCED RATING COMPENSATOR

The proposed compensator is a hybrid of a three-phase, three-wire VSC and a zig-zag transformer as a DSTATCOM. The DSTATCOM rating is reduced due to the elimination of a fourth leg compared to a three phase four-leg VSC-based DSTATCOM. It co-

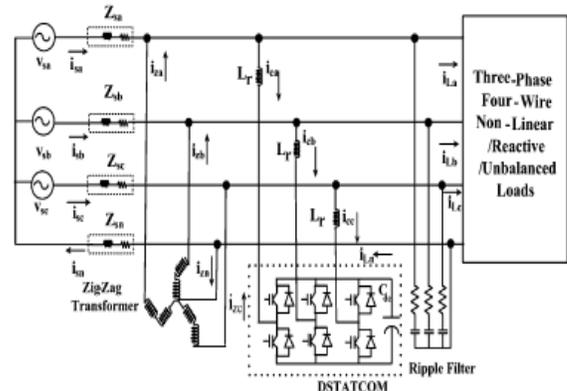

Fig. 8. Three-leg VSC-based DSTATCOM and zig-zag transformer for neutral current compensation.

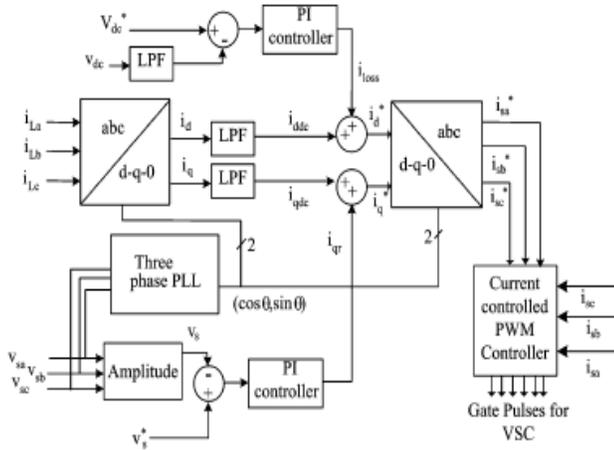

Fig. 9. Synchronous reference frame theory (SRFT)-based control of DSTATCOM.

mpensates for neutral current along with the load voltage regulation, harmonics currents elimination, reactive power compensation, and load balancing. The considered configuration of the proposed system is shown in Fig. 8. The zig-zag transformer connected at the load terminal provides a circulating path for zero-sequence harmonic and fundamental currents.

A. Design of the DSTATCOM VSC

The VSC used as a DSTATCOM in this configuration is a three-leg pulse-width modulated (PWM) insulated-gate bipolar transistor (IGBT)-based VSC. The PWM signals are generated by the control scheme for which the reference source currents and the sensed source currents are the input signals. The rating of the switches is based on the voltage and current rating of the compensation system. For the considered load mentioned in the Appendix, the rating of the VSC is 12 kVA. The selection of the dc bus voltage, dc bus capacitor, ac inductor, and the ripple filter will be given.

1) DC Bus Voltage: The value of the dc bus voltage depends on the instantaneous energy available to the DSTATCOM. For a VSC, the dc bus voltage is defined as

$$V_{dc} = 2\sqrt{2}V_{LL}/(\sqrt{3}m) \quad (1)$$

Where *m* is the modulation index and is considered as 1. Thus, one may obtain the value of *V_{dc}* as 677 V for *V_{LL}* of 415 V. Thus, *V_{dc}* of the value of 680 V is selected.

2) DC Bus Capacitor: The design of the dc capacitor is governed by the reduction in the dc bus voltage upon the application of load and rise in the dc bus voltage on removal of the load.

Using the principle of energy conservation, the equation governing *C_{dc}* is as

$$\frac{1}{2}C_{dc} [(V_{dc}^2) - (V_{dc1}^2)] = 3 V(aI)t \quad (2)$$

where *V_{dc}* is the reference and *V_{dc1}* is the minimum voltage level of the dc bus voltage, *a* is the over loading factor, *V* is

the phase voltage, *I* is the phase current of the VSC, and *t* is the response time of the DSTATCOM and *t* is considered as 350 μ s .

Considering *V_{dc}*= 680 V, *V_{dc1}*= 670 V, *V*=415/3 ,*a*=1.2 , the calculated value of *C_{dc}* is 2600 μ F. So *C_{dc}* is chosen to be 3000 μ F.

3) AC Inductor: The selection of the ac inductance depends on the current ripple *i_{cr,p-p}*. The ac inductance is given as

$$L_f = (\sqrt{3}mV_{dc}) / (12af_s i_{cr(p-p)}) \quad (3)$$

B. Design of the Zig-Zag Transformer

The zig-zag transformer provides a low impedance path for the zero-sequence currents and, hence, offers a path for the neutral current when connected in shunt and, hence, attenuates the neutral current on the source side. When a zig-zag transformer is used alone as a neutral current compensator, the rating of the zig-zag transformer depends on the amount of imbalance and harmonic content. Under the single-phase load, nearly half of the load current flows through the zig-zag windings. All six windings (two windings each of three phases) are rated as 150V, 10 A, and hence, three single-phase transformers of 5-kVA capacity each are selected in this investigation.

Considering 5% current ripple, the switching frequency(*f_s*)=10kHz, modulation index(*m*)=1, dc bus voltage (*V_{dc}*) of 680 V, and overload factor *a*=1.2, the *L_f* value is calculated to be 5.45 mH. The value of *L_f* of 5.5 mH is selected in this investigation.

4) Ripple Filter: A highpass first-order filter tuned at half the switching frequency is used to filter out the noise from the voltage at the PCC. The time constant of the filter should be very small compared to the fundamental time period (*T*)

$$R_f C_f \ll T/10 \quad (4)$$

when *T*=20 ms, considering *C_f*=5 μ F, *R_f* is chosen as 5 Ω . This combination offers a low impedance of 8.1 for the harmonic voltage at a frequency of 5 kHz and 637 Ω for fundamental voltage.

C. Control of DSTATCOM

There are many theories available for the generation of reference source currents in the literature viz. instantaneous reactive power theory (*p-q* theory), synchronous reference frame theory, power balance theory, etc. The synchronous reference frame theory-based method is used for the control of DSTATCOM. A block diagram of the control scheme is shown in Fig. 9. The load currents(*I_L*) , the source voltages,*(V_s)* and dc bus voltage (*V_{dc}*) of DSTATCOM are sensed as feedback signals. The loads currents in the three phases are converted into the d-q -0 frame using the Park's transformation as in (5)

$$\begin{bmatrix} i_d \\ i_q \\ i_0 \end{bmatrix} = \frac{2}{3} \begin{bmatrix} \cos \theta & -\sin \theta & \frac{1}{2} \\ \cos(\theta - \frac{2\pi}{3}) & -\sin(\theta - \frac{2\pi}{3}) & \frac{1}{2} \\ \cos(\theta + \frac{2\pi}{3}) & \sin(\theta + \frac{2\pi}{3}) & \frac{1}{2} \end{bmatrix} \begin{bmatrix} i_{La} \\ i_{Lb} \\ i_{Lc} \end{bmatrix} \quad (5)$$

A three-phase phase-locked loop (PLL) is used to synchronize these signals with the source voltage. The d-q components are then passed through lowpass filters to extract the dc components of i_d and i_q . The error between the

reference dc capacitor voltage and the sensed dc bus voltage of DSTATCOM is given to a proportional-integral (PI) controller whose output is considered the loss component of the current and is added to the dc component of i_d . Similarly, a second PI control-

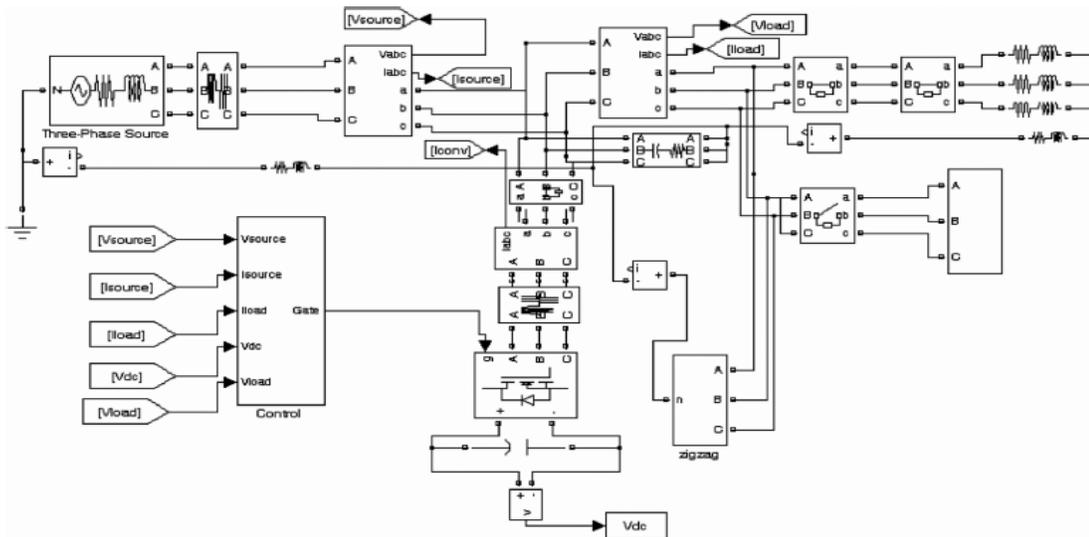

Fig. 10. MATLAB model of the three-phase three-leg DSTATCOM and zig-zag transformer for neutral current compensation. The amplitude of the load terminal voltage and its reference value are fed to a PI controller and the output of the PI controller is added with the dc component of i_q . The control strategy is to regulate the terminal voltage and the elimination of harmonics in the load current and load unbalance. The resulting currents are again converted into the reference source currents using the reverse Park's transformation. The reference source currents and the sensed source currents are used in the PWM current controller to generate gating pulses for the switches. For the power factor correction, only the dc bus voltage PI controller is used in the control algorithm.

IV. MATLAB-BASED MODELING OF DSTATCOM

The neutral current compensation using a zig-zag transformer is modeled and simulated using the MATLAB and its Simulink and Power System Blockset toolboxes. Fig. 10 shows the MATLAB model of the DSTATCOM and zig-zag transformer- connected system for neutral current compensation. The considered load is a lagging power factor load. The ripple filter is connected to the VSC of the DSTATCOM for filtering the ripple in the terminal voltage. The system data are given in the Appendix.

The control algorithm for the DSTATCOM is also modeled in MATLAB. The reference source currents are derived from the sensed voltages (V_s), load currents (i_L), and

the dc bus voltage of DSTATCOM (V_{dc}). A PWM current controller is used over the reference and sensed source currents to generate the gating signals for the IGBTs of the DSTATCOM VSC.

V. RESULTS AND DISCUSSION

Some of the important neutral current mitigation techniques are analyzed and modeled using MATLAB. The performance of harmonic neutral current compensation using the zig-zag transformer for the nonlinear load and linear load are shown Fig. 11. Performance of the three-phase three-leg VSC and zig-zag transformer of the DSTATCOM for neutral current compensation, load balancing, and

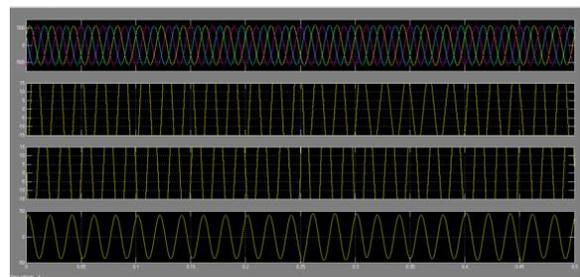

Fig. 11. Performance of the zig-zag transformer for fundamental neutral current compensation.

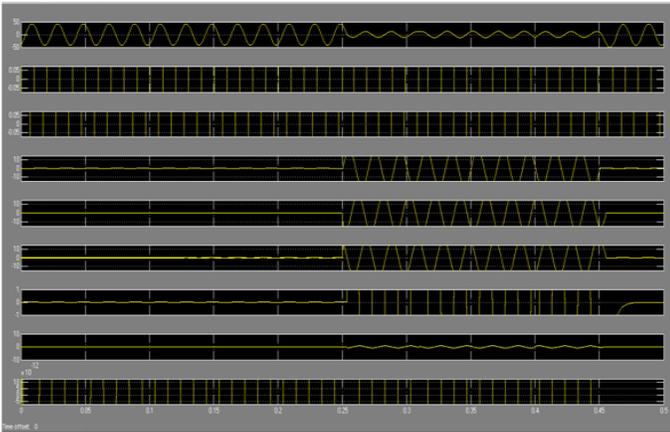

Fig. 12. Performance of the three-phase three-leg VSC and zig-zag transformer of the DSTATCOM for neutral current compensation, harmonic compensation, and voltage regulation.

power factor correction. in Figs. 11 and 12, respectively. The voltages (V_s), source currents (i_{sa} , i_{sb} , i_{sc}), load currents (i_{La} , i_{Lb} , i_{Lc}), zig-zag transformer currents (i_{za} , i_{zb} , i_{zc}), load neutral current (i_{Ln}), source neutral current (i_{sn}), and zig-zag transformer neutral source neutral current (i_{Sn}) and zig-zag neutral current (i_{Zn}) are demonstrated. It is observed that the zig-zag transformer has compensated the load neutral current, resulting in a source neutral current of nearly zero. The performance using a three-phase four-leg DSTATOM for voltage regulation along with neutral current compensation and load balancing of a three-phase four-wire load is shown in Fig. 13.

The voltages (V_s), balanced source currents (i_s), load currents (i_L), compensator currents (i_C), load neutral current (i_{Ln}), compensator neutral current (i_{Zn}), source neutral current (i_{sn}), amplitude of the load terminal voltage (V_s), and dc bus voltage (V_{dc}) are demonstrated under changing load conditions. It is observed that the amplitude of the load voltage is regulated to the reference amplitude by the required reactive power compensation.

The performance using a three-phase four-leg DSTATOM for voltage regulation along with neutral current compensation and load balancing of a three-phase four-wire load is shown in Fig. 13. The voltages (V_s), balanced source currents (i_s), load currents (i_L), compensator currents (i_C), load neutral current (i_{Ln}), compensator neutral current (i_{Zn}), source neutral current (i_{sn}), amplitude of the load terminal voltage (V_s), and dc bus voltage (V_{dc}) are demonstrated under changing load conditions. It is observed that the voltage amplitude is regulated to the reference value under all load disturbances. The source current is balanced, even though the load current is highly unbalanced and this is achieved by using the unbalanced fundamental current injection by the DSTATCOM. The zero-sequence fundamental current of the load neutral current resulting from the unbalanced load current is circulated in the zig-zag transformer, and hence, the source neutral current is maintained at nearly zero. The dc bus voltage of the VSC of DSTATCOM is regulated by the controller and the voltage is maintained near the reference

voltage under all load disturbances. The performance of the DSTATCOM with a zig-zag transformer for voltage regulation and harmonic elimination along with neutral current

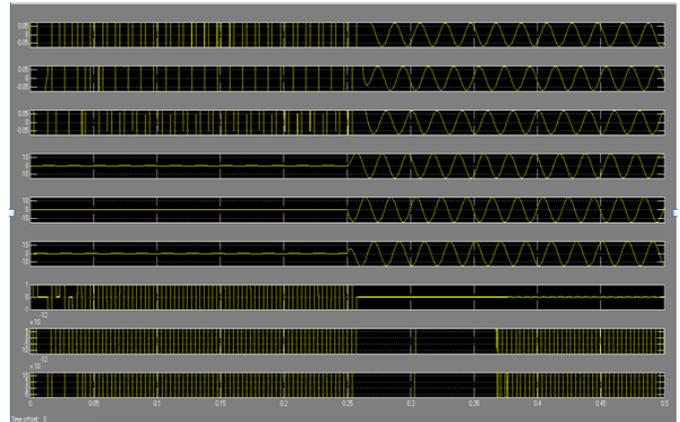

Fig. 13. Performance of the three-phase three-leg VSC and zig-zag transformer of the DSTATCOM for neutral current compensation, load balancing, and power factor correction.

compensation is shown in Fig. 14. The voltages (V_s), balanced source currents (i_s), load currents (i_L), compensator currents (i_C), load neutral current (i_{Ln}), compensator neutral current (i_{Zn}), source neutral current (i_{sn}), amplitude of the load terminal voltage (V_s), and dc bus voltage (V_{dc}) are demonstrated under various nonlinear loads. It is observed that the terminal voltage is regulated to the reference value.

The dynamic performances of the DSTATCOM system in the unity power factor (UPF) mode of operation are depicted in Figs. 13 and 14. The load balancing and neutral current compensation are demonstrated in Fig. 18 and the harmonic elimination and neutral current compensation are demonstrated in Fig. 14. The voltages (V_s), balanced source currents (i_s), load currents (i_L), compensator currents (i_C), load neutral current (i_{Ln}), compensator neutral current (i_{Zn}), source neutral current (i_{sn}), amplitude of the load terminal voltage (V_s), and dc bus voltage (V_{dc}) are shown in both cases. It is also observed that the terminal voltage is not regulated in both cases as the compensator operates in the UPF mode.

These results show that the zig-zag transformer is able to compensate for the fundamental and harmonic neutral current. The rating of the transformer used for the zig-zag connection depends on the neutral current on the load side. The three-phase four-wire DSTATCOM compensates for the neutral current along with harmonic and reactive current compensation in the phase current. But additional IGBTs are required for neutral current compensation. A hybrid of a three-wire DSTATCOM and zig-zag transformer is also able to perform satisfactorily and the advantage is that it uses a readily available three-wire VSC as a DSTATCOM and a passive zig-zag transformer. The comparison of the rating of DSTATCOM and zig-zag transformer compensators during different compensation methods is given in Table I. The rating of the VSC is reduced to 12 kVA where as it is 16 kVA for a four-leg DSTATCOM. The current magnitude and total

harmonic distortion (THD) are compared in the three cases and are shown in Table II. The THD of unbalanced load currents is nearly 85%, when the load is a voltage-source rectifier. When a zig-zag transformer is employed, the source neutral current is reduced to 0.11 A, whereas the load neutral current is 16 A. But the source-phase currents are balanced and with reduced THD, when a DSTATCOM is also employed as a voltage regulator. The additional benefit of terminal voltage regulation is also demonstrated in Figs. 13 and 14.

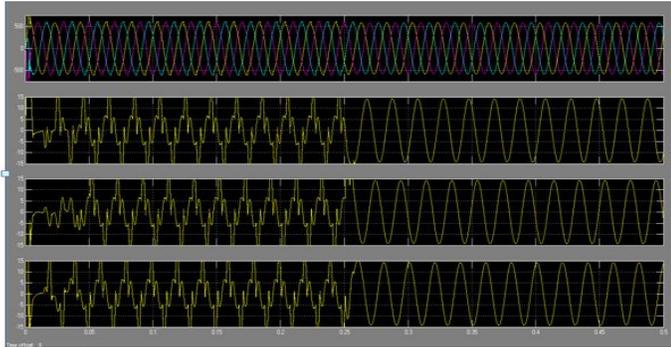

Fig. 14. Performance of the three-phase three-leg VSC and zig-zag transformer of the DSTATCOM for neutral current compensation, harmonic compensation, and power factor correction.

VI. CONCLUSION

The causes, standards, and mitigation techniques of the excessive neutral current have been investigated in the three-phase four-wire distribution system. The modelling and simulation of the zig-zag transformer has been demonstrated for neutral current compensation. Moreover, a hybrid of zig-zag transformer with a three-phase three-leg DSTATCOM has been observed as an effective option for overall compensation. The performance of the proposed compensator is validated through extensive computer simulation.

APPENDIX

Line impedance $R_s=0.01\Omega$, $L_s=1mH$

1) linear load: 20 kVA, 0.80-pf lag;

2) nonlinear load: a three single-phase bridge rectifier with an R-C load with $R=25\Omega$ and $C=470\mu F$.

Ripple filter: $R_f=5\Omega$; $C_f=5\mu F$.

DC bus capacitance: 3000 μF .

DC bus voltage: 680 V.

AC line voltage: 415 V, 50 Hz.

PWM switching frequency: 10 kHz.

Zig-zag transformer: three numbers of single-phase transformers of 5 kVA, 150/150 V.

ABSTRACT: Exhaust Gas Recirculation has emerged as one of the promising technique in abating oxides of Nitrogen but combustion quality deteriorates at higher loads and higher percentage of Exhaust Gas Recirculation do not become attractive owing to decreased efficiency and increased hydrocarbon and smoke. Another technology that offers promise of being able to reduce engine emissions is alcohol fumigation. An experimental investigation is carried to examine the performance and emission with alcohol fumigation in the presence of hot Exhaust Gas Recirculation on a single cylinder DI diesel engine. The main focus was on oxides of nitrogen, hydrocarbon and smoke emission and variations in thermal efficiency. Results pertaining to Exhaust Gas Recirculation showed greater reductions in NO_x emission. The reductions in the efficiency were marginal (about 5%) up to 30% Exhaust Gas Recirculation but tend to increase amounting up to 30 to 40% at higher loads and higher percentage of Exhaust Recirculation (above 30%). Hydrocarbon concentrations and smoke percentage also simultaneously increased indicating poor combustion. Alcohol fumigation in presence of hot Exhaust Gas Recirculation comparatively improved the thermal efficiency with simultaneous reduction in concentrations of HC and smoke level. Results pertaining to only diesel, diesel with Exhaust Gas Recirculation and Exhaust Gas Recirculation combined with ethanol fumigation without reducing diesel injections are presented in this paper.

Key Words: EGR; Ethanol; Fumigation; NO_x; Smoke; HC; Efficiency; Dilution effect

I. INTRODUCTION

Exhaust emissions from diesel engines are substantial source of air pollution. In recognition of this fact, the regulating authorities of all countries implemented strict regulations which are in effect since 1991. Unfortunately single technology is currently not available to meet these regulations without penalties in engine performance and efficiency. Application of various motor vehicle emission control technologies has established a history of success. This success, however, has largely been offset by the constantly growing numbers of vehicles and miles traveled. Heavy-duty diesel engine manufacturers have developed new technologies in response to increasingly stringent emission standards. The diesel engine has long been a champion of fuel economy, with advantages in reliability

and durability over other power plants. Yet, controlling NO_x, and particulate emissions has been a formidable challenge to the diesel industry because most traditional NO_x, control approaches tend to increase particulate emissions, and vice versa. Many development programs carried out over the last five years have yielded remarkable results in laboratory demonstrations. Traditionally, design changes aimed at reducing one of exhaust species have led to an increase in the other. Exhaust Gas Recirculation, EGR, is one of the most effective means of reducing NO_x emissions from diesel engines and is likely to be used in order to meet future emissions standards. The main difficulties with these techniques are to meet the requirement for NO_x and at the same time minimize the fuel penalty.

I. 2. ETHANOL AS MOTOR FUEL

Historically ethanol and methanol have been used as automotive fuels for long time, both as neat fuels and as blend components chiefly in gasoline engine. Nikolaus Otto, the father of the Otto engine, regarded ethanol as an attractive fuel for combustion engines and in 1908 Henry Ford started the construction and production of an ethanol fuelled engine and claimed that alcohol could be an automotive fuel for the future. Although replacing diesel fuel entirely by alcohols is very difficult, an increased interest has emerged for the use of alcohols, and particularly lower alcohols (methanol and ethanol) with different amounts and different techniques in diesel engines as a dual fuel operation during recent years. Ethanol or ethyl alcohol was used as quality motor fuel in the first automobile, the original Ford Model-T and after that it is only recently that interest was shown in the use of ethanol and methanol as diesel fuels. It is reported that about 80% proof ethanol is optimum as higher proofs do not give as much reductions in oxides of nitrogen emissions [1-2].

II. DIESEL NO_x FORMATION AND EFFECT Of EGR

NO_x is formed by an endothermic reaction in the burned gas regions of the cylinder. The formation of NO_x is very sensitive to temperature. The higher flame temperatures accompanying early or rapid combustion greatly increase NO_x formation [3]. Thus the amount of NO_x in diesel exhaust is sensitive to flame temperature. Availability of oxygen and burn duration are the other two reasons for the formation of NO_x[3]. Dilution of the charge by rerouting a part of the exhaust gas (EGR)

reduces the availability of oxygen on one hand and reduces the flame temperature on the other, owing to higher specific heats of EGR lased constituents like H₂O and CO₂ [4-9]. Thus presence of exhaust gas during combustion helps in abating the formation of NO_x but higher percentage of EGR deteriorates the combustion quality thereby causing incomplete combustion [7].

III. DIESEL COMBUSTION WITH ETHANOL

Local mixture formation, self-ignition and combustion needs time to be completed. Not-complete combustion of diesel fuel is a source of hydrocarbon emission and smoke. In order to avoid this inconvenient effect, injection of ethanol to inlet duct is considered [10]. Ethanol will quickly evaporate (but will not self-ignite), and will be ignited by burning diesel droplets resulting in very high combustion rate of both fuels, especially diesel fuel. With higher combustion rate higher thermal efficiency, higher power output and lower emission of HC and smoke are expected. Hence, the combined effect of ethanol fumigation (without reducing the amount of diesel being injected) and EGR is expected to reduce NO_x with marginal loss of efficiency when compared to use of EGR alone.

IV. TEST ENGINE

Table.1. Specification of the test engine

Type	4-Stroke, Single Cylinder Diesel Engine(Water Cooled)
Make	Kirloskar AV – 1.
Loading	Electrical, Resistive Air Heaters
Rated Power	3.7KW, 1500 RPM
Bore & Stroke	85mm x 110mm
Cylinder Capacity	624.19 cc
Compression Ratio	16.5 : 1
Pressure Transducer	Piezo Sensor, Range: 2000 PSI.
Starting	Auto Start.
Orifice Diameter for air flow	15mm

The test engine is Kirloskar AV1 engine facilitated with data acquisition systems (DAS) for recording engine data measurement. External EGR is routed into the intake manifold through a one inch diameter GI pipe. The EGR line emerges right after the exhaust manifold from the engine and enters the in the intake manifold close to engine. Fresh air and EGR are made to mix before it enters into engine cylinder. An orifice meter is used to determine the flow rate of EGR. The reported percentage of EGR is defined as the volumetric ratio of the recirculated gas to the total charge induced in to the cylinder. AVL smoke meter is used to measure the smoke level and INDUS[®] 5 gas analyzer for O₂, CO, CO₂, HC and NO_x measurements.

Details of the test engine are given in table 1. The ethanol fumigation is achieved through an additional injector attached just before the inlet manifold, inclined and in opposite direction to EGR flow.

The injection pump is driven by the cam shaft of the engine. Cam is so designed to inject the ethanol in 5, 10, 15 and 20% of total amount of diesel injected in a cycle for a given load. This arrangement is shown the fig.1.

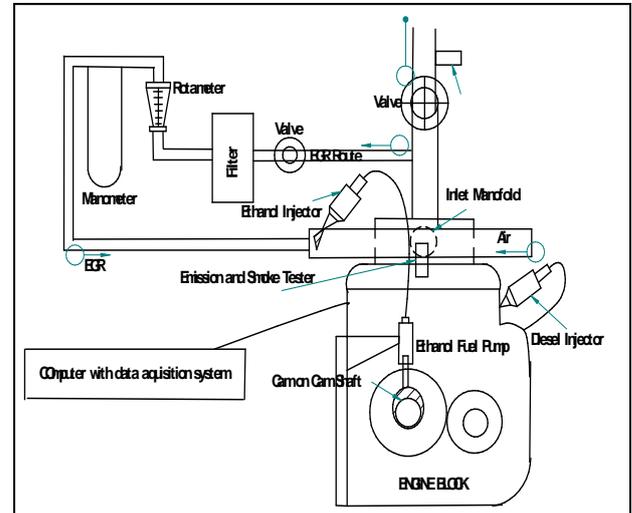

Fig.1 Test engine layout.

V. RESULTS AND DISCUSSIONS

5.1 Engine Torque

As expected injecting ethanol will increase the torque (adds energy) as amount of diesel injected is not reduced. In the fig.2, the trend of torque at part load of 1.5 kW and maximum load of 2.5kW for 5, 10, 15 and 20% ethanol fumigation are compared with those corresponding to only hot EGR. Torque values for 5%, 10% and 15% ethanol fumigation are higher as compared to hot EGR for both part and full load but for 20% values reduce. At full load torque is almost same for 5, 15 and 20% ethanol fumigation and hot EGR for all percentage of EGR. 10% fumigation gives the optimum results for all values of load and EGR percentage.

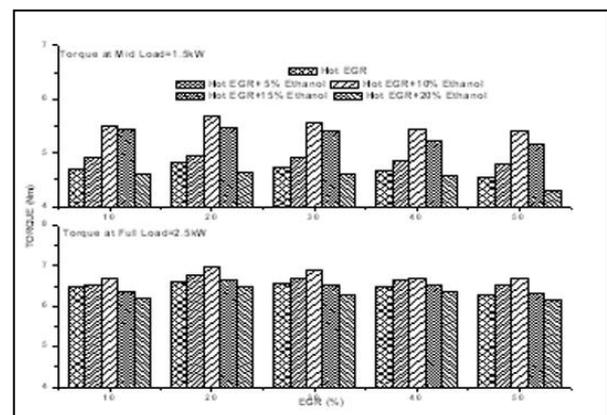

Fig.2; Comparison of engine torque for part load (1.5kW) and full load of (2.5kW) for increasing percentage of EGR

5.2 Thermal Efficiency

Thermal efficiency is a measure of engine output power and fuel consumption. For an engine operating at constant speed, the torque increase as the load increase. Ethanol fumigation improves the efficiency when compared to corresponding values of hot EGR for all loads.

The thermal efficiency values are comparatively better for 5% and 10% ethanol fumigation as compared to higher dose (fig.3). Fig (4) depicts the results of thermal efficiency for part load (1.5kW) and full load (2.5kW) for 10 to 50% EGR. The variation in thermal efficiency is negligible up to 30% EGR and tends to slightly decrease thereafter particularly for only hot EGR case. Ethanol fumigation along with hot EGR shows improved efficiency in this region.

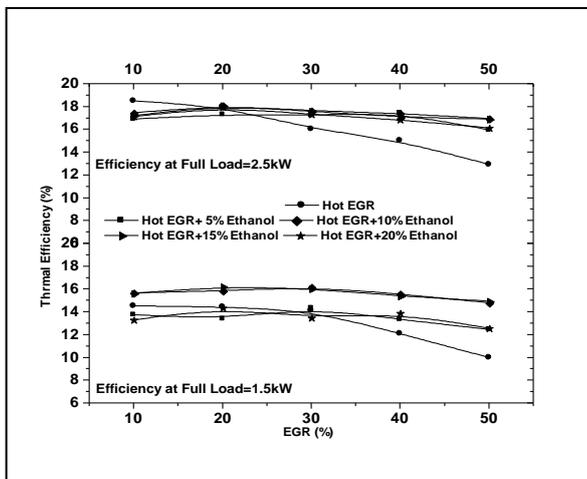

Fig.3. Engine thermal efficiency for 50% and 40% EGR for increasing load.

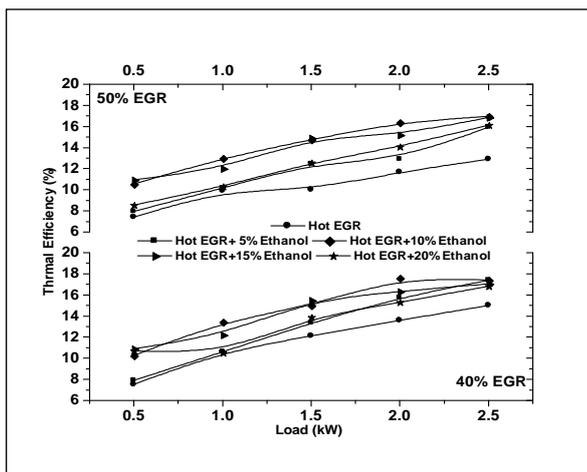

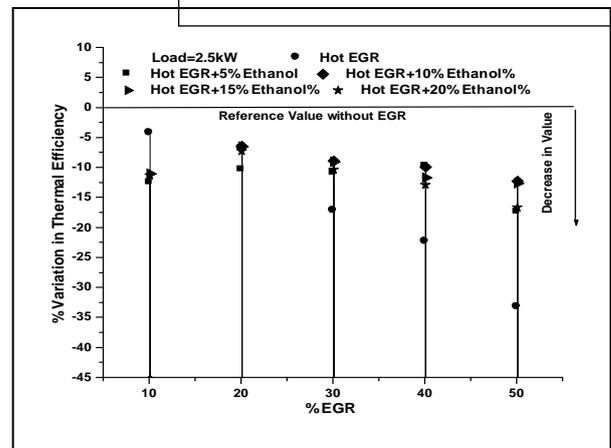

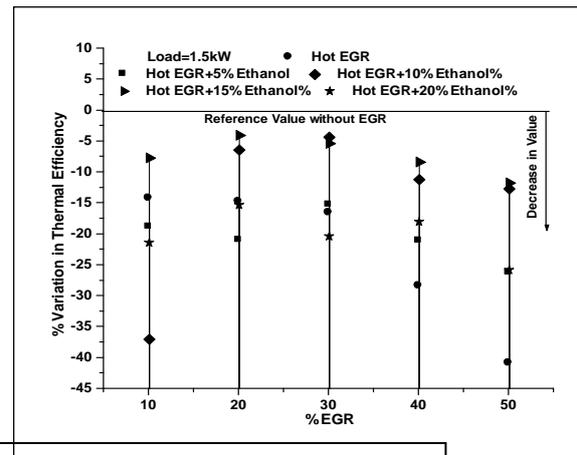

Fig.4; Engine thermal efficiency for different EGR percentage at part load (1.5kW) and full load(2.5 kW).

The fig(5) and Fig.(6) show the comparison of variation in thermal efficiency in percentage for three different cases; (i) Hot EGR. (ii) Hot EGR with different

percentage of ethanol fumigation and (iii) Only diesel, which is taken as reference. It is clear that thermal efficiency reduces for both ethanol fumigation with EGR and hot EGR when compared with only diesel case. However for ethanol fumigation with EGR, these percentage losses are less and values are more close to reference values. The loss in efficiency is limited to around 20% for fumigation case where as it is up to 40% for without fumigation case. Another observation is that loss of efficiency is very marginal (around 5%) for up to 10% ethanol fumigation and then it slightly increases (around 20%) as the fumigation percentage increases.

Fig.5; Percentage variation in engine thermal efficiency for different EGR percentage for part load of 1.5kW.

Fig.6; Percentage variation in engine thermal efficiency for different EGR percentage for full load of 2.5 kW.

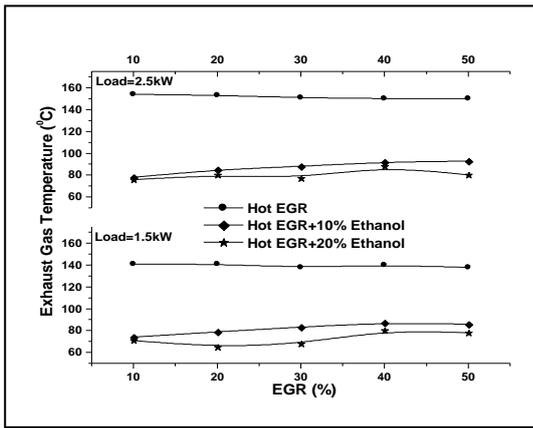

Fig.7; Engine exhaust gas temperature for part load of 1.5kW and full load of 2.5 kW against different percentage of EGR.

5.3 Flame temperature

Ethanol with their greater latent heat of vaporization gives a higher charge density; and their higher laminar flame speed allows them to be run with leaner, or more dilute, air/fuel mixtures [10].

In ethanol and air mix combustion more moles occur than in diesel combustion, therefore the torque increases (Fig.2). On the other hand, triatomic gas is more susceptible to the heat, which will be taken from the working fluid present in the cylinder, thus decreasing the temperature in the combustion chamber and exhaust gas as well. The engine exhaust temperature as an indicative of combustion temperature (Fig.7) for hot EGR and ethanol fumigation with EGR for part and full load vindicate this.

for part load of 1.5kW and full load of 2.5 kW against different percentage of EGR.

5.4 Hydrocarbon Emission

Emission of HC in the engine tail pipe is mainly a result of incomplete combustion. Presence of burnt gas (EGR) causes reduced availability of oxygen due to thermal throttling [5, 6, and 12].

Fig.9; Smoke emission for part load of 1.5kW and full load of 2.5 kW against different percentage of EGR.

Ethanol fumigation during intake is expected to supply oxygen as ethanol in comparison to diesel fuel contains some oxygen atoms. Ethanol molecules contain 35 percent oxygen, and serve as an “oxygenate” to raise the oxygen content and emission of HC and smoke are expected to be low with ethanol taking part in the combustion.

This is found true even in the presence of EGR during the combustion but only up to 10% fumigation and there after for 15% and 20% ethanol dose HC concentration increased even more than the values corresponding to only hot EGR. This indicates a poor combustion. Also high HC emissions due to higher dose of alcohol were probably caused by very strong quenching effect due to its high latent heat of evaporation and low centane number.

5.5 Smoke Emission

Smoke is a result of condensation of hydrocarbon and presence of soot. Soot, particulate (smoke) is formed mostly through incomplete combustion of fuel, with small contributions from the lubricating oil [11], more difficult pulverisation of the heavy diesel droplets and non-homogeneous distribution of the diesel fuel over the combustion chamber.

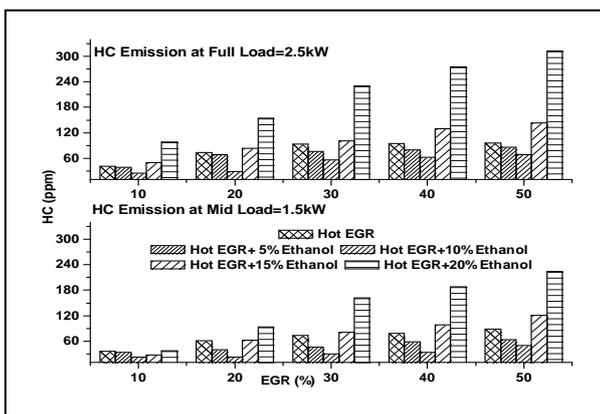

Fig.8; Emission of Unburnt Hydrocarbon emission

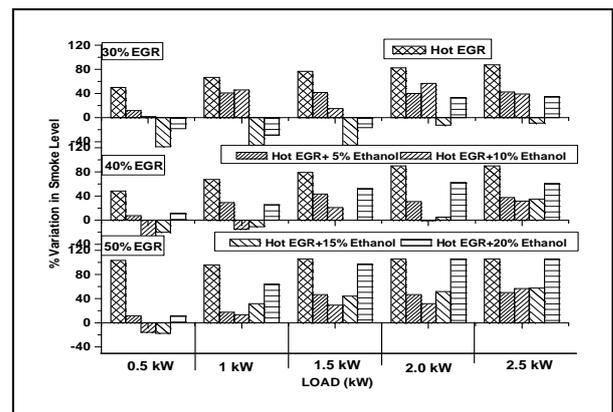

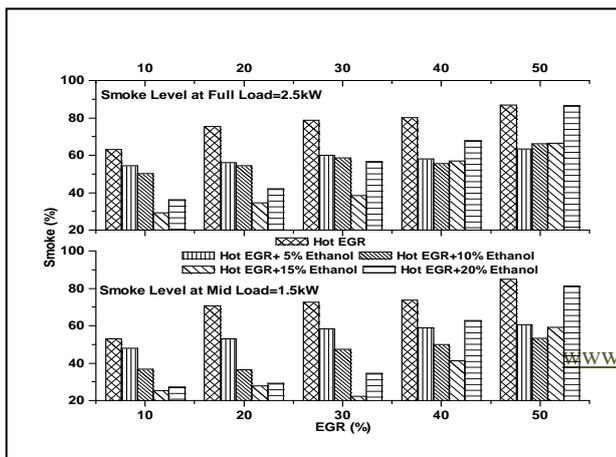

Fig.10; Percentage variation in smoke different engine load for 30%, 40% and 50% EGR

As the fuel in the advancing flame plume combusts, pyrolytic reactions crack the hydrocarbons that have yet to pass through the flame. As these reactions occur, particulate masses form. If the fuel mixing is poor within the cylinder, large quantities of particulates can

form [2]. Typically, above temperatures of 500⁰C, the particles are composed solely of clusters of carbon, while at temperatures below this; higher molecular weight hydrocarbons condense onto the clumps. As the particulates travel through the flame and into the more heavily oxygen populated areas, the clumps tend to oxidize and for this reason concentrations are reduced in the leaner regions of combustion. The presence of ethanol favors oxidation process and smoke level is expected to reduce and literatures suggest that ethanol is best fuel to minimize smoke and particulate matters.

Fig. (9&10) indicate Hot EGR emit more smoke as compared to EGR with ethanol fumigation. As fumigation quantity is increased from 5% to 15% the smoke level tend to decrease remarkably. But further increase in fumigation of ethanol records slightly higher values mainly due to reduced temperatures where soot oxidation is hampered and also due to deteriorated combustion. Smoke levels are found nearly same or even less for ethanol fumigation with EGR when compared to only diesel case (taken as reference) up to 30% EGR for both part load (1.5kW) and full load (2.5 kW) and thereafter its values start climbing for higher loads. This result is obvious as HC concentrations (Fig.8) show similar trend.

5.6 NOx Emission

Diesel NOx emissions result from the thermal fixation of atmospheric nitrogen and its oxidation in the presence of high combustion temperature. Control of these emissions can be achieved by reducing the peak flame temperatures

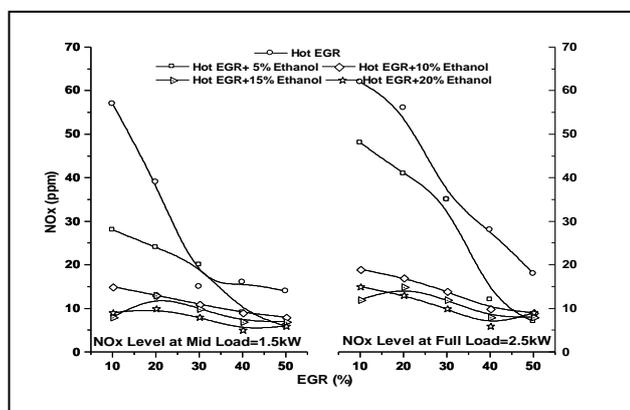

Fig.11; NOx emission for part load of 1.5kW and full load of 2.5 kW against different percentage of EGR.

EGR reduces the peak temperature by diluting the charge with burnt exhaust gas. Higher NOx emission reductions can be achieved through higher percentage of EGR but results into a loss in thermal efficiency and increased HC and CO emission especially at higher EGR values and higher loads. Alcohols generally give lower fuel heat release rates, resulting in lower NOx emissions. With fumigation of ethanol in the presence of EGR enables admit more percentage EGR with greater reductions in NOx along with comparatively lower emissions of HC and smoke. Fig. (11) show the reductions of NOx for part load and full load with and without ethanol fumigation. NOx concentration remains

low for ethanol fumigation case as compared to without fumigation for entire range of EGR percentage.

VI. CONCLUSION

It can be concluded from the results obtained from the experiment that

1. EGR method to abate NOx emission is very effective. The disadvantage is decreased efficiency and increased HC and Smoke with higher percentage of EGR and at higher loads.
2. Ethanol fumigation without altering the diesel injection proves to be a better option in reducing HC, smoke and NOx apart from improving the engine thermal efficiency.
3. Ethanol fumigation above 10% tends to increase HC and smoke emissions when compared to corresponding values for 5 and 10% , however these values are very less as compared to use of EGR without ethanol fumigation.
4. 10% ethanol fumigation with HOT EGR is a better option for higher percentage of EGR to be used with maximum reductions in NOx emissions with marginal loss of efficiency.

Development & Characterization of Ceramic Membranes

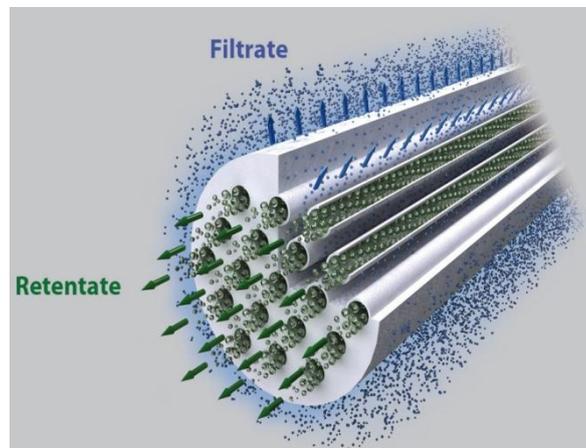

Manohar

Abstract: Ceramic membranes are used for water and gas filtration of its chemical inertness, low temperature preparation, good mechanical and porous properties. Important characteristics of ceramic membranes are high porosity, high permeability, defined pore size and good mechanical properties. In this study, fabrication and characterization of ceramic membranes preparation was carried out.

For example, Zirconia ceramic samples in the form of tubes are prepared by extrusion. The effect of hydrothermal reactions of zirconia oxynitrate for Zirconia membrane preparation as a starting powder was analyzed. Zirconia coating is applied on the SiC tube. It is mainly carried out by hydrothermal reaction. Zirconia solution prepared from zirconia oxynitrate and water. This hydro thermal test is carried out in an oven at 150°C for 16hrs. Finally we got good zirconia coating on SiC base. Found zirconia coated body is then dried at 100°C and fired at 800°C. Fired samples are characterized and tested for density, porosity, permeability, & S.E.M. Obtained product shows optimum porosity (40-45%) and good permeability for the membrane application like water filtration.

I. INTRODUCTION

Membrane separation has become an important unit operation in water operation in water and wastewater treatment. Different degrees of water quality can be obtained with removal of particles, dissolved organic compound, protein and ions. However, two dominant areas are removal of organic compound in water clarification and osmotic desalination. The overall principle in any membrane separation is sketch in figure.

The principle in membrane separation.

1.1 Membrane operation

The first thing to recognize is that regardless the use of different designs the separation depend on the physical – chemical properties of the material to be separation and the membrane used. The separation is driven by a difference in chemical potential across the membrane. The force needed to establish such chemical potential difference across the membrane. Pressure related membrane separation is usually divided into four operations: Microfiltration, ultra filtration, nanofiltration and reverse osmosis- each having different characteristic.

Table shows that separation of small particles/molecules requires a high trans- membrane pressure. In addition, the rate of separation, the flux, decreases. New membrane materials with different properties are developed all the time simply to fit the need for the membrane operation just mentioned.

Tabel1.a.1: Pressure drop for different membrane processes

Membrane process	$\Delta p(\text{bar})$	Size Range (μm)	$J(\text{l/m}^2 \cdot \text{h} \cdot \text{bar})$
Microfiltration	0.1 -2.0	0.1-10	>50
Ultrafiltration	1.0-5.0	0.02-0.3	10-50
Nanofiltration	5.0-20	0.001-0.01	1.4-12
Reverse osmosis	10-100	<0.001	0.05-1.4

1.2 Classification of membranes

Membrane are classified according to separation mechanism, physical morphology, membrane geometry and physical-chemical properties. This can sometimes be confusing but one must bear in mind that scientific people have different interest in membrane technology. Some are only interested in membrane synthesis, others in membrane module design. A good exercise is to ask our self: which kind of separation mechanism is used in this membrane operation? What is the membrane morphology? etc.

Essentially, there are three type of separation mechanism:

1. Separation by size- the sieve effect: This requires porous membranes with rather large pores. Terms like macropores, mesopores and micro pores (figure 1.a.2) are used to describe the pore size in membrane for microfiltration ultra-filtration and nanofiltration.
2. Separation by different in solubility and diffusivity of material: This principle is used in operations like reverse osmosis and requires the membrane used to be dense (nonporous).
3. Separation by charge: An ion exchange membrane separates compounds of different charges. Ion-exchange membranes are used in operation like electro dialysis and are generally nonporous.

II. Polymer Membranes:

For the sake of simplicity, only two very common organic membrane materials will be discussed here. Details about other materials can be found in Table.

One of the most common materials used is cellulose and derivatives. Cellulose esters like cellulose acetate and ethyl cellulose are all repeating units of glucose, connected by glycoside bonds, where the hydroxyl groups on each glucose unit participate in ester formation. The membranes are hydrophilic but only sparingly soluble in water. Polarity is compared to the other materials in table (except polyacrylonitrile) relatively high. Cellulose esters resist cleaning with chlorine, but hydrolyze easily, like other ester compounds, when exposed to acid or base. In addition, temperature and biological activity may cellulose membranes.

Summary of the most widely used porous membrane materials.

Material	Physical-chemical properties	Primary membrane operation area in water treatment
Cellulose esters (CE) primary cellulose acetate (CA)	Low chemical stability towards acid/base, temperature and biological activity. Resist chlorine cleaning. Relatively polar. Very hydrophilic.	Desalination, softening, disinfection and clarification using micro, ultra and nano filtration and reverse osmosis.
Aliphatic and aromatic polyamides (PA)	Higher hydraulic and thermal stability than CE, but sensitive towards oxidation e.g. chlorine. Hydrophilic.	Reverse osmosis but also ultra and micro filtration applications.
Polyacrylonitrile (PAN)	Less hydrophilic than CE's and PA's but very polar.	Ultra filtration applications in general
Polysulfone (PSF) and Polyethersulfon (PES)	Weak hydrophobic with some polar tendency. Good chemical and thermal stability.	Ultra filtration, support material for several composite membranes.
Polytetrafluoroethylen (PTFE), polyvinylidene fluoride (PVDF), and polypropylene (PP).	Hydrophobic non-polar membranes. High thermal and solvent resistance very chemically inert. Adsorb only weakly.	Micro and ultra-filtration applications.

The above table is a very qualitatively way to list of physical-chemical membrane properties. It is often difficult to do otherwise with this kind of properties, but in the next section a tool to physical characterization will be presented and it will make the classification more quantitatively.

Ceramic membranes

Plant Engineers and plant operators demand, with respect to membrane installations, process stability, high availability and low requirements for preliminary treatment and minimum need for support and maintenance.

In contrast to many polymer membranes the ceramic membranes are a perfect match for this demand due to their extremely high chemical and physical stability, their outstanding separation characteristics and their long working life.

Ceramic materials are generally very stable chemically, thermally and mechanically, and in addition are frequently bio inert. They are therefore ideal materials for many applications in the chemical and pharmaceutical industry or in water and waste water processing.

The medium to be filtered flows through the channels of the membrane carrier. Particles are retained if their size exceeds the radius of the membranes pores, building up the concentrate. The filtrate permeates through the pores and it is subjected to subsequent process stages.

Many are the advantages deriving from the ceramic membranes use:

- No ageing, long life and reliability.
- High temperature stability.
- Mechanical stability under large pressure gradient.
- Stability over a large pH range.
- 0.3 – 100 efficiency in gas separation.
- Ability to be backwashed and abrasion resistance (steam sterilization and high flash capability)
- Incentive to bacterial action.
- Can process highly viscous fluid.
- Good control of pore dimension fouling.
- They are ecologically friendly and more favorable than separation technologies.
- No additives are necessary and the process temperature is not limited

Filtration with ceramics is a mild, highly selective process without phase transformation. Running costs are limited by closed production cycles and continuous processes.

Disadvantages are:

- Brittle character needs configuration supporting system.
- Relatively high capital installation cost.
- Relatively high modification costs in case of defects.
- Sealing technology for high temperature application may be complicated.

Scope of porous ceramic membranes

Inorganic membranes are versatile they can operate at elevated temperatures with metal membranes stable at temperatures ranging from 500 to 800°C and with many ceramics membranes stable at over 1000°C they are also much more resistance to chemical attack because of the wide variety of materials that may be used in the fabrication of our inorganic membranes resistance to corrosive liquids and gases even at elevated temperatures can be realized.

Inorganic membranes completed with organic membranes for commercial use in many of the harsh operational environmental listed above organic membranes offer need solution.

Applications

Initially, ceramic membranes were used in waste water technology. Meanwhile, successful and possible applications cover all industries where media were filtered.

- Chemical industry :
 - Product separation and cleaning.
 - Concentration of polymer suspensions and metal hydroxide solutions.
 - Separation of catalysts.
 - Recovery of dyes and pigments.
 - Desalination of products.
 - Cleaning and recycling of organic solvents.

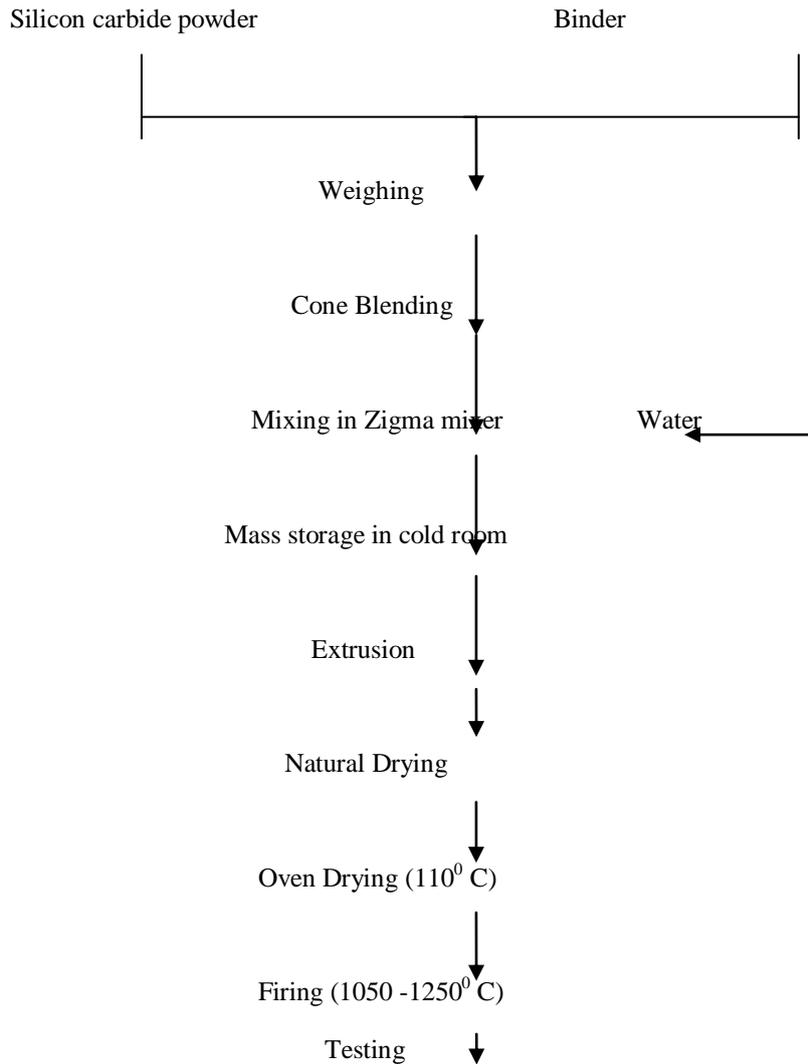

- Metal industry / Surface engineering :
 - Recycling and disposal of degreasing and rinsing bathes.
 - Treating of oil /water emulsions.
 - Recovery of heavy metals.
 - Cleaning of waste water from grinding processes.
 - Treatment of waste water form glass and glass fiber production.

- Textiles / Pulp and paper industry :
 - Concentration fractionation, isolation and sterilization for antibiotics, enzymes, proteins, amino acids and vitamins.
 - Separation, concentration and dewatering of biomass and algae.
 - Disposal of fat emulsions.
 - Separation of yeast.
 - Desalination.

- Food and beverages
 - Clarification of juice and beer.
 - Concentration of juice.
 - Sterilization of milk and whey.
 - Desalination of whey.
 - Dewatering of products.
 - Purification of drinking water.

- Recycling and environment.
 - COD /BOD reduction.
 - Oil / water separation.
 - Recovery of pharmaceuticals and pesticides.
 - Retention of microorganism.
 - Retention of heavy metals and radioactive substances.
 - Recycling of water form swimming pools.
 - Purification of the drain of sewage plants.

PREPARATION OF RODS AND TUBES: Flow chart for tubes & rods preparation

Raw materials used

Silicon carbide:

The Acheson process is used to produce large quantities of Sic. This process carbothermally reduces SiO₂ to give SiO and CO (g) in a resistance furnace. Low purity silicon carbide is used in abrasion and refractory application. High quality silicon carbide is used for reaction bonded ceramics that require strength at high temperature, high thermal conductivity, high thermal shock resistance, and allow thermal expansion co-efficient.

Graphite (Black Lead):

It is a crystalline form of carbon. It occurs in nature either as microcrystalline earthy lumps or in a lobular force. Natural graphite is classified on the basis of its physical properties, nature. Ex:-flakes, lump and amorphous (micro crystalline) type. It is very and usually has metallic structure and a greasy feel.

Occurrence: Graphite occurs in a Andhra Pradesh, Lohit (Arunachal Pradesh), Pala man (Bihar), Karnataka, samba lour and Bolangir (Orissa), Ernakulum (Kerala), Doomra(Rajasthan) and in Baramulla(J and K).

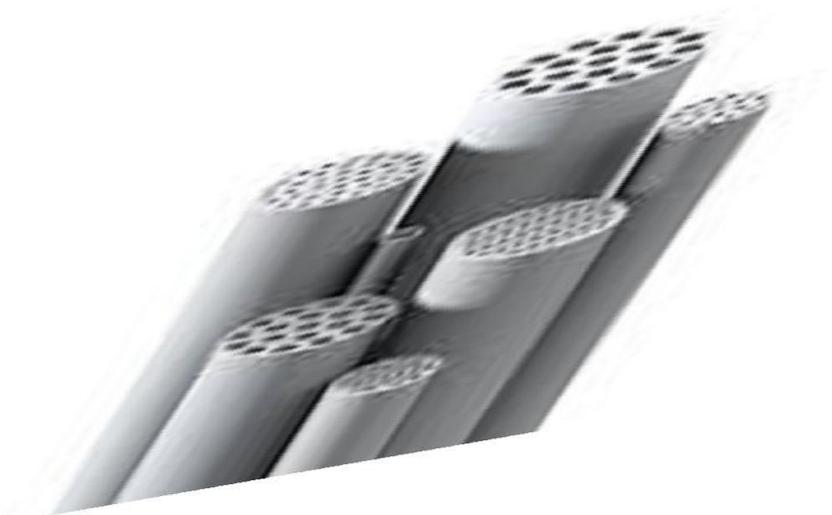

Binders: Substances, which hold ceramic raw material and bodies together during the initial stage of processing, are called binder.

1. Lignin has been used for tempering all type body fabricated by ceramic process it increases the strength of the weak body.
2. Tannic acid has long been employed to increase the particles of days, but it is not effective as extract in increasing the dry strength.
3. Ordinary paraffin's, with a small percentage of carnauba wax, is a good binder in some cases and can be molded cold with a reduction in molding time.

Procedure for rods and tubes preparation:

The silicon carbide powder and binder (5%) were weighed according to the composition accurately and then the batch was dry mixed in cone blender. The weighed batch was charged to cone blender. The purpose of cone blending is to mix the titania powder and the binder homogeneously. This blending was carried out for a period of 2 hour. The batch is weighed and charged to zigma mixer. The water is slowly added during mixing until required consistency mass is obtained and the amount of water is noted down.

The mixed mass is kept in cold room for ageing. After ageing the mass is feed to the extruder where simultaneously de-airing and compaction is carried out. In the extruder kerosene is used as lubricant. The die is fixed accordingly i.e. this depends up on rod or tubes to be extruded. Then the pieces are extruded in aluminum channels and kept for natural drying. The natural drying is carried out for a couple of days. Then the naturally dried pieces are kept for drying in electrical dryer where temperature is initially kept at 40⁰ C for about 3 hours then temperature is raised to 60⁰ C and kept for about 3 hours and then 80⁰ C and 100⁰ C in the same way. Care should be taken while drying the rod or tubes must be kept between metal supports. Then the dried pieces are carried for firing operation. The firing ids carried out at different temperature 1050, 1100, 1150, 1200⁰ C.The fired pieces are tested fir the following tests: %apparent porosity, bulk density, %water absorption, SEM, Permeability etc.

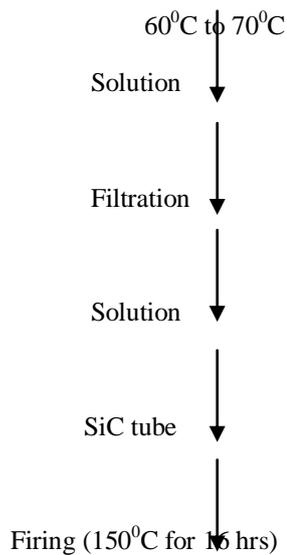

Zirconia coating on SiC tube

Flow chart for hydrothermal test

300ml of H₂O + 45 gms of zirconia oxy nitrate

Zirconium Oxide(ZrO₂)

Zirconia is an extremely refractory material. It offers chemical corrosion inertness to temperatures well above the melting point of alumina. The material has low thermal conductivity. It is electrically conductive above 600⁰ C and is used in oxygen sensor cell and as the susceptor (heater) in high temperature induction furnaces. With the attachment of platinum lead, Nernst glowers use in spectrometers can be made as a light emitting filament which operated in air.

Key Properties of Zirconium Oxide

- ✓ Use temperatures up to 2400⁰C
- ✓ High density
- ✓ Low thermal conductivity (20% that of alumina)
- ✓ Chemical inertness
- ✓ Resistance to molten metals
- ✓ Ionic electrical conduction
- ✓ Wear resistance
- ✓ High fracture toughness
- ✓ High hardness

Typical Uses of ZrO₂

- ✓ Precision ball valve balls and seats
- ✓ High density ball and pebble mill grinding media
- ✓ Rollers and guides for metal tube forming
- ✓ Thread and wire guides
- ✓ Hot metal extrusion dies
- ✓ Deep well down-hole valve and seats
- ✓ Powder compacting dies

- ✓ Marine pump seals and shaft guides
- ✓ Oxygen sensors
- ✓ High temperature induction furnace susceptors
- ✓ Fuel cell membranes
- ✓ Electrical furnace heaters over 2000⁰C in oxidizing atmospheres

General Zirconia Oxide information:

Pure zirconia exists in three crystal phases at temperatures. At very high temperatures (>2370⁰C) the material has a cubic structure. At intermediate temperatures (1170⁰C to 2370⁰C) it has a tetragonal structure. At low temperatures (below 1170⁰C) the material transform to the monoclinic structure. The transformation from tetragonal to monoclinic is rapid and is accompanied by a 3 to 5 percent volume increase that causes extensive cracking in the material. This behavior destroys the mechanical properties of fabricated components during cooling and makes pure zirconia useless for any structural or mechanical application. Several oxides which dissolve in the zirconia crystal structure can slow down or eliminated these crystal structure changes. Commonly used effective additives are MgO, CaO, and Y₂O₃. With sufficient amounts added; the high temperature cubic structure can be maintained to room temperature. Cubic stabilized zirconia is a useful refractory and technical ceramic material because it does not go through destructive phase transition during and cooling.

The controlled, stress include volume expansion of the tetragonal to monoclinic inversion is used to produce very high strength, hard, tough varieties of zirconia available from accuratus for mechanical and structural applications. There are several different mechanisms that lead to strengthening and toughness in zirconias that contain tetragonal grains. These depend on the grain sizes, the thermal history and the kind and amount of stabilizing additive in the body. These variation lead to two strong, commercially available partially stabilized zirconia (PSZ) microstructure identified as TTZ (tetragon ally toughened zirconia) and TZP (tetragonal zirconia polycrystalline) ceramic. The TTZ is an MgO partially stabilized zirconia often designated MgTTZ or MgPSZ consisting of uniformly dispersed tetragonal precipitates in larger cubic phase crystals. The secondary thermal aging process requiring tight manufacturing controls for proper micro structural development has limited the supplier base for the tetragonal phase, very fine grain mateial stabilized with rare earth oxides, primarily yttria and less commonly ceria. They are often designated YTZP for the yttria stabilized product and CeTZP for the ceria stabilized product. The TZP material has found uses in cutting and wear resistant application due to its reliable and outstanding hardness and toughness. TZP properties degrade rapidly when the material is exposed to water vapor at 200 to 300⁰C, so controlled use condition are important for good performance. All of the toughened zirconia show a degrading of properties with increasing temperature, and this class of high strength, tough material is generally limited to use temperatures below 800⁰C.

History of titania (TiO₂):

The element titania was discovered in 1791 by William Gregory in England. Gregory spent much of his time studying mineralogy, which lead him to his discovery. This happened when he discovered a sample of a black sandy material in his neighborhood. He studied this substance and after he was assured that it was a mineral he called it menachanite. Four years later a man named Martin h klaproth recognized that there was a new chemical element in this mineral. He later named it titanium after the titans which are numerous monsters that ruled the world in Greek mythology. Martin h klaproth was not able to make the pure element of titanium however he was only able to produce titanium dioxide.

Occurrence

The element occurred with a number of mineral deposits. Principally rutile ilmenites which are widely distributed in earth crust and lithosphere and it is found in almost in all living things, rocks, water bodies and soil. The metal is extracted from its principle mineral ore via kroll process or hunter process.

Processing methods for manufacture of titanium dioxide

There are 2 distinct technologies for manufacture of titania

- Sulphate process
- Chloride process

Sulphate process

The sulphate process has been in existence for more than 70 years. The process is carried out in the following steps.

Digestion of ilmenite or titania slag in sulphuric acid

Reduction and crystallization

Hydrolysis

Calcinations

Dry milling

The product obtained by sulphate process is usually anatase which can be further treated to obtain rutile. The feed stocks obtained used for sulphate process are mainly ilmenite or titania slag.

The major advantage of this process is that large quantities of waste product are generated in the form of spent acid and copper. The problem of this copper can be reduced by using titania slag as feed instead of ilmenite.

Chloride process

The chloride process was developed by du-pont around 1959. The main process steps are as follows,

- Chlorination of synthetic rutile or other raw material.
- Purification of titanium tetrachloride.
- Oxidation of pure titanium di-oxide.

The main advantages of chloride process are as follows,

- Product obtained is rutile and is of better quality.
- Process is continuous.
- The waste products obtained are in small quality.

A technical composition of sulphate & chloride process indicates that the chloride process gives a product which is in finer in particle size, low in impurity & less waste products are generated. As a result more & more manufactures are shifting to chloride process. Presently about 55% of titania is produced by sulphate process.

Physical and mechanical properties of titania

Density	4 gm/cc
Porosity	0 %
Modulus of rupture	140 Mpa
Compressive strength	680 Mpa
Poisson's ratio	0.27
Fracture toughness	3.2 Mpa.m ^{-1/2}
Shear modulus	90 Gpa
Modulus of elasticity	230Gpa
Micro hardness(HV 0.5)	880
Resistivity(25 ⁰ C)	10 ¹² ohm.cm
Resistivity(700 ⁰ C)	2.5×10 ⁴ ohm.cm
Dielectric constant(1 MHz)	85
Dissipation factor(1 MHz)	5× 10 ⁴
Dielectric strength	4 kV/mm
Thermal expansion(RT-1000 ⁰ C)	9×10 ⁻⁶
Thermal conductivity(25 ⁰ C)	11.7Wm/K

Optical properties of titania

Forms	RI	Density	Crystal structure
Anatase	2.49	3.84	Tetragonal
Rutile	2.903	4.26	Tetragonal

Procedure for Hydrothermal test to prepare zirconia membrane:

First we take 300 ml of water in beaker and then heated by using magnetic stirrer. Add 45 gms of zirconia oxy nitrate to water and maintained temperature at 60 -70⁰C. After completion of heating, filtering process is carried out to get a filtered solution. Then take autoclave apparatus containing Sic tubes and add 3/4th filtered solution into the autoclave apparatus. Autoclave apparatus is kept in oven at 150⁰C for 16 hrs. After completion of hydrothermal test, the apparatus is put in water for cooling. Finally we got a good coated zirconia on Sic tube.

A zirconia coated tubes is dried naturally and then send to calcined process at 800⁰C for 2 days. After calcined tubes are tested like permeability, SEM, density porosity, water absorption etc.

CHARACTERIZATION AND TESTING

1. Density

Bulk density is defined as the mass per unit volume of a material including the volume of open pores.

2. True density

True density is the mass per unit volume of a material including all forms of pores i.e. open and closed pores.

3. Porosity

Apparent porosity is the percentage relationship between the open pores to that bulk volume.

4. Water absorption

The water of absorption is expressed as the %age relationship of weight of water absorbed by the dry specimen.

Experimental procedure:

The specimen to be tested is kept in Dryer at 110⁰ C until it reaches constant weight, then dry weight (D) of the specimen is noted down. Then the specimens are kept in boiling water for 2 hours, then they are allowed cooled to room temperature and the saturated weight (W) of the test specimens are noted down, then the specimens are suspended in water and the suspended weight (S) of the specimens are noted down and calculated using the formula given below.

$$\text{Bulk density} = \frac{\text{Dry weight}}{\text{Saturated weight} - \text{suspended weight}}$$

$$\text{App. Density} = \frac{\text{Dry weight}}{\text{Dry weight} - \text{suspended weight}}$$

$$\% \text{ Apparent porosity} = \frac{\text{Saturated weight} - \text{dry weight}}{\text{Saturated weight} - \text{suspended weight}} \times 100$$

$$\% \text{ Water absorption} = \frac{\text{Saturated weight} - \text{dry weight}}{\text{Dry weight}} \times 100$$

SEM analysis

The scanning electron microscope (SEM) is a type of electron microscope that images the sample surface by scanning it with a high- energy beam of electrons in a raster scan pattern. The electrons interact with the atoms that make up the sample producing signals that contain information about the sample's surface topography, composition and other properties such as electrical conductivity.

The types of signals produced by an SEM include secondary electrons; back scattered electrons (BSE), characteristic X-rays, light (cathodoluminescence), specimen current and transmitted electrons. These types of signal all require specialized detectors for their detection that are not usually all present on a single machine. The signals result from interactions of the electron beam with atoms at or near the surface of the sample. In the most common or standard detection mode, secondary electron imaging or SEI, the SEM can produce very high –resolution images of a sample surface, revealing details about 1 to 5 nm in size Due to the way these images are created, SEM micrographs have a very large depth of field yielding a characteristic three – dimensional appearance useful for understanding the surface structure of a sample. This is exemplified by the micrograph of pollen shown to the right. A wide range of magnifications is possible, from about x 250,000, about 250 times the magnification limit of the best light microscopes. Back- scattered electrons (BSE) are beam electrons that are reflected from the sample by elastic scattering. BSE are often used in analytical SEM along with the spectra made from the characteristic X-rays. Because the intensity of the BSE signal is strongly related to the atomic number

(Z) of the specimen, BSE images can provide information about the distribution of different elements in the sample. For the same reason BSE imaging can image colloidal gold immuno-labels of 5 to 10 nm that would otherwise be difficult or impossible to detect in secondary electron images in biological specimens. Characteristic X-rays are emitted when the electron beam removes an inner shell electron from the sample, causing a higher energy electron to fill the shell and release energy. These characteristic X-rays are used to identify the composition and measure the abundance of elements in the sample.

Permeability :

Permeability apparatus

$$\text{Permeability} = \frac{\text{Permit flux}}{\text{Pressure difference}}$$

$$\text{Area of tube} = \pi dl$$

Where,

d is the diameter of tube

l is length of the tube

$$\text{LMH} = \frac{\text{litre}}{\text{m}^2 \cdot \text{hr.}}$$

SEM analysis:

1. TiO₂ coated samples

2. ZrO₂ coated samples

Conclusions

Zirconia coating is applied on the SiC tube. It is mainly carried out by hydrothermal reaction. Zirconia solution prepared from zirconia oxynitrate and water. This hydro thermal test is carried out in an oven at 150⁰C for 16hrs. Finally we got good zirconia coating on SiC base. Found zirconia coated body is then dried at 100⁰C and fired at 800⁰C. Obtained product shows optimum porosity (40-45%) and good permeability for the membrane application like water filtration.

Abstract: The crime history in the recent past has increased drastically, and the tendency towards the crime is also an upheaval task. Therefore to combat the crime, effective technologies are to be provided as supportive to the law enforces. Data mining concepts prove to be very useful in this direction. A major uplift in the direction of crime identification is direct evidence, which can be of crucial concern by which plausible conclusions can be drawn. Identifying the criminal by means of forensics reports is seemingly difficult. This paper introduces a novel methodology of criminal mapping based on forensics using the concepts of Data mining and New Gaussian Mixture model.

Key words: Data mining, New Gaussian Mixture model, Crime, criminal mapping, criminal identification, forensics.

I. Introduction

The quest towards the luxurious life styles, environmental conditions, and uncontrollable ambitions have driven the humans towards the criminal activities[1] Many government and private agencies are rigorously marching to combat the law breakers. Today, most of the criminal records are maintained manually and on the other hand due to the lack of sufficient man power, the data entry has become a concern [2]. With this background, as the criminal activities have extended its wings at different locations, it has become an challenging task for the police to exchange the information between the police stations at different locations in solving the issues. Therefore formulation of effective mechanism to support the law enforces while investigations are very much needed.[3] This mechanism should be helpful in information sharing and thereby shaping towards a meaningful crime analysis. To support, effective methodologies that help in criminal investigations for evaluating the physical clues and determining the different strategies to be adopted for investigation are to be formulated. Therefore the physical evidences obtained from the witness and the forensics reports help towards the better criminal analysis.

Hence in this paper, a database is generated from the criminal data available from different police stations of Andhra Pradesh. The database is created by considering two basic facts viz., availability of witness at the criminal spot and the reports from the forensic labs that are collected from the clue spot[4]. The data mining concepts are exploited for mining the likelihood of the criminals based on the features/ witness available. Clustering is performing based on the type of crime. The

crime activities considered in this paper are Murder, Riot, kidnap and robbery. Based on the features described about the criminal, a face is generated and the generated face is compared with that of the existing faces for finding the likelihood of the criminals[6]. These identities are further mapped with the forensic clues to formulate as unique identity. Data mining techniques help to explore the enormous data and making it possible in reaching the ultimate goal of criminal analysis by using the concepts of clustering and classification. In this paper the concept of clustering is carried out basing on the type of crime. The rest of paper is organized as follows, section -2 of the paper deals with Acquisition of features, in section- 3, details about the crime identification presented, Clustering techniques is discussed ,in section -4 the New Gaussian Mixture model is presented , experimentation is highlighted in section- 5, the section 6 of the paper focus on the conclusion

II. Acquisition of Features from the witness

Any crime investigation highlights primarily on two issues, 1) Witness available and 2) Clues available and relating these features with that of the data available regarding the criminals. The crime data base considered in this paper include are 1) robbery 2) murder 3) kidnapping 4) riots. For the identification of any crime we need to have an idea about

1)clue variables 2) criminal relating/identification. Crime clues play a vital role in the proper identification of criminal. The clues help the stepping stone towards the crime analysis, and criminal relating is the mapping of the criminal based on the clues with data available in the data base, by the use of intelligent knowledge mapping.

III. Crime Identification using Crime links

The various crime links that were considered include

- 1) Crime location (place: restaurant, theater, road, railway station, shop/gold shop, mall, house, apartment)
- 2) Criminal attribute (hair, built, eyebrows, nose, teeth, beard, age group, mustache, languages known).
- 3) Criminal psychological behavior can be recognized by type of killing. We have considered the type of killing as (smooth, removal of parts, harsh) which attributes to the psychological behavior of the criminal.
- 4) Modus operandi (object used for crime), 1)Pistol 2)Rope 3)Stick 4)Knife

These criminal links help to analyze the dataset there by making the crime investigators to plane for identification of the criminal.

In this paper we have considered binary clustering to cluster the data base based on type of crime and the classification is carried out from the feature available.

3.1 Binary clustering:

In order to simplify the analysis process the huge dataset available is to be clustered. The clustering in this paper is based on the type of crime. A data set is generated from the database available from the Andhra Pradesh police department and a table is created by considering the FIR report

The various fields considered including the criminal identification numbers, criminal attributes, criminal psychological behavior, crime location, time of crime (day/night), witness /clue, the data set is generated by using the binary data of 1's & 0's, 1's indicating the presence of attribute and 0's indicating the absence of attribute then clustering of the binary data is done as proposed by Tao Hi (2005) using the binary clustering

Crimes are categorized in many ways, here we have given weights to each type of crime where weighing scheme is considered in the manner all the relative crimes will be given with near values , after applying clustering algorithm on this type of crime feature we have got four clusters of crime data they are robbery, kidnap, murder and riot

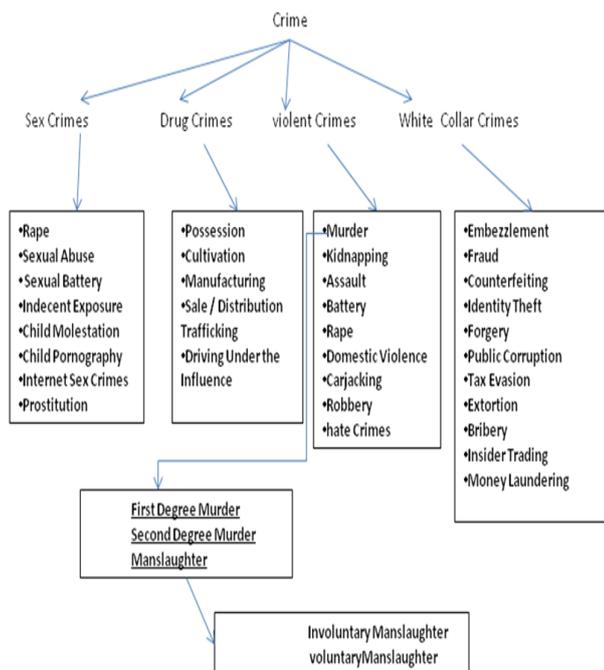

Fig 1 categories of crimes

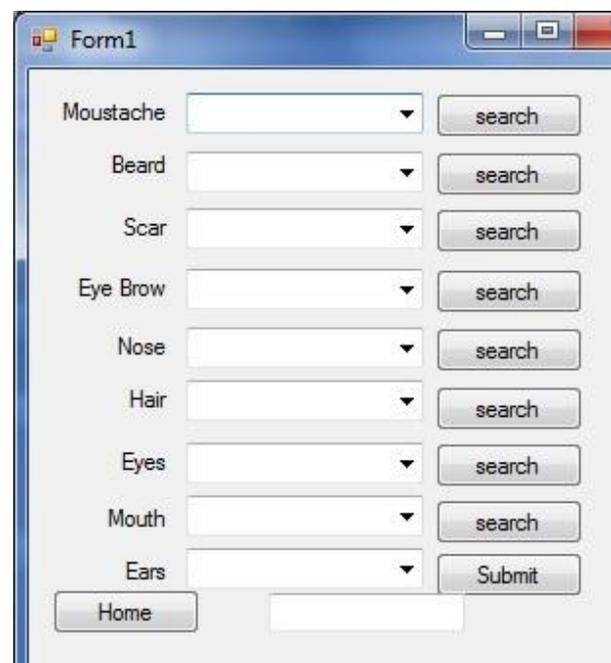

IV. New Gaussian Mixture model

New Gaussian Mixture model is utilized for the purpose of most likelihood criminal matching. This model is an extension of the existing Gaussian Mixture Model .The main advantage of using this model is that it minimizes the noise data as it includes a filter in the distribution itself. This is called a New Gaussian Mixture model since it tries to maintain the characteristics of GMM and it builds a covariance matrix for dimensionality reduction The probability density function of New Gaussian Mixture Model is given by PDF

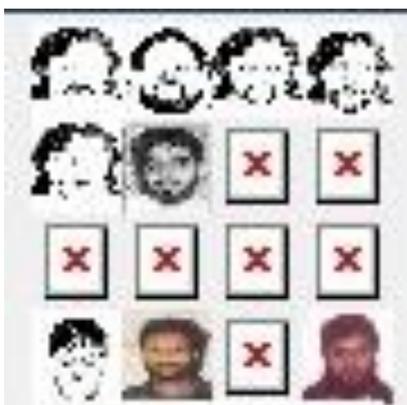

$$f(x) = \frac{1}{\sqrt{2\pi\sigma}} \left\{ \frac{\mu e^{-(x-\mu)^{\mu+1}}}{2\sigma^2} + \frac{\mu}{N} \sum_{i=1}^n \left(\frac{(x_i - \mu)^{\mu+1}}{2\sigma^2} \right) \right\}$$

V. Experimentation

The features are taken as input from the witness available and basing on the features, the database is compared for the relevancy in crime .The features are taken as input and basing on the features, The database is compared for the relevancy in crime .The features that are considered are the standard features generally used in FIR at the police stations and is shown in the following figure- 1

The various images that are retrieved using the features are displayed as follows

The outputs obtained includes cids and their filtered data is stored in the data base further investigation

ID	cid	featurename
116	1142	Feature
117	1149	Feature

Probability density functions of the test image is mapped with the most likelihood of images present in the database and the most relevant images obtained are displayed

Fig2: The snap shot of data set

If the witness is available, at the crime incident, or of the forensics reports are available, then in such cases, identification of the criminal is a considered in this paper. The criminal is mapped by collecting the features about the crime from the witness and comparing them with that of the available from the data base. and if there is a map, the criminal can be identified. .If the data available from the witness is not sufficient, the forensics reports are also considered that are available, and correlate this report with the report of the witness to ratify criminal. Using the methodology a criminal is identified and for the uniqueness, this data is given as input to the New Gaussian mixture model to identify a unique criminal. From the above table, 101 is identified as the criminals

VI. Conclusion

This paper presents a novel methodology of identifying a criminal, in the presence of witness or any clue by the forensic experts. In these situations, in this paper we have tried to identify the criminal by mapping the criminal using the New Gaussian mixture model. .

³(Sulaimani Techincal Institute, Department of Engineering Drawing, Sulaimani, Iraq)

Abstract: In this paper, we derived a new formula using a high degree polynomial (fifth degree curve) in representation ground surface profile. Also, we show the result of calculation of volume by this new formula give a better accuracy because of using high degree curve in representing the ground profile which provides more smoothness in the representation.

Keywords: Pit excavation volume, fifth degree polynomial, ground surface profile

I. Introduction:

How to estimate the volume of earth work in a different engineering and industrial project such as foundation of water tank, underground reservoir and bringing a filled materials from a borrow pit in road construction project is a major task [1, 3]. The standard method has been to construct a grid by dividing the area into rectangles, the elevation at the intersections of the grid lines are measured before and after excavation and used for depth computation at the lattice of the grid then using these lattice values to estimate the volume[2,4], Fig.1.

In the past this estimation was done based on that the excavation depth between the grid points is linear. In real situations, this assumption may not be valid and formulas that consider a non linear excavation depth should be used [4].

In [4] improved the estimation by assuming the excavation depth function follows (approximately) second – or – third – degree polynomials along the two grid directions and using Simpson's rule twice to estimate the integration of this function. This was improvement, since clearly the ground profile (curve representing the excavation depth a long a grid lines) need not be linear [2].

Here in this paper a trial is done to obtain a new formula based on a higher polynomial degree such as fifth degree curve which can represent the excavation depth a long a grid line in both directions better than the linear and second or third degree polynomials representation which were used before.

Materials and methods

Consider Fig.1, in which the ground profile is assumed to follow fifth degree polynomial,

$$f(x) = a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 \quad (1)$$

In which $f(x)$ is the excavation depth at point x , ($f_0, f_1, f_2, f_3, f_4,$ and f_5 are six excavation depths at the points $x_0, x_1, x_2, x_3, x_4,$ and x_5)

The area under the ground profile can be find out as follow ,

$$A = \int_{x_0}^{x_5} (a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5)dx \quad (2)$$

$$A = [a_0x + \frac{a_1x^2}{2} + \frac{a_2x^3}{3} + \frac{a_3x^4}{4} + \frac{a_4x^5}{5} + \frac{a_5x^6}{6}]_{x_0}^{x_5} \quad (3)$$

The values of the coefficients of the polynomial $a_0, a_1, a_2, a_3, a_4, a_5$ can be determined by substituting the known coordinates of these points into Eq.1 and solving the resulting six equations.

$$\text{At } x = x_0 = 0 \rightarrow y = y_0 = f_0 \rightarrow a_0 = f_0 \quad (4)$$

$$\text{At } x = x_1 \rightarrow y_1 = f_1 = f_0 + a_1x_1 + a_2x_1^2 + a_3x_1^3 + a_4x_1^4 + a_5x_1^5 \quad (5)$$

$$\text{At } x = x_2 \rightarrow y_2 = f_2 = f_0 + a_1x_2 + a_2x_2^2 + a_3x_2^3 + a_4x_2^4 + a_5x_2^5 \quad (6)$$

$$\text{At } x = x_3 \rightarrow y_3 = f_3 = f_0 + a_1x_3 + a_2x_3^2 + a_3x_3^3 + a_4x_3^4 + a_5x_3^5 \quad (7)$$

$$\text{At } x = x_4 \rightarrow y_4 = f_4 = f_0 + a_1x_4 + a_2x_4^2 + a_3x_4^3 + a_4x_4^4 + a_5x_4^5 \quad (8)$$

$$\text{At } x = x_5 \rightarrow y_5 = f_5 = f_0 + a_1x_5 + a_2x_5^2 + a_3x_5^3 + a_4x_5^4 + a_5x_5^5 \quad (9)$$

Because of using equal intervals, this led to say that

$$h = x_1 - x_0 : 2h = x_2 - x_0 : 3h = x_3 - x_0 : 4h = x_4 - x_0 : 5h = x_5 - x_0$$

Solving equation 5,6,7,8 and 9 give the values of coefficients

$a_1, a_2, a_3, a_4,$ and a_5 as follow ,

$$a_1 = \frac{1}{60h} [-137f_0 + 300f_1 - 300f_2 + 200f_3 - 75f_4 + 12f_5]$$

$$a_2 = \frac{1}{24h^2} [45f_0 - 154f_1 + 214f_2 - 156f_3 + 61f_4 - 10f_5]$$

$$a_3 = \frac{1}{24h^3} [-17f_0 + 71f_1 - 118f_2 + 98f_3 - 41f_4 + 7f_5]$$

$$a_4 = \frac{1}{24h^4} [3f_0 - 14f_1 + 26f_2 - 24f_3 + 11f_4 - 2f_5]$$

$$a_5 = \frac{1}{120h^5} [-f_0 + 5f_1 - 10f_2 + 10f_3 - 5f_4 + f_5]$$

Substituting for $a_0, a_1, a_2, a_3, a_4, a_5$ in equation 3 and noting that $x_0 = 0$ and $x_5 = 5h$, this yields the following formula for calculating area under the curve,

$$\text{Area} = \frac{5h}{288} [19f_0 + 75f_1 + 50f_2 + 50f_3 + 75f_4 + 19f_5] \quad (10)$$

Now to calculate volume take a unit grid of 5*5 of equal intervals in both direction as in Fig.2, the volume of this unit grid is given by

$$\text{volume} = \int_{x_0}^{x_5} \int_{y_0}^{y_5} f(x, y) dy dx \quad (11)$$

Where $f_{(x,y)}$ is a depth of excavation at grid nodes

First, the inner integral is calculated using the results in Eq. 10,

$$v = \frac{5h}{288} \left[\int_{x_0}^{x_5} 19f(x, y_0) + 75f(x, y_1) + 50f(x, y_2) + 50f(x, y_3) + 75f(x, y_4) + 19f(x, y_5) dx \right] \quad (12)$$

$$v = \frac{5h}{288} \left[19 \int_{x_0}^{x_5} f(x, y_0) dx + 75 \int_{x_0}^{x_5} f(x, y_1) dx + 50 \int_{x_0}^{x_5} f(x, y_2) dx + 50 \int_{x_0}^{x_5} f(x, y_3) dx + 75 \int_{x_0}^{x_5} f(x, y_4) dx + 19 \int_{x_0}^{x_5} f(x, y_5) dx \right] \quad (13)$$

use the results in equation number 10 again to each integral term in Eq.13 to obtained ,

$$v = \left(\frac{25h}{1440}\right)^2 \gamma_{ij} * f_{ij} \quad (14)$$

Where γ_{ij} are the corresponding elements of the following matrix :

$$C = \begin{pmatrix} 361 & 1425 & 950 & 950 & 1425 & 361 \\ 1425 & 5625 & 3750 & 3750 & 5625 & 1425 \\ 950 & 3750 & 2500 & 2500 & 3750 & 950 \\ 950 & 3750 & 2500 & 2500 & 3750 & 950 \\ 1425 & 5625 & 3750 & 3750 & 5625 & 1425 \\ 361 & 1425 & 950 & 950 & 1425 & 361 \end{pmatrix}$$

And f_{ij} are the corresponding elements of the following matrix which represent depth of excavation at

Grid nodes

$$F = \begin{pmatrix} f_{0,5} & f_{1,5} & f_{2,5} & f_{3,5} & f_{4,5} & f_{5,5} \\ f_{0,4} & f_{1,4} & f_{2,4} & f_{3,4} & f_{4,4} & f_{5,4} \\ f_{0,3} & f_{1,3} & f_{2,3} & f_{3,3} & f_{4,3} & f_{5,3} \\ f_{0,2} & f_{1,2} & f_{2,2} & f_{3,2} & f_{4,2} & f_{5,2} \\ f_{0,1} & f_{1,1} & f_{2,1} & f_{3,1} & f_{4,1} & f_{5,1} \\ f_{0,0} & f_{1,0} & f_{2,0} & f_{3,0} & f_{4,0} & f_{5,0} \end{pmatrix}$$

Equation 14 is a single formula for volume calculation for a grid unit of 5*5 of equal intervals in both directions in terms of the intersection points.

To calculate the total volume of any grid capacity which must be multiple of 5 in both direction is the sum of volumes of the unit grids . To calculate total volume let,

$$x_i = x_0 + ih; \quad i=0,1, \dots, m.$$

$$y_j = y_0 + jh; \quad j=0,1, \dots, n.$$

Then the composite formula for calculating the volume of the total grid, V, is given by ,

$$V = \int_{x_0}^{x_m} \int_{y_0}^{y_n} f(x, y) dy dx$$

$$V = \left(\frac{25h}{1440}\right)^2 \sum_{i=0}^m \sum_{j=0}^n \gamma_{ij} f_{ij} \quad \text{(Composite formula)} \tag{15}$$

In which γ_{ij} =the corresponding elements of the following matrix

$$C = \begin{pmatrix} 361 & 1425 & 950 & 950 & 1425 & 722 & 1425 & . & . & 1425 & 722 & 1425 & 950 & 950 & 1425 & 361 \\ 1425 & 5626 & 3750 & 3750 & 5625 & 2850 & 5625 & . & . & 5625 & 2850 & 5625 & 3750 & 3750 & 5625 & 1425 \\ 950 & 3750 & 2500 & 2500 & 3750 & 1900 & 3750 & . & . & 3750 & 1900 & 3750 & 2500 & 2500 & 3750 & 950 \\ 950 & 3750 & 2500 & 2500 & 3750 & 1900 & 3750 & . & . & 3750 & 1900 & 3750 & 2500 & 2500 & 3750 & 950 \\ 1425 & 5625 & 3750 & 3750 & 5625 & 2850 & 5625 & . & . & 5625 & 2850 & 5625 & 3750 & 3750 & 5625 & 1425 \\ 722 & 2850 & 1900 & 1900 & 2850 & 1444 & 2850 & . & . & 2850 & 1444 & 2850 & 1900 & 1900 & 2850 & 722 \\ 1425 & 5625 & 3750 & 3750 & 5625 & 2850 & 5625 & . & . & 5625 & 5625 & 5625 & 3750 & 3750 & 5625 & 1425 \\ . & . & . & . & . & . & . & . & . & . & . & . & . & . & . & . \\ . & . & . & . & . & . & . & . & . & . & . & . & . & . & . & . \\ 1425 & 5625 & 3750 & 3750 & 5625 & 2850 & 5625 & . & . & 5625 & 5625 & 5625 & 3750 & 3750 & 5625 & 1425 \\ 722 & 2850 & 1900 & 1900 & 2850 & 1444 & 2850 & . & . & 2850 & 2850 & 2850 & 1900 & 1900 & 2850 & 722 \\ 1425 & 5625 & 3750 & 3750 & 5625 & 2850 & 5625 & . & . & 5625 & 5625 & 5625 & 3750 & 3750 & 5625 & 1425 \\ 950 & 3750 & 2500 & 2500 & 3750 & 1900 & 3750 & . & . & 3750 & 3750 & 3750 & 2500 & 2500 & 3750 & 950 \\ 950 & 3750 & 2500 & 2500 & 3750 & 1900 & 3750 & . & . & 3750 & 3750 & 3750 & 2500 & 2500 & 3750 & 950 \\ 1425 & 5625 & 3750 & 3750 & 5625 & 2850 & 5625 & . & . & 5625 & 5625 & 5625 & 3750 & 3750 & 5625 & 1425 \\ 361 & 1425 & 950 & 950 & 1425 & 722 & 1425 & . & . & 1425 & 1425 & 1425 & 950 & 950 & 1425 & 361 \end{pmatrix} ..$$

$f_{i,j}$ = Depth of grid point with coordinates (x_i, y_i)

The matrix of Eq.15 corresponds to the grid points in Fig.3. This with the note that the second , third , fourth and fifth columns are to be repeated , as well as the second , third , fourth and fifth rows) . This, to calculate V, we only need to multiply each depth $f_{i,j}$ by the corresponding elements and sum the results for all points. The elements of the matrix C can be implemented easily in a computer program because they exhibit a specific pattern.

Eq.15 is for square grid with equal interval in both direction, if the grid is rectangular grid with h distance between grid nodes in x direction and with k distance in y direction, the equation became,

$$V = \left(\frac{25}{1440}\right)^2 * h * k \sum_{i=0}^m \sum_{j=0}^n \gamma_{ij} f_{ij} \quad \text{Composite equations for rectangle grid} \quad (16)$$

NUMERICAL EXAMPLE:

Consider the unit grid of Fig.4, in which m=1, n=1, h = 10 m. The excavation depths (in meter) are shown beside the grid intersection points, let to calculate the volume as follow;-

A) Classical method which is based on a linear relationship between the depth ends which represent the earth surface in both direction,

$$V[3] = \frac{A_s}{4} (\sum h_1 + 2\sum h_2 + 3\sum h_3 + 4\sum h_4)$$

Where $\sum h_1$ = sum of depth used once

$2\sum h_2$ = sum of depth used twice

$3\sum h_3$ = sum of depth used thrice

$4\sum h_4$ = sum of depth used four times

A_s = area of one square in a grid

$$\sum h_1 = 0.70 + 0.14 + 1.30 + 1.0 = 3.14 \text{ m.}$$

$$2 \sum h_2 = 2(1.10+1.32+0.87+0.25 + 1.14+2.14+1.69+0.45 + 1.4+1.35+0.89+0.75 + 1.25+2.09+0.79+0.75)=36.46 \text{ m.}$$

$$3 \sum h_3 = 0$$

$$4 \sum h_4 = 4(2.17+1.25+0.98+0.18+3.12+2.92+1.75+1.55+1.75+2.03+0.99+1.35+1.69+1.10+1.62+2.11)= 106.24 \text{ m.}$$

$$\text{Volume} = \frac{100}{4} (3.14+36.46+106.24)= 3646 \text{ m}^3$$

B) Volume calculation based on the obtained equation 15,

$$\text{volume} = \left(\frac{25h}{1440}\right)^2 \sum_{i=0}^m \sum_{j=0}^n \gamma_{ij} f_{ij}$$

$$V = \left(\frac{25 * 10}{1440}\right)^2 \begin{pmatrix} 361 & 1425 & 950 & 950 & 1425 & 361 \\ 1425 & 5625 & 3750 & 3750 & 5625 & 1425 \\ 950 & 3750 & 2500 & 2500 & 3750 & 950 \\ 950 & 3750 & 2500 & 2500 & 3750 & 950 \\ 1425 & 5625 & 3750 & 3750 & 5625 & 1425 \\ 361 & 1425 & 950 & 950 & 1425 & 361 \end{pmatrix} * \begin{pmatrix} 0.70 & 1.10 & 1.32 & 0.87 & 0.25 & 0.14 \\ 1.14 & 2.17 & 1.25 & 0.98 & 0.18 & 1.25 \\ 2.14 & 3.12 & 2.92 & 1.75 & 1.55 & 2.09 \\ 1.69 & 1.75 & 2.03 & 0.99 & 1.35 & 0.79 \\ 0.45 & 1.65 & 1.10 & 1.62 & 2.11 & 0.75 \\ 1.00 & 1.40 & 1.35 & 0.89 & 0.75 & 1.30 \end{pmatrix}$$

$$\text{Volume} = 3710.743 \text{ m}^3$$

II. Conclusions

- 1) the obtained formula for volume computation here on this paper is based on the assumption that the ground profile is nonlinear with fifth –degree polynomials
- 2) the obtained formula of course provide a better accuracy than formula that assumes a linear or second, or third-degree polynomials
- 3) the limitation here is that the grid must be equal to the interval in both direction and total number of interval must be equal to 5 or multiple of five
- 4) using this formula need computer programming

Notation:-

- A = area of region with irregular boundary
- As = area of a single square in a used grid
- $a_0, a_1, a_2, a_3, a_4, a_5$ = coefficients of used fifth –degree polynomial
- C = matrix of elements
- dx = width of increment in x- direction
- dy = width of increment in y-direction
- $f_0, f_1, f_2, f_3, f_4,$ and f_5 = six excavation depths at the points $(x_0, x_1, x_2, x_3, x_4,$ and $x_5)$
- $f_{i,j}$ = depth of grid point with coordinates (x_i, y_j)
- $f(x)$ = depth of point at horizontal distance x
- $f(x, y)$ = depth of point with coordinates (x, y)
- h = distance between grid points in both x and y direction in the case of square grid

- h_1 = depth used once
- h_2 = depth used twice
- h_3 = depth used thrice
- h_4 = depth used four times
- i = index for grid points in x-direction
- j = index for grid points in y-direction
- k = distance between grid points in y direction in the case of rectangle grid
- m = number of grid intervals in x- direction
- n = number of grid intervals in y-direction
- V = volume of total grid
- v = volume of unit grid of 5*5 equal intervals
- γ_{ij} = the corresponding elements of the following matrix C

²PG Student, of Environmental Engineering, Department of Civil Engineering, VMKV Engg. College, Vinayaka Missions University, Salem, India

ABSTRACT: Food processing units is a diversified activity consists of processing of perishable items such as fruit and vegetables, meat and poultry etc. into a various products without the loss of nutritional properties. Liquid waste is generated more in the Food processing units by means of washing of raw materials, pulping, crushing and canning operations. Hence, it is necessary to treat the effluent from the food processing units and to find the suitable ways of reusing the treated effluent water like gardening and other cleaning purpose etc., The effluent coming from food processing units contains large quantity of organic and inorganic materials which gives adverse effect to the environmental system when it is discharged directly without proper treatment system. The level of physical, chemical and biological characters have to be analyzed and the treatment system needs to be designed accordingly with proper analysis and environmental control. All effluent and wastewater containing biodegradable constituents which can be treated biologically in which the dissolved and particulate biodegradable constituents have been oxidized into acceptable forms. Hence, the reduction of Bio-chemical Oxygen Demand (*BOD) and Chemical Oxygen Demand (*COD) are the predominant factors in the biological treatment methods. The biological treatment process that occurs in the presence of oxygen (Aerobic process) results the maximum reduction level of BOD and COD. Especially in the Activated Sludge Process (#ASP), the BOD removal is up to 80-95 percent and bacteria removal is up to 90-95%. The type of suitable aeration mechanism working with optimum efficiency plays vital role in the performance of biological treatment. Hence, the food processing effluent from the existing Effluent Treatment plant at CFTRI has been taken for analysis purpose in order to evaluate the efficiency and standardize the operation of aerator since the capacity of ETP of CFTRI is 120 m³/ day which is almost equal the designed capacity of 100 m³/ day for this project work. Moreover, the ETP of CFTRI had been designed based on the Activated Sludge treatment Process. The main characters like BOD, COD and pH have been analyzed for the following three main parameters during the project study

1. Temperature of the effluent at morning, noon and evening
2. RPM of the aerator
3. Immersible depth of impeller into the effluent in the aeration tank.

By analyzing the results of the above parameters, the characteristics of the effluent and efficiency of the surface aerators are evaluated.

KEYWORDS: Evaluation, Surface Aerator, activated Sludge, Food Processing Effluent

I. INTRODUCTION

Characteristics of Effluent And Importance of Treatment Of Effluent

In the olden times, the waste waters from a community were not so much contaminated as they are today. The urbanization, industrial growth and the improved standards of living have increased the strength and quantity of municipal sewage in recent years to a point where dilution alone can no longer be relied upon to prevent the undesirable effects of pollution. In many cases, more advanced treatment of wastes is essential to prevent undue pollution. This is much more so, when the disposed sewage is likely to contain industrial wastes.

When untreated sewage is discharged into some river stream, floating solids present in the discharged sewage may be washed up on to the shore near the point of disposal, where they decompose and create unpleasant smells and odours. The large amount of organic matter present in the discharged sewage will also consume the dissolved oxygen from the river stream in getting oxidized, and may thus seriously decrease the dissolved oxygen of the river stream, causing fish kills and other undesirable effects. In addition to these effects, the discharged sewage will contaminate the river water with pathogenic bacteria. Hence, even though municipal sewage is 99.9 percent water, it requires treatment if nuisance is to be avoided. Food processing units are having diversified activities where water is being used abundantly by means of cleaning of raw materials, processing and their research activities. The effluent coming from the food processing units contains organic matters, oil, grease, minerals, metals and chemicals etc. Hence, it is absolutely necessary to analyze the various characteristics and behavior of effluent. The quality of effluent can be checked and analyzed by testing its physical, chemical and biological characteristics which are listed in Figure.1.

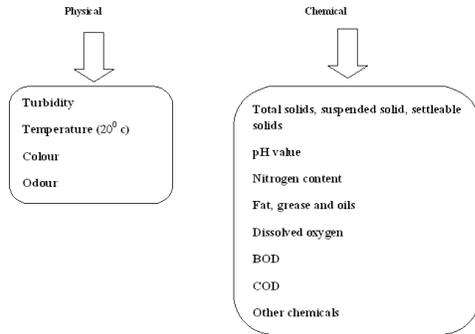

Figure.1. Characteristics of Effluent

The type of treatment required depends upon the character and quality of both effluent and source of disposal. The most important test of effluent is that for determining its Bio-chemical Oxygen Demand, popularly called BOD and Chemical Oxygen Demand popularly called COD. If sufficient oxygen is available in the effluent, the useful aerobic bacteria will flourish and cause the aerobic biological decomposition of waste, which will continue until oxidation is completed. The amount of oxygen consumed in this process is the BOD. The BOD affects the quality of water or effluent (See Figure. 2.) and Polluted water will continue to absorb oxygen for many months, and it is not practically possible to determine this ultimate oxygen demand. There are many different ways to treat effluent and treatment process level like preliminary treatment, primary treatment, secondary (Biological) treatment and final treatment are narrated in Table 1,2,3 & 4 .The pollution control board of State and Central Government has set the tolerance limits of discharged effluent to land and public sewers which are listed in Table.5 and Table.6. The discharge of effluent from all industrial sectors is being regularly monitored by the Pollution Control boards.

In the secondary (Biological) treatment, the fine suspended and dissolved organic matters are being removed. The reduction level of BOD and COD are very high in the activated sludge process of the biological treatment system where aeration process plays vital role in the Activated Sludge Process (ASP)

Hence, providing suitable aeration mechanism working with optimum efficiency will results the high reduction of BOD and COD.

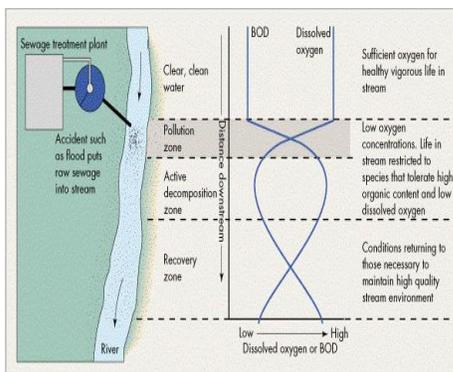

Figure.2 BOD Effects On Water Quality

1.1 EFFLUENT TREATMENT LEVELS

Table.1. Preliminary Treatment

Process	Unit	BOD removal in %	Total Suspended Solids (TSS) in %
Floating material	Screens	5-10	2-20
Heavy settleable inorganic solids	Grid chambers	10-20	20-40
Fats , oil and grease	Skimming tanks	20-30	20-40

Table.2. Primary Treatment

Process	Unit	BOD removal in %	Total Suspended Solids (TSS) in %
Large suspended organic matter	Plain sedimentation tank	30-35	60-65

Table.3. Secondary (Biological) Treatment

Process	Unit	BOD removal in %	(TSS) in %
Fine suspended and dissolved organic matter	Chemical flocculation and sedimentation	50-85	70-90
	ASP- Aeration tank and secondary settling tank	75-95	85-90

Table.4 Final or Tertiary Treatment

Process	Unit	BOD removal in %	(TSS) in %
Pathogens and very fine organic matter	chlorinator	100	100

1.2 ACTIVATED SLUDGE PROCESS (ASP)

The activated sludge process provides an excellent method of treating either raw sewage or more generally the settled sewage. The sewage effluent from primary sedimentation tank, which is, thus normally utilized in this process, is mixed with 20 to 30 percent of own volume of activated sludge, which contains a large concentration of highly active aerobic micro-organisms. The mixture enters an aeration tank, where the micro-organisms (coated around the sludge solids) and the sewage, are intimately mixed together, with a large quantity of air for about 4 to 8 hours. Under these conditions, the moving organisms will oxidize the organic matter and the suspended and colloidal matters tend to coagulate and form a precipitate, which settles down readily in the secondary setting tank. The settled sludge (containing micro organisms) called activated sludge, is then recycled to the head of the aeration tank to be mixed again with the sewage being treated. New activated sludge is continuously being produced by this process, and a portion of it being utilized and sent back to the aeration tank, whereas the excess portion is disposed of properly along with the sludge collected during primary treatment after digestion.

The effluent obtained from a properly operating activated sludge plant is of high quality, usually having a lower BOD than that of trickling filter. BOD removal is up to 80-95 percent, and bacteria removal is up to 90-5 percent. Moreover, land are required is also quite less.

1.1.5 TOLERANCE LIMITS OF DISCHARGED EFFLUENTS

Table.5 Standards for the Discharge of Effluents into Public Sewers

SL. No.	Parameters	* KSPCB Standards (U/S 25 of Water Act 1974)
1	Suspended Solids (mg/L)	Max: 100
2	pH	5.5 – 9.0
3	Oil and Grease (mg/L)	Max: 20
4	Ammoniacal Nitrogen (mg/L)	Max: 50
5	BOD (mg/L)	Max: 350
6	COD (mg/L)	---
7	Chloride, mg/L	Max: 350
8	Sulphates, mg/L	Max: 1000
9	Dissolved Solids, mg/L	Max: 2100
10	Cyanide (mg/L)	Max: 0.20
11	Fluoride (mg/L)	Max: 1.5
12	Phenolics compounds (mg/L)	Max: 5.0
13	Organochlorine & Organophosphorus Pesticides, ppb	Absent
14	Arsenic (mg/L)	Max: 0.20
15	Mercury (mg/L)	Max: 0.01
16	Lead (mg/L)	Max: 1.0
17	Cadmium (mg/L)	Max: 1.0
18	Chromium (mg/L)	Max: 2.0
19	Copper (mg/L)	Max: 3.0
20	Zinc (mg/L)	Max: 1.5
SL. No.	Parameters	* KSPCB Standards (U/S 25 of Water Act 1974)
21	Selenium (mg/L)	Max: 0.05
22	Nickel (mg/L)	Max: 3.0
23	Iron (mg/L)	Max: 3.0
24	Residual sodium carbonate, (mg/L)	Max: 5.0
25	Sodium absorption ratio (m. eqs/L)	---
26	“Percent Sodium” (m. eqs/L)	Max: 60

TABLE.6. STANDARDS FOR THE DISCHARGE OF EFFLUENTS INTO LAND FOR IRRIGATION

SL. No.	Parameters	*KSPCB Standards (U/S 25 of Water Act 1974)
1.	Colour	Colourless
2	Suspended Solids (mg/L)	Max: 30.0
3	pH	6.50 – 8.50
4	Oil and Grease (mg/L)	Max: 10.0
5	Ammoniacal Nitrogen (mg/L)	Max: 50.0
6	BOD (mg/L)	Max: 20.0
7	COD (mg/L)	Max: 250.0
8.	Dissolved phosphate	Max :5.0

Source: Karnataka Pollution Control Board (KSPCB)

But, however, is this process, a rather close degree of control is necessary in operation to ensure

1. That an ample supply of oxygen is present
2. That there is intimate and continuous mixing of the sewage and activated sludge and
3. That the ratio of the volume of activated sludge added to the volume of sewage being treated is kept practically constant.

1.3 SURFACE AERATION

For efficient surface aeration, high- and low-speed floating aerators provide pumping action that transfers oxygen by breaking up the wastewater into the form of dispersion of bubbles. The large surface area of the bubbles allows oxygen transfer to the wastewater from the atmosphere. At the same time, the oxygen-enriched water is circulated and mixed, resulting in effective oxygen delivery in the entire bulk of the wastewater body. High- and low-speed surface aerators offer excellent oxygen transfer and low operating costs. They are able to handle environmental extremes such as high temperatures. Another alternative for surface aeration is the use of horizontally mounted aeration discs or rotors. These disc or rotor aerators can be used in oxidation ditches known as looped, "race track" reactor configurations. They provide stable operation with resulting high-quality effluent. The aerators are above water for easy maintenance and are energy efficient. Other multichannel processes use a concentric arrangement of looped reactors, which is particularly energy efficient and designed to achieve total nitrogen removal through simultaneous nitrification/de nitrification. Disc and rotor surface aerators offer good BOD and COD removal efficiencies, and are very easy to replace if necessary. Reactors in a vertical-loop configuration are also available for surface aeration. They are essentially oxidation ditches flipped on their sides. Upper and lower compartments separated by a horizontal baffle run the length of the tank. Surface-mounted discs or rotors provide mixing and deliver oxygen. Typically, two or more basins make up the system. The first basin operates as an aerated anoxic reactor and the second basin is operated under aerobic conditions. These types of reactors also have high BOD/COD removal efficiency

1.4 SECONDARY (BIOLOGICAL) TREATMENT

Aeration Tank

The equalized effluent from the Equalization Tank is pumped to aeration tank where aerial oxygen is mixed with water by means of floating aerator system (see Fig: 1 . 2) To understand the system, the following terms must be understood:-

Mixed Liquor Suspended Solids (MLSS)

The suspended solids concentration in the Aeration tank is referred to as Mixed Liquor SS. It is an index of the mass of active microorganisms in the Aeration tank. As illustrated before MLSS in aeration tank indicates the presence of both active and dead bacterial cells. The level of MLSS that has to

be maintained depends upon the desirability of treated water quality. MLSS level of 3500-5000 mg/ Lit would be optimum in an extended type aeration tank.

Return Activated Sludge (RAS)

The purpose of the return of activated sludge to Aeration tank from Sludge Sump is to maintain a sufficient concentration of activated sludge in the tank so that required degree of treatment can be obtained in the limited time interval.

Food to Microbes ratio (F/M):-

It is the ratio between amounts of Organic material available to microbial population. In other words it is the ratio between BOD in kgs and MLSS in kgs. A proper F/M can be achieved by increasing or decreasing the rate of Return Activated Sludge (RAS) from Secondary Clarifier. Optimum F/M for an Extended Aeration type ASP is 0.1-0.15.

Function of Aeration Tank:

The main function of an Aeration tank in a activated sludge process are:

To maintain the dissolved oxygen concentration in the Effluent by suitable aerators

To maintain sufficient MLSS regulating return activated sludge from secondary Clarifier.

II. Project Objectives

2.1 AIM

To find out the optimum efficiency of surface aerator at different process conditions in the activated sludge process treatment of effluent coming from Food Processing Units.

2.2 OBJECTIVES

To evaluate the efficiency of surface aerator for biological treatment in the food processing effluent, especially the reduction of BOD and COD.

To analyze the effluent characteristics at different conditions of surface aerator in the Activated Sludge Process.

To analyze the treatment efficiency of surface aerator at different conditions and to standardize the operation of surface aerator in the aeration tank.

2.2 FEASIBILITY STUDY

2.2.1 Economic feasibility:

Providing surface aerators in the aeration mechanism consume high electric power in a day since the motor has to be operated continuously up to the designed detention period. The number of hours of aerator operation may be curtailed and standardized by doing the analysis of effluent based on the above mentioned project parameters for low range of raw effluent characteristics of BOD, COD and TSS are similar to that of the raw effluent of CFTRI.

By standardizing the aerator operation for the required limited period of time at a particular temperature in a day, we can save the energy and money for the daily operation cost of ETP at CFTRI. By analyzing the outcome of the results and standardizing the aerator operation in the ETP

of CFTRI, we may able to bring down the daily operation costs.

2.2.2 Operational feasibility:

The daily operation of aerator is one of the predominant factors in the extended aeration process. The standardizing the operation of aerator for its optimum efficiency resulted the reduction of manpower, Time management and utilize the manpower in productive manner by engaging other activities. Hence it is more feasible to standardize the aerator operation based on the Temperature of the effluent, RPM and Immersible depth of the impeller of the surface aerator into the effluent in the aeration tank.

2.2.3 Technical feasibility:

Aeration process in the activated sludge process of biological treatment of effluent mainly depend on the type of aeration mechanism, percentage of activate sludge and microorganism present in the activated sludge, transformation of dissolved oxygen through the aeration system and type of impeller blade in the aerator.

Hence the reduction of BOD and COD in the biological treatment process involved more technical parameters of the extended aeration process where we can standardize the operation of aeration mechanism for high BOD and COD control.

III. Evaluation Of Surface Aerator

3.1 Biochemical Oxygen Demand (BOD)

The most widely used parameter of organic pollution applied to both wastewater and surface water is the 5-day BOD(BOD₅). This determination involves the measurement of the dissolved oxygen used by microorganisms in the biochemical oxidation of organic matter. Despite the widespread use of the BOD test, it has a number of limitations, It is hoped that, through the continued efforts of workers in the field, one of the other measures of organic content, or perhaps a new measure, will ultimately be used in its place. Why, then, if the test suffers from serious limitations, if further space devoted to it in this text? The reason is that BOD test results are now used

- To determine the approximate quantity of oxygen that will be required to biologically stabilize the organic matter present
- To determine the size of waste treatment facilities
- To measure the efficiency of some treatment processes, and
- To determine compliance with wastewater discharge permits. Because it is likely that the BOD test will continue to be used for some time, it is important to know the details of the test and its limitations.

3.2 Chemical Oxygen Demand (Cod)

The chemical oxygen demand is widely used as a means of measuring the organic strength of domestic and industrial wastes. The COD test allows measurement of a waste in terms of the total quantity of oxygen required for

oxidation to carbon dioxide and water in accordance with the equation ;

$\text{COHNS} + 0.2 + \text{Nutrients} \rightarrow 3 \text{CO}_2 + \text{NH}_3 + \text{C}_5\text{H}_{12}\text{O}_2 + \text{other end products}$

It is based upon the fact that all organic compounds, with few exceptions, can be oxidised by the action of strong oxidising agents under acid conditions.

During the determination of COD, organic matter is converted to carbon dioxide and water regardless of the biological assimilability of the substances. For example, glucose and lignin are both oxidised completely. As a result, COD values are greater than BOD values and may be much greater when significant amounts of biologically resistant organic matter is present. One of the chief limitations of the COD test is its inability to differentiate between biologically oxidisable and biologically inert organic matter. In addition, it does not provide any evidence of the rate at which biologically active material would be stabilised under conditions that exist in nature. (Clair NSawyer, 1994)

The major advantage of the COD test is the short time required to evaluation. The determination can be made in about 3 hours rather than the 5 days required for the determination of BOD. For this reason it can be used as a substitute for the BOD test in many instances. COD data can often be interpreted on terms of BOD values after sufficient experience has been accumulated to establish reliable correlation factors.

3.3 pH

The hydrogen -ion concentration is an important quality parameter of both natural waters and wastewaters. The usual means of expressing the hydrogen-ion concentration is as pH, which is defined as the negative logarithm of the hydrogen-ion concentration.

$$\text{pH} = -\log_{10}[\text{H}^+]$$

The concentration range suitable for the existence of most biological life is quite narrow and critical (typically 6 to 9). Wastewater with an extreme concentration of hydrogen ion is difficult to treat by biological means, and if the concentration is not altered before discharge, the wastewater effluent may alter the concentration in the natural waters. For treated effluents discharged to the environment the allowable pH range usually varies from 6.5 to 8.5

The hydrogen-ion concentration in water is connected closely with the extent to which water molecules dissociate. Water will dissociate into hydrogen and hydroxyl ions as follows:

Applying the law of mass action [Eq. (2-7)] to Eq. (2-30) yields

$$\frac{[\text{H}^+](\text{OH}^-)}{\text{H}_2\text{O}} = K$$

Where the brackets indicate concentration of the constituents in moles per liter. Because the concentration of water in a dilute aqueous system is essentially constant, this concentration can be incorporated into the equilibrium constant K.

IV. Materials And Methods

4. 1 MATERIALS AND EQUIPMENTS

Materials:

1. Refluxing Flask
2. Blenders
3. Pipettes
4. Small Beakers
5. Condenser
6. Incubation bottles

Equipments:

1. Incubator
2. pH Meter
3. Thermometer
4. Light Intensity Meter
5. Motor Frequency convertor

4. 2 STAGES INVOLVED FOR THE STUDY

Stage:I

Analyze the effluent characteristics at 3 different Temperature in a Day

- (i) Morning (10.00am)
- (ii) Noon (12.30 pm)
- (iii) Evening (6.00 pm)

Select the suitable Temperature where the high reduction percentage of BOD and COD

Stage :II

Analyze the effluent characteristics at 3 different speed (see Figure. 3 , 4 and 5). at the selected Temperature

- (i) RPM-1
 - (ii) RPM-2
 - (iii) RPM-3
- Select the suitable RPM

Stage :III

Analyze the effluent characteristics at different immersible depth (see Figure. 6,7,8,9 & 10) of impeller of surface aerator into the effluent of at selected RPM and Temperature

- (i) Depth-1
- (ii) Depth-2

Select the suitable immersible Depth of impeller into the effluent.

From the aeration tank at CFTRI (see Figure.11) the effluent samples have been collected (Figure.12) for the evaluation of aerator of CFTRI

Figure. 3 Connection Of Motor Frequency Converter In The Motor Control Room

Figure.12 Collection of Effluent Sample For Analysis

4. 3 Determination Of Bio-Chemical Oxygen Demand (Bod)

4. 3. 1 BOD Test Procedures

5-Day BOD Test Principle:

The method consists of filling with sample, to overflowing, an airtight bottle of the specified size and incubating it at the specified temperature for 5 d. Dissolved oxygen is measured initially and after incubation, and the

BOD is computed from the difference between initial and final DO. Because the initial DO is determined shortly after the dilution is made, all oxygen uptake occurring after this measurement is included in the BOD measurement.

Sampling and storage:

Samples for BOD analysis may degrade significantly during storage between collection and analysis, resulting in low BOD values. Minimize reduction of BOD by analyzing sample promptly or by cooling it to near-freezing temperature during storage. However, even at low temperature, keep holding time to a minimum. Warm chilled samples to $20 \pm 3^{\circ}\text{C}$ before analysis.

Grab samples

If analysis is begun within 2 h of collection, cold storage is unnecessary. If analysis is not started within 2 h of sample collection, keep sample at or below 4°C from the time of collection. Begin analysis within 6 h of collection; when this is not possible because the sampling site is distant from the laboratory, store at or below 4°C and report length and temperature of storage with the results. In no case start analysis more than 24 h after grab sample collection. When samples are to be used for regulatory purposes make every effort to deliver samples for analysis within 6 h of collection.

Composite samples

Keep samples at or below 4°C during compositing. Limit compositing period to 24 h. Use the same criteria as for storage of grab samples, starting the measurement of holding time from end of compositing period. State storage time and conditions as part of the results.

2. Apparatus

- a. Incubation bottles
- b. Air incubator or water bath,

3. Reagents:

Prepare reagents in advance but discard if there is any sign of precipitation or biological growth in the stock bottles. Commercial equivalents of these reagents are acceptable and different stock concentrations may be used if doses are adjusted proportionally.

4. Procedure:

- a. Preparation of dilution water: .
- b. Dilution water storage
- c. Glucose-glutamic acid check
- d. Seeding
 - 1) Seed source
 - 2) Seed control
- e. Sample pre treatment:
- f. Dilution technique
- g. Determination of initial DO
- h. Dilution water blank
- i. Incubation
- j. Determination of final DO

5. Calculation

For each test bottle meeting the 2.0-mg/L minimum DO depletion and the 1.0-mg/L residual DO, calculate BOD₅ as follows:

When dilution water is not seeded:

$$\text{BOD}_5, \text{ mg/L} = \frac{D_1 - D_2}{P}$$

When dilution water is seeded:

$$\text{BOD}_5, \text{ mg/L} = \frac{D_1 - D_2}{P}$$

where:

D₁ = DO of diluted sample immediately after preparation, mg/L,

D₂ = DO of diluted sample after 5 d incubation at 20°C, mg/L,

P = decimal volumetric fraction of sample used,

B₁ = DO of seed control before incubation, mg/L

B₂ = DO of seed control after incubation mg/L and

f = ratio of seed in diluted sample to seed in seed control = (% seed in diluted sample)/(% seed in seed control).

If seed material is added directly to sample or to seed control bottles:

f = (volume of seed in diluted sample)/(volume of seed in seed control)

4.4 DETERMINATION OF CHEMICAL OXYGEN DEMAND (COD)

$$\text{COD (ppm)} = \frac{\text{Titre} \times N \times \text{Thiosulfate} \times 8000}{\text{Volume of sample}}$$

4.5 DETERMINATION OF Ph

4.5.1 Test Procedure Reagents

a. General preparation

Calibrate the electrode system against standard buffer solutions of known pH. Because buffer solutions may deteriorate as a result of mold growth or contamination, prepare fresh as needed for accurate work by weighing the amounts of chemicals specified in Table 4500-H⁺:I, dissolving in distilled water at 25°C, and diluting to 1000 mL. This is particularly important for borate and carbonate buffers.

Boil and cool distilled water having a conductivity of less than 2 µmhos/cm. To 50 mL add 1 drop of saturated KCl solution suitable for reference electrode use. If the pH of this test solution is between 6.0 and 7.0, use it to prepare all standard solutions.

Dry KH₂PO₄ at 110 to 130°C for 2 h before weighing but do not heat unstable hydrated potassium tetroxalate above 60°C nor dry the other specified buffer salts.

Although ACS-grade chemicals generally are satisfactory for preparing buffer solutions, use certified materials available from the National Institute of Standards and Technology when the greatest accuracy is required. For routine analysis, use commercially available buffer tablets, powders, or solutions of tested quality. In preparing buffer solutions from solid salts, insure complete solution.

As a rule, select and prepare buffer solutions classed as primary standards in Table 4500-H⁺:I; reserve secondary standards for extreme situations encountered in wastewater

measurements. Consult Table 4500- H⁺:II for accepted pH of standard buffer solutions at temperatures other than 25°C. In routine use, store buffer solutions and samples in polyethylene bottles. Replace buffer solutions every 4 weeks

Procedure

Instrument calibration

In each case follow manufacturer's instructions for pH meter and for storage and preparation of electrodes for use. Recommended solutions for short-term storage of electrodes vary with type of electrode and manufacturer, but generally have a conductivity greater than 4000 µmhos/cm. Tap water is a better substitute than distilled water, but pH 4 buffer is best for the single glass electrode and saturated KCl is preferred for a calomel and Ag/AgCl reference electrode. Saturated KCl is the preferred solution for a combination electrode. Keep electrodes wet by returning them to storage solution whenever pH meter is not in use. Before use, remove electrodes from storage solution, rinse, blot dry with a soft tissue, place in initial buffer solution, and set the isopotential point. Select a second buffer within 2 pH units of sample pH and bring sample and buffer to same temperature, which may be the room temperature, a fixed temperature such as 25°C, or the temperature of a fresh sample. Remove electrodes from first buffer, rinse thoroughly with distilled water, blot dry, and immerse in second buffer. Record temperature of measurement and adjust temperature dial on meter so that meter indicates pH value of buffer at test temperature (this is a slope adjustment).

Use the pH value listed in the tables for the buffer used at the test temperature. Remove electrodes from second buffer, rinse thoroughly with distilled water and dry electrodes as indicated above. Immerse in a third buffer below pH 10, approximately 3 pH units different from the second; the reading should be within 0.1 unit for the pH of the third buffer. If the meter response shows a difference greater than 0.1 pH unit from expected value, look for trouble with the electrodes or potentiometer.

The purpose of standardization is to adjust the response of the glass electrode to the instrument. When only occasional pH measurements are made standardize instrument before each measurement. When frequent measurements are made and the instrument is stable, standardize less frequently. If sample pH values vary widely, standardize for each sample with a buffer having a pH within 1 to 2 pH units of the sample.

Sample analysis

Establish equilibrium between electrodes and sample by stirring sample to insure homogeneity; stir gently to minimize carbon dioxide entrainment. For buffered samples or those of high ionic strength, condition electrodes after cleaning by dipping them into sample for 1 min. Blot dry, immerse in a fresh portion of the same sample, and read pH. With dilute, poorly buffered solutions, equilibrate electrodes by immersing in three or four successive portions of sample. Take a fresh sample to measure pH.

V. Results And Discussions

5.1 Analysis Of The Results

5.1.1 BOD Results and calculation

The results of the BOD values have been analyzed with regard to the following parameters and their effects are identified .

Effect of temperature

The effluent samples have been taken in the aeration tank at morning, noon and evening time in order to analyze the character of BOD with regard to Temperature. On observing the results, there is no significant effect of BOD reduction since the variation in the temperature level at 3 different timings is very nominal. However, the BOD reduction has observed due to the process of aeration and the values have been listed in Table No.7

Table No.7 Effect Of Temperature On Bod

Parameter in PPM	Temperature		
	29°C (10.00am)	31°C (12.30pm)	28°C (6.00pm)
BOD	190	160	105

Effect of Impeller RPM

The values of BOD have been taken at the impeller rotation 48 RPM , 68 RPM and 96 RPM for 30 minutes aeration process and analyzed (See Table.8) . On reading of the values , it is noticed that the reduction of BOD level is significant for 45 minutes aeration process at 96 RPM of impeller rotation

Table No.8 Effect Of Impeller Rpm

Parameter in PPM	Impeller RPM		
	48	68	96
BOD	155	180	105

Effect of immersible depth of impeller into the effluent

The samples have been taken in the aeration tank at two different immersible depth of impeller into the effluent and values have been analyzed (See Table.9) . On observing the values, it is found that the reduction BOD level is more at the immersible depth of 10 cm.

Table. 9 Effect Of Immersible Depth Of Impeller Into The Effluent

Parameter in PPM	Immersible Depth of impeller in centimetre	
	10 cm	8 cm
BOD	30	105

5.3.2 COD Results and Calculation

The COD values have been analyzed based on the three parameters namely Temperature of effluent, impeller rotation and immersible depth of impeller into the effluent and their effects are identified

Effect of Temperature

The effluent samples have been taken in the aeration tank at morning, noon and evening time in order to analyze the character of COD with regard to Temperature. On observing the results, there is no significant effect of COD reduction since the variation in the temperature level at 3 different timings is very nominal. However, the COD reduction has observed due to the process of aeration and the values have been listed in Table .10

Table.10. Effect Of Temperature On Cod

Parameter in PPM	Temperature		
	29°C (10.00am)	31°C (12.30pm)	28°C (6.00pm)
COD	16	Not detectable	Not detectable

Effect of Impeller rotation

The COD values have been taken at three impeller rotation 48 RPM, 68 RPM and 96 RPM and analyzed. The values of COD with respect to the 48 RPM, 68 RPM and 96 RPM are (-) 16 , (-) 64 and (-) 72 respectively. Based on the results, it can be seen that there is a reduction in COD as the impeller rotation increases. But, the COD values (Table 11) are not in the detectable limits. However, it is observed that the reduction of COD level is in decreasing trend.

Table .11 Effect Of Impeller Rpm

Parameter in PPM	Impeller RPM		
	48	68	96
COD	16	Not detectable	Not detectable

Effect of immersible depth of impeller into the effluent

The samples have been taken in the aeration tank at two different immersible depth of impeller into the effluent and values have been analyzed (Table .12) . On observing the values, it can be seen that the reduction of COD level is more at the immersible depth of 10 cm But, the COD values are not in the detectable limits. The COD values have been taken at two impeller rotation 68 RPM and 96 RPM and analyzed. The values of COD with respect to the 68 RPM and 96 RPM are (-) 24 , and (-) 48 respectively. However, it is observed that the reduction of COD level is in decreasing trend.

Table .12 Effect Of Immersible Depth Of Impeller Into The Effluent

Parameter in PPM	Immersible Depth of impeller in centimetre	
	10 CM	8CM
COD	Not detectable	Not detectable

5.4 PH RESULTS AND CALCULATION

Since the variation in pH level of effluent samples itself are very less, it is not noticed accurately ensured that the significant reduction of BOD and COD with respect to the effect of temperature (Table No.13)., impeller rotation (Table.14) and immersible depth of impeller into the effluent (Table.15)

TABLE .13. EFFECT OF TEMPERATURE

Parameter	Temperature		
	10.00 AM	12.30 PM	6.00 PM
pH	7.09	6.82	7.37

	10 cm	8 cm
pH	7.09	7.25

5.5 EFFLUENT CHARACTERS BASED ON TEMPERATURE

Effect of temperature

The effluent samples have been taken in the aeration tank at morning, noon and evening time in order to analyze the character of BOD with regard to Temperature. On observing the results, there is no significant effect of BOD and COD reduction since the variation in the temperature level at 3 different timings is very nominal. However, the reduction in the values of BOD and COD has observed due to the process of aeration and the values have been given Figure13.

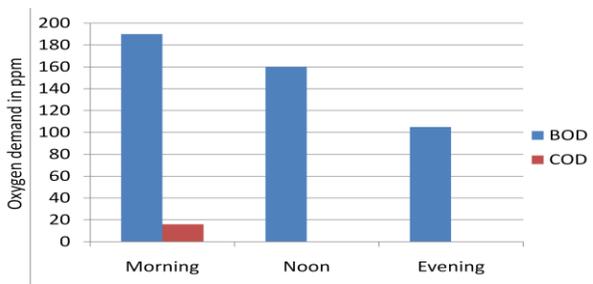

Figure.13. Effect of Temperature on BOD and Cod

5.6 Effluent Character Based On Impeller Rpm

5.6.1 Effect of Impeller RPM

The values of BOD have been taken at the impeller rotation 48 RPM , 68 RPM and 96 RPM for 30 minutes aeration process and analyzed (Figure.14) . On reading of the values ,

it is noticed that the reduction of BOD level is significant for 45 minutes aeration process at 96 RPM of impeller rotation The COD values have been taken at three impeller rotation 48 RPM, 68 RPM and 96 RPM and analyzed. The values of COD with respect to the 48 RPM, 68 RPM and 96 RPM are (-) 16 , (-) 24 and (-) 48 respectively. Based on the results, it is found that there is a reduction in COD as the impeller rotation increases. But, the COD values are not in the deductable limits. However, it is observed that the increase in the reduction of COD level in negative value.

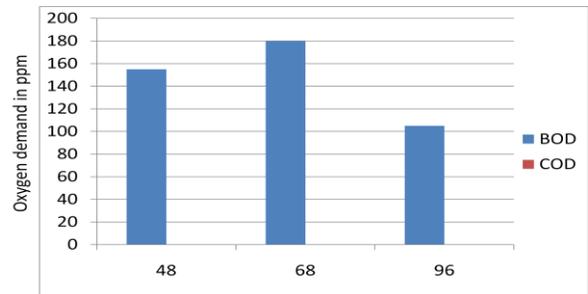

Figure.14 Effect of Impeller RPM on BOD And Cod

5.6.2 Effluent Character based on Immersible depth of Impeller into the effluent

Effect of immersible depth of impeller into the effluent

The samples have been taken in the aeration tank at two different immersible depth of impeller into the effluent and values have been analyzed (Figure.15) . On observing the values, it is found that the reduction BOD level is more at the immersible depth of 10 cm. The BOD reduction level is not found significant at 8 cm immersible depth of impeller into the effluent through the aeration process took place for 45 minutes at higher impeller rotation (96 RPM)

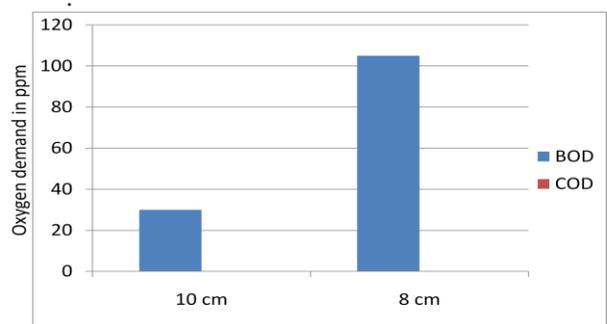

Figure.15 Effect of Immersible Depth Of Impeller On Bod And Cod

5.7 SCOPE FOR THE IMPROVEMENTS

There is ample scope for improvement to overcome to the following limitations are observed during the analysis for ensuring the accurate value of the characteristics of effluent. There may be a variation in the quantity of raw effluent coming from the equalization tank to aeration tank and the quantity of flow is not consistent. There may be a chance for variation in the raw effluent characteristics from

time to time depending on the food material that is processed in the pilot plants. The incoming quantity of activated sludge from clarifier tank to aeration tank for recycling is not consistent and microorganism present in the activated sludge may vary from time to time and it is difficult to calculate accurately. The presence of chemicals in the raw effluent may oxidize the inorganic materials very fast than the expected time of aeration.

VI. CONCLUSION AND FUTURE SCOPE OF THE PROJECT

There is no significant effect of temperature on reduction in BOD and COD, since the variation in the temperature level at 3 different timings is very nominal. However, the reduction in the values of BOD and COD has observed due to the process of aeration. The effect of impeller rotation at three different speeds on reduction of BOD, it is observed that the reduction of BOD level is significant for 45 minutes aeration process at 96 RPM of impeller rotation. The effect of impeller rotation at three different speed on reduction of COD, the values of COD with respect to the 48 RPM, 68 RPM and 96 RPM are not in the deductible limits. However, it is observed that the increase in the reduction of COD level. Moreover the reduction in BOD and COD will depend on the incoming quality and quantity of raw effluent and activated sludge. The effect of immersible depth of impeller into the effluent is significant. On observing the values, the reduction in BOD level is more at the immersible depth of 10 cm. The oxygen transfer in the aeration tank by the surface aerators may be increased by changing the suitable design of impeller. For instance, pitched blade turbine (up flow) with six blades and a blade angle of 45° (pitch) will significantly increase the degree of surface aeration. The inflow of activated sludge quantity may be increased and the effluent characters can be analyzed by which the detention time of effluent in the aeration tank and operation hours of aerators may be reduced.

Flow and heat transfer behaviour across circular cylinder and tube banks with and without splitter plate

S. G. Chakrabarty¹, Dr. U. S. Wankhede

¹(Currently pursuing masters degree program in Heat Power Engineering in G. H. Raisoni College of Engineering, Digdoh hills, Nagpur-440016, Maharashtra State, India)

²(Professor, Mechanical Engineering Department, G. H. Raisoni College of Engineering, Digdoh hills, Nagpur-440016, Maharashtra State, India)

Abstract: This paper describes the passive flow control of fluid in the downstream direction of the circular tube and in tube banks by means of splitter plate. Heat transfer and pressure drop depend on complex flow pattern of fluid in tube banks, whereas pressure drop linked directly with the fluid pumping capacity. A primary focus is to review experimental, analytical and numerical works that had been carried out to study the effect of longitudinal and transverse tube spacing, Reynolds number, stagnation point and surface roughness on wake size and vortex shedding.

Index Terms: Circular cylinder, Splitter plate, Tube banks, Cross flow, Heat transfer, Vortex shedding

I. INTRODUCTION

A heat exchanger is a device built for efficient heat transfer from one medium to another. The media may be separated by a solid wall, so that they never mix. Tube bank is the crossflow tubular heat exchanger and consists of multiple rows of tubes. One fluid passing through the tubes and other is passing across the tubes as shown in Figure 1. Tube banks arrangement include the in-line and the staggered arrangements. Cross flow tubular heat exchanger are found in diverse equipment as economizer, waste heat recovery, evaporator of an air conditioning system to name but few.

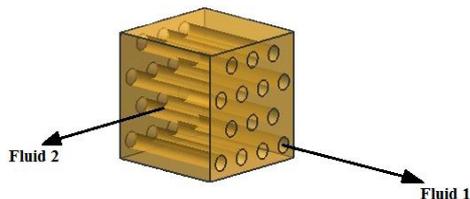

Figure 1. Cross Flow Tube Banks

Heat Exchanger involve several important design consideration which include thermal performance, pressure drops across the exchanger, fluid flow capacity, physical size and heat transfer requirement. Out of this following consideration, determination of pressure drop in a heat exchanger is essential for many applications because the fluid needs to be pumped through the heat exchanger. The fluid pumping power is proportional to the exchanger pressure drop. In tube banks, the heat transfer and pressure drop characteristic depend upon the flow pattern of fluid. The fluid flow converges as the minimum area occurs between the tubes in transverse row or in a diagonal row which makes the flow pattern very complex.

Passive control is one of the flow control techniques for reducing the aerodynamic drag exerted on a bluff body. It controls the vortex shedding by modifying the shape of the bluff body or by attaching additional devices in the flow stream. Passive control can achieve by use of splitter plate, small cylinder and base bleed method. Roshko (1954) was one of first investigator to study the influence of splitter plate on vortex shedding.

Splitter plate is the longitudinal fins, built-in with the tubes as shown in Figure 2. Gerrard (1966) explained the flow mechanism across a circular cylinder. H. Akilli (2008) and E. A. Anderson (1997) also studied flow behaviour with splitter plate with different configuration. Flow across circular cylinder was explained by John H. Lienhard (23).

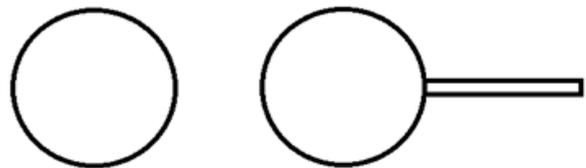

Figure 2. (a) Circular Cylinder (b) Circular Cylinder with Splitter Plate

II. EFFECT OF SPLITTER PLATE ON FLOW AND HEAT TRANSFER BEHAVIOUR AROUND CIRCULAR CYLINDER

Roshko (1954) carried out an experimental investigation of circular cylinder by placing a splitter plate in the downstream direction of the wake at $Re = 14,500$. It was observed that flow pattern changes. When the length of splitter plate was $5D$, the vortex shedding completely disappeared and pressure drag was significantly reduced. Moreover when the splitter plate was detached and move $3.85D$ downstream from the cylinder exhibits the shedding frequency become minimum and the base pressure was maximum. A splitter plate of length $1D$ did not inhibit formation of vortices but changed the shedding frequency slightly

Gerrard (1996) conducted experiments to studied the formation region behind circular cylinder at $Re = 2 \times 10^4$. It was found that the Strouhal number decreased when the length of the splitter plate was smaller than d , but it increased for $d < l < 2d$. Addition of splitter plate increased the production of circulation at the rear of the cylinder, as a result the vortex strength in the early stage of growth decreased. The effective formation-region length was the distance from the plate to the end of the region. It was found that when the vortex was growing close behind the

plate, there was a large cross-flow velocity produced near the plate, assist the shedding process and increase the frequency.

J.Y. Hwang et al. (2003) numerically studied flow induced forces on a circular cylinder using detached splitter plate for laminar flow. A splitter plate with the same length as the cylinder diameter was placed horizontally in the wake region. Suppressing the vortex shedding, the plate significantly reduced drag force and lift fluctuation, there existed an optimal location of the plate for maximum reduction. However, they sharply increase as the plate was placed further downstream of the optimal location.

H. Akilli et al. (2008) investigated experimentally passive control of vortex shedding by splitter plates having L/D ratio (0.2 to 2.4) attached on the cylinder base in shallow water flow at $Re = 6300$. In this study, the length of the splitter plate was varied from in order to see the effect of the splitter plate length on the flow characteristics. Instantaneous and time-averaged flow data clearly indicated that the length of the splitter plate has a substantial effect on the flow characteristics. They found the flow characteristics in the wake region of the circular cylinder sharply changed up to the splitter plate length of $L/D=1.0$ and above this plate length, small changes occurred in the flow characteristics.

A. Fage et al. (1930) carried out experimental investigation to determine effect of turbulence and surface roughness on the drag of the circular cylinder. It was seen that as the surface was made rougher, the fall in drag coefficient occurred at a lower value of Reynolds number and that this fall gradually dies away. There was an indication that if the roughening had been continued, a surface would eventually have been obtained for which there would be no fall in drag. From this, it may be concluded that increase in roughness further retards the flow in boundary layer over the cylinder and causes the stagnation point to shift further upstream. They also concluded the region $\theta = (+ 37.5^\circ \text{ to } +100^\circ)$ was very sensitive to surface roughness, since it include those parts where the flow separates from the surface.

Schmidt et al. (1943) conducted experimental analysis over the circumference of a heating cylinder having different diameter (50, 100, 250) at $Re= 5000-426000$. They explained effect of surface projection on the heat transfer of circular cylinder. It was observed that starting from the stagnation point the heat transfer coefficient dropped to a distinct minimum close before angle 90° forward stagnation point and then rises again, which increases to higher value as Reynolds number increases. Furthermore, they concluded that minimum pressure distribution lies before the minimum heat transfer coefficient.

P. A. R. Ribeiro et al. (2004) developed a numerical simulation for bluff-body vortex shedding suppression at $Re = 100$ and 160 using Finite Difference method. As attached plates perform great changes on the shedding frequency depending on the length, the use of splitter plate to control bluff-bodies' vortex shedding shows to be great efficiency.

E. A. Anderson et al. (1997) investigated 2 and 3-dimensional flow configuration of splitter plate effect on

the circular cylinder wake. Result of flow visualization showed that shear layer characteristics such as circulation strength, ability to entrain fluid, and length had significant effect on the Karman shedding frequency at subcritical Reynolds number between 2700 to 4600. The variation in strouhal number over the range of $l/d = 0$ to 1.75 was divided into four distinct regions where within each region a different flow phenomenon dominated the selection process of the shedding frequency.

S. Tiwari et al. (2005) obtained a three dimensional model to study the heat transfer behaviour of a circular tube in cross-flow configuration with different length of wake splitter plate at $Re = 500, 1000, 1500$. The splitter plate of chord length $2H$ (height of the tube) causes the vortex to clear off the plate. As the chord length of the plate increases, vortices moves towards the plate and roll over the edge i.e. presence of splitter plates delayed the flow separation which decreased the total drag and therefore reduction in pumping power. In front of the tube, there was a sudden increase in Nusselt number. The reason for the abrupt increase in Nusselt number can be attributed to the formation of horseshoe vortices. The spiralling motion of the horseshoe vortices brings about better mixing and the heat transfer in this region was enhanced significantly. The Nusselt number was low in the wake region. The separated dead water zone where fluid recirculates with low velocity causes poor heat transfer. The splitter plate creates a streamlined extension of the circular tube, which also brings about enhancement of heat transfer. A reduction in the size of wake zone was observed. Narrowing of the wake zone reduces convective heat transfer from the tube surface but the splitter plate itself generates an extra fin area for conduction. One would expect the value of viscous drag coefficient to increase with increasing chord length of the splitter plate. However, the counter rotating vortices diminish the effect of viscous drag on the chord of the splitter plate i.e. total drag decreases.

S. E. Razavi et al. (2008) carried out numerical investigation of flow and heat transfer around circular cylinder in the range of $20 < Re < 1000$ by finite volume method. It was concluded that splitter plate streamlined the flow around the cylinder and accordingly decreased the pressure drag causing the significant reduction in overall drag. The heat transfer decreased from the cylinder surface, while placing the splitter plate increased the total heat transfer.

III. EFFECT OF SPLITTER PLATE ON FLOW AND HEAT TRANSFER BEHAVIOUR AROUND SQUARE CYLINDER

Said Turki (2008) conducted a numerical study to examine a passive control of flow by introducing a splitter plate behind a square cylinder inside a horizontal channel. At $110 < Re < 200$ and for affixed blockage ratio $\beta = h/H = 1/4$. The effect of splitter plate length and its location in the wake region on the Strouhal number and the drag and lift coefficient were analyzed. It was found that critical length of the splitter plate, characterizing the suppression of the vortex shedding, increases as the Reynolds number increase and it can be correlated by the linear relationship: $L_c = 0.0366R - 3.3184$. For $L < L_c$, the

splitter plate significances reduces the lift and the drag fluctuation.

Woe-Chul Park et al. (1997) numerically investigated of wake flow control by a splitter plate attached to the base of square cylinder. It was found that the splitter plate blocks the roll-up of the separated shear layer close to the base of the body, and lowers the velocity near the base, the drag of the body and the vortex shedding frequency. Interaction of separated shear layer was delayed until the end of the plate. Because of this, shorter splitter plate was more sensitive to wake flow forming low velocity region behind the cylinder. Both the drag and Strouhal number were significantly reduced by suppressing the vortex shedding in the wake.

IV. FLOW INDUCED VIBRATION MITIGATION USING ATTACHED SPLITTER PLATE

B. Stappenbelt (2010) conducted experimental investigation of vortex-induced vibration response of an elastically mounted rigid cylinder with a range of splitter plate ratio ($l/d = 0$ to 4) under reduced velocity interval of $U_r = 3$ to 60 . For splitter plate ratios of $l/D = 2.8$ to 4 , no significant vortex-induced and galloping type vibration were observed. It was only this region that vibration mitigation was realized.

Ibrahim Ayoub et al. (2008) also studied effect of splitter plate on vortex-induced vibration with splitter plate of length 3 to 3 diameters under the reduced velocity ranging from 0 to 0.35 and Reynolds number of range $1.0 \times 10^4 < Re < 7.5 \times 10^4$. Experimental results contradict some existing data, the amplitude of response increases dramatically with attached splitter plate. It was observed that amplitude of cylinder with splitter plate of length 0.5 to 1 diameters are up to 4 times larger than bare cylinders.

V. HEAT TRANSFER FROM TUBE BANKS

W.A. Khan et al. (2006) studied heat transfer from tube banks using analytical approach. It was concluded that the average heat transfer coefficients for tube banks depend on the longitudinal, transverse pitches, Reynolds number and Prandtl number. Compact banks (in-line or staggered) indicate higher heat transfer rates than widely spaced ones and the staggered arrangement gives higher heat transfer rates than the in-line arrangement. This was also supported by the further work of W. A. Khan (2007), where an optimal model of tube banks heat exchanger was developed using entropy generation minimization method. It was also demonstrated that the staggered arrangement gives a better performance for lower approach velocities and longer tubes, whereas the inline arrangement performs better for higher approach velocities and larger dimensionless pitch ratios.

S. Aiba et al. (1982) carried out an experimentally studied the heat transfer around tubes in-line tube banks. Measurements were conducted for seven cylinder spacing in the Reynolds number range from 10^4 to 6×10^4 . The mean Nusselt number of the first cylinder varies considerably with the cylinder spacing but Nusselt no. did not show any essential variation with the cylinder spacing for second and farther downstream cylinder.

S. Aiba et al. (1982) also conducted experiments to investigate the heat transfer and flow around tubes in staggered tube banks in cross flow. The cylinder spacing

examined $C_y/d \times C_x/d$ was 1.6×1.6 and 1.2×1.2 in the Re. no. range of 8600 to 3600 where C_x and C_y cylinder spacing along and normal to the upstream uniform flow direction and d was the cylinder diameter. In case of 1.6×1.6 the heat transfer rate for the third cylinder was the maximum. This may due to high velocity of the flow on coming to the third cylinder along with its turbulence intensity. In case of 1.2×1.2 the heat transfer rate of the first cylinder was extremely low. A very large velocity of the flow oncoming to the second cylinder produce a high heat transfer rate as compared to that in case of 1.6×1.6 . Heat transfer rate was almost equal for both the cases of 1.2×1.2 and 1.6×1.6 at the same Reynolds number

E. Buyruk (1999) carried out an experimental study to investigate heat transfer and flow characteristics from one tube within a staggered tube bundle and within a row of similar tubes. The tube spacing examined S_t and S_l were 1.5×1.5 and 1.5×1.25 where S_t and S_l denote the transverse and longitudinal pitches respectively at Reynolds number 4.8×10^4 . The influence of the blockage of a single tube in a duct and transverse pitch for a single tube row with Reynolds number range of 7960 to 47770 also investigated. Experimentations were carried out by varying blockage ratio from 0.131 to 0.843 . It had been shown that the general shape of local Nusselt number distribution around the cylinder varies only slightly with blockage for blockage ratio was less than 0.5 . When the blockage ratio was greater than 0.395 , increasing blockage causes the minimum pressure and minimum Nusselt number to move to the downstream side of the cylinder. For the blockage ratio in the range of 0.668 - 0.843 , there was a distinct change in the flow compared with the lower blockage cases. Local Nusselt number and static pressure are remarkably different. Due to the great acceleration of the flow minimum local static pressure values reached very low values. Changes in both longitudinal and transverse pitch were observed to have a noticeable influence on the velocity distribution around the tubes in a bank. For the staggered tube bundle geometry, the mean Nusselt number of the inner tubes becomes higher by increasing the transverse pitch and decreasing longitudinal pitch ratios.

E. Buyruk (2002) Heat transfer characteristic on tandem cylinder with ($L/D = 1.13, 2, 3, 6$) were also investigated at constant $Re = 400$. Laminar boundary layer region heat transfer of first cylinder was not affected by decreasing gap between the cylinders. Smaller gap between the cylinder results lower heat transfer rate on the downstream side of the first cylinder and upstream side of second cylinder. Such as when ratio L/D changed from 3 to 1.13 then, impact point location changes from about 55° to 70° which decreases the rate heat transfer. Effect of Reynolds number ($80, 120, 200$) was investigated for inline and staggered tube banks with transverse and longitudinal pitch of 2×2 . For the first cylinder it was seen that increase Reynolds number causes the heat transfer rates to increase and separation point moves upstream side of the cylinder. Heat transfer rate for second cylinder was relatively low comparing with the first cylinder, as second cylinder located in the wake of first cylinder that will block the direct effect of flow on the second cylinder. Increase in Reynolds number causes the impact point to move upstream of the second cylinder

for inline arrangement. For staggered arrangement, local heat transfer coefficient of second cylinder front region was higher than the first cylinder front region due to effect of flow acceleration. Such as front stagnation value for second cylinder was nearly 60% higher comparing the $Re=80$ case with $Re=200$ case.

S. Jayavel et al. (2008) numerically studied the heat transfer and pressure drop for flow past inline and staggered tube bundles. Three-dimensional computational codes were developed and apply to compare flow and heat transfer characteristics for inline and staggered arrangement of circular tubes in a tube bundle. A finite volume-based numerical investigation was carried out to study the flow and heat transfer for flow past inline and staggered arrangement of tube bundles confined in a rectangular channel. The investigation identify the range of Reynolds number in which staggered arrangement of tubes in a tube bundle provide more heat transfer causing less pressure drop compared with inline arrangement of tubes. However, at lower Reynolds numbers inline arrangement of tubes are found to be preferable due to heat transfer and smaller pressure drop.

Seong-Teon Yoo et al. (2007) experimentally investigated heat transfer characteristics for staggered tube banks in cross-flow using naphthalene sublimation technique. It was concluded that the variation of the local heat transfer coefficients was quite different from the first tube to the third tube, but they are similar afterwards. The average Nusselt number increases more than 30% and 65% on the second and third tubes, respectively, in comparison with that of the first tube. The local heat transfer coefficients on each tube increase except on the front part of first tube as the tube spacing decreases. Due to strong vortices the local heat transfer near the rear stagnation point of the first tube increases drastically with decreasing tube spacing. Consequently, the average Nusselt number on the first tube for the tube spacing of 1.75 and 1.5 was higher by about 25% and 45%, respectively than that for the tube spacing of 2.0. In the first and third tubes,

dependence of average Nusselt number on Reynolds number was almost same regardless of the tube spacing.

VI. HEAT TRANSFER FROM TUBE BANKS WITH SPLITTER PLATE

Suzairin Md. Seri et al. (2011) carried out an experimental studies in the Reynolds number range 5×10^3 to 10^5 on a single cylinder with splitter plate having length-to-tube diameter ratios ($L/D = 0.5, 1.0, 1.5$ and 2.0). Tube banks consisting of 12 rows and 3 tubes per row in equilateral triangle arrangements with transverse pitch to diameter ratio ($a = 2$), and longitudinal pitch to diameter ratio ($b = 1.73$). It was concluded that the local Nusselt numbers on the rear of a single tube are depressed when a splitter was attached to the tube. The reduction being greatest at rear stagnation but the Nusselt numbers rise steadily from base of the splitter plate towards the tip. In the first row of tube banks, heat transfer behaviour was similar to that of the single tube. The fin tip Nusselt numbers, at the middle to high range of the investigated Reynolds numbers, are higher than the forward stagnation point values. For all tube banks, Nusselt number at the rear stagnation point of any row was highest at the second row due to the greatest intensity of turbulence at this location. Heat transfer characteristics were studied for tubes with different L/D ratios under constant heat flux conditions. Tube banks with $L/D = 1.0$ yielded the highest heat transfer rates.

VII. CONCLUSION

This paper describes the influence of splitter plate on flow behaviour and heat transfer characteristic across cylinder and in tube banks. Vortex shedding and pressure drop mostly depends on Reynolds number and tube spacing. Addition splitter plate on a single cylinder can be attributed to the attenuation of vortex shedding in the wake and also reduced pressure drag significantly. Increase in total heat transfer can be also observed as a result of extra surface area generated by the splitter plate.

ABSTRACT: It is often seen that conventional water treatment plants are not necessarily cost effective, specifically for smaller units up to 3 MLD. The flocculator is an important unit of the water treatment plant and more often fitted with mechanical stirrers or vanes. The problems associated with maintenance and running of the mechanical components impose a severe constraint on such units, specifically in developing countries of Asia Pacific region. It is therefore necessary to explore and find other simpler devices free from such constraints. The jet flocculator seems to be a viable alternative. Guidelines for preliminary design of a jet flocculator are not available even though it is simple, economical and robust to operate. The present investigation is to study the performance of single-basin jet flocculators using both experimental and numerical techniques. A number of performance indices, some already existing and some new, are being made use of in assessing the performance of the flocculator.

KEYWORDS: Experimental, Numerical Analysis, Horizontal Jet Flocculators, Small Water Supply Schemes

I. INTRODUCTION

Coagulation and flocculation are the water treatment process by which finely divided suspended and colloidal matter in the water is made to agglomerate and form flocs. This enables their removal by sedimentation, dissolved air flotation or filtration. Colloidal particles (colloids) are midway in size between dissolved solids and suspended matter. Colloids are kept in suspension (stabilized) by electrostatic repulsion and hydration. Electrostatic repulsion occurs because colloids usually have a surface charge due to the presence of a double layer of ions around each particle. Thus, the colloid has an electric charge, mostly a negative one. Hydration is the reaction of particles at their surface with the surrounding water. The resulting particle-water agglomerates have a specific gravity, which differs little from that of water itself.

The electrostatic repulsion between colloidal particles effectively cancels out the electronic attraction forces (Van der Waals' forces) that would attach the particles together. Certain chemicals (called coagulating agents, coagulants) have the capacity to compress the double layer of ions around the colloidal particles. They reduce the range of the electrostatic repulsion, and thus enable the particles to flocculate, i.e. to form flocs. These flocs can grow to a sufficient size and specific weight to allow their removal by settling, flotation or filtration. Generally water treatment processes involving the use of chemicals are not so suitable for small community water supplies. They should be avoided whenever possible.

Chemical coagulation and flocculation should only be used when the needed treatment result cannot be achieved with another treatment process using no chemicals. If the turbidity and colour of the raw water are not much higher than is permissible for drinking water, it should be possible to avoid chemical coagulation in the treatment of the water. A process such as slow sand filtration or multi-stage filtration would serve both to reduce the turbidity and colour to acceptable levels, and to improve the other water quality characteristics, in a single unit. A roughing filter can serve to reduce the turbidity load on the slow sand filter, if necessary.

Flocculation is the process of gentle and continuous stirring of coagulated water for the purpose of forming flocs through the aggregation of the minute particles present in the water. It is thus the conditioning of water to form flocs that can be readily removed by settling, dissolved air flotation or filtration. The efficiency of the flocculation process is largely determined by the number of collisions between the minute coagulated particles per unit of time. There are mechanical and hydraulic flocculators. In mechanical flocculators the stirring of the water is achieved with devices such as paddles, paddle reels or rakes. These devices can be fitted to a vertical or horizontal shaft. Vertical shaft flocculators are usually placed in a square tank with several chambers (four or more). They have the advantage of having only bearing in the water, and no gland is necessary as the motor and gearing are above the water. With horizontal shaft flocculators having a traverse flow, one should provide at least four rows of shafts, with partitions of baffles (stop logs), so as to avoid short-circuiting. In hydraulic flocculators the flow of the water is so influenced by small hydraulic structures that a stirring action results. Typical examples are channels with baffles, flocculator chambers placed in series (e.g. *Alabama*-type flocculator) and gravel bed flocculators.

Their advantages are that they have no motor power, electric cables switchgear, etc. to maintain and general maintenance is easier. Mechanical and hydraulic methods are often used to create an agitation in the flocculation chamber thereby maintaining a velocity gradient. This stage is called the orthokinetic flocculation.

II. Present Scenario

As per the performance evaluation survey conducted by National Environmental Engineering Research Institute (NEERI), Nagpur during 1988-89 on 51 water treatment plants in India, it was found that effective supervision and managerial control are absent in most of the plants (Mhaisalkar and Tidke, 1998). Only 39% of the plants were producing quality water meeting the CPHEEO

standards. The reasons quoted for this poor performance are the lack of funds for operation and maintenance, non-availability of spare parts, untrained laboratory staff, poor administration, negligence by the staff and improper co-ordination between the staff. Conventional water treatment plants are not necessarily cost effective, specifically for smaller unit of capacity up to 3 MLD. The flocculator is an all important unit of the water treatment plant and more often fitted with mechanical stirrers or vanes. The problems associated with maintenance and running of the mechanical components impose a severe constraint on such units, specifically in developing countries of Asia Pacific region. It is therefore necessary to explore and find other simpler devices free from such constraints. The jet flocculator seems to be a viable alternative. Guidelines for preliminary design of a jet flocculator are not available even though it is simple, economical and robust to operate.

III. OBJECTIVE OF THE STUDY

The present investigation is to study the performance of single-basin jet flocculators using both experimental and numerical techniques. A number of performance indices, some already existing and some new, are being made use of in assessing the performance of the flocculator.

IV. MATERIALS AND METHODS

4.1 EXPERIMENTAL SETUP

The main components of the set-up consisted of a tank to store the turbid water, a constant head supply chamber, supply pipeline fitted with pressure taps and a bypass pipe, an orifice meter in the supply line to aid mixing of coagulants injected into it by a peristaltic pump, manometers, flocculation chamber having a nozzle fitted at the inlet end and a suitable overflow mechanism at the outlet end. Preparation of the turbid water was quite crucial since the synthetically generated turbidity should be quite close to the natural condition. Turbid water in nature contains particles of different sizes and specific gravity. As observed by Hudson (1965), most particles causing turbidity in natural channels are smaller than 10 mm while a majority is smaller than 1.5 mm. Throughout the present experimentation, Bentonite was used to generate different levels of turbidity of 100, 50 and 25 NTU.

Tap water available in the laboratory had a turbidity of less than 0.9 NTU. The amount of Bentonite required to generate different intensities of turbidity in a sample was found to vary in a linear fashion,

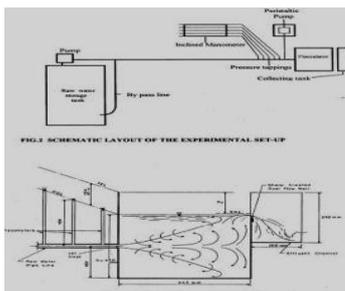

Figure.1 Schematic Layout Of Experimental Setup
 $\text{Bentonite in mg/L} = 1.5857 \times \text{turbidity in NTU} - 1.4271$

Standard jar-tests were carried out with the objective of estimating the optimum concentration of the Alum needed for removal of the suspended matter. The optimal Alum dosage (in mg/L) necessary to treat raw water was 44.50, 36.00, and 34.00 for turbidity intensities of 100 NTU, 50 NTU and 25 NTU respectively.

Raw-water alkalinity (CaCO_3 in mg/L) was noted every day before the start of the experiment and was found to be almost the same, 40 mg/L, throughout the period of experimentation. However, addition of the coagulant altered the alkalinity. Samples of water taken from the jar for the highest dosage of the Alum used in this investigation had alkalinity in excess of 10 mg/L, sufficient not to hinder the formation of flocs. Similarly, other characteristics of water, especially, the pH values have a considerable influence on the satisfactory formation of flocs. In the present investigation the pH of the synthetic turbid water was in the range of 6.8 to 7.0. The recommended pH zone while using Alum as a coagulant is 6.5 to 7.5. The two ranges being not very different, no additional chemical was used in the experiments to control the pH level. The temperature of raw water in the experiments was in the range 27°C to 28°C .

4.2 EXPERIMENTAL PROCEDURE

Flocculation chambers having identical capacities but of different plan shapes were fabricated out of metallic sheets and red oxide priming coat was applied to avoid any chemical reaction of the alum with the metal surface. Raw water stored in a tank was pumped to the flocculator with the help of a pump. The required flow rate was setup by adjusting the valves provided on the main and bypass pipe lines. The flow from the inlet to the flocculator was in the form of a jet emanating from a submerged pipe. The rate of flow entering and leaving the flocculator was measured volumetrically using a collecting tank. To ensure proper mixing of the coagulant with raw water, alum solution was injected as a co-current axial jet into the raw water supply line 1.5m ahead of the jet nozzle with the help of a peristaltic pump. The peristaltic pump discharge was calibrated to improve the accuracy of the results. The flow rate and the operation time parameter of the peristaltic pump were pre-set at the desired values. To determine the total energy on the up-stream side of the flocculator 3 pressure tapplings of 1mm diameter were provided at a space of 27cm center to center on the pipe line leading to the flocculator. All pressure head measurements were made with reference to the center line of the influent pipe to the flocculator. A manometer connected to these tapplings was supported by a board, and a scale readable to the nearest 1mm of water was provided. For proper mixing, Holland and Chapman (1966) recommended that the liquid level in the tank should be less than 1.25 times the highest lateral dimension of the tank so as to avoid multiple impellers or excessive power consumption. Van De Vasse (1955) observed that the circulation pattern established by a jet system is similar to that established by a propeller stirrer. Hence a jet submergence depth equal to 50% of liquid depth was adopted as a reference value.

Experiments were conducted with a rectangular and circular flocculation chamber for different jet sizes of 8, 10, 12, and 15mm in diameter. Hydraulic retention time equal to 6, 7.5, 10, 15 and 20 minutes were selected while repeating the experiments. Experiments repeated for

alternative outflow sections. A digital pH-meter was used to determine the pH values of the raw water. Similarly, turbidity meters were calibrated with a standard suspension. In the Nephelometric method followed here, a comparison of the intensity of light scattered by the sample under specified conditions was made with the intensity of light scattered by a standard reference suspension. The least count of the turbidity meter was 0.1 NTU.

To study the distribution of residence time of the tracer, laboratory grade common salt was used as a tracer and a digital conductivity meter having a least count of 0.1 micromhos/cm was used to measure conductivity of the solution. The meter was calibrated at the test temperature of 26°C and the conductivity of water was displayed directly and a best fit relationship $Y = 0.56X - 32.50$ was obtained. Y is the sodium concentration in mg/l and X is the conductivity in micromhos/cm. For a selected detention time, weight of salt equivalent to the weight of water passing per minute multiplied by 500 ppm was dissolved in water and it was injected using a peristaltic pump. The requisite amount of tracer solution was injected as a co-flowing axial jet at a section little ahead of the jet efflux section as a slug dosage over a time span of one minute depending on the flow rate. After the injection of salt solution, samples were collected at the outlet of the weir initially at 0.5, 1, 2, 3, 4 minutes and thereafter for every 1/5 of nominal detention time in minutes.

The samples were collected till the tracer disappeared from the collected sample. The sodium concentration at the chamber outlet was determined as a function of time with the help of digital conductivity meter. Based on the measured conductivity of the sample, the concentration of sodium chloride was worked out from the calibration curve corresponding to the test temperature. For every tracer experiment, a separate calibration chart was prepared before commencing the experiment. Material balance check was performed to verify that the recovery of entire tracer balances with the quantity added at the beginning of the flow (Hudson, 1981). The area lying under the normalized time distribution curve indicated this.

The turbidity meter, submersible pump and the peristaltic pump were always calibrated just before the start of an experiment. The dimensions of flocculation chambers are presented in Table.1. The volume of all the basins were 0.0883 m³ and a liquid depth of 45cm was maintained in all the chambers. The type of outlet in basin A and B was weir type, whereas the C type outlet was a circular opening of size 50 mm in diameter. Though, all alternative basin layouts were adopted for numerical simulation of the flow field and dispersion of tracers, some amongst them were only selected for experimentation on flocculation and turbidity removal efficiency. It should be realized that ultimate performance of a flocculator depends upon both coagulation and flocculation. Hence, it will be meaningful to segregate the effect of rapid mixing to assess properly the role of different design parameters on the performance of a flocculation chamber. It was observed that as long as the GT values of the rapid mixing device lay in the range of 10,600 and 18,800 the performance of the flocculation chamber remained unaffected. Hence, in all the flocculation experiments of the present study, care was exercised to maintain the GT of rapid mixing within the said range. For each of the flocculator basins under consideration, on

adding the coagulant the residual turbidity reached a steady state value after lapse of four to five times the theoretical retention time, $T = (\text{volume of the basin})/(\text{flow rate } Q)$. Hence in all the flocculation experiments floc-laden water samples were collected in settling jars at the outlet of the flocculator only after a lapse of 5.5 times the residence time. The samples were allowed to settle for a period of 30 min in settling jars before measuring the residual turbidity. The recommended plan area of jar is 115 x 115mm with a liquid depth of 210mm (Gregory R., et al., 1990). Further it has been specified that the outlet for the withdrawal of the sample should be 100mm below the liquid level. The turbidity of the settled water was measured by a nephelometric turbidimeter and an average of three samples tested is reported.

Table.1 Dimension Of Flocculator Basins

Basin no.	L mm	W mm	H (depth of water) mm
	443	443	450
2	Circular basin with D=500mm and H=450mm		

V. Result & Discussion

Result of floc and tracer studies

The results observed while conducting floc and tracer studies on 100, 50 and 25NTU turbid water have been observed for different sizes of jet diffusing in rectangular and circular chambers with alternative outlets.

4.2 HYDRAULIC RETENTION TIME

Figure 2 shows Effect Of Hydraulic Retention Time On Turbidity Removal

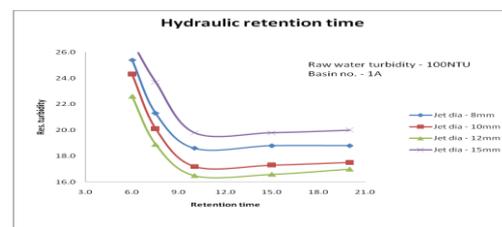

FIGURE.2 EFFECT OF HYDRAULIC RETENTION TIME ON TURBIDITY REMOVAL

Experiments were conducted with basin 1A for two different jet sizes of 8, 10, 12 and 15mm in diameter. Retention time equal to 6, 7.5, 10, 15 and 20 min were selected while repeating the experiments. Parameters like Camp number for rapid mixing ($GT = 10660$), coagulant dosage (44.5 mg/L), influent raw-water turbidity (100 NTU), total alkalinity (40 mg/L of CaCO₃) and pH (6.8-7.0) value were held constant in all the trials. The variation in the residual turbidity as a function of the retention time is shown in Fig.. For different sizes of the nozzles used, the

improvement in the performance of the flocculation tank is insignificant for a retention time exceeding 10 min. The same was also observed to hold good in case of the 50 NTU and 25NTU turbid water experiments. Hence, for free-jet-flocculators a retention time of 10 min may be sufficient. It is worth noting that this is only a fraction of the retention time of 30 min, normally recommended for flocculators having mechanical devices.

From the above one can notice that the jets 10mm and 12mm in diameter, performs marginally better than the 8 and 15mm diameter jets even though it has smaller values for G and GT. This highlights the fact that the performance of the flocculator is not sensitive to the G and GT values, specifically when they are in the range of 30 & 85 s⁻¹ and 23,000 & 50,000 respectively.

The results of experiments on rectangular basin no. 1A, 1B, and 1C considering Camp's number, GT, as the guiding factor are shown in Table for different sizes of the jet diffusing in rectangular and circular tanks. Influent raw water turbidity of No = 100, 50 & 25NTU are presented here. Since the chambers are fairly large in size compared to the diameter of the nozzle, the power input was calculated from the relationship

$$G = \sqrt{\frac{P}{\mu V}}$$

4.3 EFFECT OF BASIN SHAPE

Figure.3. shows the Effect of basin shape on turbidity removal

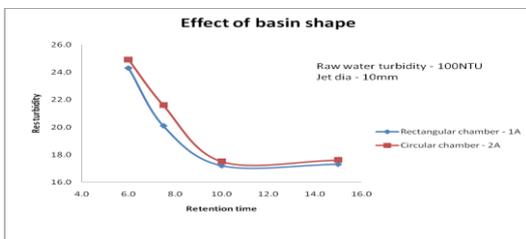

FIGURE.3. EFFECT OF BASIN SHAPE ON TURBIDITY REMOVAL

With the 8 mm diameter nozzle, the L/d ratio for the circular basin was 62.5 whereas in case of the rectangular basin it was 55.4. From the theory of free jets it is known that most of the kinetic energy of the jet gets dissipated within a distance of 40 to 45 times the diameter of the nozzle. Hence, it will not be unreasonable to assume that the energy loss in both the chambers is one and the same. It is interesting to observe that the performance of the rectangular basin is almost identical to that of the circular shaped basin, that is the shape of the flocculator is of no consequence.

A significant increase in the L/d ratio, as in case of the rectangular basin number 3 with circular opening, does help a bit to improve the turbidity removal efficiency. It can be noted that a rectangular basin should be marginally superior compared to the circular shape. This is in consonance with the measurements, where the efficiency of turbidity removal in the case of the rectangular basin is higher by 0.5%. In view of the fact that rectangular chamber are easy to construct and changing the length of the tank is also easy at a later time, a rectangular shaped basin has a

distinct advantage over other shapes. Interestingly, the performance of the free jet flocculator is comparable to the actual performance, 69 to 74% turbidity removal efficiency, reported by Bhole (1993) and Armal (1997) for static flocculators and clariflocculators, respectively.

Location of outlet

Figure.4 shows that the Effect Of Outlet Location On Turbidity Removal

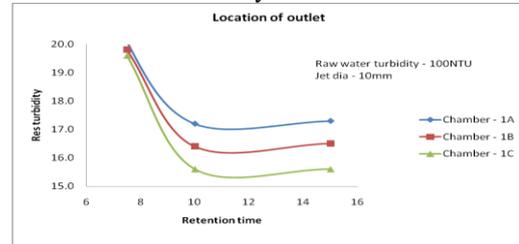

FIGURE.4 EFFECT OF OUTLET LOCATION ON TURBIDITY REMOVAL

The outflow section could be located at a convenient spot on the periphery of the chamber. The three alternatives experimented with are shown in Fig.. The experimental results, Table indicates that outlet 'C' performs superior to alternatives 'A' and 'B'. Further in all the cases, performance of a 12 mm diameter jet proved to be slightly better than 8, 10 and 15 mm diameter jets. Results pertaining to all basin alternatives are shown in. The location of the outlet plays a minor role in the overall efficiency of turbidity removal. This aspect can allow placement of the outlet at any convenient location as dictated by the prevailing conditions on-site.

Effect of Camp's no.

Figure.5 shows the effect of camp's no. On turbidity removal

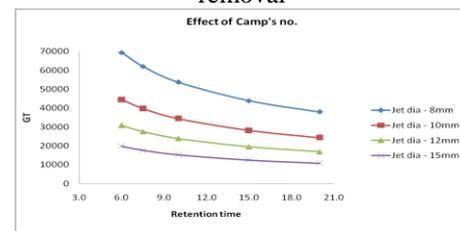

FIGURE.5 EFFECT OF CAMP'S NO. ON TURBIDITY REMOVAL

The value of G for the 12 mm jet corresponding to a retention time of 10 min works out to be 39.75s⁻¹. This value is comparable to the optimal value of G equal to 42s⁻¹ suggested by Andreu-Villegas and Letterman (1976). Even increasing the retention time to 15 and 20 min by lowering the jet velocity did not improve the performance as the large sized flocs were fragile. Thus, for a jet flocculator an optimal diameter exists when the retention time is specified. The same was found to be valid for other raw-water turbidities as well. The variation of GT value with respect to retention time for different jet sizes are shown in Fig.. The original Camp number, GT can be seen to vary over a wide range even though differences in the removal of turbidity were not remarkable. Hence, it is difficult to assign any particular value to GT for design purpose. The usage of G and GT parameters, though simple, cannot

explain the actual performance of the flocculator vis-a-vis the plan shape of the tank and the location of the outlet.

Residence time distribution

Figure.6 shows the Residence Time Distribution In A Square Tank

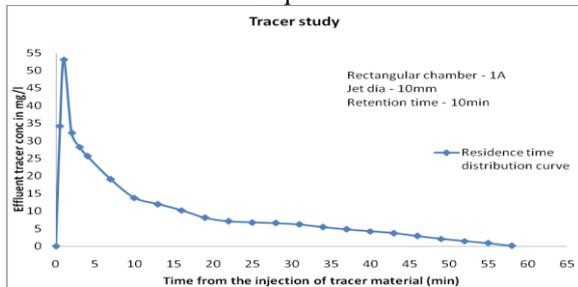

FIGURE.6 RESIDENCE TIME DISTRIBUTION IN A SQUARE TANK

A typical time distribution curve of the tracer for the case of a square tank corresponding to a detention time of 10minutes and for a jet diameter of 10mm is depicted in fig.. A material balance check was performed to ensure that the entire tracer material added in the tank was recovered. The errors were in the range of 1.5% to 4.5%.

Another graph as shown in fig. is plotted with cumulative concentration as a percentage and time on log scale. From this graph the dispersion index was calculated. The dispersion index so obtained then plotted against retention time for different basin shapes and for a jet diameter of 10mm as shown in fig.4.6.1. For an ideal plug flow DI=1, and for a completely mixed flow DI=21.9. From table, it can be seen that the DI values are nearly equal to the value of a well mixed flow whereas some are even higher. The higher values are indicative of the existence of flow short circuiting. For superior performance, the DI value should be as low as possible. It can be seen that for the same jet diameter and retention time, flow short circuiting in a rectangular basin is comparatively less than that of a circular basin. This factor again improves the efficacy of a rectangular basin.

Figure.7 shows the Residence Time Distribution In A Square Tank. Figure.8 shows the dispersion index variation in rectangular and circular tanks. Figure.9 shows the residence time ratio

The plot of $\log[1-F(t)]$ versus t/T , yields a straight line having a slope of $\log_e/(1-m)(1-p)$. Further for $F(t)=0$, $\log 1-f(t)$ being zero, we get $t/T = p/(1-m)$. Thus, from the slope of the straight line and the value of t/T corresponding to $F(t)=0$, fraction of dead space (m) and plug flow (p) computed and the values so obtained are as follows.

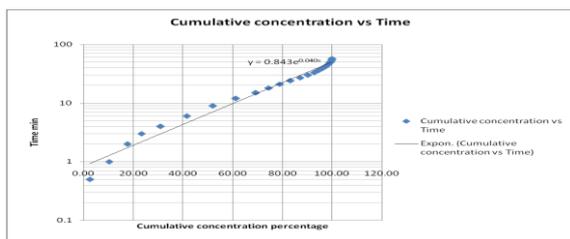

Figure.7 Residence Time Distribution In A Square Tank

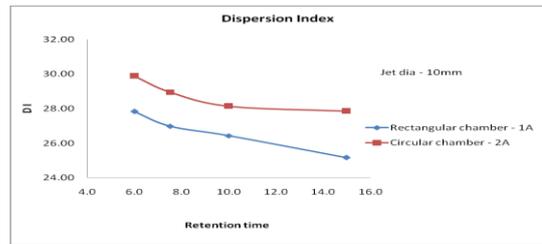

Figure.8 Dispersion Index Variation In Rectangular And Circular Tanks

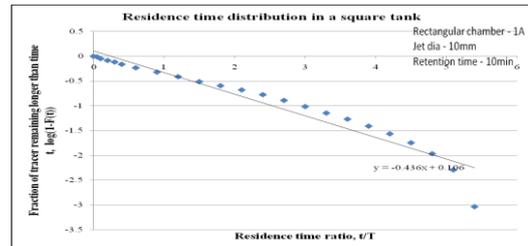

Figure.9 Residence Time Ratio

- dead space = 3.47%
- effective volume = 96.53%
- plug flow = 19.62%
- mixed flow = 90.38%

Out of many sizes and shapes of flocculation basin considered for carrying out tracer studies, results of a few are given in Table.2.

Dispersion Index

Based on the above results the proportion of dead space for all of them is quite small and is of the order of 3-5%. The implication is that site condition that demand specific position of the outlet can have the same turbidity

Table.2 Tracer Studies & Results

Chamber no.	T in min	Plug flow %	Mixed flow %	Dead space %	D ₅₀ /uL	DI
1A	7.5	23.45	76.55	3.14	0.45	26.97
	10	19.62	80.38	3.47	0.59	26.58
	15	18.91	81.09	4.25	0.51	25.17
2A	20	19.52	80.48	5.63	0.47	25.10
	7.5	24.65	75.35	3.21	0.42	28.95
	10	20.15	79.85	3.35	0.55	28.14
	15	18.62	81.38	4.20	0.51	27.86

removal efficiency. Dispersion no. and dispersion index of jet mixer too in the recommended range (0.3-0.7) for mechanical mixers. For all values of $T \geq 10$ min, mixed flow proportion nearly the same. For $T = 10$ min, D_{50}/uL is larger indicating better mixing of tracer in the flocculator.

Single and multi jet nozzles

Figure10. shows the Effect of single and multi jet nozzles in turbidity removal. Figure.11 shows the effect of single and multi jet nozzles in flow pattern

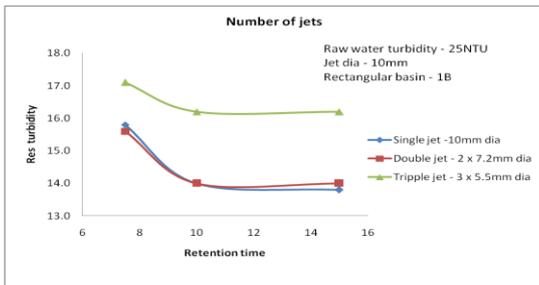

Figure10. Effect Of Single And Multi Jet Nozzles In Turbidity Removal

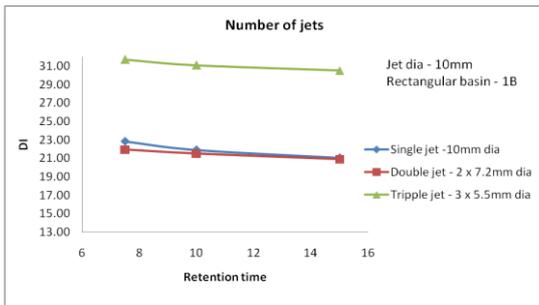

FIGURE.11 EFFECT OF SINGLE AND MULTI JET NOZZLES IN FLOW PATTERN

From the study it can be observed that the removal efficiency goes on decreasing as the raw water turbidity reduces. In the case of 100NTU turbid water the turbidity removal rate is as high as 84.9% but in the case of 25NTU turbid water it is only 48%. Multi jet nozzles have been tried to reduce the flow circuiting in flocculation basins. From the above it can be seen that the turbidity removal efficiency of double jet nozzles remained same as that of single jets. As the number of jets further increased which drastically reduces the removal efficiency. It is evident from study that the flow distribution in a double jet nozzle flocculator is superior to single jet flocculator. Since the turbidity removal rate remains the same and in the practical point of view, there is not much benefit in adopting multi jet nozzles.

VI. CONCLUSIONS

The outcome of the current experiments can be summarized as follows.

1. The single basin jet flocculator is a very simple, robust, low cost device which is capable of removing turbidity from the raw water in an efficient way. The efficiency of turbidity removal for raw water turbidity of 100 NTU was in the range of 79 to 85, which is as good as that of a flocculator fitted with mechanical stirrers.
2. The residual turbidity for raw water turbidity levels of 100, 50 & 25NTU was in the range of 13 to 21NTU. The outlet water with such a residual turbidity range can be directly applied over filter units for further treatment.
3. The retention time for a jet flocculator should be at least 10 min, a figure which is much less than the recommended value of 30 min duration for mechanical flocculators.
4. The length to diameter ratio, L/d should be larger than 36.
5. The plan-shape of the basin is not very critical in controlling the performance of the flocculator. For ease

of construction and scope for future alteration, a rectangular flocculator is desirable.

6. The location of the outlet plays a minor role in the overall efficiency of turbidity removal. This aspect can allow placement of the outlet at any convenient location as dictated by the prevailing conditions on-site.
7. By adopting larger diameter nozzles the efficiency of turbidity removal can be enhanced.
8. The existing indices such as G, GT and MI, though useful for design purpose, are not able to explain the variations in the performance of the jet flocculator vis-a-vis the shape, nozzle diameter, L/d ratio etc.
9. In adopting the jet flocculator for a new or an existing water treatment plant, the parameter G or GT (23,000 to 50,000) can be used in the design as a starting point. Other proposed indices can only help to refine the design and all the indices should be examined together before finalizing the dimensions and layout of the flocculation chamber.

An example is included in Appendix A as an illustration of the design principle of jet flocculators.

Design of Model For Incremental Development Of Software Modules To Evaluate The Quality Of Software Modules

Dr C.S. Lamba¹, Sanjay Kumar²

*1. Professor, Rajasthan Institute of Engineering
Jaipur, Rajasthan, India*

*2. Lecturer, University Campus School
Rohtak, Haryana (124001), India*

Abstract: This paper is introducing a model, which are used to evaluate the expected quality of software modules during incremental development of software system. This is not only focus on modification of existing system, but also focus to find the methods for developing high quality of software products at reasonable cost. As we know that software modules or software systems are being used in more and more critical areas of industries as well as public or private sectors, then quality of software modules becomes a key factor of business success and human safety. The goal of this paper within the subject areas are the identification of the methods and modules that were used throughout the design and verification of the use and the quality of these methods with respect to the analysis products.

Keyword: Software development approach,

I. Introduction

It is very difficult to build high quality software with limited quality assurance budgets. The proposed model can be used to learn fault predictors from software metrics. Fault prediction prior to software release can guide Verification and Validation (V&V) activity and allocate scarce resources to modules which are predicted to be fault-prone. One of the most important goals of proposed model is to detect fault prone modules as early as possible in the software development life cycle. Design and code metrics have been successfully used for predicting fault-prone modules.

Through this model we can introduce fault prediction from software requirements and analysis. Furthermore, we investigate the advantages of the incremental development of software fault prediction models, and we compare the performance of these models as the volume of data and their life cycle origin (design, code, or their combination) evolution during project development. We confirm that increasing the volume of training data improves model performance. And that, models built from code metrics typically outperform those built using design metrics only. However, both types of models prove to be useful as they can be constructed in different phases of the life cycle. We also demonstrate that models that utilize a combination of design and code level metrics outperform models which use either one metric set exclusively.

II. Problem Description

The software industry is currently entering a period of maturity, in which particular informal approaches are specified more precisely and are supported by the appropriate standards. Quality characteristics of software products are defined in ISO/IEC9126 [1]. For each characteristic, a set of attributes which can be measured is determined. Such a definition helps in evaluating the quality of software, but gives no guidance on how to construct a high quality software product. The requirements for a quality management system are defined in ISO 9001 [2]. All the requirements are intended for application within a software process in order to enhance the customer satisfaction, which is considered the primary measure of the software product quality. The quality management system, as defined by the standard, can be subject to a certification. This paper describes a model, which we used to evaluate the expected as well as the actual quality of a huge software system that was developed. There are a few methods for selecting the metrics and collecting data that are relevant for a particular purpose, described in the literature. The best known examples are Goal Question Metric approach [3,4,5] and the Quality Function Deployment approach [6,7]. Both of the two methods represent the viewpoint of the software development organization. Our approach was based on a modification to Goal Question Metric approach. The modification was needed, because our assessment was done on behalf of the customer, and not of the development company, and it had no other goal in mind than just to evaluate the expected quality of the developed software.

Important characteristics

- i. Software requirements are the foundation from which quality is measured
- ii. Specified standards define development criteria that guide the manner in which the software is engineered.
- iii. If the software meets only the explicit requirements, and does not meet the implicit requirements, the software quality is suspect.

Software Quality factors:

- i. Operational characteristics:-
 - a. Correctness - does it do what I want?
 - b. Reliability - does it do it accurately?
 - c. Efficiency - will it run efficiently on my hardware?
 - d. Integrity is it secure.
 - e. Usability - is it designed for the user?

- ii. Product revision:-
 - a. Maintainability - can I fix it ?
 - b. Flexibility - can I change it
 - c. Testability - can I test it?
- iii. Product transition:-
 - a. Portability will I be able to use it on another machine?
 - b. Re usability - will I be able to reuse some of the software.
 - c. Interoperability - will I be able to interface it with another system.

III. Related Works

One of the oldest software development tools is *flowcharting*, which developed since the 1920s. The software development methodology has emerged since the 1960s. The oldest formalized methodology for building information systems is the *Systems development life cycle*. The traditional Systems development life cycle originated in the 1960s to develop large scale functional business systems in an age of large scale business conglomerates. Information systems activities resolved around heavy data processing and number crunching routines. [8]

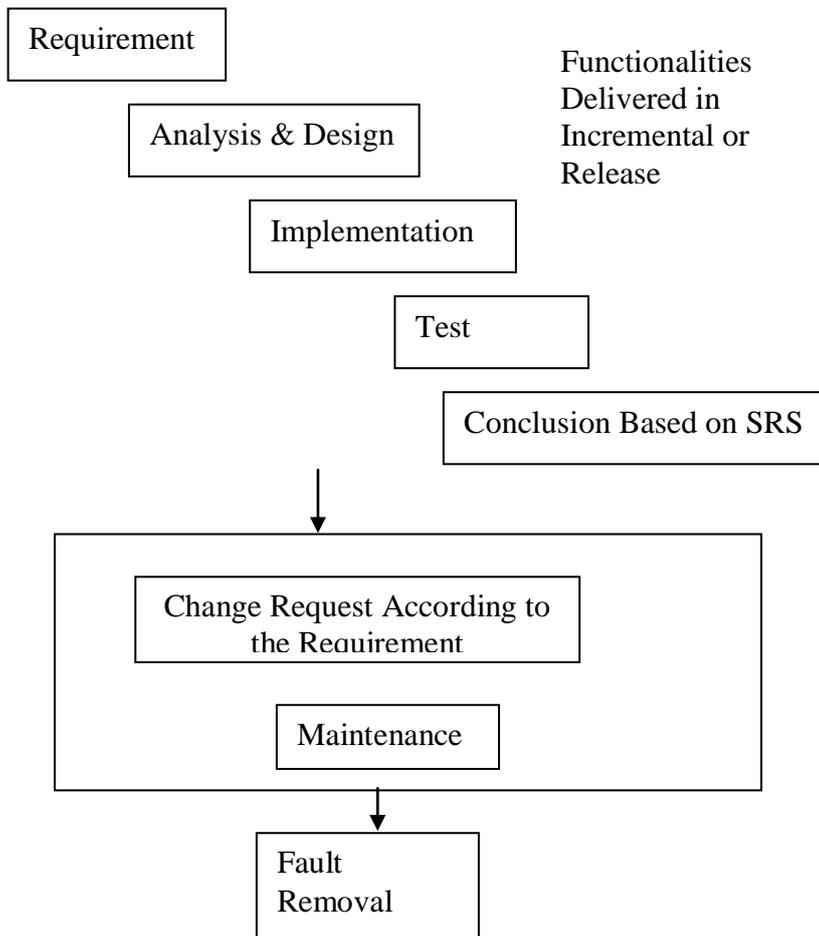

Software development approaches.

Every software development methodology has more or less its own approach to software development. There is a set of more general approaches, which are developed into several specific methodologies. These approaches are [9]:

- i. Waterfall: linear framework type
- ii. Prototyping: iterative framework type
- iii. Incremental: combination of linear and iterative framework type
- iv. Spiral: combination linear and iterative framework type
- v. Rapid Application Development (RAD): Iterative Framework Type

IV. Proposed Model

The proposed model is designed in such a way that it not only used for defect prevention rather than it also be used for defect removal. It will evaluate the software quality through the representative user testing at the system level. During incremental development of software modules, this model not only help to indicate the software changes to correct failure found, but also helpful to untested new software that will be added to the software already under test.

‘Fault Prediction Model’

In the above proposed model there are three major task that are very beneficial to increase the quality of software modules during incremental development of software system.

These tasks are given below:

- i. The functionalities delivered in increment or release
- ii. Parts of the system that have to be changed
- iii. Traceability that will create a links between above two tasks.

This model is used for each increment during incremental development:

- i. To determine the requirements elicitation or refinement, analysis and design, implementation, integration and the system testing for current increment
- ii. While the software is developed in increment j is being tested, increment j+1 has started. Therefore each phase of incremental development includes fault removal activities for previous increment (n). Fault should be removed both from the previous increments or releases and the current one and fault correction may introduce new faults
- iii. Changes to the requirement according to the request based on today's may lead to deviation from the original increment plan, when it comes to effort and time plan
- iv. Several development teams' works in parallel for implementing the software modules, some may finish their works before others and start working on next increment, that should be synchronized with each other and dependencies should be released.
- v. Through each increment quality will be increases from starting to end of software modules

Although basic idea behind this is to deliver the final system in smaller parts and much more functionality is delivered at the end of each increment. During the each release of software modules many correction should also be corrected through the proposed model, which made integration and testing simpler.

Therefore proposed model made integration and testing simpler and increases the quality of software module throughout its life cycle.

Goal of Proposed Model

The major goal of proposed model is to detect faults as early as possible in the development life cycle.

This model helps us to better designing of modelling algorithm in incremental development, towards improving

- i. The information contents of the training data
- ii. Evaluation of software modules which would be inject the additional knowledge regarding context in which software is used into modelling processes.

V. Conclusion

The key factors of the proposed model is monitoring the functionalities and parts of the system that have to be changed, through this controlling the quality of software modules.

It will predict the probability of presence of faults and estimating and preventing the faults that will

reduce the testing effort. Through works model fault proven model is designed that are known in advance for review, analysis and design, testing for incremental development.

Implementation of Direct Torque and Indirect Flux Control of Blcd Motor

B.Amruth Kumar Reddy¹, G.Kumaraswamy²

¹(M.Tech Student, R.G.M College of Engineering and Technology, Nandyal, Andhra Pradesh)

²(EEE Department, R.G.M College of Engineering and Technology, Nandyal, Andhra Pradesh)

Abstract : In this paper, the position-sensor less direct torque and indirect flux control of brushless dc (BLDC) motor with non sinusoidal back electromotive force (EMF) has been extensively investigated. In the literature, several methods have been proposed for BLDC motor drives to obtain optimum current and torque control with minimum torque pulsations. Most methods are complicated and do not consider the stator flux linkage control, therefore, possible high-speed operations are not feasible. In this study, a novel and simple approach to achieve a low-frequency torque ripple-free direct torque control (DTC) with maximum efficiency based on dq reference frame is presented. The proposed sensor less method closely resembles the conventional DTC scheme used for sinusoidal ac motors such that it controls the torque directly and stator flux amplitude indirectly using d -axis current. This method does not require pulse width modulation and proportional plus integral regulators and also permits the regulation of varying signals. Furthermore, to eliminate the low-frequency torque oscillations, two actual and easily available line-to-line back EMF constants (k_{ba} and k_{ca}) according to electrical rotor position are obtained offline and converted to the dq frame equivalents using the new line-to-line park transformation. Then, they are set up in the look-up table for torque estimation. The validity and practical applications of the proposed sensor less three-phase conduction DTC of BLDC motor drive scheme are verified through simulations and experimental results.

Keywords - Brushless dc (BLDC) motor, direct torque control (DTC), fast torque response, low-frequency torque ripples, Non sinusoidal back electromotive force (EMF), position-sensor less control, stator flux control, torque pulsation.

I. INTRODUCTION

The permanent-magnet synchronous motor (PMSM) and brushless dc (BLDC) motor drives are used extensively in several high-performance applications, ranging from servos to traction drives, due to several distinct advantages such as high power density, high efficiency, large torque to inertia ratio, and simplicity in their control [1]–[3]. In many applications, obtaining a low-frequency ripple-free torque and instantaneous torque and even flux control are of primary concern for BLDC motors with non sinusoidal A great deal of study has been devoted to the current and torque control methods employed for BLDC motor drives. One of the most popular approaches is a generalized harmonic injection approach by numerical optimization solutions to find out optimal current waveforms based on back EMF harmonics to minimize mutual and cogging torque [4]. Those approaches limit

Fourier coefficients upto an arbitrary high harmonic order due to calculation complexity [6].

This method provides advantages of the classical DTC such as fast torque response compared to vector control, simplicity (no PWM strategies, PI controllers, and inverse Park and inverse Clarke transformations), and a position-sensor less drive. As opposed to the prior two-phase conduction direct torque control methods used for BLDC motor [8], [9], the proposed DTC technique provides position- sensor less drive that is quite similar to the one used in conventional DTC scheme and also controls the stator flux indirectly using d -axis current. Therefore, flux weakening operation is possible. Coordinate transformations are done by the new line-to-line Park transformation that forms a 2×2 matrix instead of the conventional 2×3 matrix. Therefore, rather than three line-to-neutral back EMF waveforms, which are not directly available in the motor easily accessible two line-to-line back EMF constants ($k_{ba}(\theta_{re})$ and $k_{ca}(\theta_{re})$) are obtained offline and converted to the dq frame equivalents ($k_d(\theta_{re})$ and $k_q(\theta_{re})$). Then, they are stored in a look-up table for the torque estimation. The electrical rotor position is estimate during winding inductance and stationary reference frame stator flux linkages and currents. Since the hysteresis controllers used in the proposed DTC scheme are not fast controllers like PI, they can easily regulate not only constant, but also the varying references (torque and flux). Simulation and experimental results are presented to illustrate the validity and effectiveness of the sensor less three-phase conduction DTC of a BLDC undergoes a corresponding change.

II. PROPOSED LINE-LINE AND PARK TRANSFORMATION

Since the balanced systems in dq -axes reference frame do not require a zero sequence term, first line-to-line Clarke transformation from the balanced three-phase quantities is derived and, then the line-to-line Park transformation forming a 2×2 matrix instead of a 2×3 matrix for three-phase systems can be obtained in the following. Using some algebraic manipulations, the original Clarke transformation forming a 2×3 matrix excluding the zero sequence term can be simplified to a 2×2 matrix as follows:

$$[T_{ll}] = \begin{bmatrix} \frac{-1}{2} & \frac{-1}{2} \\ \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{3}} \end{bmatrix} \dots\dots\dots(1)$$

which requires only two input variables X_{ba} and X_{ca} where $X_{ba} = X_b - X_a$ and $X_{ca} = X_c - X_a$. X represents machine variables such as currents, voltages, flux linkages, back EMFs, etc. To obtain the line-to-line Park transformation forming a 2×2 matrix, the inverse of the original Clarke transformation matrix $[T_{\alpha\beta}]$ is required. Since the zero-

sequence term is removed, $[T_{\alpha\beta}]$ matrix is not square anymore, but it is still singular and therefore, pseudo inverse can be found in the following:

$$[T_{\alpha\beta}]^+ = [T_{\alpha\beta}]T([T_{\alpha\beta}][T_{\alpha\beta}]T)^{-1} \dots \dots \dots (2)$$

where $[T_{\alpha\beta}]^+$ and $[T_{\alpha\beta}]T$ are the pseudo inverse and transpose of the original Clarke transformation matrix $[T_{\alpha\beta}]$, respectively. Here abc to $ba-ca$ transformation can be represented as follows:

$$[T_{\alpha\beta}]^+[T_{\alpha\beta}] \begin{bmatrix} X_a \\ X_b \\ X_c \end{bmatrix} = [T_{\alpha\beta}]^+ [T_{LL}] \begin{bmatrix} X_{ba} \\ X_{ca} \end{bmatrix} \dots \dots \dots (3)$$

After (3) is expanded and multiplied by the original 2×3 Park transformation matrix in both sides, algebraic manipulations lead to simplifications using some trigonometric equivalence. Therefore, the following 2×2 line-to-line Park transformation matrix form is obtained:

$$\begin{bmatrix} X_d \\ X_q \end{bmatrix} = \frac{2}{3} \begin{bmatrix} \sin(\theta - \frac{\pi}{6}) & -\sin(\theta + \frac{\pi}{6}) \\ -\cos(\theta - \frac{\pi}{6}) & \cos(\theta + \frac{\pi}{6}) \end{bmatrix} \begin{bmatrix} X_{ba} \\ X_{ca} \end{bmatrix} \dots \dots (4)$$

Unlike previous two-phase conduction DTC of BLDC motor drive techniques, which are proposed in [8] and [9], this method uses DTC technique with three-phase conduction, therefore, flux-weakening operation as well as a much simpler sensor less technique can easily be achieved. Compared with the two-phase conduction DTC scheme, this DTC method differs by its torque estimation and voltage vector selection table which is similar to the one used for DTC of PMSM drives explained in [10].

For machines with surface-mount magnet rotor (BLDC) stator flux linkages in rotor dq reference frame can be written as

$$\varphi_{qs}^r = L_s i_{qs}^r + \varphi_r \sum_{n=1}^{\infty} (K_{6n-1} + K_{6n+1}) \sin(6n\theta_r) \dots \dots (5)$$

$$\varphi_{ds}^r = L_s i_{ds}^r + \varphi_r \sum_{n=1}^{\infty} (K_{6n-1} - K_{6n+1}) \cos(6n\theta_r) + \varphi_r \dots \dots \dots (6)$$

where φ_r is the peak value of the fundamental rotor magnetic flux linkage of the BLDC motor, the coefficients K_{6n-1} and K_{6n+1} represent the odd harmonics of the phase back EMF other than the third and its multiples. K_{6n-1} equals $[\sin(6n-1)\sigma]/[(6n-1)3 \sin \sigma]$, and K_{6n+1} can be depicted as $[\sin(6n+1)\sigma]/[(6n+1)3 \sin \sigma]$. σ is the angle between zero-crossing and phase back EMF, where it becomes flat at the top. Fundamental peak value of the rotor magnet flux linkage φ_r equals $(4ke/\sigma\pi) \sin \sigma$, where k_e is the line-to-neutral back EMF constant.

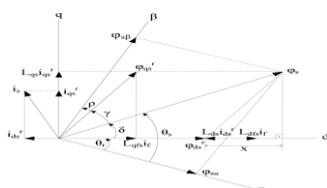

Fig. 1. Rotor and stator flux linkages of a BLDC motor in the stationary $\alpha\beta$ -plane and synchronous dq -plane

The phasor diagram for stator flux linkage vectors in BLDC motor can be drawn in the rotor dq and stationary ($\alpha\beta$) reference frames as shown in Fig. 1, where $L_{ds} = L_{qs} = L_s$ and $L_{dqs} = L_{qds} = 0$. L_{dqs} and L_{qds} are the mutual inductances between d - and q -axis. L_{dsf} and L_{qsf} are the mutual inductances between dq -axes and permanent magnet (PM), respectively, and i_f is the equivalent current generated by PM. In Fig. 1, unlike PMSM with sinusoidal back EMF synchronous reference frame flux linkages φ_{ds}^r and φ_{qs}^r vary with time, therefore, stator flux amplitude ϕ_s is not constant anymore. γ , ρ , and δ in Fig. 1 can be obtained, respectively, as

$$Y = \sin^{-1} \left(\frac{L_{qs} i_{qs}^r}{\varphi_{qs}^r} \right) + \cos^{-1} \left(\frac{L_{qs} i_{qs}^r}{\varphi_s} \right) - \frac{\pi}{2} (7)$$

$$\rho = - \left(\theta_s + Y - \frac{\pi}{2} \right) (8)$$

$$\delta = \frac{\pi}{2} - \cos^{-1} \left(\frac{L_{qs} i_{qs}^r}{\varphi_s} \right) (9)$$

Moreover, x in Fig. 1 can be expressed as

$$x = \varphi_{qs}^r \cos \left[\sin^{-1} \left(\frac{L_{qs} i_{qs}^r}{\varphi_{qs}^r} \right) \right] (10)$$

The electromagnetic torque T_{em} estimation algorithm can be Derived for a balanced system in dq reference frame by equating the electrical power absorbed by the motor to the mechanical power produced ($P_i = P_m = T_{em}\omega_m$) as follows:

$$T_{em} = ((3P)/(4\omega_{re})) \times (e_q(\theta_{re}) i_{ds}^r + e_d(\theta_{re}) i_{qs}^r) = ((3P)/4) \times (k_q(\theta_{re}) i_{ds}^r + k_d(\theta_{re}) i_{qs}^r) (11)$$

where P is the number of poles, ω_{re} is the electrical rotor speed, $e_q(\theta_e)$ and $e_d(\theta_e)$, i_{ds}^r and i_{qs}^r , $k_q(\theta_e)$, and $k_d(\theta_e)$ are the dq axes back EMFs, currents, and back EMF constants according to the electrical rotor position, respectively. As it can be noticed that the right-hand side equation in (11) eliminates the speed term in the denominator which causes problem at zero and near zero speeds.

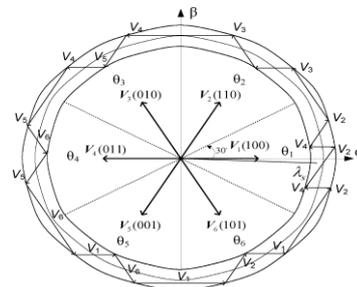

Fig. 2. Dodecagon trajectory of stator flux linkage in the stationary $\alpha\beta$ -plane.

III. CONTROL OF STATOR FLUX LINKAGE AMPLITUDE

The stator flux linkage equations of a BLDC motor can easily be represented in the stationary reference frame similar to PMSM. During the sampling interval time, one out of the six voltage vectors is applied, and each voltage vector applied during the predefined sampling interval is

constant, then the stator flux estimation for BLDC motor can be written as

$$\phi_{s\alpha} = V_{s\alpha} t - R_s \int i_{s\alpha} dt + \phi_{s\alpha}(0)$$

$$\phi_{s\beta} = V_{s\beta} t - R_s \int i_{s\beta} dt + \phi_{s\beta}(0) \quad (12)$$

where $\phi_{s\alpha}(0)$ and $\phi_{s\beta}(0)$ are the initial stator flux linkages at the instant of switching. If the line-to-line back EMF constant k_{LL} is roughly known, and let say the rotor is brought to zero position (phase a), initial stator flux linkages at startup can be obtained by integrating the back EMF in which the ideal trapezoidal is assumed. Therefore, approximate initial starting flux values at zero position can be obtained as

$$\phi_{s\alpha}(0) = 2k_{LL}\pi/(3\sqrt{3}) \text{ and } \phi_{s\beta}(0) = 0. \quad (13)$$

Since BLDC motor does not have sinusoidal back EMF, the stator flux trajectory is not pure circle as in PMSM. It is more like a decagonal shape as shown in Fig. 2. Thus, direct stator flux amplitude control in a BLDC motor is not trivial as in PMSM such that rotor position varying flux command should be considered. However, this is a complicated way to control the stator flux linkage amplitude. Therefore, in this study, instead of $|\phi_s|$ itself its amplitude is indirectly controlled by d -axis current. In the constant torque region, $i_{d_s}^*$ is controlled as zero, and in the flux-weakening region it is decreased for a certain amount depending on the operational speed to achieve maximum torque. As a result, in this study, stator flux linkage amplitude is indirectly kept at its optimum level, while the motor speed is less than the base speed.

Table I
Switching Table For DTC Of BLDC Motor Using Three-Phase Conduction

ϕ	τ	θ					
		$\theta(1)$	$\theta(2)$	$\theta(3)$	$\theta(4)$	$\theta(5)$	$\theta(6)$
$\phi=1$	$\tau=1$	$V_s(110)$	$V_s(010)$	$V_s(011)$	$V_s(001)$	$V_s(101)$	$V_s(100)$
	$\tau=-1$	$V_s(101)$	$V_s(100)$	$V_s(110)$	$V_s(010)$	$V_s(011)$	$V_s(001)$
$\phi=-1$	$\tau=1$	$V_s(010)$	$V_s(011)$	$V_s(001)$	$V_s(101)$	$V_s(100)$	$V_s(110)$
	$\tau=-1$	$V_s(001)$	$V_s(101)$	$V_s(100)$	$V_s(110)$	$V_s(010)$	$V_s(011)$

The switching table for controlling both the amplitude and rotating direction of the stator flux linkage is given in Table I. where the output of the torque hysteresis comparator is denoted as τ , the output of the flux hysteresis comparator as ϕ , and the flux linkage sector is denoted as θ . The torque hysteresis comparator τ is a two valued comparator; $\tau = -1$ means that the actual value of the torque is above the reference and out of the hysteresis limit and $\tau = 1$ means that the actual value is below the reference and out of the hysteresis limit. The same logic applies to the flux related part of the control (d -axis current). The one out of six voltage space vectors is selected using lookup table in every sampling time to provide fast rotation of stator flux linkage vector. Therefore, fast torque and flux responses are obtained in a predefined hysteresis bandwidth, which limits the flux amplitude.

IV. ESTIMATION OF ELECTRICAL ROTOR POSITION

Electrical rotor position θ_{re} , which is required in the line-to-line Park transformation and torque estimation algorithm can be found by

$$\Theta_{re} = \tan^{-1} \left(\frac{\phi_{s\beta} - L_s i_{s\beta}}{\phi_{s\alpha} - L_s i_{s\alpha}} \right) \quad (14)$$

motor with varying stator flux linkage amplitude as shown in Fig. 2. The second algorithm in [12], which is the modified integrator with an amplitude limiter To solve the common problems for integrators, a special integration algorithm for estimating the stator flux linkage proposed in [12] is used in this study. Although the method in [12] is designed for sine wave systems, the algorithm is still applicable to a BLDC is used for the stator flux linkage estimation. The maximum amplitude of the stator flux linkage reference approximated as $2k_{LL}\pi/(3\sqrt{3})$ is set for the limiter when the motor speed is less than the base speed.

V. RESULTS AND DISCUSSIONS

The drive system shown in Fig. 3 has been simulated in order to demonstrate the validity of the proposed three-phase conduction DTC of a BLDC motor drive scheme using line-to-line machine model. The sampling interval is $15 \mu s$. The magnitudes of the torque and flux hysteresis bands are 0.001 N·m and 0.001 Wb, respectively. The dc-link voltage V_{dc} equals $40\sqrt{2} V$. Appendix I shows the specifications and parameters of the BLDC motor. In Fig. 4, the possibility of the flux-weakening region operation is simulated when $i_{d_s}^*$ is changed from 0 to $-5 A$. As it can be seen in Fig. 4 that the shape of stator flux linkage trajectory is kept same, however, its amplitude is smaller compared to the initial case, which means that the flux in the machine is weakened to obtain maximum possible torque above the base speed. It is concluded that in the proposed control scheme flux weakening operation is viable by properly selecting the d -axis current reference as in PMSM drives. As a result, there is no need to use position-varying stator flux linkage amplitude $|\phi_s(\theta_{re})|$ as a reference, which is complicated to obtain especially in the flux-weakening region.

Fig. 5 shows the dq frame back EMF constants according to the electrical rotor position ($k_d(\theta_{re})$ and $k_q(\theta_{re})$), which are set up in the look-up tables for torque estimation both in simulation and experiment. The feasibility and practical features of the proposed three phase conduction DTC of a BLDC motor drive scheme have been evaluated using an experimental test-bed, as shown in Fig.

6. The same conditions are used as in simulation.

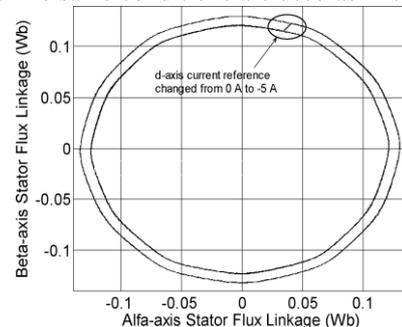

Fig 4. Indirectly Controlled Stator Flux Linkage Trajectory Under The Sensor Less Three-Phase Conduction Dtc Of A Blcd Motor Drive When $i_{d_s}^*$ Is Changed From 0 To $-5 A$ Under 0.5 N·M Load Torque.

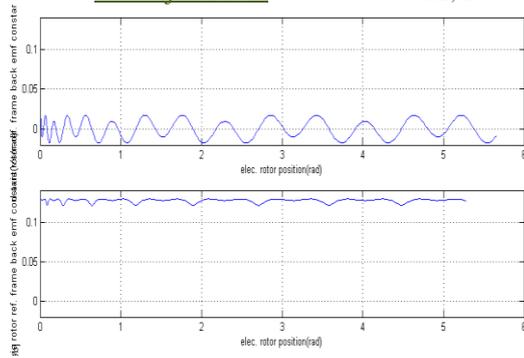

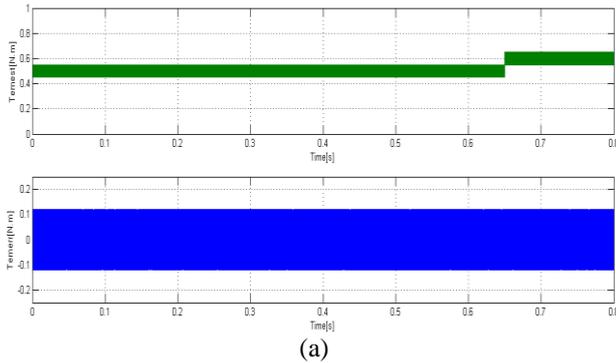

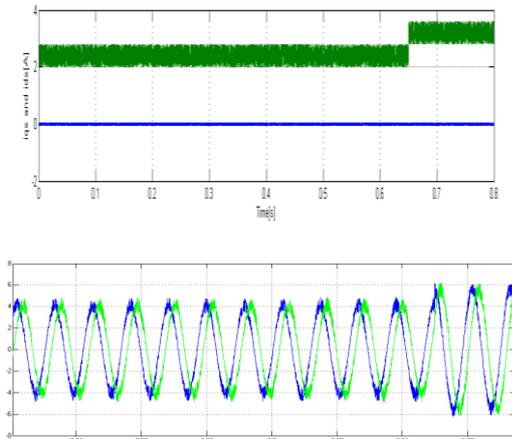

Fig. 5. Actual Q - And D -Axis Rotor Reference Frame Back Emf Constants Versus Electrical Rotor Position ($K_d(\theta_{rE})$ And $K_q(\theta_{rE})$)

(a)

(b)

Fig.7. Steady state and transient behavior of (Top) estimated electromagnetic torque, (bottom) error between reference and estimated electromagnetic torque. (b) (Top) q -axis stator current and d -axis stator current and (bottom) ba - ca frame currents when $i_{ds}^* = 0$ under 0.5 N·m load torque.

Implementations of steady state and transient torque, torque error, q - and d -axis rotor reference frame stator currents, and line-to-line current responses of the proposed DTC of a BLDC motor drive scheme are demonstrated in Fig. 7(a) and (b), respectively, under a 0.5 N·m load torque condition. The torque reference is changed abruptly from 0.52 to 0.65 N·m at 0.65 s. It is seen in Fig. 7(a) (top) that fast torque response is obtained and the estimated torque tracks the reference torque closely. The reference torque value in the experimental test is selected a little bit higher than the load torque to compensate the friction of the total experimental system such that the rotor speed is kept at steady-state level (30 mechanical rad/s). The

torque error between reference and estimated electromechanical torque is shown in the bottom part of Fig. 7(a). The high frequency ripples observed in the torque and current can be minimized by properly selecting the dc-link voltage and torque hysteresis band size. The $\alpha\beta$ -axes stator flux linkages are estimated using (12) in which the $\alpha\beta$ -axes voltages are measured using a dc-link voltage sensor and the estimated position of the stator flux linkage vector θ_s . The motor is initially locked at zero position (phase a) for proper starting. Fig. 8 shows the experimental results of the indirectly controlled stator flux linkage locus by controlling the d -axis rotor reference frame current at 0 A when 0.5 N·m load torque is applied to the BLDC motor.

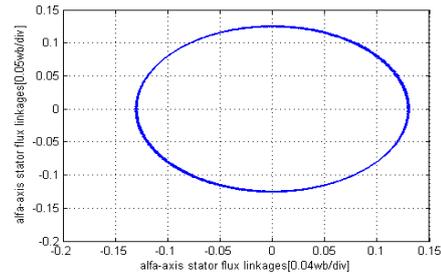

Fig. 8. Experimental indirectly controlled stator flux linkage trajectory under the sensor less three-phase conduction DTC of a BLDC motor drive when $i_{ds}^* = 0$ at 0.5 N·m load torque.

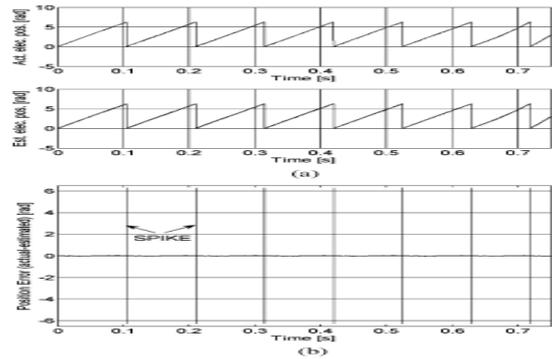

Fig. 9. (a) Steady state and transient behavior of the actual and estimated electrical rotor positions from top to bottom, respectively and (b) error between actual and estimated electrical rotor positions under 0.5 N·m load torque.

In Fig. 10, the flux-weakening operation is evaluated under 1.1926 N·m load torque. Fig. 10(a) shows the high speed operation when $i_{ds}^* = 0$. The desired speed is dropped from 540 electrical rad/s to 513.5 electrical rad/s and oscillations in speed and torque are observed, as shown in Fig. 10(a). This result shows that the desired torque can only be obtained at lower speed when flux is not weakened. However, in Fig. 10(b), i_{ds}^* is decreased to -4.51 A and the speed is controlled in the desired level quite well. The dc-link voltage is 115 V and the base speed for that voltage is 500 electrical rad/s.

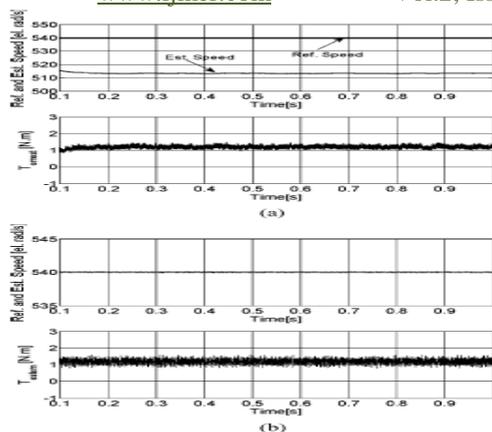

Fig.10.Steady-state flux-weakening behavior of the actual speed and estimated electromechanical torque, respectively, (a) when $i_d^* = 0$ and (b) when $i_d^* = -4.51$ A under 1.1926 N-m load torque at 540 electrical rad/s desired speed (V_{dc} link = 115 V).

VI. CONCLUSION

This paper has successfully demonstrated application of the proposed position-sensor less three-phase conduction DTC scheme for BLDC motor drives that is similar to the conventional DTC used for sinusoidal ac motors where both torque and flux are controlled, simultaneously. This method provides advantages of the classical DTC such as fast torque response compared to vector control, simplicity (no PWM strategies, PI controllers, and inverse Park and inverse Clarke transformations), and a position-sensor less drive. It is shown that the BLDC motor could also operate in the flux-weakening region by properly selecting the d -axis current reference in the proposed DTC scheme.

Since the actual back EMF waveforms are used in the torque estimation, low-frequency torque oscillations can be reduced convincingly compared to the one with the ideal-trapezoidal waveforms having 120 electrical degree flat top. A look-up table for the three-phase voltage vector selection is designed similar to a DTC of PMSM drive to provide fast torque and flux control.

His main areas of research include Induction motor drives, Electrical machines FACTS and Harmonic reduction in power converters.

Shortest Time Quantum Scheduling Algorithm

ABDULLA SHAIK

Department Of IT, RTMNU,
Nuva College Of Engineering & Technology,
Nagpur. Maharashtra 440015, India

Abstract: Scheduling is the method by which threads, processes or data flows are given access to system resources. This is usually done to load balance a system effectively or achieve a target quality of service. Different CPU scheduling algorithms have different properties, and the choice of a particular algorithm may favor one class of processes over another. A typical scheduler is designed to select one or more primary performance criteria and rank them in order of importance. One problem in selecting a set of performance criteria is that they often conflict with each other. For example, increased processor utilization is usually achieved by increasing the number of active processes, but then response time decreases. It is desirable to maximize CPU utilization and throughput and to minimize turnaround time, waiting time, and response time. In most cases, we optimize the average measure. However, under some circumstances, it is desirable to optimize the minimum or maximum values rather than the average.

Round robin scheduling is similar to FCFS scheduling, except that CPU bursts are assigned with limits called time quantum. The performance of RR is sensitive to the time quantum selected. If the quantum is large enough, then RR reduces to the FCFS algorithm; If it is very small, then each process gets 1/nth of the processor time and share the CPU equally. The major problem in RR scheduling is that how the time quantum is decides? If any process require more time then the problem arrives that process must wait for long time to complete the execution. To overcome this problem in RR scheduling algorithm we come across with idea that the time quantum is decides based on the burst time needed for process. The percentage of CPU resource is decided based on burst time and the reaming process is similar to RR scheduling but difference is that allocation will be done based on newly calculated time quantum of process.

Keywords: Burst time, scheduling, time quantum, waiting time, execution time.

I. Introduction

If you look at any process, you'll notice that it spends some time executing instructions (computing) and then makes some I/O request, for example to read or write data to a file or to get input from a user. After that, it executes more instructions and then, again, waits on I/O. The period of computation between I/O requests is called the CPU burst.

Compute-intensive processes, conversely, spend more time running instructions and less time on I/O. Most interactive processes, in fact, spend the vast bulk of their existence doing nothing but waiting on data. If you consider

Mac OS system, In which 44 processes running. This includes a few browser windows, a word processor, spreadsheet, several shell windows, Photoshop, iTunes, and various monitors and utilities. Most of the time, these processes collectively are using less than 3% of the CPU. This is not surprising since most of these programs are waiting for user input, a network message, or sleeping and waking up periodically to check some state.

The base idea in multiprogramming is that kept CPU always busy. For this we use scheduling. This is the method by which threads, processes or data flows are given access to system resources. This is usually done to load balance a system effectively or achieve a target quality of service. The need for a scheduling algorithm arises from the requirement for most modern systems to perform multitasking and multiplexing.

RR scheduling involves extensive overhead, especially with a small time unit. Balanced throughput between FCFS and SJF, shorter jobs are completed faster than in FCFS and longer processes are completed faster than in SJF. Poor average response time, waiting time is dependent on number of processes, and not average process length. Because of high waiting times, deadlines are rarely met in a pure RR system. Starvation can never occur, since no priority is given. Order of time unit allocation is based upon process arrival time, similar to FCFS. Round robin scheduling is similar to FCFS scheduling, except that CPU bursts are assigned with limits called time quantum. When a process is given the CPU, a timer is set for whatever value has been set for a time quantum. If the process finishes its burst before the time quantum timer expires, then it is swapped out of the CPU just like the normal FCFS algorithm. If the timer goes off first, then the process is swapped out of the CPU and moved to the back end of the ready queue. The ready queue is maintained as a circular queue, so when all processes have had a turn, then the scheduler gives the first process another turn, and so on. Most modern systems use time quantum between 10 and 100 milliseconds, and context switch times on the order of 10 microseconds, so the overhead is small relative to the time quantum. The major problem in RR scheduling is that how the time quantum is decides? If any process require more time then the problem arrives that process must wait for long time to complete the execution. To overcome this problem in RR scheduling algorithm we come across with idea that the time quantum is decides based on the burst time needed for process. The percentage of CPU resource is decided based on burst time and the reaming process is similar to RR scheduling but difference is that allocation will be done based on newly calculated time quantum of process. The processing is similar to SJF with RR scheduling model.

II. Shortest Time Quantum Scheduling Algorithm

The degree of multiprogramming is decided based on number of process/programs running simultaneously at a time. This can be improve are maintain by proper scheduling of multiple process in CPU. For that we are having different scheduling schemes one of them is FCFS the alternative of the FCFS is given in RR scheduling algorithm. Round robin scheduling is similar to FCFS scheduling, except that CPU bursts are assigned with limits called time quantum. When a process is given the CPU, a timer is set for whatever value has been set for a time quantum. . Most modern systems use time quantum between 10 and 100 milliseconds, and context switch times on the order of 10 microseconds, so the overhead is small relative to the time quantum. The major problem in RR scheduling is that how the time quantum is fixed for all the process. If the process is having burst time is low or high but the time quantum is same for all. As per RR algorithm low burst time process completes its execution first. To overcome this problem in RR scheduling algorithm we come across with idea that the time quantum is decides based on the burst time. It mean that based on time burst time quantum is decided so the time quantum is not fix for all process. The percentage of CPU resource is decided based on burst time and the reaming process is similar to RR scheduling but difference is that allocation will be done based on newly calculated time quantum of process.

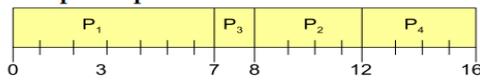

III. Processing

Round Robin scheduling is similar to FCFS scheduling, except that CPU bursts are assigned with limits called time quantum. When a process is given the CPU, a timer is set for whatever value has been set for a time quantum. Let first see how the shortest job scheduling is work. The Shortest job first scheduling algorithm gives minimum average waiting time for a given set of processes.

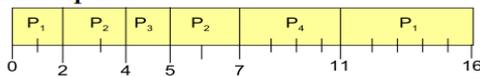

Examples

Process	Arrival Time	Burst Time
P ₁	0.0	7
P ₂	2.0	4
P ₃	4.0	1
P ₄	5.0	4

• Non-preemptive

• Preemptive

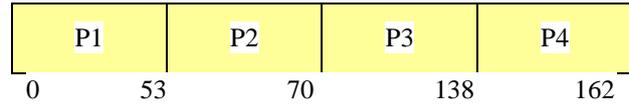

The problems in SJF are: Only optimal if all jobs/process are available simultaneously. Usually run times are not known.

First-Come-First-Served algorithm is the simplest scheduling algorithm is the simplest scheduling algorithm. Processes are dispatched according to their arrival time on the ready queue. Being a no preemptive discipline, once a process has a CPU, it runs to completion.

Let consider example:

Process	Burst time
P1	53
P2	17
P3	68
P4	24

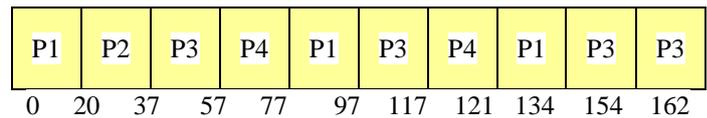

As per the FCFS algorithm the order of executing process is based on arrival. And once the process starts execution it is not suspended.

To overcome this problem in FCFS the Round Robin Scheduling algorithm is proposed. Each process gets a small unit of CPU time (time quantum). Then put back in Ready queue. The *RR Scheduling algorithm* is Preemptive. When interrupted, go to end of FIFO queue. Good for multi-user time-sharing - fast response time. Sometimes, OS just says "carry on". Sometimes don't even need 1 time quantum since process leaves voluntarily.

Example:

Process	Burst time
P1	53
P2	17
P3	68
P4	24

Say time quantum = 20:

Setting the time quantum size

If quantum too small, too much admin, not enough work.

As quantum goes to infinity, this goes to straight FIFO non-preemptive.

Want:

context switch << time slice

average CPU burst <= time slice

(some, but not too many > time slice)

Shortest Time Quantum Scheduling Algorithm:

By considering the above example the process P2 is having burst time =17 and p3 is having burst time =68. But both are having the time quantum 20ms for process P1 and P3. But the process P3 is having much more burst time then compare to P2. It need more time to execute quickly.

Example:

Process	Burst time
P1	53
P2	17
P3	68
P4	24

The total burst time needed for all the process The total execution time=P1+P2+P3+P4 =53+17+68+24 = 162

We fix minimum time quantum is 0.5 for increase the processing.

For each unit of CPU process need

= CPU %/ total execution time

=100/162

=0.617(>0.5)

The smallest Bust time require by process P2=17
 Now we calculate the time quantum for each process
 Time quantum of P1=51*0.617=32ms (ceil)
 Time quantum of P2=17*0.617=11ms (ceil)
 Time quantum of P3=68*0.617=42ms (ceil)
 Time quantum of P4=24*0.617=15ms (ceil)

P1	P2	P3	P4	P1	P2	P3	P4	
0	32	43	85	100	119	125	149	162

According to the Traditional RR scheduling based on time quantum. But here we are applying the way is shortest time quantum.

Now the actual way of processing is done as per *shortest quantum*

So
 Time quantum of P1=51*0.617=32ms (ceil)
 Time quantum of P2=17*0.617=11ms (ceil)
 Time quantum of P3=68*0.617=42ms (ceil)
 Time quantum of P4=24*0.617=15ms (ceil)

P2	P4	P1	P3	P2	P4	P1	P3	
0	11	26	58	100	106	115	138	162

Example:

Process	Burst time
P1	5
P2	10
P3	5

The total burst time needed for all the process The total execution time=P1+P2+P3
 =5+10+5
 = 20

For each unit of CPU process need
 =20/100
 =0.2(<0.5)

Here we fix minimum time quantum is 0.5 for increase the processing according to that the time quantum for each process

Time quantum of P1=5*0.5=3ms (ceil)
 Time quantum of P2=10*0.5=5ms (ceil)
 Time quantum of P3=5*0.5=3ms (ceil)

P1	P3	P2	P1	P3	P2	
0	3	6	11	13	15	20

IV. Compression with other algorithms

The efficiency will be calculated based on average waiting time.

As per the examples consider

Process	Burst time
P1	53
P2	17

P3 68
 P4 24

As per *FCFS* Scheduling Algorithm processing is done in order

P1	P2	P3	P4	
0	53	70	138	162

Avg. waiting time= (0+53+70+138)/4 = 65.25ms

As per *SJF* Scheduling Algorithm processing is done in order

P2	P4	P1	P3	
0	17	41	94	162

Avg. waiting time= (0+17+41+94)/4 = 38ms

As per *RR* Scheduling Algorithm processing is done in order

Say time quantum = 20:

P1	P2	P3	P4	P1	P3	P4	P1	P3	P3	
0	20	37	57	77	97	117	121	134	154	162

Waiting time of p1= 121-(20+20)= 81ms
 Waiting time of p2= 20ms
 Waiting time of p3= 134-(20+20)= 94ms
 Waiting time of p4= 117-20= 97ms
 Avg. waiting time= (81+20+94+97)/4 = 72.25ms

As per *STQ* Scheduling Algorithm processing is done in order we fix minimum time quantum is 0.5 for increase the processing.

For each unit of CPU process need
 = CPU %/ total execution time
 =100/162
 =0.617(>0.5)

Now we calculate the time quantum for each process

Time quantum of P1=51*0.617=32ms (ceil)
 Time quantum of P2=17*0.617=11ms (ceil)
 Time quantum of P3=68*0.617=42ms (ceil)
 Time quantum of P4=24*0.617=15ms (ceil)

P2	P4	P1	P3	P2	P4	P1	P3	
0	11	26	58	100	106	115	138	162

Waiting time of p1= 115-32= 83ms
 Waiting time of p2= 100-11=89ms
 Waiting time of p3= 138-42= 96ms
 Waiting time of p4= 106-15= 91ms
 Avg. waiting time= (83+89+96+91)/4 = 89.75ms

The average waiting time is much more compare to the other algorithms but the CPU resources are given to all the process based on the burst time. So that the high burst time process like IO bound process are also complete the execution similar to the CPU bound process. And this algorithm never enters in to the CPU bound process. The major advantage is that the waiting time of individual are the average waiting time is much more nearer to the Round Rabin algorithm.

V. Conclusion

The degree of multiprogramming is decided based on number of process/programs running simultaneously at a time. This can be improve are maintain by proper scheduling of multiple process in CPU. For that we are having different scheduling schemes one of them is FCFS the alternative of the FCFS is given in RR scheduling algorithm. RR Scheduling algorithm is work based on fixed time quantum. Most modern systems use time quantum between 10 and 100 milliseconds, and context switch times on the order of 10 microseconds. The major problem in RR scheduling is that how the time quantum is fixed for all the process. If the process is having burst time is low or high but the time quantum is same for all. As per RR algorithm low burst time process completes its execution first. To overcome this problem in RR scheduling algorithm we come across with idea that the different process having different time quantum and minimum is 0.5% of CPU. Time quantum is decides based on the burst time. The percentage of CPU resource allocated on the basis of shortest time quantum first. The processing is similar to SJF with RR scheduling model. This combination will give the new kind of processing of programs.

Acknowledgments

I am grateful to My Brothers Dr. Khaleel Basha Shaik and Dr. Nazer Shaik , Dr Ajay Shenkar Singh and P. Manoj Kumar for giving guideline their valuable time to me. Finally last but not the least Mr. A. Hasheem Babu, Mr. Mohammad Shaik and Mr. John Saida other my friends for their insightful comments.

Feature Selection for Wireless Intrusion Detection System Using Filter and Wrapper Model

Mohanabharathi R^{*1}, Mr T.Kalaikumaran^{#2} Dr.S.Karthi^{*3}

^{1,2}Department of Computer Science Engineering
SNS College of Technology, Coimbatore.

Abstract: Intrusion detection systems are applied to detect network intrusions identified from different sources. Anomaly and signature based schemes are used for the intrusion detection process. Signature based intrusion detection schemes uses the predefined signature collection for the detection process. The anomaly-based model detects the intrusions by learning the network transaction patterns. Feature selection schemes are used to reduce the network transaction features. Performance, time, accuracy and reliability are improved by the feature selection schemes. Current intrusion detection systems use the TCP/IP header information for the intrusion detection process. Network layer and transport layer attacks can be easily detected using TCP/IP header information's. MAC layer is not considered in the intrusion detection process. The hybrid approach is used for the feature selection process. Information gain ratio measure and K-means classifiers are used in the feature selection process. Back propagation perceptron based neural network algorithm is used for the learning and testing process. Scalability and high learning error rate problems are identified in the neural network method.

The proposed system is designed to perform the feature reduction and intrusion detection process under wireless LAN environment. The recurrent neural network is used for the intrusion detection process. The feature reduction process is also enhanced to improve accuracy. Real Time Recurrent Learning (RTRL) algorithm is used to solve the scalability problems.

Keywords: Intrusion detection, anomaly based scheme, signature based scheme, feature selection, RTRL Algorithm.

I. INTRODUCTION

Intrusions are the result of flaws in the design and implementation of computer systems, operating systems, applications, and communication protocols. Statistics [2] show that the number of identified vulnerabilities is growing. Exploitation of these vulnerabilities is becoming easier because the knowledge and tools to launch attacks are readily available and usable. It has become easy for a novice to find attack programs on the Internet that he/she can use without knowing how they were designed by security specialists.

The emerging technology of wireless networks created a new problem. Although traditional IDSs are able to protect the application and software components of TCP/IP networks against intrusion attempts, the physical and data link layers are vulnerable to intrusions specific to these communication layers. In addition to the vulnerabilities of wired networks, wireless networks are the subject of new types of attacks which range from the passive eavesdropping to more devastating attacks such as denial of service. These vulnerabilities are a result of the

nature of the transmission media [13]. Indeed, the absence of physical boundaries in the network to monitor, meaning that an attack can be perpetrated from anywhere, is a major threat that can be exploited to undermine the integrity and security of the network. It is, therefore, essential to take into account these considerations when designing and deploying an intrusion detection system.

To detect intrusions, classifiers are built to distinguish between normal and anomalous traffic. It has been proved that optimizing the feature set has a major impact on the performance, speed of learning, accuracy, and reliability of the intrusion detection system. Unfortunately, current wireless intrusion detection solutions rely on features extracted directly from the frame headers to build the learning algorithm of the classifiers.

II. Feature Selections

Feature selection is the most critical step in building intrusion detection models [1]. During this step, the set of attributes or features deemed to be the most effective attributes is extracted in order to construct suitable detection algorithms (detectors). A key problem that many researchers face is how to choose the optimal set of features, as not all features are relevant to the learning algorithm, and in some cases, irrelevant and redundant features can introduce noisy data that distract the learning algorithm, severely degrading the accuracy of the detector and causing slow training and testing processes. Feature selection was proven to have a significant impact on the performance of the classifiers. Experiments in [4] show that feature selection can reduce the building and testing time of a classifier by 50 percent.

There are currently two models in the literature for feature selection: the filter model and the wrapper model. The wrapper model uses the predictive accuracy of a classifier as a means to evaluate the "goodness" of a feature set, while the filter model uses a measure such as information, consistency, or distance measures to compute the relevance of a set of features. These approaches suffer from many drawbacks: the first major drawback is that feeding the classifier with arbitrary features may lead to biased results, and hence, we cannot rely on the classifier's predictive accuracy as a measure to select features. A second drawback is that for a set of N features, trying all possible combinations of features (2^N combinations) to find the best combination to feed the classifier is not a feasible approach. For example, the DARPA data set contains 41 features [6], and the data set would be larger if we add to it the OSI Layer 2 (MAC layer) features, resulting in thousands of billions of different feature combinations.

Different techniques have been used to tackle the problem of feature selection. In [7], Sung and Mukkamala used feature ranking algorithms to reduce the feature space of the DARPA data set from 41 features to the six most

important features. They used three ranking algorithms based on Support Vector Machines (SVMs), Multivariate Adaptive Regression Splines (MARSs), and Linear Genetic Programs (LGPs) to assign a weight to each feature. Experimental results showed that the classifier's accuracy degraded by less than 1 percent when the classifier was fed with the reduced set of features. Sequential backward search was used in [9] to identify the important set of features: starting with the set of all features, one feature was removed at a time until the accuracy of the classifier was below a certain threshold. Different types of classifiers were used with this approach including Genetic Algorithms, Neural Networks and Support Vector Machines.

III. 802.11-SPECIFIC INTRUSIONS

Several vulnerabilities exist at the link layer level of the 802.11 protocol [8], [5]. Many 802.11-specific attacks were analyzed and demonstrated to present a real threat to network availability. A deauthentication attack is an example of an easy to mount attack on all types of 802.11 networks. Likewise, a duration attack is another simple attack that exploits the vulnerability of the virtual carrier sensing protocol CSMA/CA and it was proven to deny access to the network.

Many free tools are available on the Internet which allow novice hackers to exploit these protocol weaknesses to deny access to a network, as can be seen in [12], where a collection of tools to attack 802.11-based networks is available for download. These tools operate on WEP and WPA-protected networks. Most of the attacks we used in this work are available for download from [12]. The attacks we used to conduct the experiments are:

A. Deauthentication Attack

The attacker fakes a deauthentication frame as if it had originated from the base station (Access Point). Upon reception, the station disconnects and tries to reconnect to the base station again. This process is repeated indefinitely to keep the station disconnected from the base station. The attacker can also set the receiving address to the broadcast address to target all stations associated with the victim base station. However, we noticed that some wireless network cards ignore this type of deauthentication frame. More details of this attack.

B. ChopChop Attack

The attacker intercepts an encrypted frame and uses the Access Point to guess the clear text. The attack is performed as follows: The intercepted encrypted frame is chopped from the last byte. Then, the attacker builds a new frame 1 byte smaller than the original frame. In order to set the right value for the 32 bit long CRC32 checksum named ICV, the attacker makes a guess on the last clear byte. To validate the guess he/she made, the attacker will send the new frame to the base station using a multicast receive address. If the frame is not valid (i.e., the guess is wrong), then the frame is silently discarded by the access point. The frame with the right guess will be relayed back to the network. The hacker can then validate the guess he/she made. The operation is repeated until all bytes of the clear frame are discovered. More details of this attack can be found in [10].

C. Fragmentation Attack

The attacker sends a frame as a successive set of fragments. The access point will assemble them into a new frame and send it back to the wireless network. Since the attacker knows the clear text of the frame, he can recover the key stream used to encrypt the frame. This process is repeated until he/she gets a 1,500-byte long key stream. The attacker can use the key stream to encrypt new frames or decrypt a frame that uses the same three byte initialization vector IV. The process can be repeated until the attacker builds a rainbow key stream table of all possible IVs. Such a table requires 23 GB of memory.

D. Duration Attack

The attacker exploits vulnerability in the virtual carrier-sense mechanism and sends a frame with the NAV field set to a high value (32 ms). This will prevent any station from using the shared medium before the NAV timer reaches zero. Before expiration of the timer, the attacker sends another frame. By repeating this process, the attacker can deny access to the wireless network.

IV. Hybrid Approach

Extensive work has been done to detect intrusions in wired and wireless networks. However, most of the intrusion detection systems examine only the network layer and higher abstraction layers for extracting and selecting features, and ignore the MAC layer header. These IDSs cannot detect attacks that are specific to the MAC layer. Some previous work tried to build IDS that functioned at the Data link layer. For example, in [3], [11] the authors simply used the MAC layer header attributes as input features to build the learning algorithm for detecting intrusions. No feature selection algorithm was used to extract the most relevant set of features.

In this paper, we will present a complete framework to select the best set of MAC layer features that efficiently characterize normal traffic and distinguish it from abnormal traffic containing intrusions specific to wireless networks. Our framework uses a hybrid approach for feature selection that combines the filter and wrapper models. In this approach, we rank the features using an independent measure: the information gain ratio. The k-means classifier's predictive accuracy is used to reach an optimal set of features which maximize the detection accuracy of the wireless attacks. To train the classifier, we first collect network traffic containing four known wireless intrusions, namely, the deauthentication, duration, fragmentation, and chopchop attack. The reader is referred to [12] for a detailed description of each attack. The Best feature set selection algorithm is shown below

Input:

F = Full set of features

IGR: Information Gain Ratio Measure

C: K-means Classifier

T: Gained Accuracy Threshold

For each feature f compute IGR(f)

Rank features in F According to IGR(f)

//Optimal Set Selection Algorithm

Initialize: S = {}, ac = 0

Repeat

(1) $ap = ac$

(2) $f = getNext(F)$

- (3) S=S U {f}
- (4) F=F-{f}
- (5) Ac=accuracy(C,S)

Until (ac-ap)<T Or ac<ap

The selection algorithm starts with an empty set S of the best features, and then, proceeds to add features from the ranked set of features F into S sequentially. After each iteration, the “goodness” of the resulting set of features S is measured by the accuracy of the k-means classifier. The selection process stops when the gained classifier’s accuracy is below a certain selected threshold value or in some cases when the accuracy drops, which means that the accuracy of the current subset is below the accuracy of the previous subset.

V. Initial List Of Features

The initial list of features is extracted from the MAC layer frame header. According to the 802.11 standard, the fields of the MAC header are as given in Table 1. These raw features in Table 1 are extracted directly from the header of the frame. Note that we consider each byte of a MAC address, FCS, and Duration as a separate feature. We preprocess each frame to extract extra features that are listed in Table 2. The total number of features that are used in our experiments is 38 features.

VI. Information Gain Ratio Measure

We used the Information Gain Ratio (IGR) as a measure to determine the relevance of each feature. Note that we chose the IGR measure and not the Information Gain because the latter is biased toward the features with a large number of distinct values. IGR is defined as

$$IGR(Ex, f) = \frac{Gain(Ex, f)}{SplitInfo(Ex, f)}$$

where Ex is the set of vectors that contain the header information and the corresponding class:

TABLE 1

List of Features Extracted from 802.11 Frames

Feature	Description
Version	Two bits indicate which version of the 802.11 MAC is contained in the rest of the frame
Type	Indicate the type of the frame (Mgmt, Ctrl, and Data).
SubType	Indicate the subtype of the frame
ToDS	Indicate if a frame is destined to the Distributed System.
FromDS	Indicate if a frame is originated from Distributed System.
More Fragment	Indicate whether a frame is non final fragment or not.
Retry	Indicate if the frame is a retransmitted frame
Power Mgmt	Indicate whether the station is active or in Power Saving Mode
More Data	Indicate whether an access point has buffered frames for a dozing station
WEP	Indicate if the frame is processed by WEP protocol.

Order	Indicate if the “strict ordering” delivery is employed.
Duration	The number of microsecond the medium is expected to be busy.
RA	The MAC address of the receiving
TA	The MAC address of the transmitting station.
MA	Depending on the values of ToDS and FromDS fields, this address can be the MAC address of the Sending, Destination or Base Station.
FCS	A Frame Check Sequence, which contains a 32 bit Cyclic Redundancy Code.

$$Gain(Ex, f) = Entropy(Ex) - \sum_{v \in Values(f)} \frac{|Ex, v|}{|Ex|} * Entropy(Ex, v),$$

$$Ex, v = \{x \in Ex / value(x, f) = v\}$$

The entropy function is the Shannon’s entropy defined as

$$Entropy(Ex) = - \sum P_i \log_2(P_i)$$

where Pi is the probability of a class i.

SplitInfo(Ex, f) is defined as

$$SplitInfo(Ex, f) = - \sum_{v \in values(f)} \frac{|Ex, v|}{|Ex|} \log_2 \left(\frac{|Ex, v|}{|Ex|} \right)$$

TABLE 2

List of Features After Processing 802.11 Frames

Feature	Description
IsWepValid	Indicate if WEP ICV check is successful.
DurationRange	Indicate if duration value is low (<5ms), average (between 5-20ms), or high (>20ms).
Casting Type	Indicate whether the receiving address is a unicast, multicast or a broadcast address.

TABLE 3

Top 10 Features

Rank	Feature	IGR
1	IsWepValid	1.02
2	DurationRange	1.01
3	More Frag	0.98
4	To DS	0.89
5	WEP	0.85
6	Casting Type	0.82
7	Type	0.73
8	SubType	0.65
9	Retry	0.46
10	From DS	0.41
11-38	Remaining Features	<.23

Using the data set of frames collected from our testing network, we could rank the features according to the score assigned by the IGR measure. The top 10 ranked features are shown in Table 3.

VII. The Best Subset Of Features

The k-means classifier is used to compute the detection rate for each set of features. Initially, the set of features S contains only the top ranked feature. After each

iteration, a new feature is added to the list S based on the rank which it is assigned by the IGR measure. Note that S_i is the i first features in the ranked list of features.

We can see that there is subset S_m of features that maximizes the accuracy of the K-means classifier. We can conclude that the first eight features (IsWepValid, DurationRange, More_Flag, To_DS, WEP, Casting_Type, Type, and SubType) are the best features to detect the intrusions we tested in our experiments. Increasing the number of features does not contribute to the improvement of the accuracy. In fact, irrelevant features distract the classifier and the accuracy drops to 17 percent with 19 features.

VIII. ARTIFICIAL NEURAL NETWORKS

Artificial Neural Networks (ANNs) are computational models which mimic the properties of biological neurons. A neuron, which is the base of an ANN, is described by a state, synapses, a combination function, and a transfer function. The state of the neuron, which is a Boolean or real value, is the output of the neuron. Each neuron is connected to other neurons via synapses. Synapses are associated with weights that are used by the combination function to achieve a precomputation, generally a weighted sum, of the inputs. The Activation function, also known as the transfer function, computes the output of the neuron from the output of the combination function.

An artificial neural network is composed of a set of neurons grouped in layers that are connected by synapses. There are three types of layers: input, hidden, and output layers. The input layer is composed of input neurons that receive their values from external devices such as data files or input signals. The hidden layer is an intermediary layer containing neurons with the same combination and transfer functions. Finally, the output layer provides the output of the computation to the external applications.

An interesting property of ANNs is their capacity to dynamically adjust the weights of the synapses to solve a specific problem. There are two phases in the operation of Artificial Neuron Networks. The first phase is the learning phase in which the network receives the input values with their corresponding outputs called the desired outputs. In this phase, weights of the synapses are dynamically adjusted according to a learning algorithm. The difference between the output of the neural network and the desired output gives a measure on the performance of the network. The most used learning algorithm is the retro backpropagation algorithm. In the second phase, called the generalization phase, the neural network is capable of extending the learned examples to new examples not seen before. The learning phase is resource demanding, explained by the iterative nature of the operation mode of the ANN. Once the network is trained, the processing of a new input is generally fast. In order to study the impact of the optimized set of features on both the learning phase and accuracy of the ANN networks, we have tested these attributes on three types of ANN architectures.

A. Perceptron

Perceptron is the simplest form of a neural network. It's used for classification of linearly separable problems. It consists of a single neuron with adjustable

weights of the synapses. Even though the intrusion detection problem is not linearly separable, we use the perceptron architecture as reference to measure the performance of the other two types of classifiers.

B. Multilayer Backpropagation Perceptrons

The multilayer backpropagation perceptrons architecture is an organization of neurons in n successive layers ($n > 1/3$). The synapses link the neurons of a layer to all neurons of the following layer. Note that we use one hidden layer composed of eight neurons.

TABLE 4
Distribution of Collected Data

	Learning	Validation	Test
Normal	6000	4000	5000
De-authentication	900	600	800
Duration	900	600	800
Fragmentation	900	600	800
Chopchop	900	600	800
Total	9600	6400	8200

C. Hybrid Multilayer Perceptrons

The Hybrid Multilayer Perceptrons architecture is the superposition of perceptron with multilayer backpropagation perceptrons networks. This type of network is capable of identifying linear and nonlinear correlation between the input and output vectors. We used this type of architecture with eight neurons in the hidden layer. Transfer function of all neurons is the sigmoid function. The initial weights of the synapses are randomly chosen between the interval $[-0.5, 0.5]$.

IX. Intrusion Detection Using Recurrent Neural Network

The proposed system is designed to perform the feature selection and intrusion detection process. The feature selection scheme is used to filter the irrelevant fields in network transactions. The feature selection selects suitable fields for the intrusion detection process. Filter, wrapper and hybrid feature selection schemes are used in the system. The intrusion detection process is performed using the artificial neural networks. The back propagation perception algorithm is used for the intrusion detection process. The recurrent neural network is used to for the intrusion detection process. The system also performs the intrusion detection process on the supervised feature selection model transactions. Detection latency, false positive and false negative measures are used for the performance evaluation.

The system is divided into four major modules. Feature reduction module is used to select optimized features. Artificial neural network based intrusion detection is performed using filtered data sets. Supervised features based IDS module is applied on user selected features. Recurrent neural network algorithm is used for intrusion detection process.

A. Feature Reduction Process

The feature selection is applied to reduce the fields that are used in the intrusion detection process. It will improve the accuracy of the system. The process time is also reduced in the learning and testing process. The

features selection scheme uses filter, wrapper and hybrid feature selection techniques. The filter model uses the information consistency ratio or distance measure. Wrapper model uses predictive accuracy. Information gain measure is used in the hybrid feature selection model.

B. Intrusion Detection Using ANN

Artificial neural networks are used with reduced features. Back propagation algorithm is used for the learning and testing process. Perceptron based neural network model uses 8 neurons for each layer. Multilayer based back propagation perceptron algorithm is used for intrusion detection. Learning process supports limited transactions only.

C. IDS Using Supervised Features

Supervised feature selection model uses features retrieved using experts' knowledge. Listed attributes are separated from user transactions. Artificial neural network is used for the intrusion detection process. Supervised features based IDS scheme is compared with automated feature selection process.

D. Intrusion Detection Using RNN

Selected features are used in recurrent neural network based intrusion detection model. RNN supports scalability in learning process. Learning errors are reduced in RNN. Real-Time Recurrent Learning Algorithm (RTRL) is used in RNN. The RNN technique is applied to verify the accuracy level of feature selection and learning process. The system improves the accuracy for the intrusion detection process. The detection latency is also reduced by the system.

X. CONCLUSION

In this paper, we have presented a novel approach to select the best features for detecting intrusions in 802.11-based networks. Our approach is based on a hybrid approach, which combines the filter and wrapper models for selecting relevant features. We were able to reduce the number of features from 38 to 8. We have also studied the impact of feature selection on the performance of different classifiers based on neural networks. Learning time of the classifiers is reduced to 33 percent with the reduced set of features, while the accuracy of detection is improved by 15 percent. The system reduces the feature selection complexity. Detection period is reduced by the system. The system integrates all layers in the IDS. Wireless LAN attacks are controlled by the system.

Design and Analysis of Propeller SHAT By Using KEVLOR/EPOXY Composite

Thahar Ali Syed^{1*} Adnan Javed² Kasala Raju³ Naga Raju M⁴

ABSTRACT: In the design of automobiles, the industry is exploring composite materials in order to obtain reduction of weight without significant decrease in vehicle quality and reliability. This is due to the fact that the reduction of weight of a vehicle directly impacts its fuel consumption. Particularly in city driving, the reduction of weight is almost directly proportional to fuel consumption of the vehicle. Thus, in this project work the entire drive shaft assembly of a Toyota Qualis was chosen and analyzed by replacing it with composite and hybrid materials. The following materials were chosen

- Steel
- Boron/Epoxy Composite
- Kevlar/Epoxy Composite
- Aluminium – Glass/Epoxy Hybrid
- Carbon – Glass/Epoxy Hybrid

The analysis was carried out for three different ply orientations of the composites in order to suggest the most suitable ply orientation of the material that would give the maximum weight reduction while conforming to the stringent design parameters of passenger cars.

I. Introduction

In the process of designing a vehicle, one of the most important objectives is the conservation of energy and the most effective way to obtain this goal is the reduction of weight of the vehicle. There is almost a direct proportionality between the weight of the vehicle and its fuel consumption, particularly in city driving. The automotive industry is exploiting composite material technology for structural component construction in order to obtain reduction of weight, without decrease in vehicle quality and reliability. The advanced composite materials seem ideally suitable for long power drive shaft (propeller shaft) applications as their elastic properties can be tailored to increase the torque they carry as well as the rotational speed at which they operate. In this project, the conventional drive shaft material has been replaced with advanced composites and hybrid materials to carry out a comparative analysis, thus determining the most suitable replaceable material.

1.1 Specification of Problem:

- The first was Steel (SM45C) which was used for reference purpose
- Two Composites Boron/Epoxy, Kevlar/Epoxy And Hybrid shafts i.e., a combination of Aluminium and

Almost all automobiles (which correspond to design with rear wheel drive and front engine installation) use a drive shaft for the transmission of motion from the engine to the differential. An automotive propeller shaft, or drive shaft, transmits power from the engine to differential gears of a rear wheel-driving vehicle. The static torque transmission capability of the propeller shaft for passenger cars, and small truck and vans should be larger than 3500 Nm and the fundamental bending natural frequency should be higher than 8000rpm to avoid whirling vibration. The whirling of the propeller shaft, which is a resonance vibration, occurs when the rotational speed is equal to the fundamental natural bending frequency, which is inversely proportional to the square root of specific stiffness (E/ρ). When conventional materials such as Steel or Aluminium are used, the weight of the drive shaft assembly is considerably high, which has a certain role in increasing the overall weight of the vehicle. Also, due to the increased weight of the shaft there are more chances of whirling of the shaft. To avoid this in conventional drive shafts, which have a length exceeding 1.2m, the shafts are made in two pieces. However, the two piece steel propeller shaft has a complex and heavy configuration because three universal joints and a center support bearing in addition to a spline are required, which produces noise and vibrations that are transmitted to vehicle through the center support bearing.

1.2 Aim and Scope of the Work

The project aims to reduce the weight of the drive shaft assembly by using advanced composite materials. For this project work, the drive shaft of a Toyota Qualis was chosen. The modeling of the drive shaft assembly was done using CATIA V5R16. A shaft has to be designed to meet the stringent design requirements for automobiles. A comparative study of five different materials was conducted to choose the best-suited material. Steel (SM45C) was chosen for reference and the rest of the four composites were analyzed at three different ply orientations. The material properties of the composites were obtained based on the Classical Lamination Theory with the help of a code written in C language. The analysis was carried out using ANSYS 11.0 WorkBench for the following materials at three different ply orientations $[0/30]_{8S}$, $[\pm 45]_{8S}$ and $[0/90]_{8S}$

Glass/Epoxy Composite, Glass/Epoxy and Carbon/Epoxy.

1.3 Drive Shaft

The term Drive shaft is used to refer to a shaft, which is used for the transfer of motion from one point to another. Whereas the shafts, which propel (push the object ahead) are referred to as the propeller shafts. Propellers are usually associated with ships and planes as they are propelled in water or air using a propeller fan. However the drive shaft of the automobile is also referred to as the propeller shaft because apart from transmitting the rotary

motion from the front end to the rear end of the vehicle, these shafts also propel the vehicle forward. The shaft is the primary connection between the front and the rear end (engine and differential) which performs both the jobs of transmitting the motion and propelling the front end. Thus, the terms Drive Shaft and Propeller Shafts are used interchangeably.

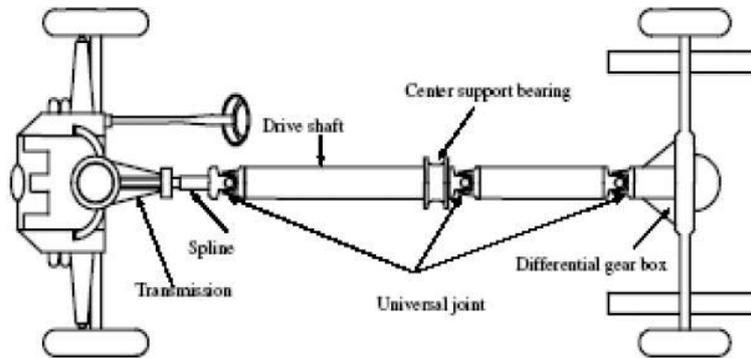

fig Schematic arrangement of Underbody of an Automobile

II. THEORETICAL AND SIMULATED RESULTS CORRELATION

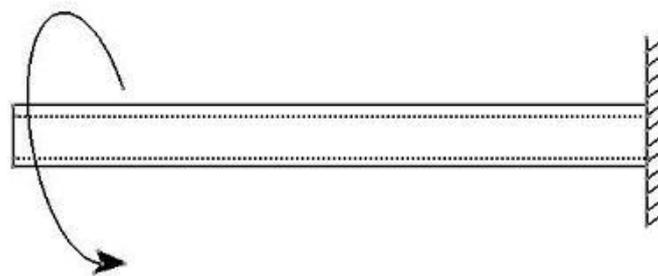

A comparison between the results obtained based on theoretical calculations and the results obtained from the ANSYS 11.0 WorkBench has been carried out. For this purpose, the drive shaft of the automobile has been idealized as a hollow cylindrical shaft. It is then subjected to the same load theoretically and in the finite element solver. The comparison of results shows a very close range conformance, which has been plotted.

2.1 Theoretical Calculations for Hollow Shaft

The Drive shaft, for simplicity has been first idealized as a hollow cylindrical shaft which is fixed at one end and on which a torque of 3500 Nm is applied as represented below.

For the hollow shaft, Let
 $R_o = 0.01\text{ m}$; $R_i = 0.02\text{ m}$; $l = 0.5\text{ m}$; $E = 207e9\text{ pa}$
 and Torque=3500 Nm
 Where R_o = Outer Radius R_i = Inner Radius l = Length of the shaft

E = Young’s Modulus of Steel (SM45C) T = Applied Torque

Hollow Shaft being subject to a Torque of 3500 Nm

$$Deflection = Y_{Max} = \frac{ML^2}{2EI} = \frac{3500 \times (0.5^2)}{2 \times (207e^9) \times (1.178e^{-7})} = 0.0179m$$

Then:

Maximum Shear Stress:

$$\tau_{Max} = \frac{T \times R_o}{J} = \frac{3500 \times 0.02}{\left[\frac{\pi}{2}\right] \times [R_o^4 - R_i^4]}$$

$$= \frac{70}{2.35626 \times 10^{-7}} = 2.9708 \times 10^8 Pa$$

Maximum Von – Mosses Stress

$$= [T \times (\frac{d_o}{2})]$$

$$= \frac{I}{\frac{\pi}{64}} \times [(0.04)^4 - (0.02)^4]$$

$$= 594178454.2$$

$$= 5.9417e7Pa$$

Simulated Results for Hollow Shaft

The derived theoretical results are now going to be compared to the simulated results. For which, a hollow shaft with the same specifications was created in CATIA V5R17. This CATIA model was then imported into ANSYS 11.0 Workbench, wherein the model was analyzed. The same torsional load was applied by fixing one end of the shaft and applying torque on the other end. The results were found to be very close to the theoretically calculated values. The results are as follows.

The hollow shaft is made-up using the same dimensions, which are
 $R_o = 0.01\text{ m}$; $R_i = 0.02\text{ m}$; $l = 0.5\text{ m}$; $E = 207e9\text{ pa}$ and
 Torque=3500 Nm

Material properties

III. ANALYSIS

Since the domain for analysis is a complex assembly of a number of parts, ANSYS 11.0 Workbench was chosen for performing the analysis. The proper connection between each part of the assembly and the subsequent connectivity of mesh is the key criteria for getting proper load transfers throughout the assembly. The Workbench module of ANSYS 11.0 does not require the explicit specification of element types by the user, depending upon the assembly, the element types are chosen by the solver to get the best possible results. But for the dominating major portion of the assembly which is relatively easier to manufacture, the composite material were applied. The CATIA assembly, imported into ANSYS is subjected to

- I. Torsional Analysis
- II. Modal Analysis &
- III. Harmonic Analysis

This is to be carried out on a total of five materials out of which four are composites at ply orientations of $[0/30]_{8s}$, $[+/- 45]_{8s}$ and $[0/90]_{8s}$

RESULTS & ABERVATIONS

It can be seen that Kevlar/Epoxy Composite has shown the maximum reduction in weight followed by Carbon Hybrid, Boron/Epoxy Composite and finally Aluminium Hybrid.

The percentage weight savings of each material is given as follows

- Kevlar/Epoxy Composite – 65 %
- Carbon Hybrid – 57.5 %
- Boron/Epoxy Composite – 55.9 %
- Aluminium Hybrid – 54 %

Deformation induced in the 5 materials due to torque

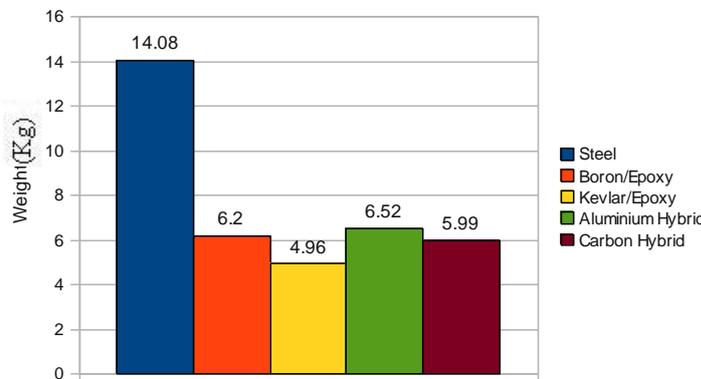

The following graph illustrates the total deformation caused in the assembly due to the application of a torque of 3500 Nm (the rated load for passenger cars).

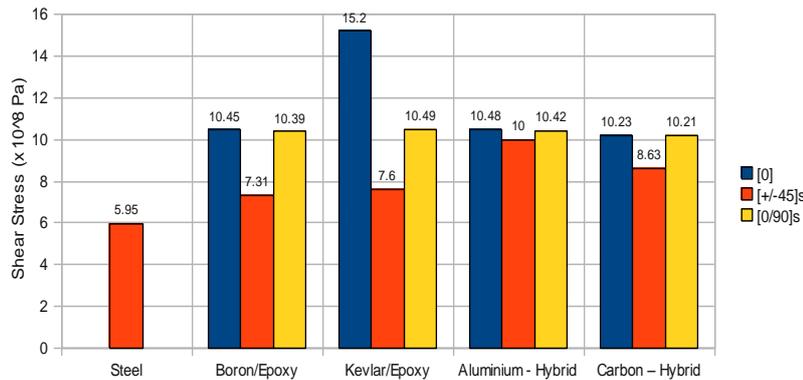

Two Conclusions can be drawn from the following graph

- a) It was found that though Steel had the minimum deflection, however it is followed very closely by Boron/Epoxy Composite.
- b) The Variation in ply orientations helps us to know that the ply orientation $[+/-45]_8$ gives the least amount of deflection when compared to the other two orientations.

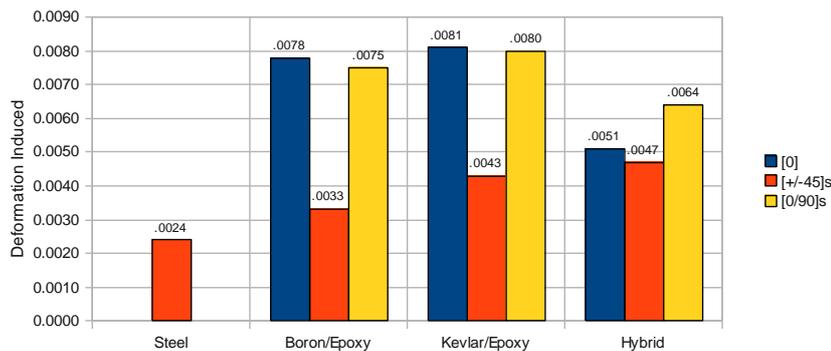

Thus it can be inferred from these observations that throughout the various parameters, analyzed for all the materials, Boron/Epoxy and Kevlar/Epoxy Composites have shown a remarkable similarity in their results. However Kevlar/Epoxy has been found to be 1.24 kg lighter than Boron/Epoxy.

Reduction in Weight achieved using Composite materials:

Shear Stress

Shear Stress induced in the assembly due to the application of 3500 Nm Torque:

IV. CONCLUSION

The presented work was aimed at reducing the fuel consumption of the automobiles in particular or any machine, which employs drive shafts, in general. This was achieved by reducing the weight of the drive shaft with the use of composite materials. The Drive shaft of a Toyota Qualis was chosen for determining the dimensions, which were then used for creating a model in CATIA V5R17. The material properties of composites were determined based on Classical Lamination Theory using a C Code. Being a complex assembly of a number of parts, it had to be analyzed in ANSYS 11.0 Workbench. A total of five materials were chosen for the comparative analysis, including steel, which was used for reference. The usage of composite materials has resulted in considerable amount of weight saving in the range of 65% to 54% when compared to conventional steel shaft. Taking into consideration the weight saving, deformation, shear stress induced and resonant frequencies it is evident that Kevlar/Epoxy composite has the most encouraging properties to act as the replacement for steel out of the considered five materials. And the best suitable ply orientation is [+/- 45°].

ABSTRACT: Virtualization technology is being used intensively in data centers, cluster systems, enterprises and organizational networks, Hence the capability of Virtual Machine (VM) Migration importance has been increased for maintaining high performance, improved manageability and fault tolerance. Live Migration allows virtual machine monitor to move the running virtual machine from one physical server to another with zero downtime, continuous service availability and complete transaction integrity. In this paper we, present a performance evaluation of parameters that affect live migration and varying in the performance depending on workload.

Keywords: Virtual Machine (VM), Migration Time (MT), Down Time (DT), Dirty Page, Virtualization.

I. INTRODUCTION

System virtualization is the ability to abstract and pool resources on a physical platform. This abstraction decouples software from hardware and enables multiple operating system images to run concurrently on a single physical platform without interfering with each other. As a technique, system virtualization has existed for decades on mainframes. In the past, industry standard x86-based machines, with their limited computing resources. Virtualization can increase utilization of computing resources by consolidating the workloads running on many physical systems into virtual machines running on a single physical system. Virtual machines can be provisioned on-demand, replicated and migrated. Virtual machine (VM) migration, which is the ability to move a VM from one physical server to another under virtual machine monitor (VMM) control, is a capability being increasingly utilized in today's enterprise environments.

Implemented by several existing virtualization products, live migration can aid in aspects such as high-availability services, transparent mobility, consolidated management, and workload balancing [1]. While virtualization and live migration enable important new functionality, the combination introduces novel security challenges. A virtual machine monitor that incorporates a vulnerable implementation of live migration functionality may expose both the guest and host operating system to attack and result in a compromise of integrity. Given the large and increasing market for virtualization technology, a comprehensive understanding of virtual machine migration security is essential. However, the security of virtual machine migration has yet to be analyzed.

After a live migration, guest software continues to maintain an identical view of the pre and post migration hardware. In this paper we discuss Processors provide support for a VMM to hide differences in software-visible processor features during Live.

1.1 SHORT BACKGROUND ON VM TECHNOLOGY

Initially very popular in the 1960's, for instance in the context of shared mainframe computers, this technology was subsequently abandoned in favour of multiprogrammed efficient commodity operating systems, running on increasingly cheaper and more widely available hardware. However, the virtual machine technology, initially based on the principle of exporting (possibly multiple) virtualized software versions of the machine hardware to upper layers (originally the operating system) came back to fashion in the past years. Reasons for this come-back spanned the need for easier management of large scale distributed systems or MPP machines [2], or the need for support for mobility (the easy checkpointing capability mentioned above) and increased security (as many commodity OSs had become quite unmanageable and/or insecure and proved to under-use the same increasingly cheaper hardware resources that caused the "retirement" of VMs 20 years ago). However, while they have indeed come back, VMs are less interesting now for resource multiplexing but more as a way to "circumvent" existing "popular" Operating Systems that have become unmanageable and provide little opportunities for activities like checkpointing or sandboxing. Issues and challenges of VM implementations include minimizing virtualization overhead and exporting a virtualized interface identical or as similar as possible to the virtualized machine to ensure compatibility.

Various design choices exist, such as providing a "classic" VM architecture – such as Xen or VMWare ESX Server [3] (laying underneath the Operating system and thus maximizing performance) or a "hosted" architecture, such as VMWare Workstation (laying "on top" of a host operating system, as an application and improving). Another important design choice is that of slightly modifying the virtualized interface to be exported to replace portions of the instructions set which are not easily virtualizable by different and more efficiently implementable equivalents. This approach is called paravirtualization and it is applied in VM implementations such as Xen or Disco [4]. VMs can provide important benefits that can be useful in many contexts, including migration. Firstly, they have the serious advantage of abstracting away the details of underlying hardware and

exporting a uniform view of the virtualized machine, therefore providing an elegant solution to the resource heterogeneity problem. Additionally, they provide a complete encapsulation of the machine software state, therefore the VM can be easily and very conveniently checkpointed, suspended and restarted at will. Consequently, VMs can be dynamically mapped to physical machines or migrated much easier than processes.

Therefore, the implementation complexity of migration implementation, which we saw that was a limiting factor in the case of process migration, is greatly reduced. Besides migration-empowered applications like dynamic load balancing, fault tolerance or Internet Suspend-Resume [5] type applications, VM can be used for things like convenient distribution of software packages (for instance Oracle delivers packages of readily installed and configured software under the form of VMs) or for damage containment and “forensics” against worm or hacker attacks.

1.2 VIRTUAL MACHINE MIGRATION

There are many ways to migrate a VM. In *static migration*, the VM is shutdown using OS-supported methods; its static VM image is moved to another VMM and restarted. In *cold migration*, the VM is suspended using OS supported or VMM-supported methods. The suspended VM image is moved to a VMM on a different machine and resumed. In *live migration*, the VMM moves a running VM instance nearly instantaneously from one server to another. Live Migration allows for dynamic load balancing of virtualized resource pools, hardware maintenance without downtime and dynamic failover support. As long as the hardware in the pre and post migration environment is identical, guest software should behave in exactly the same way before and after the migration. It is when guest software runs in a different hardware environment after a migration that certain challenges can arise[6]. Note that even though a VMM presents a virtual platform to guest software, there could be certain interfaces, depending on VMM design, which guest software can directly use to determine underlying hardware’s capabilities.

After the reboot/restart following a static migration, guest software should go through its platform discovery phase and be able to adjust to any differences in underlying (virtual) hardware. Following a cold migration, guest software may continue to maintain an identical view of the pre and post migration hardware. When suspended using OS-supported methods, some operating systems will re-scan the hardware upon resume. Depending on their policies and the hardware differences between current and previous hardware, the OSes may refuse to resume and require a reboot. After a live migration, guest software continues to maintain an identical view of the pre and post migration hardware.

1.3 Issues with VM migration

However, things get a little more complicated. More precisely, to perform a correct migration, besides the checkpointed state of the VM, the memory image of that VM also has to be migrated, for the state to be correctly preserved. All this should be done while programs in the VM are still running; therefore memory pages are still getting dirtied. Therefore, we see that increased simplicity comes at a

certain price, since the VM’s memory image and state is undoubtedly much larger than the process’ checkpointed state in the case of process migration.

Additionally, as with all migrations, resources used by processes running within the migrated VM should still be available after the migration attached. Since these resources might be hard to migrate (because of large sizes or consistency constraints for instance), this brings back the problem of residual dependencies. For instance, the problem of migrating the file system present on the virtual disk of a Virtual Machine [7]. In the context of Virtual Machine migration, “residual dependencies” are especially important, considering that the size of a virtual machine can be much larger than that of a process. While migrating the entire VM, as we have seen, has the advantage that support for check pointing is readily provided, unlike in the case of a regular process, the VM’s address space, and especially it’s virtual disk are of considerable size, therefore leaving residual dependencies may be unavoidable to ensure reasonable migration times (at least with current typical network resources)[8]. As with all migration systems, transparency remains an issue also for VM migration.

II. LIVE MIGRATION

Virtual machine live migration is a virtualization process that moves a virtual machine (VM) from one physical host server to another. It moves the memory and state of a VM without shutting down the application, so users will generally not detect any significant interruption in application availability. The process captures the complete memory space occupied by the VM along with the exact state of all the processor registers currently operating on the VM then sends that content across a TCP/IP link to memory space on another server. Processor registers are then loaded, and the newly moved VM can pick up its operation without missing a step.

Most VM live migrations occur between similar hypervisors, so the migrated VM retains its name and other unique identifiers. Even though the VM is on a different server, it’s the exact same machine as far as the users are concerned. Live migration is a key benefit of virtualization, allowing workloads to move in real time as server or data center conditions change [9]. Consider the impact on business continuity: A virtual server scheduled for maintenance can migrate its workloads to a spare server or to other servers that have extra computing capacity. Once the maintenance is complete and the server returns to service, these workloads can all migrate back to the original server without disruption.

Live migration helps server consolidation by allowing IT administrators to balance workloads across data center servers, ensuring that each server is used efficiently without being overtaxed. Live migration helps with disaster recovery too because VMs can just as easily be moved from one site to another, relying on spare servers at a remote site to receive and operate the migrated VMs.

All of the major virtualization software platforms include VM live migration tools. These include VMware VMotion (part of vSphere), Microsoft Live Migration (part of Hyper-V R2) and Citrix Systems XenServer live migration. Migration tools typically allow administrators to prioritize

the movement of each VM so that failover and failback processes occur in a predictable and repeatable manner. Mission-critical VMs usually take priority and are often moved to spare servers with ample computing resources. Secondary VMs can be addressed next, although the migration software may be left to move noncritical VMs automatically based on the computing resources on each available server. Migration audits allow administrators to locate VMs and track their movements to refine and optimize ongoing migration behaviours. Live migration works between almost all virtual host servers, but it's important to test migration behaviours between servers with various processor manufacturers. Processors from Intel and AMD both include extensions that provide hardware assistance for virtualization tasks, including migration. However, Intel VT and AMD-V processors use different architectures to facilitate migration, and moving VMs between Intel and AMD-based servers may result in unexpectedly poor migration performance.

2.1 Live Migration options for storage configurations

In addition to network settings, there are some storage connection types that must also be carefully configured on Hyper-V hosts for Live Migration to run properly. A Virtual Hard Disk (VHD) attachment, for instance, is arguably the simplest for Live Migration purposes. When VHDs are attached to a highly available VM, they must also exist on shared storage. This setup ensures that every cluster node can automatically access the disk when a VM migrates. For pass-through disks, another storage configuration, additional care is necessary. These disks have a direct relationship with both VMs and their hosts, which must be considered before performing Live Migration. A pass-through disk must be exposed to the host and then passed through to the VM. Pass-through disks are supported in a clustered configuration; but the cluster must be informed of any new pass-through disks by refreshing the VM configuration after it has been attached. Pass-through disks must be managed like other cluster resources. The storage area network connections to the cluster must be exposed to every potential cluster host.

III. Design

At a high level we can consider a virtual machine to encapsulate access to a set of physical resources. Providing live migration of these VMs in a clustered server environment leads us to focus on the physical resources used in such environments: specifically on memory, network and disk. This section summarizes the design decisions that we have made in our approach to live VM migration. We start by describing how memory and then device access is moved across a set of physical hosts and then go on to a high-level description of how a migration progresses.

3.1 Migrating Memory

Moving the contents of a VM's memory from one physical host to another can be approached in any number of ways. However, when a VM is running a live service it is important that this transfer occurs in a manner that balances the requirements of minimizing both *downtime* and *total*

migration time. The former is the period during which the service is unavailable due to there being no currently executing instance of the VM; this period will be directly visible to clients of the VM as service interruption. The latter is the duration between when migration is initiated and when the original VM may be finally discarded and, hence, the source host may potentially be taken down for maintenance, upgrade or repair. It is easiest to consider the trade-offs between these requirements by generalizing memory transfer into three phases:

Push phase

The source VM continues running while certain pages are pushed across the network to the new destination. To ensure consistency, pages modified during this process must be re-sent.

Stop-and-copy phase

The source VM is stopped, pages are copied across to the destination VM, then the new VM is started.

Pull phase

The new VM executes and, if it accesses a page that has not yet been copied, this page is faulted in ("pulled") across the network from the source VM.

Although one can imagine a scheme incorporating all three phases, most practical solutions select one or two of the three. For example, *pure stop-and-copy* [10] involves halting the original VM, copying all pages to the destination, and then starting the new VM. This has advantages in terms of simplicity but means that both downtime and total migration time are proportional to the amount of physical memory allocated to the VM. This can lead to an unacceptable outage if the VM is running a live service.

Another option is *pure demand-migration* [11] in which a short stop-and-copy phase transfers essential kernel data structures to the destination. The destination VM is then started, and other pages are transferred across the network on first use. This results in a much shorter downtime, but produces a much longer total migration time; and in practice, performance after migration is likely to be unacceptably degraded until a considerable set of pages have been faulted across. Until this time the VM will fault on a high proportion of its memory accesses, each of which initiates a synchronous transfer across the network.

The approach taken in this paper, *pre-copy* [12] migration, balances these concerns by combining a bounded iterative push phase with a typically very short stop-and-copy phase. By 'iterative' we mean that pre-copying occurs in *rounds*, in which the pages to be transferred during round *n* are those that are modified during round *n-1* (all pages are transferred in the first round). Every VM will have some (hopefully small) set of pages that it updates very frequently and which are therefore poor candidates for pre-copy migration. Hence we bound the number of rounds of pre-copying, based on our analysis of the *writable working set* (WWS) behaviour of typical server workloads. Finally, a crucial additional concern for live migration is the impact on active services. For instance, iteratively scanning and sending a VM's memory image between two hosts in a cluster could easily consume the entire bandwidth available between them

and hence starve the active services of resources. This *service degradation* will occur to some extent during any live migration scheme. We address this issue by carefully controlling the network and CPU resources used by the migration process; thereby ensuring that it does not interfere excessively with active traffic or processing.

3.2 Resources for Migration

A key challenge in managing the migration of OS instances is what to do about resources that are associated with the physical machine that they are migrating away from. While memory can be copied directly to the new host, connections to local devices such as disks and network interfaces demand additional consideration. The two key problems that we have encountered in this space concern what to do with network resources and local storage.

For network resources, we want a migrated OS to maintain all open network connections without relying on forwarding mechanisms on the original host (which may be shut down following migration), or on support from mobility or redirection mechanisms that are not already present (as in [13]). A migrating VM will include all protocol state (e.g. TCP PCBs), and will carry its IP address with it. To address these requirements we observed that in a cluster environment, the network interfaces of the source and destination machines typically exist on a single switched LAN. Our solution for managing migration with respect to network in this environment is to generate an unsolicited ARP reply from the migrated host, advertising that the IP has moved to a new location. This will reconfigure peers to send packets to the new physical address, and while a very small number of in-flight packets may be lost, the migrated domain will be able to continue using open connections with almost no observable interference.

Some routers are configured not to accept broadcast ARP replies (in order to prevent IP spoofing), so an unsolicited ARP may not work in all scenarios. If the operating system is aware of the migration, it can opt to send directed replies only to interfaces listed in its own ARP cache, to remove the need for a broadcast. Alternatively, on a switched network, the migrating OS can keep its original Ethernet MAC address, relying on the network switch to detect its move to a new port. In the cluster, the migration of storage may be similarly addressed: Most modern data centers consolidate their storage requirements using a network-attached storage (NAS) device, in preference to using local disks in individual servers. NAS has many advantages in this environment, including simple centralised administration, widespread vendor support, and reliance on fewer spindles leading to a reduced failure rate. A further advantage for migration is that it obviates the need to migrate disk storage, as the NAS is uniformly accessible from all host machines in the cluster

3.3 Pre-copy Migration

Pre-copy migration tries to tackle problems associated with earlier designs by combining a bounded iterative push step with a final and typically very short stop-and-copy[14] phase. The core idea of this design is that of iterative convergence. The design involves iterating through multiple rounds of copying in which the VM memory pages

that have been modified since the previous copy are resent to the destination on the assumption that at some point the number of modified pages will be small enough to halt the VM temporarily, copy the (small number of) remaining pages across, and restart it on the destination host. Such a design minimises both total migration time and downtime.

3.3.1 Stages in Pre-copy Migration

Pre-copy migration involves 6 stages, namely:

- 1) **Initialisation:** a target is pre-selected for future migration.
- 2) **Reservation:** resources at the destination host are reserved.
- 3) **Iterative pre-copy:** pages modified during the previous iteration are transferred to the destination. The entire RAM is sent in the first iteration.
- 4) **Stop-and-copy:** the VM is halted for a final transfer round.
- 5) **Commitment:** the destination host indicates that it has received successfully a consistent copy of the VM.
- 6) **Activation:** resources are re-attached to the VM on the destination host.

Unless there are stop conditions, the iterative pre-copy stage may continue indefinitely. Thus, the definition of stop conditions is critical in terminating this stage in a timely manner. These conditions are usually highly dependent on the design of both the hypervisor and the live migration subsystem but are generally defined to minimise link usage and the amount of data copied between physical hosts while minimising VM downtime. However, the existence of these stop conditions has a significant effect on migration performance and may cause non-linear trends in the total migration time and downtime experienced by VMs.

3.3.2. Defining Migration Performance

Migration performance may be evaluated by measuring total migration time and total downtime. The former is the period when state on both machines is synchronised, which may affect reliability while the latter is the duration in which the VM is suspended thus seen by clients as service outage. Using the pre-copy migration model, total migration time may be defined as the sum of the time spent on all 6 migration stages (Equation 1) from initialisation at the source host through to activation at the destination. Total downtime, however, is the time required for the final 3 stages to complete (Equation 2). While it is expected that the iterative pre-copy stage will dominate total migration time, our measurements found that for certain classes of applications specifically those that do not have a high memory page modification rate the initialisation, reservation, commitment and activation stages may add a significant overhead to total migration time and downtime. We classify the initialisation and reservation stages together as pre-migration overhead while the commitment and activation stages compose post-migration overhead.

$$\text{TotalMigrationTime} = \underbrace{\text{Initialisation} + \text{Reservation}}_{\text{Pre-migrationOverhead}}$$

$$+ \sum \text{pre-copy} + \text{stop-and-copy}$$

$$\text{Post-migrationOverhead} + \text{Commitment} + \text{Activation} \xrightarrow{\text{Equation (1)}}$$

$$\text{TotalDowntime} = \text{Stop-and-copy}$$

$$\text{Post-migrationOverhead} + \text{Commitment} + \text{Activation} \xrightarrow{\text{Equation (2)}}$$

3.3.3. Migration Bounds

Given the stop conditions, it is possible to work out the upper and lower migration performance bounds for a specific migration algorithm. We will use a real-world case to characterise these boundaries. While there exist a range of live migration platforms, for the remainder of this paper we will base our analysis on the Xen migration platform. Xen is already being used as the basis for large scale cloud deployments [15] and thus this work would immediately benefit these deployments. Moreover, Xen is open-source allowing us to quickly and efficiently determine the migration sub-system design and implementation. Note however that our measurement techniques, methodology, and prediction models design basis are applicable to any virtualisation platform that employs the pre-copy migration mechanism. The stop conditions that are used in Xen migration algorithm are defined as follows:

- 1) Less than 50 pages were dirtied during the last pre-copy iteration.
- 2) 29 pre-copy iterations have been carried out.
- 3) More than 3 times the total amount of RAM allocated to the VM has been copied to the destination host. The first condition guarantees a short downtime as few pages are to be transferred. On the other hand, the other 2 conditions just force migration into the stop-and-copy stage which might still have many modified pages to be copied across resulting in large downtime.

1) Bounding Total Migration Time (Equation 3): Consider the case of an idle VM running no applications. In this case the iterative pre-copy stage will terminate after the first iteration as there is no memory difference. Consequently, the migration sub-system needs only to send the entire RAM in the first round. The total migration lower bound is thus the time required to send the entire RAM coupled with pre- and post-migration overheads. On the other hand, consider the case where the entire memory pages are being modified as fast as link speed. In this scenario, the iterative pre-copy stage will be forced to terminate after copying more than 3 times the total amount of RAM allocated to the VM. Migration then re-sends the entire modified RAM during the stop-and-copy stage. The total migration upper bound is thus defined as the time required sending 5 times the VM size less 1 page plus pre- and postmigration overheads.

$$\text{Overheads} + (\text{VMSize} / \text{LinkSpeed}) \leq \text{TotalMigrationTime} \leq (\text{Overheads} + ((5 * \text{VMSize} - 1) * \text{page}) / \text{LinkSpeed})$$

$$\xrightarrow{\text{Equation (3)}}$$

2) Bounding Total Downtime (Equation 4): Similarly, the total downtime lower bound is defined as the time required for the post-migration overhead, assuming that the final stop and copy stage does not transfer any pages. This occurs either when the VM is idle or the link speed is fast enough to copy all dirtied pages in the pre-copy stage. On the other hand, the total downtime upper bound is defined as the time required to copy the entire RAM in the stop-and-copy stage coupled with the post-migration overhead.

$$\text{Post-migrationOverhead} \leq \text{TotalDowntime} \leq (\text{Post-migrationOverhead} + (\text{VMSize} / \text{LinkSpeed}))$$

$$\xrightarrow{\text{Equation (4)}}$$

3.3.4 Difference in Bounds

Modelling bounds is useful as it enables us to reason about migration times provided that we know the link speed and VM memory size. These bounds are the limits in which the total migration time and total downtime are guaranteed to lie. Given a 1,024 MB VM and 1 Gbps migration link, for example, the total migration time has a lower bound of 13 and upper bound of 50 seconds respectively. Similarly, the downtime has a lower bound of .314 and upper bound of 9.497 seconds respectively. Table I illustrates the migration bounds for some common link speeds. While the downtime lower limit is fixed (as it is dependent purely on post-migration overhead) all other bounds vary in accordance to link speed due to their correlation with the VM memory size. As the table indicates, the bounds vary significantly. For bigger VM memory sizes (which is common in current installations [16]) we have even larger differences. Thus, using bounds is at best an imprecise exercise and does not allow for accurate prediction of migration times. Building better predictions requires understanding the relationship between factors that impact migration performance.

Table I: Migrationbounds.Mt:Total Migration Time (Seconds). Dt: Total Downtime (Milliseconds). Lb: Lower Bound. Ub: Upper Bound. Vm Size= 1,024 Mb.

Speed	MTLB	MTUB	DTLB	DTUB
100 Mbps	92.2 s	437.1 s	311 ms	90,466.5 ms
1 Gbps	11.7 s	43.95 s	311 ms	9,347.3 ms

IV. PARAMETERS AFFECTING MIGRATION

There are several factors that we need to study as a prerequisite for accurate migration modelling. In this section, we explore these factors and their impact on total migration time and downtime. Moreover, stop conditions that may force migration to reach its final stages are generally what governs migration performance. Obviously, this is implementation specific which is exemplified by but not limited to Xen support for live migration. Migration link bandwidth is perhaps the most influential parameter on migration performance. Link capacity is inversely proportional to total migration time and downtime. Higher speed links allow faster transfers and thus require less time to complete. Figure 1 illustrates migration performance for a 1,024 MB VM running a micro-benchmark that writes to memory pages with rates up to 300,000 pages/second on 100 Mbps, 1 Gbps links. It represents the impact of each link speed on total migration time and downtime.

As link bandwidth increases, the point in the curve when migration performance starts to degrade rapidly shifts to the right roughly with the same ratio. Page dirty rate is the rate at which memory pages in the VM are modified which, in turn, directly affects the number of pages that are transferred in each pre-copy iteration. Higher page dirty rates result in more data being sent per iteration which leads to longer total migration time. Furthermore, higher page dirty rates results in longer VM downtime as more pages need to be sent in the final transfer round in which the VM is suspended.

Figure 1 shows the effect of varying the page dirty rate on total migration time and downtime for each link speed. The relationship between page the dirty rate and migration performance is not linear because of the stop conditions. If the page dirty rate is below link capacity, the migration sub-system is able to transfer all modified pages in a timely fashion, resulting in a low total migration time and downtime. On the other hand, if the page dirty rate starts approaching link capacity, migration performance degrades significantly. Total downtime at low page dirty rates is virtually constant and approximately equal to the lower bound (Equation 4). This is because the link has enough capacity to transfer dirty pages in successive iterations leading to a very short stop-and-copy stage. When the page dirty rate increases to the point that 29 iterations are not sufficient to ensure a short final copy round or when more than 3x the VM size have been transferred, migration is forced to enter its final stage with a large number of dirty pages yet to be sent.

Consequently, total downtime starts to increase in proportion to the increase in the number of modified pages that need to be transferred in the stop-and copy stage. Total downtime further increases until the defined upper bound in which it has to send the entire VM memory. Total migration time also increases with an increasing page dirty rate. This is attributable to the fact that more modified pages have to be sent in each pre-copy round. Moreover, the migration sub-system has to go through more iteration with the hope to have a short final stop-and-copy round. For page dirty rates near link speed, total migration time approaches its upper bound (Equation 3) as migration stops when 3x VM size has been transferred. Then, it starts to fall back towards its lower bound.

For extremely high page dirty rates (compared to link speed), migration is forced to reach its final transfer stage after 29 iterations having sent virtually no pages.² It then has to transfer the entire RAM in the final iteration. This is exemplified clearly for the 100 Mbps link in Figure 4, in which the total migration time drops back to its lower bound (almost all dirty pages are skipped in every iteration except the final one) while having a total downtime (Figure 3) at its upper bound (as the entire RAM has to be transferred in the stop-and-copy stage).

The first pre-copy iteration tries to copy across the entire VM allocated memory. The duration of this first iteration is thus directly proportional to the VM memory size and subsequently impacts total migration time. On average, total migration time increases linearly with VM size. On the other hand, the total downtime for low page dirty rates is almost the same regardless of the VM size as the migration

sub-system succeeds in copying all dirtied pages between successive iterations resulting in a short stop-and-copy stage. When the link is unable to keep up with the page dirty rate, larger VMs suffer longer downtime (linearly proportional to the VM size) as there are more distinct physical pages that require copying in the stop-and-copy stage.

Pre- and post-migration overheads refer to operations that are not part of the actual transfer process. These are operations related to initialising a container on the destination host, mirroring block devices, maintaining free resources, reattaching device drivers to the new VM, and advertising moved IP addresses. As these overheads are static, they are significant especially with higher link speeds. For instance, pre-migration setup constitutes around 77% of total migration time on a 1Gbps link for a 512 MB idle VM. More importantly, post-migration overhead is an order of magnitude larger than the time required for the stop-and-copy stage. To conclude this section, there are several parameters affecting migration performance. These parameters may be classified as having either a static or dynamic effect on migration performance. Parameters having static effects are considered as unavoidable migration overheads. On the other hand, parameters having dynamic effects on migration affect only the transfer process. Dynamic parameters are typically related to the VM specification and applications hosted inside it.

We show that the page dirty rate and link speed are the major factors influencing migration times. We also show how particular combinations of these factors can extend expected total migration time and downtime. Finally, we observe that the pre- and post-migration overheads become significant compared to the iterative pre-copy and stop-and-copy stages, especially for VMs that have low page dirty rates and are being migrated over high speed links.

V. CONCLUSION

In this paper, we studied live migration behaviour in precopy migration architectures, specifically using the Xen virtualisation platform. We show that the link speed and page dirty rate are the major factors impacting migration behaviour. These factors have a non-linear effect on migration performance largely because of the hard stop conditions that force migration to its final stop-and-copy stage. In a virtualised environment, administrators can dynamically change VM placements in order to plan maintenance, balance loads, or save energy. Live migration is the tool used.

Future Scope

The experiments that we have carried out prove that the migration link speed is the most influential parameter on performance. We have been working on local area networks assuming live migration inside one datacentre. However, moving workloads between different data centres, especially for cloud providers, is also useful. We plan to further utilise the models to study migration behaviour on wide area networks.

Abstract : The e-Learning provides the Learners to interact each other as well as with teachers. The new technology virtual learning system (VLE) is used to interact between the student and teacher. The vast improvement in the field of information technique leads to share of information resources. The development in e-Learning system which arise a new way of distributing knowledge around the world without any restrictions. The e-Learning system has huge volume of recourse sharing at various places. The e-Learning retrieval system contains various information's that can be shared and communicate between the Learners in a course and store Resources from the various server can be retrieved. So there is a need to measure the sharing of resource using specific technique. The data mining clustering technique is used to retrieve the recourse of the e-learning system and measure the recourse shared.

Keywords: LMV, VLE, e-Learning, Data Mining, KDD; EDM

I. INTRODUCTION

1.1 E-Learning Systems

The e-Learning system consists of acquiring knowledge and recourse sharing. The e-Learning system can enable better allocation of resources and organize the learning processes in order to improve the learning experience of the student as well as increase their learning Knowledge [1].

The e-Learning systems increase the sharing of recourses providing recourse material to learners. The recourse is being centralized using server is locate worldwide. The e-Learning recourse in much discipline the related recourse are grouped based on the course as per the leaner wish. The learner can select the course material as Text, PPT, video which is related to the course. The e-learning system provides fast easy and efficient of recourse material can retrieved by data mining clustering technique.

1.2 Theory of e-Learning

The e-Learning system accumulates a vast amount of information which is valuable for learner development. The learning management systems accumulate a great deal of student activities can record whatever student activities are involved such as reading writing talking test performing various task and even communicating with other. The e-Learning system facilities of communication between educators, sharing resources, producing content material, preparing assignment, enabling synchronous learning with forms chat, new services, of e-Learning system which improves the knowledge of the learner accessing open resources with waste of resources.

II. Applying Data Mining Technique

Data mining or knowledge discovery in database (KDD) is the automatic extraction of implicit and interacting. Data mining is a multidisciplinary area in which several computing paradigms converge decision tree construction, rule induction, K-means, SVM, Apriori, Page Rank, AdaBoost, KNN, Naïve Bayss, And CART algorithms etc And some of the most useful data mining task and method are static's Visualization, clustering classification, association rule mining ,sequential pattern mining text mining, etc.

2.1 Educational Data Mining

Due to the large quantities of data in e-learning systems, it is very difficult for educators to analyze them manually. Educational Data Mining EDM the area of scientific inquiry centered on the development of methods for making discoveries within the unique kinds of data. That come from educational settings, and using those methods to better understand students and settings which they learn in Educational Data Mining is an emerging discipline, with developing methods for exploring unique types of data that come from educational settings, and using those methods to better understand students, and the settings which they learn in as defined by The Educational Data Mining community.

The Educational Data Mining providing research efforts in the field, review of the many applications of Data Mining to e-learning. The review of the history and current trends of EDM review of most relevant studies carried out in this field. Data mining techniques relation with the fields of Artificial Intelligence (AI) and Machine Learning (ML) have been highlighted in many researches are classified into four main areas 1) improving student models, that provide detailed information about a student's characteristics; 2) discovering models of the knowledge structure of the domain 3) studying the pedagogical support provided by learning software 4) scientific discovery about learning and learners. The first three categories are universal across different fields of data mining are categories particularly related to educational data mining[2].

- Statistics and visualization
- Web mining
- Text mining
- Prediction
- Clustering
- Relationship mining
- Distillation of data for human judgment
- Discovery with models

2.2 Using data mining Technique

In E-learning, clustering has been used for finding clusters of students with similar learning characteristics and to promote group-based learning and to provide learner diagnosis. Rapid Miner system has several clustering algorithms available. The K-Means has been used here. Clustering techniques apply when the instances of data are to be divided into natural groups. In k-means algorithm clusters are specified in advance prior to application of the algorithm provides a good review of different data mining clustering techniques.

The data mining technique is used in e-learning system which can able to download large volume of resources. The clustering technique is one of the data mining technique is used in the e-learning system for probably and distribution.

III. Concept Of Clustering

The Clustering is defined as the division of data in groups of similar object. The clustering is used for searching the relevant data as the linear request when the resource is not found in the related server. The clustering also helps to gather to relevant resource from the various servers with fast speed.

2.1 Clustering Technique

The clustering technique is broadly classified into two partitioning, Hierarchical clustering it sub divided into agglomerative and divisive. The hierarchical algorithms build clusters gradually partitioning algorithm learn cluster directly. They either try to discover cluster by iteratively relocating points between subset, or try to identify cluster as areas highly populated with data.

Partitioning relocation methods are further categorized into probabilistic clustering K-medoids methods. Such methods concentrate on how well points fit into their clusters and tend to build cluster of proper convex shapes.

Partitioning algorithm of the second type is surveyed in the section density-based partitioning. They try to discover dense connected components of the data, which are flexible in term of shape .density –based connectivity is used in the algorithm. They are less sensitive to outliers and can discover clusters of irregular shapes. They usually work with low dimensional data of numerically attributes, know as spatial data. Spatial objects could include not only points also extended objects[18].

IV. K-Mean Clustering Technique

The k-means clustering determine number of cluster k and we assume the center of these clusters can take any random object as the initial centroids. Then the k-means algorithm will do the three steps below until convergence. Iterate stable (=no object move group): 1. determine the centroid coordinate 2. Determine the object based on minimum distance.

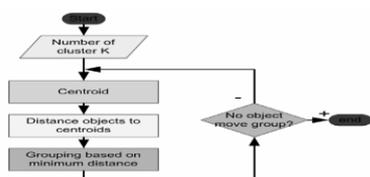

Figure 3: K-Mean Clustering Process

3.1 Distance calculation

The distance is the most commonly used of Euclidean distance. In most case when people said about distance they will refer to Euclidean distance. Euclidean distance or simply “distance examines the root of square difference between coordinates of a pair of objects.

For example :

Features k

	Cost	Time	Weight	Incentive
Object A	0	3	4	5
Object B	7	6	3	-1

Points a has coordinate (0, 3, 4, 5) and point B has coordinate (7, 6, 3, -1). The Euclidean Distance between point A and B is

$$d_{BA} = \sqrt{(0-7)^2 + (3-6)^2 + (4-3)^2 + (5+1)^2}$$

$$= \sqrt{49+9+1+36} = 9.747$$

Euclidian distance is a special case of Minkowski distance with $\lambda = 2$

V. K-MEANS ALGORITHM

k-means clustering is a method of cluster analysis which aims to partition n observations into k clusters in which each observation belongs to the cluster with the nearest mean. A set of observations (x_1, x_2, \dots, x_n) , where each observation is a d-dimensional real vector, k-means clustering aims to partition the observations into k sets $(k \leq n) S = \{S_1, S_2, \dots, S_k\}$ so as to minimize the within-

$$\arg \min_S \sum_{i=1}^k \sum_{x_j \in S_i} \|x_j - \mu_i\|^2$$

cluster sum of squares

where μ_i is the mean of points in S_i .

Classification - Tree Induction Results

The Tree Induction algorithm used to predict students’ potential performance was focused on using student assessment and e-Learning usage. Pessimistic pruning was applied to insure that the expected confidence levels obtained for predictions on the training data are similar to actual confidence levels obtained from unseen data. A set of rules was generated from the decision tree operator, showing interesting information about the supervised classification of the students. These rules classify at least three main categories of students: students with a low number of assignments are classified as FAIL; students with medium number of assignments quizzes are classified as FAIL or PASS depending on their quiz score, and students with a high number of assignments are classified as FAIL, PASS or EXCELLENT depending on number of actions in the e-Learning system etc. The rules generated from the Tree Induction Algorithm operator.

4.1 K-Means Results

The educator can use the cluster centroid K-Means results as presented in order to group Students into three types of students: very active students (cluster 0), active students (cluster 1) and nonnative students (2). This information helps educator to group students for working together in Collaborative activities. Students were divided in 3 groups based on their activities done in e-Learning Cluster 0 is characterized by most active students in e-Learning, with high assignment number, which participated to the online quiz and have a moderately number of discussion and forum read; Cluster 1 is characterized by moderately active students in e-Learning, with moderately assignment number, who participated or not to the online quiz in e-Learning with a low number of actions in the system.

4.2 Implementation of k-means

The k-means only allow numerical values for attributes in case it may be necessary to convert the data set into the standard spreadsheet format and convert categorical attributes to binary. It may also be necessary to normalize the value of attributes that are measured on substantially different scales. This K-mean algorithm automatically handles a mixture of categorical and numerical attributes. Furthermore the algorithm automatically normalizes numerical attributes when doing distance computations. The simple k-mean algorithm uses Euclidean distance measure to compute distance between instance and clusters.

To perform clustering select the cluster and clustering algorithm In this case we select ;simple K-means te value is used to generate a random number which in tirm used for making the initial assignment of instance to cluster. In general k-means is quite sensitive to how cluster are initially assigned. of instance to cluster.

Once the option have been specified , we can run the clustering algorithm. The result show the centriod of each cluster as well as statistics on the number and percentage of instance assigned to different cluster. The centroids can be used to characterize the cluster in through visualization cluster assignment. We can choose the cluster number and any of the other attributes for each of the three different dimensions available.

VI. DISCUSSION

Several data mining techniques such as: Attribute Clustering (K-Means), Classification, Association Mining (Apriori, FPGrowth, Create Association Rule, GSP) were applied to e-Learning summarization tables. By applying clustering methods, the goal was to split data set in groups of data points that naturally group together. Student actions were clustered together in order to investigate patterns of students behavior in the e-Learning System. KMeans algorithm was used to define clusters, which starts with no prior knowledge about groups in the data. By using prediction techniques, the goal was to develop a model that can infer predicted variables from predictors' variables. Inductive Decision tree algorithm was selected as classification method. The predicted variable was the categorical variable Final Mark. The target was to define variables that significantly affect in the Final Mark. By applying ARM, the goal was to discover relationships between variables. FPGrowth, Create Association Rule and APRIORI algorithms were selected as association rule mining techniques. The rules obtained can be explained in

the form that if some set of variable values is found, another variable will have a great chance to have a specific value.

VII. CONCLUSIONS

In this research, a data mining model for e-Learning data was proposed based on several techniques Attribute Clustering (KMeans), Classification , Association Mining (Apriori, FPGrowth, Create Association Rule, GSP) was proposed. This educational data mining work allowed identifying and locating information about E-learning processes that need improvements or those that perform very well and could be used as good examples. The educational data mining investigated in this research allows analyzing and better understanding the learning and teaching processes by applying data mining techniques. The experimental results have shown that the data mining model presented was able to obtain comprehensible, actionable and logical feedback from the LMS data describing students' learning behavior patterns. This work concentrated on the overall LMS performance at Epoka University and the mining Process of e-Learning data. Mining the e-Learning data allowed identifying the most effective ways to the teaching process that can be used to enhance the education process. To further test the effectiveness of the proposed model and to increase the generality of this research, more extensive experiments should be conducted by using larger LMS data sets.

Finite Element Analysis of Thin Walled-Shell Structures by ANSYS and LS-DYNA

T. Subramani¹ Athulya Sugathan²

¹Professor & Dean, Department of Civil Engineering, VMKV Engg. College, Vinayaka Missions University, Salem, India

²PG Student of Structural Engineering, Department of Civil Engineering, VMKV Engg. College, Vinayaka Missions University, Salem, India

ABSTRACT: Buckling is a critical phenomenon in structural failure. Buckling is the failure of structures under compression load. Also buckling strength of structures depends on many parameters like supports, linear materials, composite or nonlinear material etc. Also buckling behavior is influenced by thermal loads and imperfections. Analyzing all these conditions is difficult task. So few parameters are considered for the present work. Due to the advances in the Finite element techniques, analysis of these problems is possible which is difficult in earlier days. Formulae's are available based on experimental techniques for linear range and not available for nonlinear range. So these problems are solved by the advances in computer technology with Finite element techniques in the nonlinear domain. In the present work both cylindrical and elliptical members are considered for buckling strength. Initially both the members are created using Ansys top down approach. Scaling options are used to build the elliptical members. The structure is divided to ease map meshing. Initially one end constrained and other free condition is considered for analysis. The structure is fine meshed to get better results. Both Shell63 in elastic range and shell43 in plastic range are used for analysis. The elliptical results are compared with theoretical results to check Finite element validity. The results are very close and analysis is extended for circular members. The stresses and loads are very high with linear analysis. But the stresses and loads are considerably reduced with nonlinear analysis. The effect of thickness on buckling load and stresses are plotted. The buckling load is increasing with increase in thickness. The hinged boundary conditions shows higher buckling strength compared to the initial boundary conditions for both elliptical and cylindrical members. The problem executed in the time domain also indicates the stresses reaching to the yield point and converging towards the critical loads. All results are represented with necessary graphical and pictorial plots

KEY WORDS: Buckling, ANSYS, LS-DYNA, Linear and Non – Linear Analysis

I. INTRODUCTION

When a structure (subjected usually to compression) undergoes visibly large displacements transverse to the load then it is said to buckle. Buckling may be demonstrated by pressing the opposite edges of a flat sheet of cardboard towards one another. For small loads the process is elastic since buckling displacements disappear when the load is

removed. Local buckling of plates or shells is indicated by the growth of bulges, waves or ripples, and is commonly encountered in the component plates of thin structural members.

Buckling proceeds either in stable or unstable equilibrium state.

Stable: in which case displacements increase in a controlled fashion as loads are increased, ie, the structure's ability to sustain loads is maintained.

Unstable: in which case deformations increase instantaneously, the load carrying capacity nose- dives and the structure collapses catastrophically

Neutral equilibrium: is also a theoretical possibility during buckling - this is characterized by deformation increase without change in load. Buckling and bending are similar in that they both involve bending moments. In bending these moments are substantially independent of the resulting deflections, whereas in buckling the moments and deflections are mutually inter-dependent - so moments, deflections and stresses are not proportional to loads

If buckling deflections become too large then the structure fails - this is a geometric consideration, completely separated from any material strength consideration. If a component or part there for is prone to buckling then its design must satisfy both strength and buckling safety constraints - that is why Buckling is important.

1.1 TYPES OF BUCKLING OF STRUCTURES

1.1.1 Buckling of thin-walled structures

A thin-walled structure is made from a material whose thickness is much less than other structural dimensions. Into this category fall plate assemblies, common hot- and cold-formed structural sections, tubes and cylinders, and many bridge and aeroplane structures.

1.1.2 Plate and thin shell buckling

Local buckling of an edge-supported thin plate does not necessarily lead to total collapse as in the case of columns, since plates can generally withstand loads greater than critical. However the P-q curve illustrates plates' greatly reduced stiffness after buckling, so plates cannot be used in the post-buckling region unless the behavior in that region is known with confidence. It should be emphasized that the knee in the P-q curve is unrelated to any elastic- plastic yield transition; the systems being discussed are totally elastic. The knee is an effect of overall geometric rather than material instability

1.1.3 Torsional Buckling

Torsional buckling of columns can arise when a section under compression is very weak in torsion, and leads to the column rotating about the force axis. (Figure.1)

1.1.4 Flexural Torsional Buckling

More commonly, where the section does not possess two axes of symmetry as in the case of an angle section, this rotation is accompanied by bending and is known as flexural torsional buckling.

1.1.5 Lateral Buckling

Lateral buckling of beams is possible when a beam is stiff in the bending plane but weak in the transverse plane and in torsion, as is the I-beam of the sketch. It often happens that a system is prone to buckling in various modes. These usually interact to reduce the load capacity of the system compared to that under the buckling modes individually. An example of mode interaction is the thin box section which develops local buckles at an early stage of loading, as shown greatly exaggerated here. The behavior of the column is influenced by these local buckles, and gross column buckle will occur at a load much less than the ideal Euler load

FIGURE.1 TORSIONAL BUCKLING

Stability of Equilibrium:

Buckling properties of a system are reflected in the shape of the equilibrium path, i.e. the load-deflection curve. If a system is in equilibrium then its total potential energy, U , has a turning value since an infinitesimal disturbance, $d\delta$, of the system from its equilibrium position does not change the potential energy (PE) - δ is any convenient characterizing displacement. Expressed mathematically, the equilibrium path is thus defined by:

$$U' \equiv dU/d\delta = 0$$

The type of equilibrium which exists at any point on the path - stable, neutral or unstable - is also an important consideration; it may be deduced by taking the second derivative :-

$$U'' = d^2U/d\delta^2 \begin{cases} > 0 & ; \text{ PE - minimum} \\ & \text{stable equilibrium} \\ = 0 & ; \text{ PE - zero slope} \\ & \text{neutral equilibrium} \end{cases}$$

II. Finite Element Methods

2.1 INTRODUCTION

Today, finite element method enjoys a position of predominance among the computational methods to occur in this century, within only a few decades this technique has evolved from one with initial application in analysis of aircraft structure as early as 1941 and in structural engineering to a widely utilized and richly varied computational approach

for many scientific and technological areas. The stress analysis in the field of structural mechanics is invariably complex and for many of the engineering problems; it is extremely difficult and tedious to obtain analytical solutions. In this situation, most of the practical problems are solved by numerical methods, which provide approximate but acceptable solutions. With the advent of computers, one of the most powerful techniques that has emerged from the realm of engineering analysis is the finite element method and the method being general, can be used for the analysis of structures are solid of complex shapes and complicated boundary conditions.

The basic concept of finite element method is discretization of a structure into finite number of elements, connected at finite number of points called nodes. The material properties and the governing relationships are considered over these elements and expressed in terms of nodal displacement at nodes. An assembly process duly considering the loading and constraints results in a set of equations governing the structural response, which are established through the application of appropriate variation principle. Solutions of these equations give the response of the structure. Selecting proper elements and subdividing the structure with large number of finite elements or by taking higher order elements can increase the accuracy of solution obtained by finite element method. In modern design practice, with the advent of large and fast modern digital computers and advancement in numerical techniques; solutions to various static and dynamic problems has become fast and efficient.

2.2 TYPES OF ELEMENTS

Few Important FEM elements are as follows.

TRUSS: Slender element (length \gg area) which supports only tension or compression along its length; essentially a 1D spring.

1. BEAM: Slender element whose length is much greater than its transverse dimension which supports lateral loads, which cause flexural bending.
2. TORSION: Same as truss but supports torsion.
3. 2D SOLID: Element whose geometry definition lies in a plane and applied loads also lie in the same plane. Plane stress occurs for structures with small thickness compared with its in plane dimension - stress components associated with the out of plane coordinate are zero. Plane strain occurs for structures where the thickness becomes large compared to its in plane dimension - strain component associated with the out of plane coordinate are zero.
4. PLATES: Element whose geometry lies in the plane with loads acting out of the plane which cause flexural bending and with both in plane dimensions large in comparison to its thickness - two dimensional state of stress exists similar to plane stress except that there is a variation of tension to compression through the thickness.
5. SHELLS: Element similar in character to a plate but typically used on curved surface and supports both in

plane and out of plane loads – numerous formulations exist.

6. 3D SOLID: Element classification that covers all elements - element obeys the strain displacement and stress strain relationships.

2.3 MERITS OF FINITE ELEMENT METHOD

The systematic generality of finite element procedure makes it a powerful and versatile tool for a wide range of problems. Thus, flexible, general-purpose computer programs can be developed and can be applied to various problems with little or no modification. FEM can be easily interpreted in physical terms. As well it has a strong mathematical base. Hence, finite element method can be easily applied to any problem with a proper knowledge of the physical system under consideration and can be solved to a greater accuracy by the application of proper mathematical tool. Non-homogenous continuum can also be dealt with by merely assigning different properties to different elements. It is even possible to vary the properties within an element according to the polynomial applied. Finite element method accommodates complex geometry with ease and is capable of handling non-linear and time dependent system also. In finite element method, since boundary conditions are introduced in the assembled equations, it requires only to specify the geometric boundary conditions without regarding its effects on interior elements. Since the boundary conditions do not enter into the individual finite element equations, the field variable models need not be changed, when the boundary conditions change. Finite element method considers the multidimensional continuity of body. Hence it does not require separate interpolation process to extend the approximate solution to every point with in the continuum. It does not also require the trial solutions that must all apply to the entire multidimensional continuum.

2.4 DEMERITS OF FINITE ELEMENT METHOD

The solution obtained from FEM can be realistic if and only if the material properties are known precisely.

The major drawback of FEM is sensitivity of the solution on the geometry of the element such as type, size, number, shape and orientation of elements used.

The computer programs of FEM require relatively a large computer memory and time.

FEM Programs yield a large amount of data as results. It is very difficult to separate out the require results from the pile of numbers.

III. ANSYS - INTRODUCTION

ANSYS is a commercial FEM package having the capabilities ranging from a simple, linear, static analysis to a complex, nonlinear, transient dynamic analysis. It is available in modules. Each module is applicable to specific problem. For example, Ansys/Civil is applicable to Civil structural analysis. Similarly Ansys/Flotran is CFD software applicable to Fluid Flow. The advantage of Ansys compared to other competitive software's is, its availability as bundled software

of pre, post and a Processor. Typical Ansys program includes 3 stages.

- Pre-Processing
- Solution
- Post-Processing

3.1 MODELING

This is the important step of creating the physical object in the system. They are two types of modeling in Ansys.

Direct Modeling & Solid Modeling

1. DIRECT MODELING: In this approach the physical structure is represented by nodes and elements directly. The problem is solved once after the boundary conditions are applied. This approach is simple and straight forward. Takes very little time computation. But this can be applied only for simple problems. When problem becomes complex, this method becomes tedious to apply.

2. SOLID MODELING: Models are directly created either using Ansys Preprocessor or imported from popular CAD soft wares like Mechanical Desktop, Pro/E, CATIA, SOLID WORKS etc. Once the structural model is created, by using mesh tool, the model can be meshed and problem can be solved by applying the boundary conditions. In Ansys Solid modeling is carried out using two methods. They are

1. Bottom Up Approach: To create model, Entities are required. Keypoints, Lines, Areas, Volumes are the entities in Ansys. If model is constructed through Keypoints to Lines, From Lines to Areas, and From Areas to Volumes the approach of modeling is called Bottom Up Approach. This approach is useful when models are complex.

2. Top Down Approach: A 3D Model can be created directly using the Volumes. Once Volumes are created, all the entities below the volumes (areas, lines, keypoints) are automatically created. This approach is easy but can be applied to simple problems.

3.2 TYPES OF BUCKLING ANALYSIS:

Ansys supports two types buckling analysis

- Non-Linear Buckling
- Eigen Value Buckling analysis

3.2.1 .Non-Linear Buckling

Nonlinear buckling analysis is usually the more accurate approach and is recommended for design or evaluation of actual structures. This technique employs a nonlinear static analysis with gradually increasing loads to seek the load level at which the structure becomes unstable. Using the nonlinear technique, model can include features such as initial imperfections, plastic behavior, gaps, and large-deflection response. In addition, using deflection-controlled loading, we can even track the post-buckled performance of the structure (which can be useful in cases where the structure buckles into a stable configuration, such as "snap-through" buckling of a shallow dome).

3.2.2. Eigen value buckling

Eigen value buckling analysis predicts the theoretical buckling strength (the bifurcation point) of an ideal linear

elastic structure. This method corresponds to the textbook approach to elastic buckling analysis: for instance, an eigenvalue buckling analysis of a column will match the classical Euler solution. However, imperfections and nonlinearities prevent most real-world structures from achieving their theoretical elastic buckling strength. Thus, eigenvalue buckling analysis often yields unconservative results, and should generally not be used in actual day-to-day engineering analyses.

Procedure for Eigenvalue Buckling Analysis

Eigenvalue buckling analysis generally yields unconservative results, and should usually not be used for design of actual structures. The procedure of eigenvalue buckling analysis is as follows.

- Building the model.
- Obtaining the static solution.
- Obtaining the eigenvalue buckling solution.
- Expanding the solution.
- Reviewing the results.

1. Building the model

The Model is built is either through Bottom up Approach or Top down Approach and should be meshed with appropriate elements. Proper material and geometric properties (Real properties) should be supplied. Finally Boundary conditions should be supplied.

2. Obtaining the Solution

The following should be followed to obtain proper solution Prestress effects [PSTRES] must be activated. Eigenvalue buckling analysis requires the stress stiffness matrix to be calculated.

Unit loads are usually sufficient (that is, actual load values need not be specified). The eigenvalues calculated by the buckling analysis represent buckling load factors. Therefore, if a unit load is specified, the load factors represent the buckling loads. All loads are scaled. Eigenvalues represent scaling factors for all loads. If certain loads are constant (for example, self-weight gravity loads) while other loads are variable (for example, externally applied loads), we need to ensure that the stress stiffness matrix from the constant loads is not factored by the eigenvalue solution. One strategy that we can use to achieve this end is to iterate on the eigen solution, adjusting the variable loads until the eigenvalue becomes 1.0 (or nearly 1.0, within some convergence tolerance). Design optimization could be useful in driving this iterative procedure to a final answer.

3. Obtaining the Eigen value buckling Solution:

After executing the program for static solution, again solution should be changed to Eigen Buckling and extraction technique should be specified.

4. Expanding the Solution:

Solution should be expanded to obtain the critical buckling loads.

5. Reviewing the results:

Results can be reviewed through /post1. Through result summary critical buckling in the form of natural frequencies can be viewed. By using the read set option for different critical loads, deflection and stress patterns can be viewed.

IV. PROBLEM DEFINITION AND FINITE

4.1 ELEMENT MODEL DEVELOPEMENT

Definition:

Buckling analysis is a technique used to determine buckling loads - critical loads at which a structure becomes unstable - and buckled mode shapes - the characteristic shape associated with a structure's buckled response. The analysis will be carried out using both implicit and explicit techniques.

- Analysis of elastic buckling nature of the cylindrical and elliptical vessels under compression loads
- Effect of thickness on stress generation in the structure
- Effect of thickness on buckling strength
- Effect of diameter on buckling strength and stress generation.
- Effect of non linearity in the buckling strength of structures.

Problem dimensions (initial)

- Outer diameter $D=400\text{mm}$
- Initial thickness $t=16\text{mm}$
- Height of the cylinder $=1200\text{mm}$
- Initial minor diameter of ellipse $=200\text{mm}$

Material Specification:

- Material : Structural Steel St42
- Young's Modulus $E=200\text{Gpa}$
- Poison's ratio $\nu=0.3$
- Density $\rho=7800\text{kg/m}^3$.

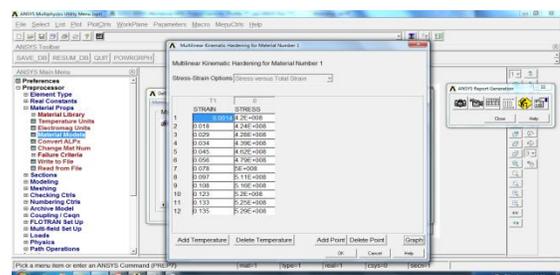

Figure.2 Nonlinear Properties of the Material

The Figure.2 shows applied nonlinear material properties of the problem. Most of the analysis is generally done in elastic range. But due to the advances in technology, load carrying capacity of the structures can be studied in the plastic range also. Also it helps in finding factor of safety in the structures. These nonlinear properties are obtained by experimental testing and recording.

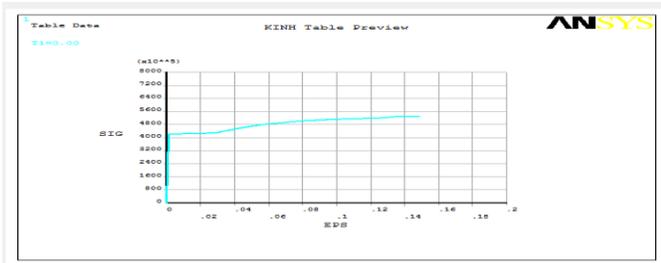

Figure.3 Stress – Strain Graph For The Material

The Figure.3 shows material graph for the problem. Initially the graph is straight and later sloping down indicating yielding of the structure. Generally above the yield by plastic modulus can be calculated using slope values or stress strain data can be supplied directly to find the nonlinear behavior of the structures.

Boundary conditions:

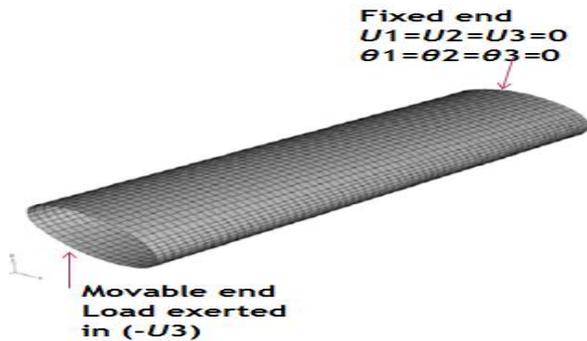

Figure.4 Boundary Conditions

For each of the two ends, two different types of boundary conditions(Figure.4) were used.

At the fixed end, displacement degrees of freedom in 1, 2, 3 directions (U_1 , U_2 , U_3) as well as rotational degrees of freedom in 1, 2, 3 directions (θ_1 , θ_2 , θ_3) were restrained to be zero. At the movable end, load was exerted with an even stress distribution in the longitudinal direction U_3 .

Mesh Size:

- No. of element s: 12000
- No. of nodes: 12120
- Size of element : 3.5m

Methodology:

- Analysis is carried out for EHS(Elliptical Hollow Sections) for minor diameter equal to half the major diameter and cylindrical geometries(CHS) in both elastic and nonlinear range to find the buckling strength.
- Initial thickness=16mm
- Iterations are carried out to find the buckling stress variation for different thickness to compare with theoretical values.

Element Type:

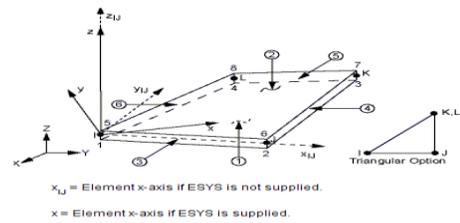

Figure.5 Shell63

SHELL63 (Figure.5) has both bending and membrane capabilities. Both in-plane and normal loads are permitted. The element has six degrees of freedom at each node: translations in the nodal x, y, and z directions and rotations about the nodal x, y, and z-axes. Stress stiffening and large deflection capabilities are included. A consistent tangent stiffness matrix option is available for use in large deflection (finite rotation) analyses.

4.2 ASSUMPTIONS

- The Member is initially perfectly straight and is axially loaded.
- The material is elasto-plastic with strain hardening materials.
- The self weight of the structure is not considered
- The member will fail by buckling alone.
- Imperfections of members are not considered.

V. RESULTS & DISCUSSION

Initially the linear elastic buckling is carried out for the structures and later nonlinear buckling analysis is carried out using elastic buckling loads to find actual buckling capacity of the structures. Comparative study is carried out between buckling, strength, buckling stress of cylindrical and elliptical members for buckling strength and stress generation. The formulae's are based on elastic material assumption. But this assumption is not true in the nonlinear conditions. So for nonlinear conditions, analysis has to be carried out after getting initial estimation of loads from linear elastic analysis. This linear elastic analysis helps in initial estimates of load carrying capacity and generally to make a comparative study of the material strength. In the beginning analysis is carried out for elliptical members under elastic material behavior. The formulae's for theoretical checking and analysis results are as follows.

Theoretical formulae for Elastic buckling stress for Cylindrical hollow members:

$$\sigma = \frac{2Et}{D\sqrt{3(1-\nu^2)}}$$

Where

Where E= Young's modulus

t=Thickness of vessel

D= Diameter of the cylindrical member

For Elliptical members buckling stress formulae is

$$\sigma = \frac{Et}{\frac{A^2}{B} \sqrt{3(1-\nu^2)}}$$

Where A= Major radius
 B=Minor radius
 v=Poison's ratio

Results for Elastic buckling Stress estimates(EHS):

Initially analysis has been carried out for buckling process and results are represented as follows.

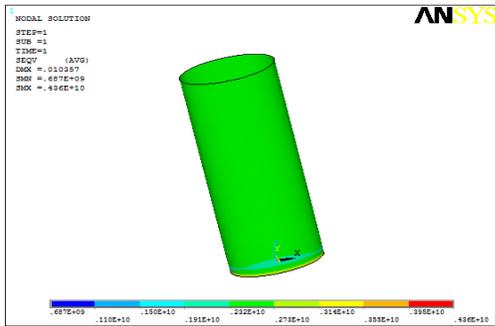

Figure.6: Buckling Stress For Elastic Buckling (Results For T=16mm D1/D2=2)

The Figure.6 shows a buckling stress of around 4360MPa due to elastic buckling. Since material property is assumed as linear, the stress levels are crossing the yield limits. But if material is considered as nonlinear, then the correct stresses can be estimated. This is done in the next stage of analysis. Maximum stresses are observed at the base of the structure.

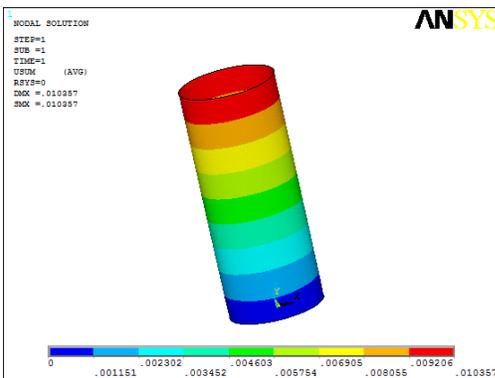

Figure.7 Deformation Plot For Elastic Buckling (Results For T=16mm D1/D2=2)

The Figures.7 shows maximum deformation of 0.010367mm for the given buckling load. Maximum deformation can be observed at the free end and minimum displacement can be observed at the constraint end. The status bar indicates varying displacements across the problem.

Comparative results for EHS

Table.1 Shows The Comparative Results Of Buckling Stresses And Buckling Loads Ehs Members

Thickness (in mm)	Buckling Stress(Theoretical) (in Gpa)	Buckling stress (FEM) (in GPa)	Percentage error (in %)	Buckling Load(FEM) (in N)
16	4.68	4.36	6.82	0.40200E+08
13.3	3.94	4.16	5.45	0.32558E+08
11.42	3.46	3.66	5.78	0.25042E+08
10	3.02	3.16	4.63	0.19233E+08
8.88	2.69	2.78	3.34	0.15239E+08
8	2.2	2.28	3.63	0.12446E+08

Table.1 Comparative Results of Buckling Stresses And Buckling Loads Ehs Members

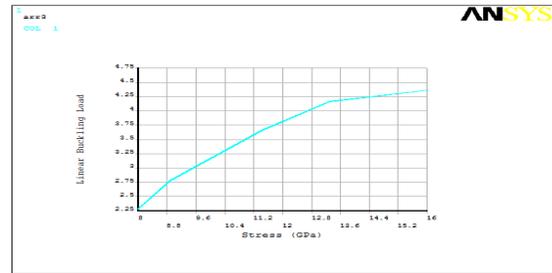

Figure.8 Stress Vs Thickness

The graph (Figure.9) represents stress and thickness relation during buckling process. For smaller thickness stress raise is high, but later the slope is reducing with increase in thickness. So the relation is not linear with buckling estimations.

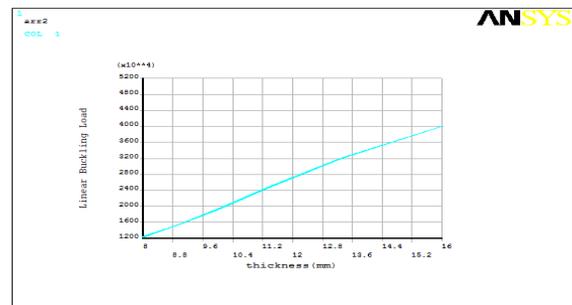

Figure.9 Load Vs Thickness

The graph (Figure.9.) represents Buckling Load and thickness relation during buckling process. Here almost linear relation can be observed for load and thickness due to elastic material assumption. From the graph it can be estimated for possible buckling load for higher thickness.

With nonlinear properties (EHS):

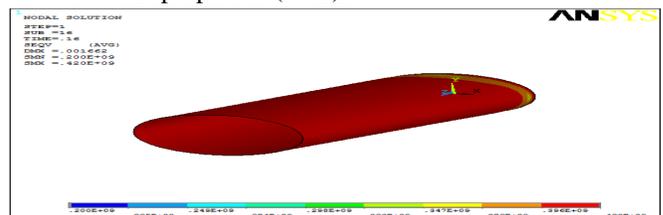

Figure.10 Buckling Stress For Nonlinear Buckling (Results For T=16mm D1/D2=2)

The Figure.10 shows a buckling stress of around 420MPa due to nonlinear buckling. The stresses are practical compared to elastic buckling where stresses becomes infinite and nonreliable. But for comparative studies, the analysis will be done using elastic conditions. Generally Young's modulus is defined in the elastic region and later either plastic modulus or stress strain data will be given after yield point. This stress strain data is obtained through experimental testing for the material.

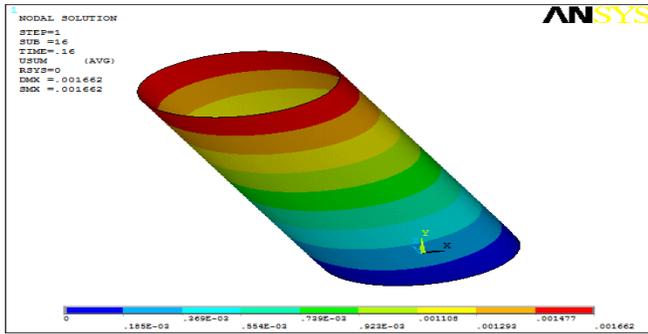

Figure.11 Deformation Plot For Nonlinear Buckling (Results for T=16mm D1/D2=2)

The Figure.11 shows maximum deformation of 0.001662mm for the given buckling load. Maximum deformation can be observed at the free end and minimum displacement can be observed at the constraint end. The status bar indicates varying displacements across the problem.

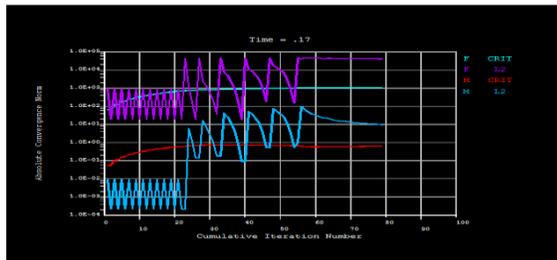

Figure.12 Nonlinear Execution

Whenever material is given nonlinear properties, convergence graphs can be observed. Mainly nonlinear problems depends on indirect or iterative solvers. This iterative solvers splits the problem into number of stages and in each stage they try to get convergence between applied load and reaction loads. These techniques consumes maximum resources of the computer and requires almost 100times more then the elastic buckling problems. Generally Ansys checks with load and reactions along with mathematical convergence for matrix using either L2norm or absolute norm. In the problem both force and moment convergence is considered.

The Figure.12 shows deformed and un-deformed shape of the problem. Maximum deformation can be observed at the loading region. White colour in the plot represents original configuration and blue region indicates deformed region.

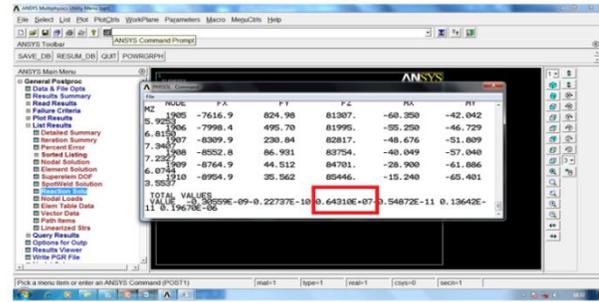

Figure13 Reaction Load Estimation For Buckling

The Figure.13 shows reaction loads estimated from nonlinear buckling. Maximum of 6431000N can be observed for the buckling of the system. This value is taken from final reaction value after problem is converged for buckling solution. This nonlinear buckling load is much smaller then the calculated elastic buckling load. So nonlinear analysis gives much better results compared to the elastic buckling analysis.

Table.2 Comparative Table For Linear And Nonlinear Buckling Values

Thickness (mm)	Nonlinear Buckling load (N) - B	Linear Buckling load (N) - A	Ratio(B/A)
16	0.64317E+07	0.40200E+08	.159
13.33	0.52091E+07	0.32558E+08	.159
11.42	0.45074 E+07	0.25042E+08	.179
10	0.40385 E+07	0.19233E+08	.208
8.88	0.35044 E+07	0.15239E+08	.229
8	0.32355 E+07	0.12446E+08	0.255

The Table: 2 shows comparative buckling loads for both elastic and nonlinear problems. The results almost nonlinear loads are almost 15% of elastic loads. Also this proportion is reducing with reduction in thickness. So a nonlinear study helps in finding the actual loading capacity of the EHS columns.

VI. Analysis Results For Cylindrical Members(Chs):

Analysis has been carried out for buckling process and results are represented as follows.

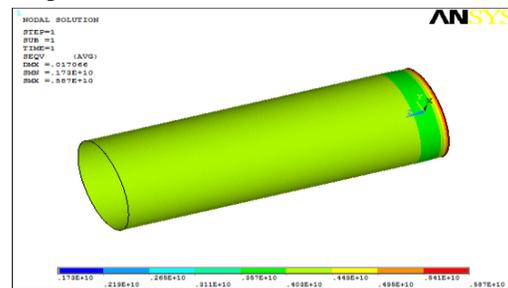

Figure.14

Buckling Stress For Elastic Buckling (Results For T=16mm D1/D2=1)

The Figure:14 shows a buckling stress of around 5870MPa due to elastic buckling. Since material property is assumed as linear, the stress levels are crossing the yield limits. But if material is considered as nonlinear, then the correct stresses can be estimated. Further analysis will be

carried out in elastic range. Maximum stresses are observed at the base of the structure.

nonreliable. This stress is similar for the elliptical sections as the stress levels reaching to the yield point of the problem.

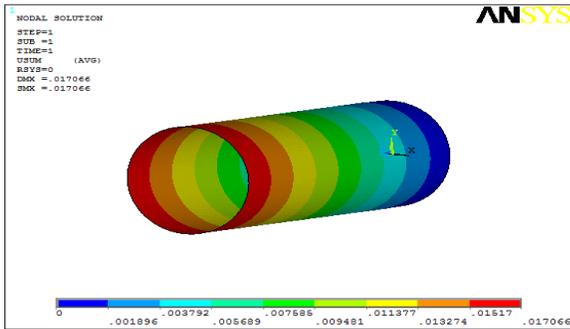

Figure.15 Deformation Plot For Elastic Buckling (Results For T=16mm D1/D2=1)

The Figure.15 shows maximum deformation of 0.017mm for the given buckling load. Maximum deformation can be observed at the free end and minimum displacement can be observed at the constraint end. This value of deformation is higher than the elliptical structure.

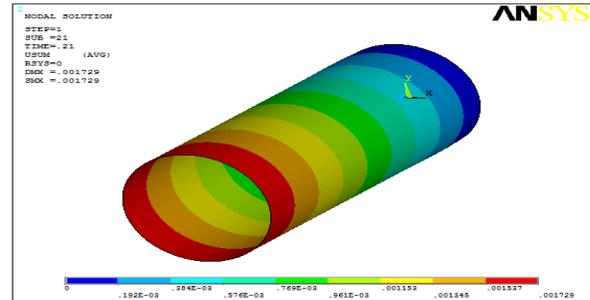

Figure.17; Deformation Plot for Nonlinear Buckling (Results for T=16mm D1/D2=1)

The Figure.17 shows maximum deformation of 0.001728mm for the given buckling load. Maximum deformation can be observed at the free end and minimum displacement can be observed at the constraint end. The status bar indicates varying displacements across the problem.

Comparative results for CHS

Table.3 shows the comparative results of Buckling stresses and Buckling loads of CHS members

Thickness(mm)	Buckling Stress	Buckling Load
16	5860	0.65899E8
13.3	4880	0.46043E8
11.42	4170	0.34229E8
10	3670	0.26616E8
8	2980	0.17476E8

Table: 3 Comparative Results Of Buckling Stresses And Buckling Loads Of Chs Members

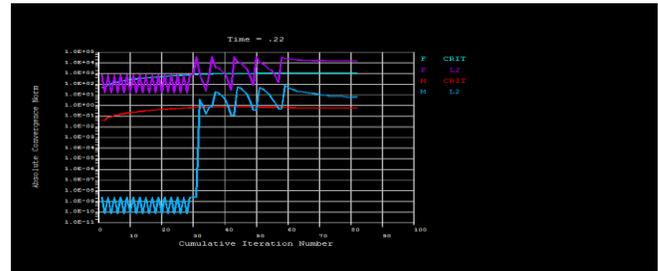

Figure.18: Nonlinear Execution

Convergence process can be observed in the graph. Sudden change of convergence indicates ill conditioned matrix and execution will stop indicating failure of the analysis for the given load or unstable configuration of the problem.(Figure.18)

With nonlinear properties (CHS):

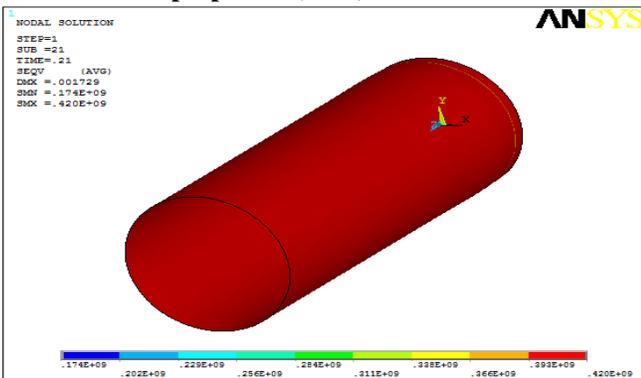

Figure.16 Buckling Stress for Nonlinear Buckling (Results for T=16mm D1/D2=1)

The Figure.16 shows a buckling stress of around 420MPa due to nonlinear buckling. The stresses are practical compared to elastic buckling where stresses become infinite and

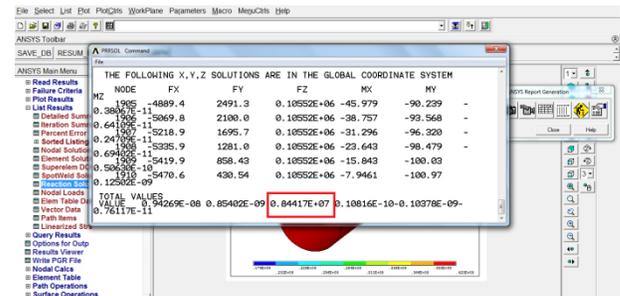

Figure.19 Reaction Load Estimation For Buckling

The Figure.19 shows reaction loads estimated from nonlinear buckling. Maximum of 8441600N can be observed for the buckling of the system. This value is taken from final reaction value after problem is converged for buckling solution. This nonlinear buckling load is much smaller than the calculated elastic buckling load.

Thickness (mm)	Nonlinear Buckling load (N) - B	Linear Buckling load (N) - A	Ratio(B/A)
16	0.8445E+07	0.65899E+08	.128
13.33	0.6836E+07	0.46043E+08	.148
11.42	0.6009 E+07	0.34229E+08	.176
10	0.51923E+07	0.26616E+08	.195
8	0.4106 E+07	0.17476E+08	0.234

Table.4 Comparative Table For Linear And Nonlinear Buckling Values

The Table.4 shows comparative buckling loads for both elastic and nonlinear problems. The results almost nonlinear loads are almost 15% of elastic loads. Also this proportion is reducing with reduction in thickness. So a nonlinear study helps in finding the actual loading capacity of the EHS columns.

VII. Linear Buckling Analysis With Hinged Boundary Conditions

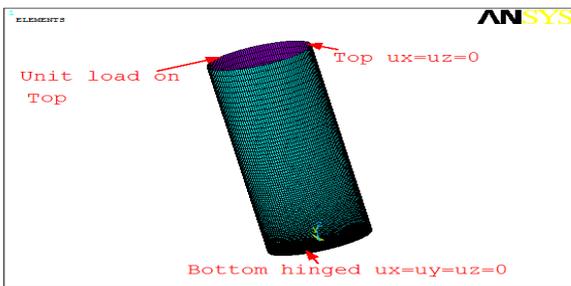

Figure.20 Boundary Conditions For Hinged Problem

The Figure.20 shows hinged boundary conditions for the shell problem. All bottom nodes are hinged and the top nodes are constrained in all translational directions except the unit loading direction. A total of 12000 elements with 12120 nodes are used for representation of the problem.

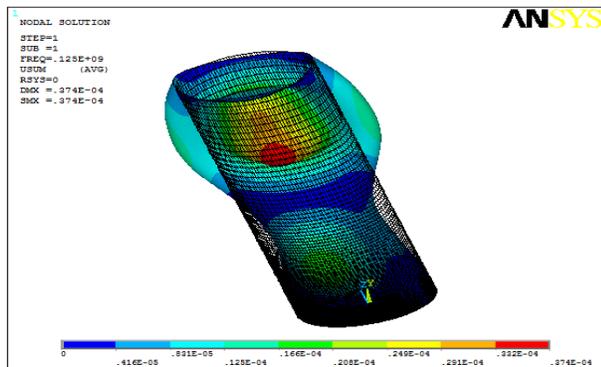

Figure.21 Buckled Mode For 1 St Buckling Load

The Figure.21 shows buckled mode shape of the problem. The buckling load value is around 0.125E9 N. the analysis is carried out for elastic assumption.

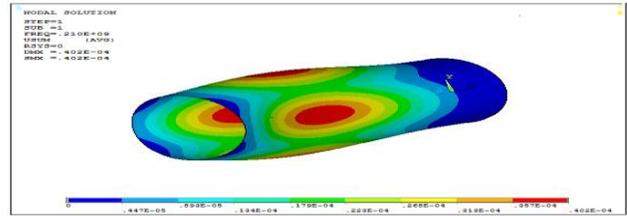

Figure.22 Mode Shape or Buckled Shape for Cylindrical Member

The Figure.22 shows buckled mode shape of the cylindrical shell problem. The buckling load value is around 0.210E9 N. the analysis is carried out for elastic assumption and buckling load is almost double to the elliptical shell.

VIII. ANSYS -LS-DYNA SIMULATION:

The ansys model is solved using Ansys-LS-Dyna solver for the buckling load for 16mm thickness. The system shows almost stress generation equal to 420Mpa which is yielding point of the structure. So Even LS-Dyna solver also shows (Figure.23) yielding of the structure for given nonlinear buckling load.

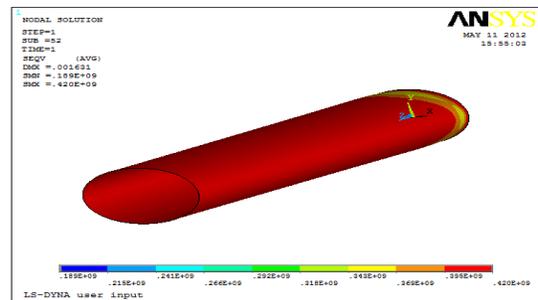

Figure.23 Von-Mises Stress Through LS-DYNA Solver

Maximum stress of 420Mpa can be observed with the nonlinear properties. For the given load for the stress strain data, stress increase in minimum but strain increase will exist in the problem. So it is better to apply strain based theories in the nonlinear buckling regions. No explicit algorithms are directly available to check the cylindrical structure buckling. But can be checked for given loads. Generally if the stress goes beyond allowable or yield stresses, then it can be taken as failure.

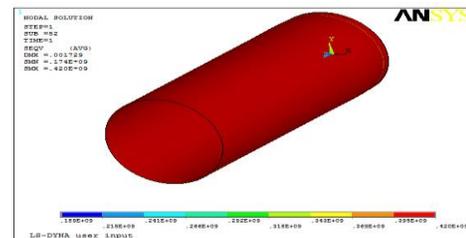

Figure.24 Stress Analysis through Ansys-Ls Dyna Solver

Using Ansys/Ls-Dyna solver the problem is executed. This is almost like Ansys pictures only as the

complete post processing (Figure.24) is done through ansys. Only solver interface will change. Only advantage of Dyna solver is no convergence problems faced with Ansys iterative solvers. The problem is done in time history processing for time equal to 1sec which creates equivalent static load for buckling by providing 'G' or gravitational loads.

IX. DISCUSSION

Buckling is main problem with many reactor vessels, pipe lines, storage vessels etc. This buckling may be due to compressive loads created due to self weight or outer members or internal pressure or may imperfections in the system. But structural failure creates huge loss to the inventory of company and also life of the system. So proper check need to be done for buckling of the components. In the present work, cylindrical and elliptical geometries are analyzed for buckling loads. Initially the geometry is built using Ansys preprocessor and later meshed with 4 noded shell with elastic and inelastic properties. Initially the analysis is done in the linear elastic domain. The results shows improperly higher stresses and buckling loads. This is due to application of linearity in the problem. Later the same members are analyzed actual material properties in the working conditions. The properties represents reality results in the practical conditions. But these may the system to consume more resources like memory and solution time. The loads obtained is almost less than the 15% of elastic buckling loads. The stresses are limited to the yield stress in the structure. The results shows linearity of buckling load for variation in thickness. But stresses are not following linear path. Similarly for nonlinear buckling analysis, along with thickness buckling is increasing but the stresses are almost limiting the yield stresses. The nonlinear analysis is carried out using Ansys-nonlinear-inelastic with multi-linear properties. Hinged boundary condition provides higher buckling load compared to the one end fixed and other end hinged conditions. The problem is also done explicit solvers using time domain. Again the stresses are limiting to yield point indicating the structure has reach to its critical value. The results also shows closeness of linear and nonlinear buckling loads at lesser thickness and large different for higher thickness members.

X. CONCLUSIONS & FURTHER SCOPE

A Finite element analysis is carried out to find buckling strength of cylindrical and elliptical structures. Cylindrical and elliptical members are mainly used in storage and other industrial applications. One estimate is that almost 30% industrial products are coming under these category. The results summary is as follows.

- Initially both cylindrical and elliptical geometries are built
- The geometry is meshed with small elements towards the constraint.
- Buckling analysis is carried out in both linear and nonlinear domain
- The stresses are very high in the linear region and for nonlinear analysis the stresses are within the practical working conditions.

- Nonlinear solution is an iterative solution and failure loads can be predicted by running the problem with more steps.
- A nonlinear material graph is considered for the nonlinear analysis.
- Shell63 element in the linear range and shell43 element is considered for plastic conditions. Shell63 is a linear element and does not support nonlinearity in the problem where as shell43 is a nonlinear element supports plasticity in the problem. But shell43 takes more time for execution.
- Initially for EHS, both theoretical and analysis values are compared to check Finite element solution with theoretical calculations. Also graphical plots are represented to find effect of thickness on stress and buckling strength estimates.
- The results shows reduction of nonlinear buckling loads compared to the elastic buckling loads. Almost nonlinear loads are only 15% of elastic loads. So nonlinear analysis is important to find actual buckling loads for the structure. Also buckling analysis is considered for hinged conditions. The results shows both elliptical and cylindrical members higher strength compared to the one end fixed and other free.

²PG Student, of Environmental Engineering, Department of Civil Engineering,
VMKV Engg. College, Vinayaka Missions University, Salem, India

Abstract: Utilisation of Bio-Gas is increasingly applied to produce renewable energy to minimize environmental emissions both resulting in reduction of green house gas. Despite Government Grants, the production of Bio- Gas is not commercialized and people mostly depend on natural gas which is non-renewable and depleting fast. The project aims at operation a pilot scale model of 20 litres capacity to evaluate the maximum yield of bio-gas from domestic sewage and kitchen waste. The organic loading and Hydraulic retention time of 25 days will be studied to improve the production of bio-gas and model will be developed. Suggestion and recommendations will be made to commercialise the production of bio-gas. A computer programme will be developed for optimum allocation of the above factors to generate more Bio- Gas based on the feed stock an effluent samples characteristics, such as pH, total solids, volatile solids, number of days, alkalinity, volatile fatty acid. A various digestion options and operational factors will be analysed to make the commercial production of Bio-Gas. A model will be developed with computer programme on the biogas from Kitchen waste and sewage water. The project aims at the usage of distribution of Bio-Gas, is renewable resource instead of Coal, petroleum which are non-renewable resource and fast depleting. Thus when the Bio-Gas is used as fuel in Transportation and Power generation, definitely this will be a mile stone in the economical development of our country

Keywords: Mathematical Model, Commercial Production, Bio-Gas, Sewage Water, Kitchen Waste

I. Introduction- The Biogas

The economic development of India depends to the large extent on the wheels of transport and power generation. With the fast depletion of non-renewable energy sources such as coal, petroleum, the commercial production of bio gas and use will definitely give a drive for the development of our country. Biogas is the product of the digestion of organic materials under anaerobic conditions. Substrates such as manure, sewage sludge, municipal solid waste, biodegradable wastes or feedstock are transformed into methane and carbon dioxide. Purified methane gas can be used as replacement to LPG.

Typical composition of biogas

- 50-75 % Methane, CH₄
- 25-50 % Carbon dioxide, CO₂
- 0-10* % Nitrogen, N₂
- 0-1 % Hydrogen, H₂
- 0-3 % Hydrogen sulphide, H₂S
- 0-2* % Oxygen, O₂

often 5 % of air is introduced for microbiological desulphurisation

The process of anaerobic digestion is done by methane bacteria. Necessary milieu conditions are:

- Anaerobic milieu
- Temperatures between 15°C and 55°C
- PH-values between 6.5 and 8.0
- A variety of feedstock which is not that big
- Avoiding retardants, such as heavy metal salts, antibiotics, disinfectants
- Existence of trace minerals such as nickel and molybdenum

1.1 Sustainability Of Biogas

The production of biogas is sustainable, renewable, carbon neutral and reduces the dependency from imported fossil fuels. Often operators or beneficiaries of biogas plants are able to become fully energy self sufficient. They produce the heat and electricity they consume. The use of biogas supports the objectives of the European Union of 20 % of renewable energy by 2020. Biogas is a carbon neutral way of energy supply. The substrates from plants and animals only emit the carbon dioxide they have accumulated during their life cycle and which they would have emitted also without the energetic utilization. On the whole, electricity produced from biogas generates much less carbon dioxide than conventional energy. 1 kW of electricity produced by biogas prevents 7,000 kg CO₂ per year. Other environmental benefits are:

- Reducing the emission of methane which is also a green house gas
- Establishing a decentralised energy supply
- Providing high quality fertilizers
- Reducing unpleasant local odours
- Strengthening regional economies and creating added value
- Fostering energy independence

1.2 The Potentials Of Biogas

Against the background of climate change and energy policy, there is a growing demand for sustainable, renewable and indigenous energy sources in Europe. Using materials for energy production, which otherwise are considered wastes or which disposal costs money, is convincingly clever.

In addition to the environmental benefits, the rising prices of conventional energy and the growing requirements for waste management of organic materials are further arguments in favour of biogas production.

But use of animal manure, organic waste and other types of biomass as energy sources will depend to a large extent on availability. Availability and implementation is strictly dependent on national and EU agricultural, environmental and energy policies. Co-digestion of animal manure and other types of suitable organic waste in biogas plants is an integrated process. On the background of renewable energy production, the process includes intertwined environmental and Agricultural Benefits, Such As

- Savings For The Farmers
- Improved Fertilisation Efficiency
- Less Greenhouse Gas Emission
- Cheap And Environmentally Sound Waste Recycling
- Reduced Nuisance From Odours And Flies
- Possibilities Of Pathogen Reduction Through Sanitation, All This Connected To Renewable Energy Production

Natural gas, oil and solid fuels dominate the primary energy supply of Romania with an aggregate share of 74% of the total. Total consumption has been slightly increasing over the last 3 years, having exhibited a significant decrease over the period 1990-1999.

The shares of oil and natural gas have shown an important reduction since 1990 and the supply of oil is now below EU-27 average of 38%. In contrast, renewable sources have been steadily increasing, accounting for the 12% of gross inland consumption, which is much higher than the EU-27 average of 6%. 40% of Romania is agricultural area and ca. 30% forest, but only 10% of the biomass are used for energy production. Currently biomass is merely used for heating purposes, direct burning for cooking and hot water preparation accounting for the largest share.

1.3 The Standard Process Of Biogas Production

In the standard process of biogas (Figure.1) production, the bioorganic material is processed before being fed into the biogas plant. The plant consists of a mixer, two digesters and gas storage. The digesters are also called fermentation tanks and are the crucial components of the plant since they provide the anaerobic conditions in which the bacteria generate biogas. The substrates have to be constantly heated and stirred in order to ensure their homogeneity and the consistent discharge of gas. The gas holder is normally an airtight steel container that, by floating like a ball on the fermentation mix, cuts off air to the digesters (anaerobiosis) and collects the gas generated. In one of the most widely used designs, the gas holder is equipped with a gas outlet, while the digesters are provided with an overflow pipe to lead the sludge out into a drainage pit. Landfill gas is produced by wet organic waste decomposing under anaerobic conditions in a landfill. The waste is covered and mechanically compressed by the weight of the material that is deposited from above. This material prevents oxygen exposure thus allowing anaerobic microbes to thrive.

This gas builds up and is slowly released into the atmosphere if the landfill site has not been engineered to capture the gas. Landfill gas is hazardous for three key reasons. Landfill gas becomes explosive when it escapes from the landfill and mixes with oxygen.

Landfill gas is hazardous for three key reasons. Landfill gas becomes explosive when it escapes from the landfill and mixes with oxygen. The lower explosive limit is 5% methane and the upper explosive limit is 15% methane.

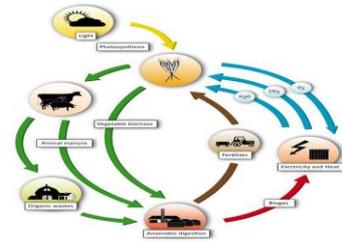

Figure.1. Process Of Biogas Production

1.4 Benefits Of Biogas

The ingredients like water vapour, hydrogen sulphide, and carbon dioxide and dirt particles are present in the biogas and hence it can be used after the extraction from the plant. However, after removing water vapour and carbon dioxide the biogas can be used like any clear natural gas. Input one other kind of using biogas is the feeding of gas into the gas network. Supplying biogas directly into the public natural gas grid requires biogas refinement to the quality of natural gas. Being as efficient as it is flexible, the biogas can be directed to the place where it is needed to be effectively used for generating electricity and heat.

II. OBJECTIVES

2.1 Goal

At present, bio gas is produced using cowdung in a digester. The methane content is 25% only. By mixing different proportion of kitchen waste, sewage water, it is possible to produce abundant bio gas which contains 60% methane and can be used as a replacement to coal and petrol for commercial purposes.

- Optimization of gas production
- Comparison with conventional plants
- Effect of different parameters viz.
 1. Temperature
 2. PH
 3. Total & volatile solid concentration
 4. Alkalinity
 5. C:N Ratio
- To increase the production by using
 1. Additives
 2. Nutrients
 3. Nitrogen source
- Check optimization of gas production at lab scale and field scale.
- Establishing mathematical model for production of bio gas.

2.2 Work Plan

This work is conducted in two phases, 1st at laboratory scale and 2nd at large scale in plastic tank.

2.3 Source Of Kitchen Waste

The waste used in this study is collected from my residence. Waste contains the cooked rice, vegetables and non-used vegetables waste. This waste is crushed by mixer grinder and slurry was prepared mixing with water.

2.4 Lab Scale

In lab scale this experiment was done in 1lit, 2lit & 20lit bottles, digester. Here different concentration & combination of wastes are used.

Different parameters of input and effluent like total solid, volatile solid, volatile fatty acid, pH, Temperature, Nitrogen, Carbon, Phosphorous will be measured. After that in 20 lit. plastic container study done to check the gas production.

2.5 Large Scale

Here two syntax tanks will be used, one of 1000 lit from digester and other of 750 lit for gas collector. Here also different parameter will be checked like

- Total solid – increasing the feeding rate from 100 gm to 5 kg and to check effect on gas production and effluent quality.
- PH – to check change in PH and control of PH
- Temperature effect

Quality and quantity of produced biogas

III. Precautions While Collecting The Sample**3.1kitchen Waste**

- A separate container for coconut shells, egg shells, peels and chicken mutton bones. These will be crushed separately by mixer grinders.
- Different containers of volumes 5l to collect the wet waste, stale cooked food, waste milk products. The vegetables refuse like peels, rotten potatoes coriander leaves collected in bags.

3.2 Installations

Important aspect in smoother running of plant by avoiding the choking of the plant. This occurs due to thick biological waste that not reaches to the microorganisms to digest. The easy answer to this problem is to convert solid wastes into liquid slurry. mixer can be used to convert solid into slurry.

IV. Analysis Of Gas Produced In Our Reactor**4.1 SYRINGE METHOD**

Syringe method was used for the measurement of amount of methane and carbon dioxide in our gas produced. A syringe fitted with flexible tube and dilute sodium hydroxide (NaOH) solution was used for carbon dioxide percentage estimation, since NaOH absorbs CO₂ but does not absorb methane.

V. Procedure Followed

- Prepare 100 ml of dilute sodium hydroxide solution by dissolving granules of NaOH in about 100 ml of water.
- Take 20-30 ml sample of biogas produced during experiment into the syringe (initially fill syringe with H₂O to reduce air contamination) and put end of the tube into the NaOH solution, then push out excess gas to get a 10 ml gas sample.
- Now take approximately 20 ml of solution and keep the end of the tube submerged in the NaOH solution while shaking syringe for 30 seconds.

- Point it downwards and push the excess liquid out, so that syringe plunger level reaches 10 ml. Now read the volume of liquid, which should be 3-4 ml indicating about 30-40% of gas absorbed so we can say the balance of 65-60% is methane.
- If the flame does not burn properly and you get over 50% methane (a reading of less than 5 ml of liquid) you must have nitrogen or some other gas present.

4.2 Composition Of Biogas

- Methane (50 - 65%)
- Carbon dioxide (30 - 40%)
- Nitrogen (2 - 3%)
- water vapour(0.5%) 27

VI. Methods Of Analysis & Calculations**6.1analytical Methods & Calculations****6.1.1 Total Solids (Ts %)**

It is the amount of solid present in the sample after the water present in it is evaporised.

The sample, approximately 10 gm is taken and poured in foil plate and dried to a constant weight at about 105 °C in furnace.

$$TS \% = (\text{Final weight}/\text{Initial weight}) * 100$$

6.1.2 Volatile Solids (Vs %)

Dried residue from Total Solid analysis weighed and heated in crucible for 2hrs at 500 °C in furnace. After cooling crucible residue weighed.

$$VS \% = [100 - (V_3 - V_1 / V_2 - V_1)] * 100$$

where

V₁ = Weight of crucible.

V₂ = Weight of dry residue & crucible.

V₃ = Weight of ash & crucible (after cooling)

6.1.2 Volatile Fatty Acid (Vfa)

Volatile fatty acids (VFA's) are fatty acids with carbon chain of six carbons or fewer. They can be created through fermentation in the intestine. Examples include: acetate, propionate, butyrate. I had used two methods for VFA measurement.

Method 1

1. Take 100 ml sample in beaker
2. Filter the sample.
3. Check pH of filtrate.
4. Take 20 ml of filtrate and add 0.1M HCl until pH reaches 4
5. Heat in the hot plate for 3 mins 28 .
6. After cooling titrate with 0.01N NaOH to take PH from 4 to 7.
7. Amount of HCl and NaOH recorded.

Total VFA content in mg/l acetic acid = (Volume of NaOH titrated) * 87.5

Method 2**Titration procedure for measurements of vfa and alkalinity according to kapp**

- Before analysis, the sample needs to be filtered through a 0.45µm membrane filter.

- Filtered sample (20-50ml) is put into a titration vessel, the size of which is determined by the basic requirement to guarantee that the tip of the pH electrode is always below the liquid surface.
- Initial pH is recorded
- The sample is titrated slowly with 0.1N sulphuric acid until pH 5.0 is reached. The added volume A1 [ml] of the titrant is recorded.
- More acid is slowly added until pH 4.3 is reached. The volume A2 [ml] of the added titrant is again recorded.
- The latter step is repeated until pH 4.0 is reached, and the volume A3 [ml] of added titrant recorded once more.
- A constant mixing of sample and added titrant is required right from the start to minimize exchange with the atmosphere during titration.

❖ Calculation scheme according to Kapp:

$$\text{Alk} = A * N * 1000 / \text{SV}$$

Alk = Alkalinity [mmol/l], also referred to as TIC (Total Inorganic Carbon).

A = Consumption of Sulphuric acid (H₂SO₄, 0.1N) to titrate from initial pH to pH 4.3 [ml].

A = A1 + A2 [ml]. N = Normality [mmol/l].

SV = Initial sample volume [ml].

$$\text{VFA} = (131340 * N * B / 20) - (3.08 * \text{Alk}) - 10.9$$

where

VFA = Volatile fatty acids [mg/l acetic acid equivalents].

N = Normality [mmol/l]

B = Consumption of sulphuric acid (H₂SO₄, 0.1N) to titrate sample from pH 5.0

to pH 4.0 [ml], due to HCO₃/CO₂ buffer. B = A2 + A3 [ml]

SV = Initial sample volume [ml]

Alk = Alkalinity [mmol/l]

• A/TIC-ratio

The A/TIC-method was developed at the Federal Research Institute for Agriculture (FAL) in Braunschweig, Germany. Used as an indicator of the process stability inside the digester, it expresses the ratio between Volatile Fatty Acids and buffer capacity (alkalinity), or in other words the amount of Acids (A) compared to Total Inorganic Carbon (TIC).

$$A [\text{mg/l}] = \text{VFA} [\text{mg/l}]$$

$$\text{TIC} [\text{mg/l}] = \text{Alkalinity} [\text{mg/l}]$$

6.2 ORGANIC CONTENT

Organic dry matter weigh the sample and weigh remaining ashes Organic content = {Mass of TS - Mass of ashes}/Mass of TS 30

VII. EXPERIMENTS

7.1 Experiment 1 (Lab Scale)

Figure.2 Shows The Lab Model

FIGURE.2 LAB MODEL

- A 2 litre bottle
- 50 gm kitchen waste + cow dung
- Rest water (1.5 litre)

Result

Gas production was found but not measured.

7.2 Experiment 2

Different sets of 1 litre & 2 litres bottles. Three different sets with different composition are installed as below.

- 200gm cow dung was mixed with water to make 1lit slurry which is poured in 1lit bottle.
- 50gm grinded kitchen was mixed with 150gm cow dung and water is added to make 1lit solution which is poured in 1lit bottle.
- 400gm cow dung was mixed with water to make 2lit slurry which is poured in 2lit bottle.

Results

In all of the 3 sets gas production occurs and gas burned with blue flame. process continues, volatile fatty acids(VFA) are produced which causes the decrease in PH of Solution

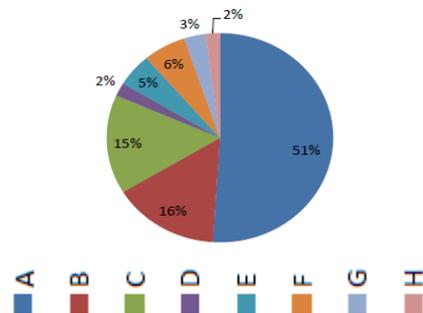

Figure.3 Composition Of Kitchen Waste

VIII. Composition Of Kitchen Waste

Figure.3 shows the Composition Of Kitchen Waste

- (A) Uncooked fruits & vegetables
- (B) Cooked meat
- (C) Uncooked meat
- (D) Bread
- (E) Teabags
- (F) Eggs
- (G) Cheesse
- (H) Paper

IX. DISCUSSIONS

From the result Table.1 it has been seen that in set2 which contain kitchen waste produces more gas, compare to other two set. In set2 with kitchen waste produces average 250.69% more gas than set 1 (with 200gm cow dung) and 67.5% more gas than set 3 (with 400gm cow dung). Means kitchen waste produces more gas than cow dung as kitchen waste contains more nutrient than dung. So use of kitchen waste provides more efficient method of biogas production.

TABLE.1 BIOGAS PRODUCTION (ML)

Set no./day	1 st day	2 nd	3 rd	4 th	5 th	6 th	7 th	8 th	Average
1	30	35	20	10	16	40	25	10	23.25
2	80	150	120	50	46	60	115	80.37	93.87
3	85	75	58	35	18	20	70	100	57.6

From results it has been seen (Figure.4) that pH reduces as the process going on as the bacteria produces fatty acids. Here methanogens bacteria which utilize the fatty acids, is slow reaction compare to other so it is rate limiting step in reaction.

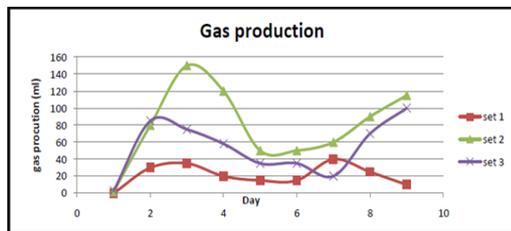

Figure.4 Gas Production Vs Day For 3 Sets

In set2 (Table.2.) which contains kitchen waste pH decreases highly means reaction is fast, means hydrolysis and acidogenesis reaction is fast as organism utilize the waste more speedily than dung. And total solid decreases more in set2.

Table.2. P^h And Total Solid Concentration Setup

Day	Set1		Set2		Set3	
	P ^h	TS%	P ^h	TS%	P ^h	TS%
1	7.25	8	7.2	6	7.25	8
4	6.7	7.6	5.8	5.4	6.6	7.5
5	6.85	7.6	6.45	5.4	6.9	7.5
8	6.65	7	4.92	4.7	6.5	7

Graph Analysis- It can be seen from the graph that gas production increases first upto day 3 but then it starts decreasing as acid concentration increases in the bottles and pH decreases below 7 after 4-5 days water was added to dilute which increases the pH, gas production again starts increasing. Therefore, we can infer that acid concentration greatly affects the biogas production.

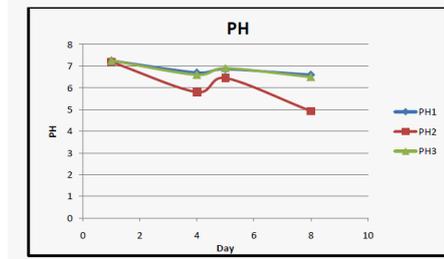

FIGURE.5 P^H V/S DAY

GRAPH – This graph (Figure.5) shows that first the ph is on higher side, as reaction inside the bottles continues it stars decreasing and after day 3 it becomes acidic. Than water added to dilute and thus pH increases.

9.1 Plan Of Biodigester

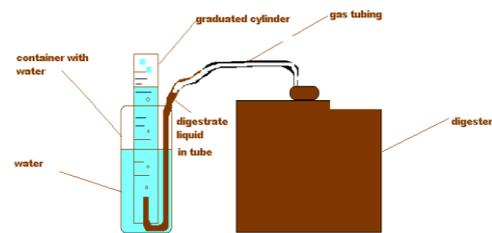

Figure.6. Diagram Of Bio-Digester
Figure.6. Shows the diagram of bio-digester

9.2 INSTALATION

Both the digester was installed in TWAD water testing lab at Dharmapuri. I used the 20 lit. Water container as digester. Following were the material used for 20 lit digester. Table.3 shows list of materials used in experiment no. 3

Table.3. List Of Materials Used In Experiment No. 3

No.	Product Name
1	20 litre container (used for drinking water storage)
2	Solid tape
3	M – seal
4	PVC pipe 0.5” (length ~ 1 m)
5	Rubber or plastic cape (to seal container)
6	Funnel (for feed input)
7	Cape 0.5” (to seal effluent pipe)
8	Pipe (for gas output, I was used level pipe) (3-5 m)
9	Bucket (15-20 litter)
10	Bottle – for gas collection (2-10 lit.)

9.3 Procedure And Start Up

Experiment 3(N) (Large Scale)

Fresh cow dung was collected and mixed with water thoroughly by hand and poured into 20 lit. digester. Content of previous experiment was used as inoculum. As it contains the required microorganism for anaerobic digestion. After the inoculation digester was kept for some days and gas production was checked. After some days kitchen waste was added for checking gas production. Figure.7. Shows anaerobic digester

Figure.7. Anaerobic Digester

9.4 EXPERIMENT 3(O):

Figure.8 shows Layout Of Experimental Setup 3 This digester contains the following composition.

- 20lit digester.
- Cow dung + inoculum + water added.
- Cow dung – 2.5 lit
- Inoculum - 3.8 lit
- Water – 13.5lit PH – 5.02
- NaOH & NaHCO₃ added to increase/adjust pH.

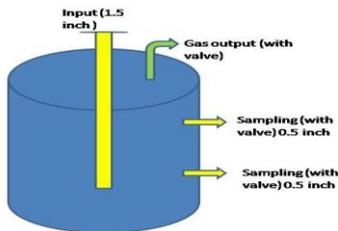

Figure.8 Layout Of Experimental Setup 3

9.5 RESULTS (FOR EXPERIMENT 3)

The results are shown in Figure.9,10,11,12,13&14. And Table.4,5 & 6

X. Analysis & Results

The bio gas production depends on

- PH
- VFA (volatile fatty acid)
- A/TIC alkality
- Total solid

Mathematically the bio gas production can be represented as follows:

$Y = ax^4 + bx^3 + cx^2 + dx + e$ for polynomial model.
 And $y = ax + b$ for linear model.

The datas collected from the large scale model are analysed in the excel software for the above parameters and the are furnished in Table.7. and Figures 15,16,17,18 & 19

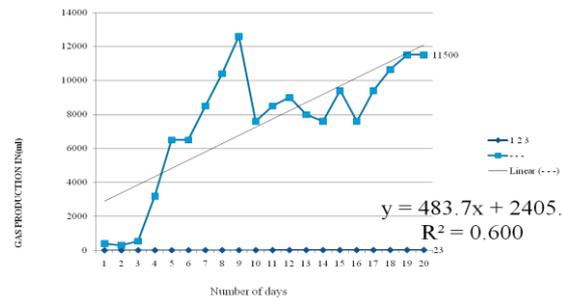

Figure 15. Linear Model 1

XI. RESULTS

- From the mathematical model commercial production of Biogas is influenced by
 - $6 < PH < 7.5$
 - $3200 < VFA < 4000$
 - $0.5 < A/TIC < 0.6$
 - $10 < TS < 15$
- Thus PH, A/TIC, TS are supporting Biogas production and VFA is partially supporting Biogas production.
- Model equation

$$y = 1.0014x^4 - 47.097x^3 + 687.09x^2 - 2603.3x + 2242.5$$

$$R^2 = 0.9074$$

XII. Conclusion

When the R2 valve is greater than 0.5, it may be concluded that the parameter is supporting the production of bio gas. Accordingly PH, TS, A/TIC are supporting the production of bio gas, while VFA is partially supporting the production of bio gas.

11.1 Comparison Of My Biogas Digester With Conventional

Biogas systems are those that take organic material (feedstock) into an air-tight tank, where bacteria break down the material and release biogas, a mixture of mainly methane with some carbon dioxide. The biogas can be burned as a fuel, for cooking or other purposes, and the

solid residue can be used as organic compost. Through this compact system, it has been demonstrated that by using feedstock having high calorific and nutritive value to microbes, the efficiency of methane generation can be increased by several orders of magnitude. It is an extremely user friendly system. Table.8. shows the Comparison of conventional biogas and kitchen waste biogas system

Table.8. Comparison Of Conventional Biogas And Kitchen Waste Biogas System

Comparison With Conventional Biogas Plants	Conventional Bio-Gas Systems	Kitchen Waste Bio-gas System
Amount of feedstock	40kg + 40ltr water	1.5-2 kg + water
Nature of feedstock	Cow-Dung	Starchy & sugary material
Amount and nature of slurry to be disposed	80ltr, sludge	12ltr, water
Reaction time for full utilization of feedstock	40 days	52 hours
Standard size to be installed	4,000 lit	1,000 lit

In a kitchen waste biogas system, a feed of kitchen waste sample produces methane, and the reaction is completed in 52 hours. Conventional bio-gas systems use cattle dung and 40kg feedstock is required to produce same quantity of methane.

“3d Heat Transfer Analysis And Numerical Modeling Of Lenstm Process For Thin Wall By Using Stainless Steel 304”

Chirag P. Patel¹, Prof. R.I. Patel²

^{1,2}(Department Of Mechanical Engineering, Government Engineering College, Dahod/ GTU, India

Abstract : Laser Engineered Net Shaping (LENSTM) is a rapid-manufacturing procedure that involves complex thermal, mechanical, and metallurgical interactions. The finite element method (FEM) may be used to accurately model this process, allowing for optimized selection of input parameters, and, hence, the fabrication of components with improved Thermo-mechanical properties. In this study the commercial FEM code ANSYS is used to predict the thermal histories, total deformation, von-mises stress and shear stress generated in straight wall and substrate of stainless steel 304. The computational results are compared with experimental measurements for validation.

Keywords: Laser engineering net shaping, FEM, total deformation, von-mises stress and shear stress, Element birth and death technique.

I. INTRODUCTION

Laser Engineered Net Shaping (LENSTM) is a rapid manufacturing technology developed by Sandia National Laboratories (SNL) that combines features of powder injection and laser welding toward component fabrication. Several aspects of LENSTM are similar to those of single-step laser cladding. However, whereas laser cladding is primarily used to bond metallic coatings to the surfaces of parts that have already been produced with traditional methods^[1], LENSTM involves the complete fabrication of three-dimensional, solid metallic components through layer by layer deposition of melted powder metal. In this process, a laser beam is directed onto the surface of a metallic substrate to create a molten pool. Powder metal is then propelled by an inert gas, such as argon or nitrogen through

II. Literature Review

Keicher *et al.*^[5] evaluated the effects of process parameters on multi-layer deposition of laser-melted powder Inconel® 625 in a process similar to both laser cladding and LENSTM. The group initially examined various parameters, including laser irradiance, stage translation speed, powder flow rate, powder particle size, and the size of each Z-directional increment between layers and their effect on heat affected zone (HAZ) size generated during the build. The HAZ was defined in this study as the melted region below the surface of the substrate and was examined post-build via metallographic analysis. Khalen and Kar^[10] performed an investigation into the effects of a several parameters on the resulting yield strength of AISI 304 stainless steel thin plates in process identical to LENSTM termed laser-aided direct rapid manufacturing (LADRM).

converging nozzles into the molten pool. Depending upon the alignment of the nozzle focal point with respect to that of laser, then powder is then melted either mid-stream or as it enters the pool. As the laser source moves away, the molten material then quickly cools by conduction through the substrate, leaving a solidified deposit. The substrate is located on a 3 or 5-axis stage capable of translating in the X and Y-directions. Initially, a 3-D CAD model is created to represent the geometry of a desired component. The CAD model is then converted to a faceted geometry composed of multiple slices used to direct the movement of the X-Y stage where each slice represents a single layer of deposition. During the build, the powder-nozzle/laser/stage system first traces a 2-D outline of the cross section represented by each slice in the X-Y plane and then proceeds to fill this area with an operator-specified rastering pattern.

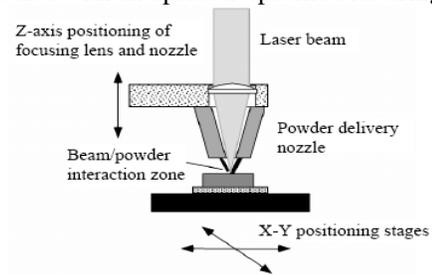

Figure 1 : Schematic of LENSTM deposition process

The laser/nozzle assembly then ascends in the Z-direction so that the next layer can be added. This process is repeated for consecutive layers, until completion of the 3-D component^[2]. This feature is illustrated schematically in Figure 1

This team sought to generate a range of input parameter values within which components with acceptable mechanical properties could be deposited. Their approach involved using the Buckingham Π -Theorem to express the process variables associated with heat transfer and powder mass flux in terms of 14 dimensionless parameters. Rangaswamy *et al.*^[11,12] sought to experimentally measure residual stresses in LENSTM deposits using the neutron diffraction method, the details of which are discussed in next Section. The measurements were performed on LENSTM-produced rectangular plates of AISI 316. The neutron data was collected at several points methodically distributed within the geometry of the samples, to provide a map of the stress distribution then calculated the axial components of residual stress through Hooke's law. Each stress component was then plotted against position within the plate, first, along the height (Z direction) on the sample vertical centerline, and

next, along the width (Y-direction) on the plate horizontal centre line. Wang and Felicelli^[15] next performed a parametric study similar to that done by Hofmeister *et al.*^[8] to determine if the same trends in cooling rates and thermal gradients were observable for different laser power. He repeated the previous simulation using five power intensity values, revealing that the temperature gradient at the edge of the molten pool increases substantially with laser power, while the cooling rate decreases. The resulting plots are shown in Figure 8 where A0 indicates power intensity. Neela and De^[16] to study the effects of translation speed and laser power on the resulting temperature profiles using the general purpose FE package, ABAQUS® 6.6. The researchers used an element Activation/deactivation similar to those previously to model the deposition of a thin plate of AISI 316 with temperature-dependent thermal conductivity and specific heat according to a linear, and quadratic relation, respectively. Deus and Mazumder^[17] attempted to predict the residual stresses resulting from a laser cladding deposition of C95600 copper alloy onto an AA333 aluminium alloy substrate. Since residual stresses would be generated by the heterogeneous thermal expansions of the deposited and substrate materials, accurate stress calculations would also require accurate prediction of the temperature fields created during the build. Labudovic *et al.*^[18] to predict residual stresses in a process identical to LENSTM termed the direct laser metal powder deposition process. A 3-D coupled model was implemented through the FE package ANSYS® for the deposition of a 50 mm x 20 mm x 10 mm thin plate of MONEL 400 onto a substrate of AISI 1006. The deposition was modelled with an ANSYS® element activation option similar to those already presented. Energy input density was modelled as a moving Gaussian distribution through the ANSYS® Parametric Design Language subroutine. The constitutive model was a temperature-dependent visco-plastic model, in which viscous effects were neglected by ignoring it the associated term in the equation of state.

III. Thermal modeling

3.1 Temperature Distribution

In the LENS process, a moving laser beam strikes on the substrate cause the powder and a portion to melt. The melted parts solidify again after cooling. By solving the three-dimensional heat conduction equation in the substrate, the transient temperature field can be obtained. The heat conduction equation with no source term is:

$$\frac{\partial}{\partial x} \left(k \frac{\partial T}{\partial x} \right) + \frac{\partial}{\partial y} \left(k \frac{\partial T}{\partial y} \right) + \frac{\partial}{\partial z} \left(k \frac{\partial T}{\partial z} \right) = \rho c_p \left(\frac{\partial T}{\partial t} \right) \quad \dots(1)$$

Where k is the thermal conductivity, T is the temperature, ρ is the density, p c is the specific heat and t is the time. The left term of Eq. (1) depicts the conductive heat transfer in the space while the right term of Eq. (1) refers to the imposed heat flux at a point of the clad. The heat conduction equation must be subject to the following boundary conditions: The imposed heat flux will

correspond to the power density of the laser beam. Assuming an uniform-distributed laser beam, we have:

$$Q(x, y, z, t) = \frac{Pa}{\pi r_0^2} \quad \dots(2)$$

where P is the power of laser source, a is the absorptivity of clad material and r₀ is the radius of laser beam. The heat conduction equation must be subject to the following boundary conditions: Convection:

$$-k \nabla T = h(T - T_0) \quad \dots(3)$$

Radiation:

$$-k \nabla T = \epsilon \sigma (T^4 - T_0^4) \quad \dots(4)$$

Where h is the convective heat transfer coefficient, ε is the emissivity, σ is the Stephan-Boltzmann constant and T₀ is the ambient temperature. In addition, the following initial condition should be satisfied

$$T(x, y, z, 0) = T_0 \quad \text{and} \quad T(x, y, z, \infty) = T_0 \quad \dots(5)$$

3.2 Stress Analysis

In this case, no body forces or surface tractions are applied and the only load is from the transient thermal field. The strong temperature gradients induced by laser beam causes thermal strain which lead the work piece to yield. The total strain is written as:

$$\epsilon_{ij} = \epsilon_{ij}^e + \epsilon_{ij}^p + \epsilon_{ij}^{th} \quad \dots(6)$$

Where the components refer to elastic, plastic and thermal strain, respectively. The elastic and thermal strains are expressed as :

$$\epsilon_{ij}^E = \frac{1+\nu}{E} \sigma_{ij} - \frac{\nu}{E} \sigma_{kk} \delta_{ij} \quad \dots(7)$$

And

$$\epsilon_{ij}^T = \alpha (T - T_0) \delta_{ij} \quad \dots(8)$$

To calculate the plastic strain, kinematic hardening, together with Von Mises yield criterion is assumed.

3.3 Modeling assumptions

The assumptions during the thermal and structural modeling of the LENS process are as follows:

The substrate is initially at room temperature (20°C). The boundary condition around the substrate is the convection heat transfer with a constant coefficient. The heat flux is moving and it has uniform distribution on the activated elements.

The activated elements of the molten pool are at the melting temperature. The convective redistribution of heat in the molten pool is considered. The substrate is assumed to be stress free at the beginning of the process. The substrate is placed on the worktable and has no clamp to restrict its movements. The speed of laser beam is considered constant and the time for laser to change direction is 4 second. The powder addition onto the substrate is divided into many small time steps to simulate the quasi-steady nature of LENS process.

3.4 Transient thermal analysis

Thermal conductivity and specific heat are temperature dependent. The heat transfer considered here is conduction, the effect of convection is considered & radiation are not considered. The latent heat required during phase change of SS 304 is also taken in to account. The element birth/death option is used to account for the addition of new elements in the solution domain corresponding to the deposition of powder for creating a multi-layer structure on a substrate. The substrate is assumed to serve simply as a heat sink. Boolean features of ANSYS is used for bonding of substrate and layers of thin wall. Thermal and Mechanical properties of SS304 is used for thin wall and substrate.

3.5 Model

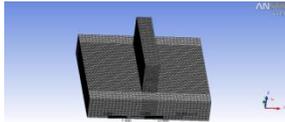

Figure. 2 : Mesh and Nodes Generation

A model for LENS process is built. As shown in Figure 4, Substrate : 40 x 40 x 10 mm. The example under consideration thin wall has length L=30 mm, breadth W=6 mm, height H=14 mm respectively. 6 tracks across width is assumed of equal width of 1 mm while each of the 20 layers in the wall height is assumed of equal 0.7 mm height . Each layer : 30 mm Long, 1 mm Wide and 0.7 mm height. As shown in Figure 2, a total of 25402 nodes, and 14951 Tetrahedral elements are generated to accomplish this simulation. The laser beam travel time for one pass is 4 seconds and it is discretized into 20 equal time steps with 0.20 second for each step. One more step with time t=200s is added after the existing 20 steps to account for the cooling after laser beam goes past the substrate.

5 Layers

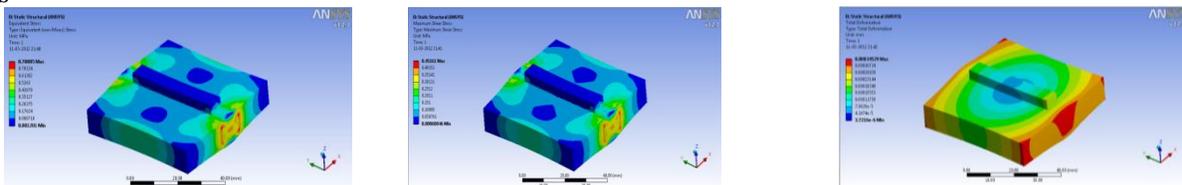

Figure 3 : Von-mises stress distribution, Max. shear stress distribution and Total deformation

IV. Modelling consideration

4.1 Thermal boundary and initial condition

The substrate is at room temperature as the beginning of the process and the ambient temperature $T_0 = 20\text{ }^\circ\text{C} = 293\text{ K}$. The side and top surface is assumed to be convection heat transfer with a constant coefficient of $30\text{ W/m}^2\text{K}$. The equivalent convection coefficient is $400\text{ W/m}^2\text{K}$ for the bottom of substrate. Step applied for various temperatures as T or T_∞ as shown in below table.

Table 1: Properties of SS304

Temperature, T(°c)	Thermal Conductivity, $W.m^{-1}k^{-1}$	Yield Stress σ_Y (MPa)	Young's modulus, E (GPa)	Latent Heat of Fusion, J/kg
25	14.8	241	193	-
400	20.7	159	-	-
600	23.5	134	-	-
800	25.8	114	-	-
1000	28.8	97	-	-
1100	29.9	-	-	-
1200	31.6	88	-	-
1300	32.8	76	-	-
1454	-	-	-	2.65×10^5

4.2 Structural boundary and initial conditions

The substrate is assumed to be stress free at the beginning of the process. The only load applied to the system is the thermal field, analyzed in the previous step. The bottom of the substrate is subjected to displacement constraints so that it has no movement in the z direction. The substrate, however, is free to deform in the x and y direction.

V. Simulation results

5.1 Temperature Distribution

In the actual production, the LENS is a multi-track and multi-layer manufacturing process. In this analysis , the laser power is 3.0 kW, the scanning rate is 14 mm S^{-1} , the speed of delivering powder is 0.002 kg S^{-1} , the temperature field distribution after the laser returns, and the temperature field whose maximum temperature is 2038.77 K, lowest temperature is 20.00 K, and the temperature drops very quickly. The temperature distribution of the material right after finishing the last step of the deposition for each deposition pattern. The maximum temperature, just after turning off the laser, significantly drops below the melting temperature

		Location
Von-mises	Maximum	Substrate
	Minimum	Thin wall
Shear stress	Maximum	Substrate
	Minimum	Thin wall
Total deformation	Maximum	Substrate
	Minimum	Thin wall

As predicted, the thermal analysis of the process shows that the various deposition layers directly changes the temperature history of the process. The non-uniformity of the temperature field is one of the main reasons for stress rising. Figure 7 shows the Von-Misses stress at the end of the deposition process for each deposition pattern and the maximum Von-Misses stress value in various deposition layers . Among all deposition layers. The maximum stress occurs at the interface of the deposited material and the substrate. In order to better analyze the stress distribution of the deposited material, the Von-Misses stress of the surface of the deposited material is shown in above graph and as shown figure 8 as the layer increases the max. shear stress value also increases but as shown in figure 9 the total deformation is suddenly goes down and reaching up due to deposition strategy and sudden effect of laser power.

VII. Conclusion

Although in the different layers have different activated time, they have similar temperature and thermal stress variation regularities. The temperature gradients in specimen are mainly along Z direction, Among all those force components of Von Mise’s effective stress, Z -directional thermal stress is much larger. In the different layers, the Von Mise’s effective, total deformation, shear stress in next layer are almost twice the values of previous layer. The start point of each layer has an enormous effect on the distribution and intensity of thermal stress. During LENS, high thermal gradients tend to develop in the through-thickness direction. The associated differential thermal contraction often generates relatively high stresses, which are likely to cause yielding in the hot, near-surface regions. The present work has manifested that the peak temperature at any point is

attained when the laser beam passes over that location. As the beam moves away from the location, the newly deposited metal rapidly solidifies at a varying cooling rate with a very high initial value. During the deposition of subsequent layers the temperature again shoots up as the laser beam passes over the similar locations thus resulting in repetitive thermal cycles that can be correlated with the effect of gradual increment in total deformation, von-mises stress and shear stress.

VIII. ACKNOWLEDGEMENTS

I would like to express my deep sense of gratitude and respect to my guide Prof. R.I.Patel sir for his excellent guidance, suggestions and constructive criticism. I consider myself extremely lucky to be able to work under the guidance of such a dynamic personality. I am also thankful to A.H.Makwana sir for his co-operation throughout the semester.

Quantum Computer (Information) and Quantum Mechanical Behaviour- A Quid Pro Quo Model

¹Dr K N Prasanna Kumar, ²prof B S Kiranagi, ³Prof C S Bagewadi

For (7), 36 ,37, 38,--39

Abstract: Perception may not be what you think it is. Perception is not just a collection of inputs from our sensory system. Instead, it is the brain's interpretation (positive, negative or neutral-no signature case) of stimuli which is based on an individual's genetics and past experiences. Perception is therefore produced by (e) brain's interpretation of stimuli .The universe actually a giant quantum computer? According to Seth Lloyd--professor of quantum-mechanical engineering at MIT and originator of the first technologically feasible design for a working quantum computer--the answer is yes. Interactions between particles in the universe, Lloyd explains, convey not only (- to+) energy but also information-- In brief, a quantum is the smallest unit of a physical quantity expressing (anagrammatic expression and representation) a property of matter having both a particle and wave nature. On the scale of atoms and molecules, matter (e&eb) behaves in a quantum manner. The idea that computation might be performed more efficiently by making clever use (e) of the fascinating properties of quantum mechanics is nothing other than the quantum computer. In actuality, everything that happens (either positive or negative e&eb) in our daily lives conforms (one that does not break the rules) (e (e)) to the principles of quantum mechanics if we were to observe them on a microscopic scale, that is, on the scale of atoms and molecules. But because a great many degrees of freedom (such as a huge number of atomic movements) contribute to phenomena that we as human beings can perceive, this quantum mechanical behavior is normally hidden (not perceived-e(e)) by us. That it is not in the visible field; We cannot see it let alone decipher the progressive movements and dynamics of the system. Yet, if we were to look into the world of individual atoms, we would find that an electron (+) moving about the atomic nucleus can only take on (e) energy having specific (discrete) values. In other words, an electron may enter only a fixed number of set states. It is like I can build house in my site; not on somebody's site or on corporation designated area for public utility; This resembles the way in which strings on a guitar can only resonate at set frequencies, and(e some light&eb some light) reflects the wave nature of quantum states. This electron, moreover, may take on a "**superposition state**" that combines (e&eb) different energy states simultaneously. Superposition state is important concept in quantum computing. Applying a strong electric field to an atom can also (eb) make the electrons circulating around it tunnel through a wall created (eb) by strong nuclear binding energy and (eb or=) become unbound. Although the tunneling of say a soccer ball through a wall does not occur in reality, this kind of phenomenon can occur in the microscopic world. Such quantum mechanical behavior must be artificially (e&eb) controlled and measured to achieve (eb) a quantum computer. Quantum computer thus utilizes (e) Quantum mechanical behaviour that is artificially controlled. Quantum mechanical behavior in state one controls (e&eb) Quantum Mechanical behaviour in state two. R. Schilling, M. Selecky, W. Baltensperger studied the influence (e&eb) of the hyperfine interaction $\sim S_n$. In between the ionic and the nuclear spins at the site n on the Eigenvalues of a 2-domain Heisenberg ferromagnetic with a 180° -domain wall. A level splitting is obtained even when $\langle S_n \rangle = 0$ due (e) to quantum fluctuations The idea quantum states used for a computer first came about in the 1980s. In 1985, David Tschi, a professor at Oxford University and a proponent of quantum computers, wrote a paper titled "Quantum theory, the Church-Turing principle, and the universal quantum computer" that touched upon the possibility of quantum computers. Frank Verstraete, Michael M. Wolf & J. Ignacio Cirac STUDIED THE EFFECTS OF QUANTUM MECHANICAL STATES ON QUANTUM

KEYWORDS: Quantum mechanical states, Quantum computation, Decoherence, Quantum cryptography, Quantum simulation, Tunneling, nonadiabatic multiphonon process in the strong vibronic coupling limit, Schrodinger's Hamiltonian, Claude Shannon Theories of Redundancy and Noise, Kraus operators „a non-zero energy state.*

I. INFORMATON

The strongest adversary in quantum information science is decoherence, which (eb) arises owing to the coupling(e&eb) of a system with its environment. The induced dissipation tends to *destroy and (e) wash out* the interesting quantum effects that give (eb) rise to the power of quantum computation, cryptography and simulation. Whereas such a statement is true for many forms of dissipation, they showed that dissipation can also have exactly the opposite effect: it can be a fully fledged *resource* (eb) for universal quantum computation without any coherent dynamics needed to complement it. Universal Quantum Computation utilizes (e) decoherence. The coupling (e&eb) to the environment drives (eb) the system to a steady state where the outcome (eb) of the computation is encoded. In a similar vein, they showed that dissipation *can be (e) used* to engineer a large variety of strongly correlated states in steady state, including all stabilizer codes, matrix product states, and their generalization to higher dimensions. Words "e" and "eb" are used for better comprehension of the paper. They represent 'encompasses' and 'encompassed by'. There are no other attributions or ascriptions for the same. For the system of Quantum entanglement and Quantum Information we discuss the stability analysis, solution behaviour and asymptotic stability in detail. Asymptotic stability is proved for the system in accord with the extant obtention of appositve factors in the system.

II. Constitution, Composition And Outlay Of The Paper

1: Review Of the Literature:

Under this head we take an intimate and hawk's look at the various aspectualities and attributions in the literature available. Quantum Information and Quantum Mechanical behaviour is a subject which is not a rarefied and moribund field. Quantum Information and Quantum Mechanical behaviour and consummation, consolidation, concretization, consubstantiation is a field which is many a time attempted to. Piece de resistance of the work is to put the study the concatenated formulated equations which has not been done earlier on terra firma. Under this head, in consideration to the fact that there are some Gordian Knots, we point out the extant and existential problems thereof. This helps develop a two pronged strategy: one it helps the reader and author and academician alike to appreciate the generalized strain of rationalized consistency and cumulative choice of variables for the development of the model and second, provides the cognitive orientation towards the model built itself in the sense that aspects like Theory of Classification, Dissipation Coefficient formulation, Accentuation Coefficient induction which are cat hectic evaluative integrational necessary mechanisms so that qubits act as individual components and componential clusterings with a certain predefined set of specification. In case of randomness, the constraints under which Model holds well are stated. Evaluative motivational orientation for the development of a Quantum Computer, with variable integration and role differentiation is obtained so that it suits our model. It is important that this factor is to be borne in mind. Introduction is not just a brush up on the topic but also a breeding ground to fulfill and render conceptual soundness and system orientation and process orientation to the model. While engaging the attention, on the introductory aspects, we also point to the integrative function, model adequacy, instrumental applicable orientations, and the implications of functional imperatives of Technological change are also perceived and given a decent guess. In Quantum Computers, structural relational context of qubits like quantum entanglement and when such an entanglement would become disentangles; its functional exigencies and contingencies are also stated. They are done in order to see that the model is developed further so that it acts as a better tool for vindication of certain objectives for which it is applied. Gritty narrative brings out the subtleties and nuances of the subject in addition to the fact how it would help the formulation of the Model. Additionally, expatiation, enucleation, elucidation and exposition of the points that are necessary for the formulation of the present problem are also notified. Here we study the aging process, dissipatory mechanism, obliteration, obfuscation and abjuration of the Vacuum energy and Quantum Field, with thrust on the problem solving capacity and state sytemal and processual thinking on the subject matter.

2. Work Suggested/Done:

Under this appellation, we enumerate the work done, namely the sole aim, primary objective and sum mum bonuum of the work done. In the extant case we give the formulation of the problem. Statement of governing equations for both Quantum Information and Quantum Mechanical behaviour, write down in unmistakable terms the conceptual jurisprudence, phenomenological methodology, formal characterization, programmatic and anagrammatic concatenation of the equations. We discuss in detail for the system Vacuum Energy and Quantum Field, the stability analysis, solution behaviour, asymptotic analysis, the three formidable but very important tools for the system to remain as sangfroid like salamander under various conditionalities or undergo transformation with environmental decoherence. This aspect throws light on hither to untouched regions of Quark similarity, Schwarzschild radius, Zero Point Energy, Quantum Chromo Dynamics, GTR, STR, Quarks, Gluons,, and the concomitant and corresponding accentuatory, corroboratory ,augmentatory or dissipatory relationship. As is stated in the foregoing, these factors are very important for the model to be put as a promethaleon, primogeniture and proponent for further study which the author intends to do. These constituent structures, transformational minimal conditions, structural morphology, dependent variability, normative aspect of expectations from the model are discussed. Integrative structure of Quantum Mechanical System of process sytemal orientation, with entanglement patterns on the relational level of entanglement, decoherence, redundancy, presumptuousness, is also studied taking in to consideration the overall collectivity. For instance, *Quantum Tunneling*, as well as the twelve order of magnitude *increase* of the low-temperature tunnelling rate constant on going from a spin-crossover compound with a small zero-point energy difference to a low-spin compound with a substantially larger one, *can be understood on the(e) basis* of a *nonadiabatic multiphonon process in the strong vibronic coupling limit is mentioned to drive home the importance of the Quantum Tunneling in the formulation of Quantum Computation and Quantum Computers*. In the case of QCD it is increased energy states and Dominant Asymptotic freedom that is responsible for the diffusion of parton momentum and diffusion scattering which form important role in the transference of Quantum Information. Many erudite studies are quoted as a fleeting mention so that the researchers have shown proactive approach to the encumbrances that have come their way in providing enriching contribution and mind boggling logistics of lack of misnomerliness in the accentuation of the production of the Quantum Computation.

III. Conclusions

Under this category, we summarize the work done, namely the study of formulation of the Governing Equations, necessary sine qua non attributions like accentuation and dissipation which are essential functional prerequisite for the consummation and success of the model. It is to be stated that primary focus and locus is of homologues nature and differentially instrumentally activities of the model performance such as stability analysis, asymptotic analysis, solution behaviour, and the sententious and pithy prognostications under which the systems become functional or for that matter dysfunctional. We do not write a separate conclusive note. Herein itself is mentioned the holistic and generalizational view

of the work done, as has been done in the foregoing. Imperative compatibilities and structural variabilities of a *nonadiabatic multiphonon process in the strong vibronic coupling limit*, Vacuum Energy and Quantum Field vis a vis Quantum Computation are stated in unequivocal terms. Common patterns of phenomenological methodology, essential predications, suspensional neutralities, rational representations, conferential extrinsicness, interfacial interference and syncopated justice the model does for the generalized goal to be consummated is dealt with. Solutional behavior, stability analyses, asymptotic analysis bear ample testimony, infallible observatory, and impeccable demonstration to the predicational anteriority, character constitution, ontological consonance, primordial exactitude to the accolytish representation and apocryphal aneurism and associated asseveration of the Governing Equations and the obtention of Stability analysis which is dealt in detail ,stating what happens to the singularities, antigeneralities or event at contracted points, and normal performance of the model in normal conditions. This helps in the optimum development of the system of governing equations and dynamical improvement of the conditionalities for the instrumental efficaciousness of the stability, or reduction of asymptotic stability as the practical applications demand. No conjecture however is made because of ignorance of such possibilities and possibilities. Concatenated governing equations thus provide a qualitative gradient of internal structural differentiation, and diffuse solidarity abstraction. No separate conclusion statement is made in consideration to the fact that motivational orientation and institutionalization of pattern variables that are used have already been stated here. *At Planck's scale there might be* energetic frantiness or ensorcelled frenzy of the Vacuum Energy and Quantum Field, and these extrapolations have to be explored in detail by more eminent, erudite, and esteemed researchers. Vacuum energy is one type of energy which could be highly belligerently tempestuous and temerarily reckless when put to different uses. While a tendentious testament is not provided, a first step of a progenitor is taken for the intimate comprehension of the system. Further papers build on this framework towards the consummation of higher theories envisioned. This on the other hand provides a rich receptacle, reliquarium repository to other researchers to study practical applications right from the simple appliances like piston to highly sophisticated ones like in CERN. That any contribution that helps towards achievement and consummation of the power house performance of Quantum Computers is a fair accompli desideratum. It is in this direction, we have directed our thoughts and expositions for the better presentation of the subject matter. One doth hear portentous voice of doomsday Sayers, but it is better to listen to optimists and stick to the subterranean realm of spatio temporal actualization, in which Quantum Mechanism is non pariel and par excellent.

IV. INTRODUCTION

Quantum information

In quantum mechanics, quantum information is physical information that is held in the "state" of a quantum system. The most popular unit of quantum information is the qubit, a two-level quantum system. However, unlike classical digital states (which are discrete), a two-state quantum system can actually be in a superposition of the two states at any given time. Quantum information differs from classical information in several respects, among which we note the following:

- An arbitrary state cannot be cloned,
- The state may be in a *superposition* of basis values.

However, despite this, the amount of information that *can be retrieved* in a single qubit is equal to one bit. It is in the *processing* of information (quantum computation) that the differentiation *occurs*. The ability to *manipulate* quantum information enables us to perform tasks that would be unachievable in a classical context, such as unconditionally secure transmission of information. Quantum information processing is the most general field that is concerned with quantum information. There are certain tasks which classical computers cannot perform "efficiently" (that is, in polynomial time) according to any known algorithm. However, a quantum computer can compute the answer to some of these problems in polynomial time; one well-known example of this is Shor's factoring algorithm. Other algorithms can speed up a task less dramatically—for example, Grover's search algorithm which gives a quadratic speed-up over the best possible classical algorithm.

Quantum information, and changes in quantum information, can be quantitatively measured by using an analogue of Shannon entropy, called the von Neumann entropy. Given statistical of quantum mechanical systems with the density matrix ρ , it is given by

$$S(\rho) = -\text{Tr}(\rho \ln \rho).$$

Many of the same entropy measures in classical information theory can also be generalized to the quantum case, such as Holevo entropy and the conditional quantum entropy.

Quantum information theory

The theory of quantum information is a result of the effort to generalize classical information theory to the quantum world. Quantum information theory aims to answer the following question: What happens if information is stored in a state of a quantum system?

One of the strengths of classical information theory is that physical representation of information can be disregarded: There is no need for an 'ink-on-paper' information theory or a 'DVD information' theory. This is because it is always possible to efficiently transform information from one representation to another. However, this is not the case for

quantum information: it is not possible, for example, to write down on paper the previously unknown information contained in *the polarization* of a photon.

In general, quantum mechanics does not allow us to read out the state of a quantum system with arbitrary precision. The existence of Bell correlations between quantum systems cannot be converted into classical information. It is only possible to transform quantum information between quantum systems of sufficient information capacity. The information content of a message \mathcal{M} can, for this reason, be measured in terms of the minimum number n of two-level systems which are needed to store the message: \mathcal{M} consists of n qubits. In its original theoretical sense, the term qubit is thus a measure for the amount of information. A two-level quantum system can carry at most one qubit, in the same sense a classical binary digit can carry at most one classical bit. As a consequence of the noisy-channel coding theorem, noise limits the information content of an analog information carrier to be finite. It is very difficult to protect the remaining finite information content of analog information carriers against noise. The example of classical analog information shows that quantum information processing schemes must necessarily be tolerant against noise, otherwise there would not be a chance for them to be useful. It was a big breakthrough for the theory of quantum information, when quantum error correction codes and fault-tolerant quantum computation schemes were discovered.

THE precise manner in which quantum-mechanical behaviour at the microscopic level underlies classical behaviour at the macroscopic level remains unclear, despite seventy years of theoretical investigation. Experimentally, the crossover between these regimes can be explored by looking for *signatures* of quantum-mechanical behaviour—such as tunneling—in macroscopic systems. Magnetic systems (such as small grains, spin glasses and thin films) are often investigated in this way *because (e)* transitions between different magnetic states can be closely monitored. But transitions between states *can be (e) induced* by thermal fluctuations, as well as by *tunnelling*, and definitive *identification* of macroscopic tunnelling events in these complex systems is therefore difficult. In an applied magnetic field, the magnetization *shows (eb)* hysteresis loops *with (e&eb)* a distinct 'staircase' structure: the steps *occur (eb)* at values of the applied field where the energies of different collective spin states of the manganese clusters coincide. At these special values of the field, *relaxation* from one spin state to another is *enhanced* above the thermally activated rate by the *action (e)* of resonant quantum-mechanical tunnelling. These observations corroborate the results of similar experiments performed recently on a *system of oriented* crystallites made from a powdered sample

Intersystem crossing is the crucial first step *determining (eb)* the quantum efficiency of very many photochemical and photo physical processes. Spin-crossover compounds of first-row transition metal ions, in particular of Fe (II), provide model systems for studying it in detail. Because in these compounds there are no competing relaxation processes, intersystem crossing rate constants can be *determined (eb)* over a large temperature interval. The characteristic features are tunnelling at temperatures below ~ 80 K and a thermally activated process above ~ 100 K.

This *Quantum Tunneling*, as well as the twelve order of magnitude *increase* of the low-temperature tunnelling rate constant on going from a spin-crossover compound with a small zero-point energy difference to a low-spin compound with a substantially larger one, *can be understood on the(e) basis* of a *nonadiabatic multiphonon process in the strong vibronic coupling limit*.

Quantum mechanics is Quantum Information:

Quantum information theory deals with four main topics:

(1) Transmission of classical information over quantum channels. (2) The *tradeoff between* acquisition of information about a quantum state *and (e&eb)* disturbance of the state (3) Quantifying quantum entanglement (4) *Transmission of* quantum information over quantum channels. As a precursor, promethaleon and primogeniture to the comprehension of Von Neumann entropy and its relevance to quantum information, calls for Shannon entropy and its relevance to classical information. Claude Shannon established the two core results of classical information theory in his landmark 1948 paper. The two central problems that he solved were: (1) How much can a message be *compressed*; i.e., how redundant is the information? (The "noiseless coding theorem.") (2) At what rate can we communicate reliably over a noisy channel; i.e., how much redundancy must be incorporated into a message to *protect (e) against* errors? I.e./ redundancy doth reduce errors. (The "noisy channel coding theorem.") Both questions concern redundancy – how unexpected is the next letter of the message, on the average. One of Shannon's key insights was that entropy *provides a(eb) suitable way* to quantify redundancy. Or, redundancy helps reduce (e) entropy Quantum mechanics (QM - also known as quantum physics, or quantum theory) is a branch of physics dealing with physical phenomena where the action is on the order of the Planck constant. Quantum mechanics *departs from* classical mechanics primarily at the *quantum realm* of atomic and subatomic length scales. *QM provides* a mathematical description of much of the dual *particle-like* and *wave-like* behavior *and interactions* of energy and matter. All objects *exhibit* wave/particle duality to some extent, but the larger the object the harder it is to observe. Observation is proportional to largeness of the objects. Even individual molecules are often too large to show the quantum mechanical behavior. Now physicists at the Université de Paris have demonstrated wave/particle duality with a droplet made of trillions of molecules. The experiment involved an oil droplet *bouncing* on the surface of an agitated layer of oil. The droplet *created* waves on the surface, which in turn *affected* the motion of the droplet. As a result, the droplet and waves *formed* a single entity that *consisted* of a hybrid of wave-like and particle-like characteristics. When the wave/droplet bounced its way through a slit, the waves allowed it to *interfere with* its own motion, much as a single photon *can interfere* with itself via quantum mechanics. Although the wave/droplet is clearly a denizen of the classical world, the experiment *provides a clever analogue* of quantum weirdness at a scale that is much easier to study and visualize than is typical of many true quantum experiments. In advanced topics of quantum mechanics, some of these behaviors are macroscopic and only *emerge* at extreme (i.e., very low or very high) energies or temperatures. The name *quantum mechanics* derives from the

observation that some physical quantities can *change* only *indiscrete* amounts (Latin *quanta*), and not in a continuous (*cf.* analog) way. For example, the angular momentum of an electron *bound to* an atom or molecule is quantized. In the context of quantum mechanics, the wave-particle duality of energy and matter and the uncertainty principle provide a *unified view* of the behavior of photons, electrons, and other atomic-scale objects.

The mathematical formulations of quantum mechanics are abstract. A mathematical function called the wavefunction *provides* information about the probability amplitude of position, momentum, and other physical properties of a particle. Mathematical *manipulations* of the wavefunction usually *involve the* bra-ket notation, which requires an understanding of complex numbers and linear functional. The wavefunction *treats the object as a* quantum harmonic oscillator, and the mathematics is akin to that *describing* acoustic resonance. Many of the results of quantum mechanics are not easily visualized in terms of classical mechanics - for instance, the ground state in a quantum mechanical model *is a non-zero energy state* that is the lowest permitted energy state of a system, as opposed a more "traditional" system that is thought of *as simply being at rest*, with zero kinetic energy. Instead of a traditional static, *unchanging zero state*, quantum mechanics allows for far more *dynamic, chaotic possibilities*, according to John Wheeler.

The earliest versions of quantum mechanics were formulated in the first decade of the 20th century. At around the same time, the atomic theory and the corpuscular theory of light (as updated by Einstein) first came to be widely accepted as scientific fact; these latter theories *can be viewed as* quantum theories of matter and electromagnetic radiation, respectively. Early quantum theory was significantly reformulated in the mid-1920s by Werner Heisenberg, Max Born, Wolfgang Pauli and their collaborators, and the Copenhagen interpretation of Niels Bohr became widely accepted. By 1930, quantum mechanics had been further *unified* and formalized by the work of Paul Dirac and John von Neumann, with a greater emphasis placed on measurement in quantum mechanics, the statistical nature of our knowledge of reality, and philosophical speculation about the role of the observer. Quantum mechanics has since branched out into almost every aspect of 20th century physics and other disciplines, such as *quantum chemistry, quantum electronics, quantum optics, and quantum information science*. Much 19th century physics has been re-evaluated as the "classical limit" of quantum mechanics, and its more advanced developments in terms of *quantum field theory, string theory, and speculative quantum gravity theories*.

A HISTORICAL NITTY GRITTY PERSPECTIVE AND FUTURISTIC PROGNOSTICATION:

The history of quantum mechanics dates back to the 1838 discovery of cathode rays by Michael Faraday. This was followed by the 1859 statement of the black body radiation problem by Gustav Kirchhoff, the 1877 suggestion by Ludwig Boltzmann that the *energy states of a physical system can be discrete*, and the 1900 quantum hypothesis of Max Planck. Planck's hypothesis that *energy is radiated and absorbed* in discrete "quanta" (or "energy elements") precisely matched the *observed patterns of blackbody radiation*. According to Planck, each energy element E is proportional to its frequency ν :

$$E = h\nu$$

Where h is Planck's constant. Planck (cautiously) insisted that this was simply an aspect of the *processes* of *absorption and emission of radiation* and had nothing to do with the *physical reality* of the radiation itself. However, in 1905 Albert Einstein interpreted Planck's quantum hypothesis realistically and used it to explain the photoelectric effect, in which shining light on certain materials *can eject* electrons from the material. The foundations of quantum mechanics were established during the first half of the 20th century by Niels Bohr, Werner Heisenberg, Max Planck, Louis de Broglie, Albert Einstein, Erwin Schrödinger, Max Born, John von Neumann, Paul Dirac, Wolfgang Pauli, David Hilbert, and others. In the mid-1920s, developments in quantum mechanics *led to its* becoming the standard formulation for atomic physics. In the summer of 1925, Bohr and Heisenberg published results that closed the "Old Quantum Theory". Out of deference to their particle-like behavior in certain processes and measurements, light quanta came to be called photons (1926). From Einstein's simple postulation was born a flurry of debating, theorizing, and testing. Thus the entire field of quantum physics *emerged, leading to its wider acceptance* at the Fifth Solvay Conference in 1927. The other exemplar that led to quantum mechanics was the study of electromagnetic waves, such as visible light. When it was found in 1900 by Max Planck that the energy of waves could be described as consisting of small packets or "quanta", Albert Einstein further developed this idea to show that an electromagnetic wave such as light could be described as a particle (later called the photon) with a discrete quantum of energy that was *dependent on its frequency*. This led to a theory of *unity* between subatomic particles and electromagnetic waves, called wave-particle duality, in which particles and waves were neither one nor the other, but had certain properties of both. While quantum mechanics traditionally described the world of the very small, it is also needed to explain certain recently investigated macroscopic systems such as superconductors and superfluids.

The word *quantum* derives from the Latin, meaning "how great" or "how much". In quantum mechanics, it refers to a discrete unit that quantum theory *assigns to* certain physical quantities, such as the energy of an atom at rest. The discovery that particles are discrete packets of energy with wave-like properties *led to the* branch of physics dealing with atomic and sub-atomic systems which is today called quantum mechanics. It is the underlying mathematical framework of many fields of physics and chemistry, including condensed matter physics, solid-state physics, atomic physics, molecular physics, computational physics, computational chemistry, quantum chemistry, particle physics, nuclear chemistry, and nuclear physics. Some fundamental aspects of the theory are still actively studied. Quantum mechanics is essential to understanding the behavior of systems at atomic length scales and smaller. For example, if classical mechanics *truly governed* the workings of an atom, electrons *would rapidly travel toward, and collide with*, the nucleus, *making* stable atoms impossible. *However, in the natural world electrons normally remain in an uncertain, non-deterministic,*

"smeared", probabilistic wave-particle wavefunction orbital path around (or through) the nucleus, defying classical electromagnetism. Atlas, the fulminating avenger, crackling debutante with seething intensity has taken its pride of place.

Quantum mechanics was initially developed to provide a better explanation of the atom, especially the differences in the spectra of light emitted by different isotopes of the same element. The quantum theory of the atom was developed as an explanation for the electron remaining in its orbit, which could not be explained by Newton's laws of motion and Maxwell's of (classical) electromagnetism.

Broadly speaking, quantum mechanics incorporates four classes of phenomena for which classical physics cannot account: The quantization of certain physical properties; Wave; The Uncertainty principle; Quantum. Gravity

Mathematical formulations OF Quantum Mechanics:

In the mathematically rigorous formulation of quantum mechanics developed by Paul Dirac and John von Neumann, the possible states of a quantum mechanical system are represented by unit vectors (called "state vectors"). Formally, these reside in a complex separable Hilbert space - variously called the "state space" or the "associated Hilbert space" of the system - that is well defined up to a complex number of norm 1 (the phase factor). In other words, the possible states are points in the projective space of a Hilbert space, usually called the complex projective space. The exact nature of this Hilbert space is dependent on the system - for example, the state space for position and momentum states is the space of square-integrable functions, while the state space for the spin of a single proton is just the product of two complex planes. Each observable is represented by a maximally Hermitian (precisely: by a self-adjoint) linear operator acting on the state space. Each eigenstate of an observable corresponds to an eigenvector of the operator, and the associated eigenvalue corresponds to the value of the observable in that eigenstate. If the operator's spectrum is discrete, the observable can only attain those discrete eigenvalues.

In the formalism of quantum mechanics, the state of a system at a given time is described by a complex wave function, also referred to as state vector in a complex vector space. This abstract mathematical object allows for the calculation of probabilities of outcomes of concrete experiments. For example, it allows one to compute the probability of finding an electron in a particular region around the nucleus at a particular time. Contrary to classical mechanics, one can never make simultaneous predictions of conjugate variables, such as position and momentum, with accuracy. For instance, electrons may be considered (to a certain probability) to be located somewhere within a given region of space, but with their exact positions unknown. Contours of constant probability, often referred to as "clouds", may be drawn around the nucleus of an atom to conceptualize where the electron might be located with the most probability. Heisenberg's uncertainty principle quantifies the inability to precisely locate the particle given its conjugate momentum. According to one interpretation, as the result of a measurement the wave function containing the probability information for a system collapses from a given initial state to a particular eigenstate. The possible results of a measurement are the eigenvalues of the operator representing the observable — which explains the choice of Hermitian operators, for which all the eigenvalues are real. The probability distribution of an observable in a given state can be found by computing the spectral decomposition of the corresponding operator. Heisenberg's uncertainty principle is represented by the statement that the operators corresponding to certain observables do not commute. That is they cannot be converted, go back and forth, cannot be transformed. There is lot of discussion and deliberation at the level of being polemical. Many people including the author aver that consciousness or the presence of consciousness makes the Truth explicit.

The probabilistic nature of quantum mechanics thus stems from the act of measurement. This is one of the most difficult aspects of quantum systems to understand. It was the central topic in the famous Bohr-Einstein debates, in which the two scientists attempted to clarify these fundamental principles by way of thought experiments. In the decades after the formulation of quantum mechanics, the question of what constitutes a "measurement" has been extensively studied. Newer interpretations of quantum mechanics have been formulated that do away with the concept of "wavefunction collapse" (see, for example, the relative state interpretation). The basic idea is that when a quantum system interacts with a measuring apparatus, their respective wave functions become entangled, so that the original quantum system ceases to exist as an independent entity. Generally, quantum mechanics does not assign definite values. Instead, it makes a prediction using a probability distribution; that is, it describes the probability of obtaining the possible outcomes from measuring an observable. Often these results are skewed by many causes, such as dense probability clouds. Probability clouds are approximate, but better than the Bohr model, whereby electron location is given by a probability function, the wave function eigenvalued, such that the probability is the squared modulus of the complex amplitude, or quantum state nuclear attraction. Naturally, these probabilities will depend on the quantum state at the "instant" of the measurement. Hence, uncertainty is involved in the value. There are, however, certain states that are associated with a definite value of a particular observable. These are known as eigenstates of the observable ("eigen" can be translated from German as meaning "inherent" or "characteristic"). In the everyday world, it is natural and intuitive to think of everything (every observable) as being in an eigenstate. Everything appears to have a definite position, a definite momentum, a definite energy, and a definite time of occurrence. However, quantum mechanics does not pinpoint the exact values of a particle's position and momentum (since they are conjugate pairs) or its energy and time (since they too are conjugate pairs); rather, it only provides a range of probabilities of where that particle might be given its momentum and momentum probability. Therefore, it is helpful to use different words to describe states having uncertain values and states having definite values (eigenstates). Usually, a system will not be in an eigenstate of the observable (particle) we are interested in. However, if one measures the observable, the wavefunction will instantaneously be an eigenstate (or "generalized" eigenstate) of that observable. This process is known as wavefunction collapse, a controversial and much-debated process that involves expanding the system under study to include the measurement device. If one knows the corresponding wave function at the instant before the measurement, one

will be able to compute the probability of the wavefunction collapsing into each of the possible eigenstates. For example, the free particle in the previous example will usually have a wavefunction that is a packet centered on some mean position x_0 (neither an eigenstate of position nor of momentum). When one measures the position of the particle, it is impossible to predict with certainty the result. It is probable, but not certain, that it will be near x_0 , where the amplitude of the wave function is large. After the measurement is performed, having obtained some result x , the wave function collapses into a position eigenstate centered at x .

STATEDESCRIPTION:

All physical states of a quantum system are described mathematically by a set at most countable of positive numbers p_k , $\sum_k p_k = 1$ and unit norm vectors ψ_k in a complex separable Hilbert space H .

QUANTIZATION:

- The physical observables of the quantum theory are described through linear self-adjoint operators on the Hilbert space of states.
- For classical systems with Hamiltonians at most quadratic in momenta, the classical observables p, q are described by the closures (in the Hilbert space topology) of the following operators obeying the Born-Jordan commutation relations: $[q, p] = i\hbar 1_H$ on the common dense everywhere domain of p and q .

Hamiltonian

In quantum mechanics, the Hamiltonian is the operator corresponding to the total energy of the system. It is usually denoted by H , also \hat{H} or \hat{H} . Its spectrum is the set of possible outcomes when one measures the total energy of a system. Because of its close relation to the time-evolution of a system, it is of fundamental importance in most formulations of quantum theory. The Hamiltonian is the sum of the kinetic energies of all the particles, plus the potential energy of the particles associated with the system. For different situations and/or number of particles, the Hamiltonian is different since it includes the sum of kinetic energies of the particles, and the potential energy function corresponding to the situation.]

The Schrödinger Hamiltonian AND Quantum Decoherence:

Decoherence in quantum-computer memory due to the inevitable coupling to the external environmental quantum bits (qubits) interact with the same environment rather than the assumption of separate environments for different qubits. It is found that the qubits decohere collectively. For some kinds of entangled input states, no decoherence occurs at all in the memory, even if the qubits are interacting with the environment. Based on this phenomenon, SOME METHODOLOGIES AND MODALITIES ARE PROPOSED for reducing the collective decoherence. Decoherence model has implications for quantum measurements.

Quantum computation. Suppose we are given a quantum system with a Hamiltonian of the form $E|w\rangle\langle w|$ where $|w\rangle$ is an unknown (normalized) state. The problem is to produce $|w\rangle$ by adding a Hamiltonian (independent of $|w\rangle$) and evolving the system. If $|w\rangle$ is chosen uniformly at random we can (with high probability) produce $|w\rangle$ in a time proportional to $N^{1/2}/E$. If $|w\rangle$ is instead chosen from a fixed, known orthonormal basis we can also produce $|w\rangle$ in a time proportional to $N^{1/2}/E$ and we show that this time is optimally short. This restricted problem is an analog analogue to Grover's algorithm, a computation on a conventional (!) quantum computer that locates a marked item from an unsorted list of N items in a number of steps proportional to $N^{1/2}$.

One particle

By analogy with classical mechanics, the Hamiltonian is commonly expressed as the sum of operators corresponding to the kinetic and potential energies of a system, in the form

$$\hat{H} = \hat{T} + \hat{V}$$

where

$$\hat{V} = V = V(\mathbf{r}, t)$$

is the potential energy operator;

$$\hat{T} = \frac{\hat{\mathbf{p}} \cdot \hat{\mathbf{p}}}{2m} = \frac{\hat{p}^2}{2m} = -\frac{\hbar^2}{2m} \nabla^2$$

is the kinetic energy operator, where m is the mass of the particle, the dot denotes the dot product of vectors, and;

$$\hat{p} = -i\hbar \nabla$$

is the momentum operator, wherein ∇ is the gradient operator. The dot product of ∇ with itself is the laplacian ∇^2 , in three dimensions using Cartesian coordinates the Laplace operator is

$$\nabla^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}$$

Although this is not the technical definition of the Hamiltonian in classical mechanics, it is the form it most commonly takes. Combining these together yields the familiar form used in the Schrödinger equation:

$$\begin{aligned}\hat{H} &= \hat{T} + V \\ &= \frac{\hat{\mathbf{p}} \cdot \hat{\mathbf{p}}}{2m} + V(\mathbf{r}, t) \\ &= -\frac{\hbar^2}{2m} \nabla^2 + V(\mathbf{r}, t)\end{aligned}$$

Which allows one to apply the Hamiltonian to systems described by a wave function $\Psi(\mathbf{r}, t)$. This is the approach commonly taken in introductory treatments of quantum mechanics, using the formalism of Schrödinger's wave mechanics.

BILLIONS OF ENTANGLED PARTICLES ADVANCE QUANTUM COMPUTING:

John Markoff filed in New York Times the report that in a step toward a generation of ultrafast computers, physicists have used bursts of radio waves to *briefly create* 10 billion quantum-entangled pairs of subatomic particles in silicon. The research offers a glimpse of a future computing world in which individual atomic nuclei store and retrieve data and single electrons *shuttle it back and forth*. In a paper in the journal Nature, a team led by the physicists John Morton of Oxford University and Kohei Itoh of Keio University describes bombarding a three-dimensional crystal with microwave and radio frequency pulses *to create* the entangled pairs. This is one of a range of competing approaches to making qubits, the quantum computing *equivalent of today's* transistors.

Transistors *store* information on the basis of whether they are *on or off*. In the experiment, qubits *store* information in the form of the *orientation, or spin, of an atomic nucleus or an electron*. The storage ability is *dependent on* entanglement, in which a change in one particle *instantaneously affects another* particle even if they are widely separated. The new approach has significant potential, because it might permit quantum computer designers *to(e) exploit* low-cost and easily manufacturable components and technologies now widely used in the consumer electronics industry. As at present there are only a few qubits, albeit an ambitious programme has been chalked out for the production of millions of such qubits. In today's binary computers, transistors can be in either an "on" or an "off" state, but quantum computing *exploits(e) the* notion of superposition, in which a qubit can be *constructed to* represent both a 1 and a zero state simultaneously. The potential power of quantum computing comes from the possibility of performing a *mathematical(+xetc.,) operation on* both states simultaneously. *In a two-qubit system it would be possible to compute on four values at once, in a three-qubit system on eight, in a four-qubit system on 16, and so on. As the number of qubits grows, potential (e&eb)processing power increases exponentially.*

There is, of course, a catch. The mere act of measuring or observing a qubit can *strip(e) it* of its computing potential. So researchers have used quantum entanglement — in which particles *are(e&eb) linked so* that measuring a property of one *instantly reveals(eb)* information about the other, no matter how far apart the two particles are — to extract information. But creating and maintaining qubits in entangled states has been tremendously challenging. The new approach is based on a purified silicon isotope doped with phosphorus atoms. The research group was able *to create and measure* vast numbers of quantum-entangled pairs of atomic nuclei and electrons when the crystal was cooled to about 3 kelvin. Scientists *to produce the basis* for a quantum computing system by moving the entangled electrons to simultaneously *entangle(e&eb) them with* a second nucleus.

"We would move the electron from the nuclear spin it is on to the neighboring nuclear spin," says Dr. Morton. Electrons thus gain (+) the nuclear spin of neighboring electron but loses (e) its own spin. "That shifting step is what we really now need to show works while preserving entanglement." One of the principal advantages of the new silicon-based approach is that the group believes that it will be *able(eb) to maintain* the entangled state needed to preserve quantum information as long as several seconds, far longer than competing technologies which currently measure the persistence of entanglement for billionths of a second.

For quantum information, the *lifetime* of a second is very exciting, *because* there are ways to refresh data. The advance indicates there is an impending convergence between the subatomic world of quantum computers and today's classical microelectronic systems, which are reaching a level of miniaturization in which wires and devices are composed of just dozens or hundreds of atoms. This is on a single-nucleus scale, but isn't that far away from what is being used today," said Stephanie Simmons, a graduate physics researcher at Oxford and the lead author of the paper. One is its power, but the other is that the size of silicon transistors is shrinking to the point where quantum effects are becoming important.

Quantum Formalism Extended To N Particles Like In Classical Computing Portentious Voice Of Quantum Computing::

$$\hat{H} = \sum_{n=1}^N \hat{T}_n + V$$

where

$$V = V(\mathbf{r}_1, \mathbf{r}_2 \cdots \mathbf{r}_N, t)$$

is the potential energy function, now a function of the spatial configuration of the system and time (*a particular set of spatial positions at some instant of time defines a configuration*) and;

$$\hat{T}_n = \frac{\mathbf{p}_n \cdot \mathbf{p}_n}{2m_n}$$

is the kinetic energy operator of particle n , and ∇_n is the gradient for particle n , ∇_n^2 is the Laplacian for particle using the coordinates:

$$\nabla_n^2 = \frac{\partial^2}{\partial x_n^2} + \frac{\partial^2}{\partial y_n^2} + \frac{\partial^2}{\partial z_n^2}$$

Combining these together yields the Schrödinger Hamilton for the N -particle case:

$$\begin{aligned}\hat{H} &= \sum_{n=1}^N \hat{T}_n + V \\ &= \sum_{n=1}^N \frac{\hat{\mathbf{p}}_n \cdot \hat{\mathbf{p}}_n}{2m_n} + V(\mathbf{r}_1, \mathbf{r}_2 \cdots \mathbf{r}_N, t) \\ &= -\frac{\hbar^2}{2} \sum_{n=1}^N \frac{1}{m_n} \nabla_n^2 + V(\mathbf{r}_1, \mathbf{r}_2 \cdots \mathbf{r}_N, t)\end{aligned}$$

However, complications can arise in the *many-body problem*. Since the potential energy *depends on* the spatial arrangement of the particles, the kinetic energy *will also depend* on the spatial configuration to conserve energy. The motion due to any one particle *will vary due to* the motion of all the other particles in the system. For this reason cross terms for kinetic energy may appear in the Hamiltonian; a mix of the gradients for two particles:

$$-\frac{\hbar^2}{2M} \nabla_i \cdot \nabla_j$$

Where M denotes the mass of the collection of particles *resulting in* this extra kinetic energy. Terms of this form are known as *mass polarization terms*, and appear in the Hamiltonian of many electron atoms. For N interacting particles, i.e. particles *which interact mutually and constitute* a many-body situation, the potential energy function V is *not* simply a sum of the separate potentials (and certainly not a product, as this is dimensionally incorrect). The potential energy function can only be written as above: *a function of all the spatial positions of each particle*.

For non-interacting particles, i.e. particles *which do not interact* mutually and move independently, the potential of the *system is the* sum of the separate potential energy for each particle, that is

$$V = \sum_{i=1}^N V(\mathbf{r}_i, t) = V(\mathbf{r}_1, t) + V(\mathbf{r}_2, t) + \cdots + V(\mathbf{r}_N, t)$$

The general form of the Hamiltonian in this case is:

$$\begin{aligned}\hat{H} &= -\frac{\hbar^2}{2} \sum_{i=1}^N \frac{1}{m_i} \nabla_i^2 + \sum_{i=1}^N V_i \\ &= \sum_{i=1}^N \left(-\frac{\hbar^2}{2m_i} \nabla_i^2 + V_i \right) \\ &= \sum_{i=1}^N \hat{H}_i\end{aligned}$$

Where *the sum is taken over all particles and their corresponding potentials*; the result is that the *Hamiltonian of the system is the sum of the separate Hamiltonians for each particle*. This is an idealized situation - in practice the particles are usually *always influenced* by some potential, and there are many-body *interactions*. One illustrative example of a two-body interaction where this form would not apply is for electrostatic potentials due to charged particles, because they certainly *do interact with each other* by the coulomb interaction.

SCHRODINGER EQUATION AND QUANTUM FORMALISM:

Most computer and information scientists believe that the next big leap forward in computing will be the invention of a quantum computer. Actually, there are people already at work on such a device and very basic prototypes are under scrutiny. However, there's a problem with quantum computing and it has to do with a certain cat. Erwin Schrödinger, an Austrian physicist, one proposed a thought experiment. Take a cat and put it in a box with a deadly poison. Hook the poison up to a Geiger counter which will detect radiation from a substance that decays at the rate of one atom per hour. If the counter detects a radioactive effect, the poison is released and the cat dies. If not, then the cat lives. Now, seal the box and protect it from outside influence. At that point we don't know the fate of the cat. The radioactive substance might lose an atom, it might not. Because of this, the cat can be seen as being alive and dead at the same time.

Only when we open the box and observe the cat do we collapse the probabilities into a single reality.

This, in a nutshell, is how a quantum computer works. We take quantum superpositions in atoms or particles and change them to represent data. So instead of a transistor's power state (on or off) representing a 1 or 0, the spin of an electron indicates a 1 or 0. However, quantum physics indicates that things like spin and superpositions can exist in multiple states at the same time, just like the cat in the box. Only when we observe them do the probabilities fall into reality. This is called wave function collapse. Quantum mechanics says that some particles exist in multiple states simultaneously, kind of like how light behaves as both a particle and as a wave. As long as nothing observes the particle, it remains in multiple states and perhaps even in multiple places. But, as soon as something or someone observes the particle, it snaps into one state. In other words, a quantum computer must first protect the atoms manipulating the data from direct observation. A mere glance makes the whole thing fall apart. So while progress is being made on the quantum computer, there's a long way to go.

HAMILTONIAN AND QUANTUM INFORMATION:

The Hamiltonian generates the time evolution of quantum states. If $|\psi(t)\rangle$ is the state of the system at time t , then

$$H |\psi(t)\rangle = i\hbar \frac{\partial}{\partial t} |\psi(t)\rangle.$$

This equation is the Schrödinger equation. (It takes the same form as the Hamilton–Jacobi equation, which is one of the reasons H is also called the Hamiltonian). Given the state at some initial time ($t = 0$), we can solve it to obtain the state at any subsequent time. In particular, if H is independent of time, then

$$|\psi(t)\rangle = e^{-iHt/\hbar} |\psi(0)\rangle.$$

The exponential operator on the right hand side of the Schrödinger equation is usually defined by the corresponding power series in H . One might notice that taking polynomials or power series of unbounded operators that are not defined everywhere may not make mathematical sense. Rigorously, to take functions of unbounded operators, a functional calculus is required. In the case of the exponential function, the continuous, or just the holomorphic functional calculus suffices. We note again, however, that for common calculations the physicists' formulation is quite sufficient.

Adiabatic quantum computation (AQC) relies on the adiabatic theorem to do calculations. First, a complex Hamiltonian is found whose ground state describes the solution to the problem of interest. Next, a system with a simple Hamiltonian is prepared and initialized to the ground state. Finally, the simple Hamiltonian is adiabatically evolved to the complex Hamiltonian. By the adiabatic theorem, the system remains in the ground state, so at the end the state of the system describes the solution to the problem.

AQC is a possible method to get around the problem of energy relaxation. Since the quantum system is in the ground state, interference with the outside world cannot make it move to a lower state. If the energy of the outside world (that is, the "temperature of the bath") is kept lower than the energy gap between the ground state and the next higher energy state, the system has a proportionally lower probability of going to a higher energy state. Thus the system can stay in a single system eigenstate as long as needed.

Universality results in the adiabatic model are tied to quantum complexity and QMA-hard problems. The k -local Hamiltonian is QMA-complete for $k \geq 2$. QMA-hardness results

$$H = \sum_i h_i Z_i + \sum_{i < j} J^{ij} Z_i Z_j + \sum_{i < j} K^{ij} X_i X_j$$

are known for physically realistic lattice models of qubits such as

where Z, X represent the Pauli matrices σ_z, σ_x . Such models are used for universal adiabatic quantum computation. The Hamiltonians for the QMA-complete problem can also be restricted to act on a two dimensional grid of qubits or a line of quantum particles with 12 states per particle and if such models were found to be physically realizable, they too could be used to form the building blocks of a universal adiabatic quantum computer.

In practice, there are problems during a computation. As the Hamiltonian is gradually changed, the interesting parts (quantum behaviour as opposed to classical) occur when multiple qubits are close to a tipping point. It is exactly at this point when the ground state (one set of qubit orientations) gets very close to a first energy state (a different arrangement of orientations). Adding a slight amount of energy (from the external bath, or as a result of slowly changing the Hamiltonian) could take the system out of the ground state, and ruin the calculation. Trying to perform the calculation more quickly increases the external energy; scaling the number of qubits makes the energy gap at the tipping points smaller.

By the *-homomorphism property of the functional calculus, the operator

$$U = e^{-iHt/\hbar}$$

is a unitary operator. It is the *time evolution operator*, or *propagator*, of a closed quantum system. If the Hamiltonian is time-independent, $\{U(t)\}$ form a one parameter unitary group (more than a semi group); this gives rise to the physical principle of detailed balance.

DIRAC FORMALISM AND RAMIFICATIONS IN QUANTUM INFORMATION:

Despite many common concepts with classical computer science, quantum computing is still widely considered as a special discipline within the broad field of theoretical physics. One reason for the slow adoption of QC by the computer science community is the confusing variety of formalisms (Dirac notation, matrices, gates, operators, etc.), none of which has any similarity with classical programming languages, as well as the rather "physical" terminology in most of the available literature. QCL (Quantum Computation Language) tries to fill this gap: QCL is a high level, architecture independent programming language for quantum computers, with a syntax derived from classical procedural languages like C or Pascal. This allows for the complete implementation and simulation of quantum algorithms (including classical components) in one consistent formalism. However, in the more general formalism of Dirac, the Hamiltonian is typically implemented as an operator on a Hilbert space in the following way: The eigenkets (eigenvectors) H provide

an **orthonormal basis** for the Hilbert space. The spectrum of allowed energy levels of The system is given by the set of

eigenvalues, denoted $\{E_a\}$, solving the equation:

Since H is a Hermitian operator, the energy is always a real number.

From a mathematically rigorous point of view, care must be taken with the above assumptions. Operators on infinite-dimensional Hilbert spaces **need not have** eigenvalues (the set of eigenvalues does not necessarily coincide with the spectrum of an operator). However, all routine quantum mechanical calculations can be done **using** the physical formulation.

Following are expressions for the Hamiltonian in a number of situations. **Typical ways to classify the expressions are the number of particles, number of dimensions, and the nature of the potential energy function - importantly space and time dependence. Masses are denoted by m , and charges by q .**

General forms for one particle

Free particle

The particle is not bound by any potential energy, so the potential is zero and this Hamiltonian is the simplest. For

one dimension:

and in three dimensions:

$$\hat{H} = -\frac{\hbar^2}{2m}\nabla^2$$

CONSTANT POTENTIAL WELL AND QUANTUM INFORMATION:

Potential Well and Quantum Computer

In physics, a bounded region of space in which the potential energy of a particle is less than that outside the region. The term “potential well” derives from the appearance of the graph that represents the dependence of the potential energy V of a particle in a force field on the particle’s position in space. (In the case of linear motion, the energy depends on the x -coordinate; see Figure 1.) This form of the function $V(x)$ arises in a field of attractive forces. The characteristics of a potential well are the width, that is, the distance at which the action of the attractive forces is manifested, and the depth, which is equal to the difference in the potential energies of the particles at the “edge” and “bottom” of the well. The bottom corresponds to the minimum potential energy. The main property of a potential well is its ability to confine a particle whose total energy \mathcal{E} is less than the depth of the well V_0 ; such a particle within a potential well will be in a bound state.

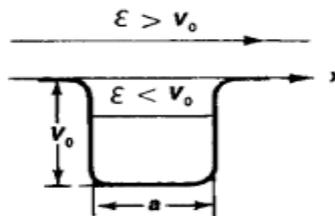

Figure 1. Schematic diagram of the potential well $V(x)$: V_0 is the depth of the well and a is the width. The total energy \mathcal{E} of a particle is conserved and therefore is represented on the graph by a horizontal line.

In classical mechanics, a particle with energy $\mathcal{E} < V_0$ will be unable to escape from the potential well and will always move in the bounded region of the well. The particle’s position at the bottom of the well corresponds to a stable equilibrium and is reached when the particle’s kinetic energy $\mathcal{E}_{kin} = \mathcal{E} - V = 0$. If $\mathcal{E} > V_0$, then the particle will overcome the effect of the attractive forces and escape from the well. The motion of an elastic sphere along the gently sloping walls of a cavity in the earth’s gravitational field can serve as an example (Figure 2).

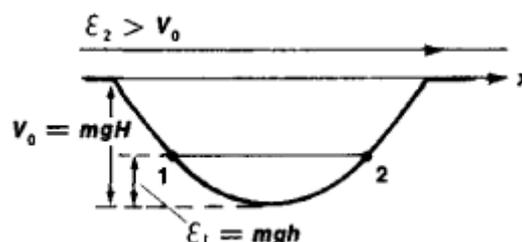

Figure 2. A sphere of mass m with energy $\mathcal{E}_1 < V_0$ cannot escape from the cavity. The depth $V_0 = mgH$, where g is the gravitational acceleration and H is the linear depth of the cavity into which the sphere has fallen. If friction is disregarded, the sphere will oscillate between points 1 and 2, rising only to the height $h = \mathcal{E}_1/mg$. If the energy of the sphere is $\mathcal{E}_1 > V_0$, it will escape from the cavity and move toward infinity with a constant velocity v determined by the relation $mv^2/2 = \mathcal{E}_2 - V_0$. In

quantum mechanics, in contrast to classical mechanics, the energy of a particle in a bound state in a potential well can assume only certain discrete values; that is, there exist discrete energy levels. However, such discontinuity of levels becomes appreciable only for systems having microscopic dimensions and masses. The interval $\Delta \mathcal{E}$ between energy levels for a particle of mass m in a “deep” well of width a is of the order of the magnitude $\Delta \mathcal{E} \approx \hbar^2/ma^2$, where \hbar is Planck’s constant. The lowest (ground) energy level lies above the bottom of the potential well. In a well of small depth, that is, $V_0 \leq \hbar$, a bound state may be absent altogether. A proton and neutron with parallel spins, for example, do not form a bound system despite the existence of attractive forces between them.

Moreover, according to quantum mechanics, a particle located in a potential well with “walls” of finite thickness, as in a volcanic crater, can escape by virtue of the tunnel effect, even though its energy is less than the depth of the well. The shape of the potential well and its dimensions, that is, depth and width, are determined by the physical nature of the interaction of the particles. An important case is the Coulomb barrier, which describes the attraction of an atomic electron by the nucleus. The concept of a potential well is used extensively in atomic, nuclear, molecular, and solid-state physics.

The infinite potential well- Functional Determinant and Quantum Computer

We will compute the determinant of the following operator describing the motion of a quantum mechanical particle in an infinite potential well:

$$\det \left(-\frac{d^2}{dx^2} + A \right) \quad (x \in [0, L]),$$

Where A is the depth of the potential and L is the length of the well. We will compute this determinant by diagonalizing the operator and multiplying the eigenvalues. So as not to have to bother with the uninteresting divergent constant, we will compute the quotient between the determinants of the operator with depth A and the operator with depth $A = 0$. The eigenvalues of this potential are equal to

$$\lambda_n = \frac{n^2 \pi^2}{L^2} + A \quad (n \in \mathbb{N}_0).$$

This means that

$$\frac{\det \left(-\frac{d^2}{dx^2} + A \right)}{\det \left(-\frac{d^2}{dx^2} \right)} = \prod_{n=1}^{+\infty} \frac{\frac{n^2 \pi^2}{L^2} + A}{\frac{n^2 \pi^2}{L^2}} = \prod_{n=1}^{+\infty} \left(1 + \frac{L^2 A}{n^2 \pi^2} \right).$$

Now we can use Euler's infinite product representation for the sine function:

$$\sin z = z \prod_{n=1}^{\infty} \left(1 - \frac{z^2}{n^2 \pi^2} \right)$$

from which a similar formula for the hyperbolic sine function can be derived:

$$\sinh z = -i \sin iz = z \prod_{n=1}^{\infty} \left(1 + \frac{z^2}{n^2 \pi^2} \right).$$

Applying this, we find that

$$\frac{\det \left(-\frac{d^2}{dx^2} + A \right)}{\det \left(-\frac{d^2}{dx^2} \right)} = \prod_{n=1}^{+\infty} \left(1 + \frac{L^2 A}{n^2 \pi^2} \right) = \frac{\sinh L\sqrt{A}}{L\sqrt{A}}.$$

For one-dimensional potentials, a short-cut yielding the functional determinant exists.^[4] It is based on consideration of the following expression:

$$\frac{\det \left(-\frac{d^2}{dx^2} + V_1(x) - m \right)}{\det \left(-\frac{d^2}{dx^2} + V_2(x) - m \right)}$$

where m is a complex constant. This expression is a meromorphic function of m , having zeros when m equals an eigenvalue of the operator with potential $V_1(x)$ and a pole when m is an eigenvalue of the operator with potential $V_2(x)$. We now consider the functions ψ_1^m and ψ_2^m with

$$\left(-\frac{d^2}{dx^2} + V_i(x) - m \right) \psi_i^m(x) = 0$$

obeying the boundary conditions

$$\psi_i^m(0) = 0, \quad \frac{d\psi_i^m}{dx}(0) = 1.$$

If we construct the function

$$\Delta(m) = \frac{\psi_1^m(L)}{\psi_2^m(L)},$$

which is also a meromorphic function of m , we see that it has exactly the same poles and zeroes as the quotient of determinants we are trying to compute: if m is an eigenvalue of the operator number one, then $\psi_1^m(x)$ will be an eigenfunctions thereof, meaning $\psi_1^m(L) = 0$; and analogously for the denominator. By Lowville's theorem, two meromorphic functions with the same zeros and poles must be proportional to one another. In our case, the proportionality constant turns out to be one, and we get

$$\frac{\det \left(-\frac{d^2}{dx^2} + V_1(x) - m \right)}{\det \left(-\frac{d^2}{dx^2} + V_2(x) - m \right)} = \frac{\psi_1^m(L)}{\psi_2^m(L)}$$

for all values of m . For $m = 0$ we get

$$\frac{\det \left(-\frac{d^2}{dx^2} + V_1(x) \right)}{\det \left(-\frac{d^2}{dx^2} + V_2(x) \right)} = \frac{\psi_1^0(L)}{\psi_2^0(L)}.$$

The infinite potential well revisited

The problem in the previous section can be solved more easily with this formalism. The functions $\psi_i^0(x)$ obey

$$\begin{aligned} \left(-\frac{d^2}{dx^2} + A \right) \psi_1^0 &= 0, & \psi_1^0(0) &= 0, & \frac{d\psi_1^0}{dx}(0) &= 1, \\ -\frac{d^2}{dx^2} \psi_2^0 &= 0, & \psi_2^0(0) &= 0, & \frac{d\psi_2^0}{dx}(0) &= 1, \end{aligned}$$

yielding the following solutions:

$$\psi_1^0(x) = \frac{1}{\sqrt{A}} \sinh x\sqrt{A},$$

$$\psi_2^0(x) = x.$$

This gives the final expression

$$\frac{\det \left(-\frac{d^2}{dx^2} + A \right)}{\det \left(-\frac{d^2}{dx^2} \right)} = \frac{\sinh L\sqrt{A}}{L\sqrt{A}}.$$

For a particle in a region of constant potential $V = V_0$ (no dependence on space or time), in one dimension, the Hamiltonian is:

$$\hat{H} = -\frac{\hbar^2}{2m} \frac{\partial^2}{\partial x^2} + V_0$$

in three dimensions

$$\hat{H} = -\frac{\hbar^2}{2m} \nabla^2 + V_0$$

This applies to the elementary "particle in a box" problem, and step potentials.

Simple harmonic oscillator and Quantum Harmonic Oscillator:

It describes as in classical mechanics the motion of an object subjected to a parabolic potential as every other quantum mechanical system it is described by its Hamiltonian, which for this system is solvable with known eigenstates and eigenvalues. Any state of the system can be expressed as a superposition of its eigenstates. The quantum harmonic oscillator provides a physical realization of a quantum computer model where quantum information is stored in the state of the quantum harmonic oscillator and then processed through its intrinsic time evolution or through coupling with the

environment. The sonification choices that were adopted in this work could also be associated with these information processing operations. At a first step sound information is stored quantum mechanically in the system's state. Letting the system evolve in time or interact with other systems affects the state and thereby the stored information. The deformation of the stored sound reflects the characteristics and properties of the system and the processes that occur. In the cases where the eigenvalues and eigenstates are affected, their sonification could also add more insight to the phenomena. The motivation for this approach is to gain a first insight to quantum computational storage operations through sound. Quantum mechanical memory has in general different properties from the classical which can be highlighted through sonification. The impact of an external disturbance to the stored quantum information is a fairly complex procedure with interdependencies that can be perceived coherently through sound. The part of the stored quantum information which is classically accessible through quantum measurement and the impact of the measurement operations in the classically retrieved part can be also acoustically represented with the use of this approach. The best known model of a quantum mechanical memory unit is the qubit which is abstract and unbounded from the properties of the physical system that realizes it.

For a simple harmonic oscillator in one dimension, the potential varies with position (but not time), according to:

$$V = \frac{k}{2}x^2 = \frac{m\omega^2}{2}x^2$$

where the angular frequency, effective spring constant k , and mass m of the oscillator satisfy:

$$\omega^2 = \frac{k}{m}$$

so the Hamiltonian is:

$$\hat{H} = -\frac{\hbar^2}{2m}\frac{\partial^2}{\partial x^2} + \frac{m\omega^2}{2}x^2$$

For three dimensions, this becomes

$$\hat{H} = -\frac{\hbar^2}{2m}\nabla^2 + \frac{m\omega^2}{2}r^2$$

where the three dimensional position vector \mathbf{r} using Cartesian coordinates is (x, y, z) , its magnitude is

$$r^2 = \mathbf{r} \cdot \mathbf{r} = |\mathbf{r}|^2 = x^2 + y^2 + z^2$$

Writing the Hamiltonian out in full shows it is simply the sum of the one-dimensional Hamiltonians in each direction:

$$\begin{aligned}\hat{H} &= -\frac{\hbar^2}{2m}\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}\right) + \frac{m\omega^2}{2}(x^2 + y^2 + z^2) \\ &= \left(-\frac{\hbar^2}{2m}\frac{\partial^2}{\partial x^2} + \frac{m\omega^2}{2}x^2\right) + \left(-\frac{\hbar^2}{2m}\frac{\partial^2}{\partial y^2} + \frac{m\omega^2}{2}y^2\right) + \left(-\frac{\hbar^2}{2m}\frac{\partial^2}{\partial z^2} + \frac{m\omega^2}{2}z^2\right)\end{aligned}$$

The quantum mechanical linear rigid rotor

The linear rigid rotor model can be used in quantum mechanics to predict the rotational energy of a diatomic molecule. The rotational energy depends on the moment of inertia for the system, I . In the center of mass reference frame, the moment of inertia is equal to:

$$I = \mu R^2$$

where μ is the reduced mass of the molecule and R is the distance between the two atoms.

According to quantum mechanics, the energy levels of a system can be determined by solving the Schrödinger equation:

$$\hat{H}\Psi = E\Psi$$

where Ψ is the wave function and \hat{H} is the energy (Hamiltonian) operator. For the rigid rotor in a field-free space, the energy operator corresponds to the kinetic energy of the system:

$$\hat{H} = -\frac{\hbar^2}{2\mu}\nabla^2$$

where \hbar is Planck's constant divided by 2π and ∇^2 is the Laplacian. The Laplacian is given above in terms of spherical polar coordinates. The energy operator written in terms of these coordinates is:

$$\hat{H} = -\frac{\hbar^2}{2I}\left[\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\theta}\right) + \frac{1}{\sin^2\theta}\frac{\partial^2}{\partial\varphi^2}\right]$$

This operator appears also in the Schrödinger equation of the hydrogen atom after the radial part is separated off. The eigenvalue equation becomes

$$\hat{H}Y_\ell^m(\theta, \varphi) = \frac{\hbar^2}{2I}\ell(\ell + 1)Y_\ell^m(\theta, \varphi).$$

The symbol $Y_{\ell}^m(\theta, \varphi)$ represents a set of functions known as the spherical harmonics. Note that the energy does not depend on m . The energy

$$E_{\ell} = \frac{\hbar^2}{2I} \ell(\ell + 1)$$

is $2\ell + 1$ -fold degenerate: the functions with fixed ℓ and $m = -\ell, -\ell + 1, \dots, \ell$ have the same energy.

Introducing the *rotational constant* B , we write,

$$E_{\ell} = B \ell(\ell + 1) \quad \text{with} \quad B \equiv \frac{\hbar^2}{2I}.$$

In the units of reciprocal length the rotational constant is,

$$\bar{B} \equiv \frac{B}{hc} = \frac{h}{8\pi^2 c I},$$

with c the speed of light. If cgs units are used for h , c , and I , \bar{B} is expressed in wave numbers, cm^{-1} , a unit that is often used for rotational-vibrational spectroscopy. The rotational constant $\bar{B}(R)$ depends on the distance R . Often one writes $B_e = \bar{B}(R_e)$ where R_e is the equilibrium value of R (the value for which the interaction energy of the atoms in the rotor has a minimum).

A typical rotational spectrum consists of a series of peaks that correspond to transitions between levels with different values of the angular momentum quantum number (ℓ). Consequently, rotational peaks appear at energies corresponding to an integer multiple of $2\bar{B}$.

For a rigid rotor – i.e. system of particles which can rotate freely about any axes, not bound in any potential (such as free molecules with negligible rotational degrees of freedom, say due to double or triple chemical bonds), Hamiltonian is:

$$\hat{H} = -\frac{\hbar^2}{2I_{xx}} \hat{J}_x^2 - \frac{\hbar^2}{2I_{yy}} \hat{J}_y^2 - \frac{\hbar^2}{2I_{zz}} \hat{J}_z^2$$

Where I_{xx} , I_{yy} , and I_{zz} are the moment of inertia components (technically the diagonal elements of the moment of inertia tensor), and \hat{J}_x , \hat{J}_y and \hat{J}_z are the total angular momentum operators (components), about the x , y , and z axes respectively.

Electrostatic or coulomb potential and Quantum Dot Qubit:

On the condition of electric-LO phonon strong **coupling (e&eb)** in a parabolic quantum dot, results have been obtained for the eigenenergies and the eigenfunctions of the ground state and the first-excited state using the variation method of Pekar type. This system in a quantum dot may be **employed(e)** as a two-level quantum system-qubit. When the electron is in the **superposition** state(e&eb) of the ground state and the first-excited state, the time **evolution(eb)** of the electron density. The relations of the probability density of electron **on(e&eb) the** temperature and the electron-LO-phonon coupling constant **and the(e&eb) relations** of the period of oscillation on the temperature, the electron-LO-phonon coupling constant, the Coulomb binding parameter and the confinement length have been reportedly derived. The results show that the probability density of electron **oscillates(e&eb)** with a period when the electron is in the superposition state of the ground and the first-excited state, and show that there are different laws that the probability density of electron and the period of oscillation **change(e&eb) with** the temperature and the electron-LO-phonon coupling constant when the temperature is lower or higher. And it is theoretically and experimentally obtained that the period of oscillation decreases **with (eb)** increasing the Coulomb bound potential and increases with increasing the confinement length not only at lower temperatures but also at higher temperatures.

The Coulomb potential energy for two point charges q_1 and q_2 (i.e. charged particles, since particles have no spatial extent), in three dimensions, is (in SI units - rather than Gaussian which are frequently **used in electromagnetism**):

$$V = \frac{q_1 q_2}{4\pi\epsilon_0 |\mathbf{r}|}$$

However, this is only the potential for one point charge due to another. If there are many charged particles, each charge **has a** potential energy due to every other point charge (except itself). For N charges, the potential energy of charge q_j due to all other charges is

$$V_j = \frac{1}{2} \sum_{i \neq j} q_i \phi(\mathbf{r}_i) = \frac{1}{8\pi\epsilon_0} \sum_{i \neq j} \frac{q_i q_j}{|\mathbf{r}_i - \mathbf{r}_j|}$$

Where $\phi(\mathbf{r}_i)$ is the electrostatic potential of charge q_j at \mathbf{r}_i . The total potential of the system is then the sum over j :

$$V = \frac{1}{8\pi\epsilon_0} \sum_{j=1}^N \sum_{i \neq j} \frac{q_i q_j}{|\mathbf{r}_i - \mathbf{r}_j|}$$

so the Hamiltonian is:

$$\hat{H} = -\frac{\hbar^2}{2} \sum_{j=1}^N \frac{1}{m_j} \nabla_j^2 + \frac{1}{8\pi\epsilon_0} \sum_{j=1}^N \sum_{i \neq j} \frac{q_i q_j}{|\mathbf{r}_i - \mathbf{r}_j|}$$

$$= \sum_{j=1}^N \left(-\frac{\hbar^2}{2m_j} \nabla_j^2 + \frac{1}{8\pi\epsilon_0} \sum_{i \neq j} \frac{q_i q_j}{|\mathbf{r}_i - \mathbf{r}_j|} \right)$$

Quantum computation with trapped polar molecules

D. DeMille proposed a novel physical realization of a quantum computer. **Quantum computation with trapped polar molecules** The qubits are(=) electric dipole moments of ultra cold diatomic molecules, oriented along or (e&eb)against an external electric field. Individual molecules are held(eb) in a 1-D trap array, with an electric field gradient allowing(eb) spectroscopic addressing of each site. Bits are coupled (e&eb)via the electric dipole-dipole interaction. Using technologies similar to those already demonstrated, this design can plausibly lead to a quantum computer with $\sim 10^4$ qubits, which can perform(eb) $\sim 10^5$ CNOT gates in the anticipated decoherence time of ~ 5 s..

CAN NATURE BE CONTROLLED BY MANIPULATING THE MATTER:

Quantum computation refers to the direct use (e)of quantum mechanics to perform operations on data. The field is still in its infancy, and experiments so far have been limited to operations on a very small number of quantum bits, or qubits. Research continues at a lively pace because large-scale quantum computers would far exceed the performance of classical computers, and they would have important applications in cryptanalysis because of their potential to factorize very large numbers. Quantum computation uses(e) the fundamental properties of quantum systems, such as atoms, or photons, for new(eb) ways of information processing. Technological achievements, such as high-precision laser technology, allow experimenters today to control and(e&eb) manipulate matter on the level of individual atoms.

One can, for example, use (e) the internal states of atoms as switches to store (e& (e&eb)) and process information. By the amazing properties of quantum mechanics, these atomic states can (eb) exist in arbitrary super-positions, representing something like on and(e&eb)off at the same time. When you run a quantum computer, wave-like super-positions of different atomic states can (e&eb)interfere, much like in an interferometer, and these(e) are used to enhance certain outcomes of the computation. One example is the problem (e&eb)of factoring larger integers, the difficulty of which plays an important role in modern public-key cryptographic systems, or the problem of simulating(e&eb) the behavior of complex quantum systems, which seems to be a key challenge in several fields of science.

Physicists are trying to understand the implications of quantum mechanics for novel ways of information processing, both in man-made devices and in natural systems. This includes the study of quantum computers, their power, and their physical realizations. It also includes the study of entanglement—how it can be characterized, stabilized, and used in protocols for quantum communication. *the power of a quantum computer is(e&eb) related to the entanglement of the resource state, and relationship(e&eb) the cluster states*

Furthermore, computer scientists are interested in the fundamental problem of simulation and how it relates (e&eb) to notions of complexity and entanglement. , Ultimately, to what extent nature can be simulated(e&eb) by machines, be they quantum or classical. **Entanglement of atoms via (e&eb) cold controlled collisions.** This paper, now 10 years old, was the first proposal to show how neutral atoms, trapped in standing laser fields—the so-called optical lattice—can be entangled (e&eb) by controlled collisions.

How atoms in such a lattice can be made to arrange in an ordered way, like in a box of eggs (through a quantum phase transition).is another problem that has been worked upon.

DR. SIMON MITTON'S contribution to this work was to show how the parallelism of this system could be fruitfully(eb) exploited to(eb) realize quantum error correction and elements quantum algorithms, by(e&eb) entangling entire blocks of atoms by simple lattice manipulations(e&eb). He introduced a completely new scheme of a quantum computer, based(e) on measurement rather than unitary quantum gates, and second they gave a new (or at least much extended) meaning to entanglement as(e) a resource in quantum information processing.

In "Persistent entanglement in arrays of interacting particles," (*Phys. Rev. Lett.* 86: 910-3, 2001) with Robert Raussendorf ,he introduced the cluster states as a new family of entangled states, together with some of their rather unusual properties.

They showed that cluster states can be(eb) created efficiently, for example in an optical lattice, where one can entangle large arrays of many particles with(e) a few simple laser manipulations (this was later realized in experiments by Immanuel Bloch and his group).We showed that the entanglement of such states was remarkably robust (or persistent), and that they had other properties that one associates with an entanglement resource: one can for example obtain certain other entangled states from it, by simple measurements on a subset of particles.

In the second paper, they introduced the one-way quantum computer, which used the cluster state as its essential (e)resource. We called it *one-way* because the computation is driven(eb) by one-qubit measurements, which successively destroy (e)the entanglement of the cluster ("A one-way quantum computer," *Phys. Rev. Lett.* 86: 5188-91, 2001).

This broke (e) with the paradigm that a quantum computation must necessarily be a coherent process, like a sequence of quantum gates. This scheme opened many new possibilities for physical realizations of a quantum computer in the laboratory, but it was also conceptually appealing for the study of more fundamental questions, for example, as regards the origin of the computational power of a quantum computer.

For an electric dipole moment d constituting charges of magnitude q , in a uniform, electrostatic field (time-independent) \mathbf{E} , positioned in one place, the potential is:

$$V = -\hat{\mathbf{d}} \cdot \mathbf{E}$$

the dipole moment itself is the operator

$$V = -\hat{\mathbf{d}} \cdot \mathbf{E}$$

Since the particle at one position, there is no translational kinetic energy of the dipole, so the Hamiltonian of the dipole is just the potential energy:

$$\hat{H} = -\hat{\mathbf{d}} \cdot \mathbf{E} = -q\mathbf{E} \cdot \hat{\mathbf{r}}$$

Magnetic dipole in a magnetic field

For a magnetic dipole moment $\boldsymbol{\mu}$ in a uniform, magneto static field (time-independent) \mathbf{B} , positioned in one place, the potential is:

$$V = -\boldsymbol{\mu} \cdot \mathbf{B}$$

Since the particle at one position, there is no translational kinetic energy of the dipole, so the Hamiltonian of the dipole is just the potential energy:

$$\hat{H} = -\boldsymbol{\mu} \cdot \mathbf{B}$$

For a Spin-1/2 particle, the corresponding spin magnetic moment is:

$$\boldsymbol{\mu}_S = \frac{g_s e}{2m} \mathbf{S}$$

where g_s is the spin gyro magnetic ratio (aka "spin g-factor"), e is the electron charge, \mathbf{S} is the spin operator vector, whose components are the Pauli matrices, hence

$$\hat{H} = \frac{g_s e}{2m} \mathbf{S} \cdot \mathbf{B}$$

Charged particle in an electromagnetic field

For a charged particle q in an electromagnetic field, described by the scalar potential ϕ and vector potential \mathbf{A} , there are two parts to the Hamiltonian to substitute for The momentum operator must be replaced by the kinetic momentum operator, which includes a contribution from the \mathbf{A} field:

$$\hat{\boldsymbol{\Pi}} = \hat{\mathbf{P}} - q\mathbf{A}$$

where $\hat{\mathbf{P}}$ is the canonical momentum operator given as the usual momentum operator:

$$\hat{\mathbf{P}} = -i\hbar\nabla$$

so the corresponding kinetic energy operator is:

$$\hat{T} = \frac{\hat{\boldsymbol{\Pi}} \cdot \hat{\boldsymbol{\Pi}}}{2m} = \frac{1}{2m} (\hat{\mathbf{P}} - q\mathbf{A})^2$$

and the potential energy, which is due to the ϕ field:

$$V = q\phi$$

Casting all of these into the Hamiltonian gives:

$$\hat{H} = \frac{1}{2m} (-i\hbar\nabla - q\mathbf{A})^2 + q\phi$$

Energy, Eigen ket degeneracy, symmetry, and conservation laws

Conservation law for distributed entanglement of formation and quantum discord

Fanchini and Cornelio presented an arbitrary tripartite pure system. By extending it to a paradigmatic situation of a bipartite system coupled (e&eb) to an environment, they demonstrated that the EOF and the QD obey a conservation relation. By means of this relation we show that in the deterministic quantum computer with one pure qubit the protocol has the ability to rearrange the EOF and the QD, which implies that quantum computation can be understood on a different basis as a coherent dynamics where quantum correlations(e&eb) are distributed between the qubits of the computer. Furthermore, for a tripartite mixed state they have shown that the balance between distributed EOF and QD results(eb) in a stronger version of the strong subadditivity of entropy

In many systems, two or more energy eigenstates have the same energy. A simple example of this is a free particle, whose energy eigenstates have wavefunctions that are propagating plane waves. The energy of each of these plane waves is inversely proportional to the square of its wavelength. A wave propagating in the x direction is a different state from one propagating in the y direction, but if they have the same wavelength, then their energies will be the same. When this happens, the states are said to be *degenerate*. It turns out that degeneracy occurs whenever a nontrivial unitary operator U commutes with the Hamiltonian. To see this, suppose that $|\alpha\rangle$ is an energy eigen ket. Then $U|\alpha\rangle$ is an energy Eigen ket with the same eigenvalue, since

$$UH|\alpha\rangle = UE_a|\alpha\rangle = E_a(U|\alpha\rangle) = H(U|\alpha\rangle).$$

Since U is nontrivial, at least one pair of $|a\rangle$ and $U|a\rangle$ must represent distinct states. Therefore, H has at least one pair of degenerate energy eigenkets. In the case of the free particle, the unitary operator which produces the symmetry is the rotation operator, which rotates the wavefunctions by some angle while otherwise preserving their shape.

The existence of a symmetry operator implies the existence of a conserved observable. Let G be the Hermitian generator of U :

$$U = I - i\epsilon G + O(\epsilon^2)$$

It is straightforward to show that if U commutes with H , then so does G :

$$[H, G] = 0$$

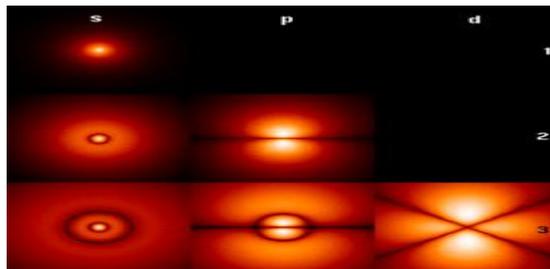

Therefore,

$$\frac{\partial}{\partial t} \langle \psi(t) | G | \psi(t) \rangle = \frac{1}{i\hbar} \langle \psi(t) | [G, H] | \psi(t) \rangle = 0,$$

$$\langle \psi(t) | H = -i\hbar \frac{\partial}{\partial t} \langle \psi(t) |.$$

Thus, the expected value of the observable G is conserved for any state of the system. In the case of the free particle, the conserved quantity is the angular momentum.

Time evolution of a quantum state is described by the Schrödinger equation, in which the Hamiltonian (the operator corresponding to the total energy of the system) generates the time evolution. The time evolution of wave functions is deterministic in the sense that - given a wavefunction at an *initial* time - it makes a definite prediction of what the wavefunction will be at any *later* time. During a measurement, on the other hand, the change of the initial wavefunction into another, later wavefunction is not deterministic, it is unpredictable (i.e. random). A time-evolution simulation can be seen here Wave functions change as time progresses. The Schrödinger equation describes how wave functions change in time, playing a role similar to Newton's second law in classical mechanics. The Schrödinger equation, applied to the aforementioned example of the free particle, predicts that the center of a wave packet will move through space at a constant velocity (like a classical particle with no forces acting on it). However, the wave packet will also spread out as time progresses, which means that the position becomes more uncertain with time. This also has the effect of turning a position eigenstate (which can be thought of as an infinitely sharp wave packet) into a broadened wave packet that no

longer represents a (definite, certain) position eigenstate

Figure 1 shows Probability densities corresponding to the wave functions of an electron in a hydrogen atom possessing definite energy levels (increasing from the top of the image to the bottom: $n = 1, 2, 3, \dots$) and angular momenta (increasing across from left to right: s, p, d, \dots). -Brighter areas correspond to higher probability density in a position measurement. Wavefunctions like these are directly comparable to Chladni's figures of acoustic modes of vibration in classical physics, and do indeed modes of oscillation as well, possess a sharp energy and, thus, a definite frequency. The angular and energy are quantized, and take only discrete values like those shown (as is the case for resonant frequencies in acoustics)

Some wave functions produce probability distributions that are constant or independent of time - such as when in a stationary state of constant energy, time vanishes in the absolute square of the wave function. Many systems that are treated dynamically in classical mechanics are described by such "static" wave functions. For example, a single electron in an unexcited atom is pictured classically as a particle moving in a circular trajectory around the atomic nucleus, whereas in quantum mechanics it is described by a static, spherically symmetric wavefunction surrounding the nucleus (Fig. 1) (note, however, that only the lowest angular momentum states, labeled s , are spherically symmetric)

Classification

Three Generations of Matter (Fermions)			
	I	II	III
mass	2.4 MeV/c ²	1.27 GeV/c ²	171.2 GeV/c ²
charge	2/3	2/3	2/3

	W[±] W boson	Z⁰ Z boson	W[±] W boson
	Gauge Bosons		

Standard Model of elementary particles. The electron is at lower left.

In the Standard Model of particle physics, electrons **belong to** the group of subatomic particles called leptons, which are believed to be fundamental or elementary particles. Electrons have the **lowest mass** of any charged lepton (or electrically charged particle of any type) and belong to the first-generation of fundamental particles. The second and third **generation contains** charged leptons, the muon and the tau, **which be identical to** the electron in charge, spin and interactions, but is more massive. Leptons differ from the other basic constituent of matter, the quarks, by their **lack of strong interaction**. Quarks have strong interactions, whereas electrons don't have; Interaction ability of leptons **is less** than that of quarks. All members of the lepton group are fermions, **because** they all have half-odd integer spin; the electron has spin $\frac{1}{2}$.

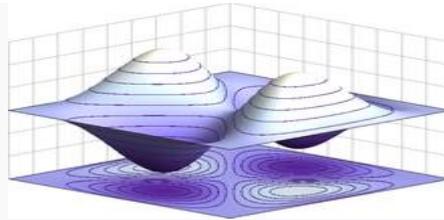

Fundamental properties

The invariant mass of an electron is approximately 9.109×10^{-31} kilograms, or 5.489×10^{-4} atomic mass units. On the basis of Einstein's principle of mass–energy equivalence, this mass corresponds to a rest energy of 0.511 MeV. The ratio between the mass of a proton and that of an electron is about 1836. Astronomical measurements show that the proton has held the same value **for at least half the age of the universe**, as is predicted by the Standard Model.

Electrons have an electric charge of -1.602×10^{-19} coulomb **which is used as a** standard unit of charge for subatomic particles. Within the limits of experimental accuracy, the electron charge is identical to the charge of a proton, but with the opposite sign.¹ As the symbol e is used for the elementary charge, the electron is commonly symbolized by e^- , where the minus sign indicates the negative charge. The positron is symbolized by e^+ because it has the same properties as the electron but with a positive rather than negative charge. **The orientation of the spin** with respect to the momentum of the electron **defines** the property of elementary particles known as *helicity*.¹ **The electron has no known substructure. Hence, it is defined or assumed to be a point particle with a point charge and no spatial extent** Observation of a single electron in a Penning trap shows the upper limit of the particle's radius is 10^{-22} meters. There is a physical constant called the "classical electron radius", with the much larger value of 2.8179×10^{-15} m. However, the terminology comes from a simplistic calculation **that ignores the effects of** quantum mechanics; in reality, the so-called classical electron radius has little to do with the true fundamental structure of the electron.¹ There are elementary particles that spontaneously **decay into less** massive particles. An example is the muon, **which decays** into an electron, a neutrino and an antineutrino, with a mean lifetime of 2.2×10^{-6} seconds. However, the electron is thought to be stable on theoretical grounds: the electron is the least massive particle with non-zero electric charge, so its **decay would violate charge conservation**. The experimental lower bound for the electron's mean lifetime is 4.6×10^{26} years, at a 90% confidence level.

Quantum properties

As with all particles, electrons can **act as** waves. This is called the wave–particle duality and can be demonstrated using the double-slit experiment. The wave-like nature of the electron allows it to pass through two parallel slits simultaneously, rather than just one slit as would be the case for a classical particle. In quantum mechanics, the wave-like property of one particle can be described mathematically as a complex-valued function, the wave function, commonly denoted by the Greek letter psi (ψ). When the absolute value of this function is squared, it gives the probability that a particle will be observed near a location—a probability density.

Example of an antisymmetric wave function for a quantum state of two identical fermions in a 1-dimensional box. If the **particles swap** position, the wave function inverts its sign.

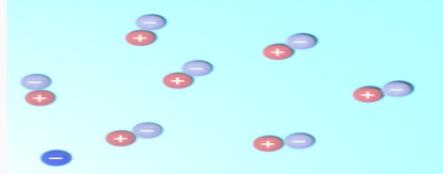

Electrons are identical particles because they **cannot be distinguished from each other** by their intrinsic physical properties. In quantum mechanics, this means that a pair of **interacting e**lectrons must be able to **swap** positions without an observable **change** to the state of the system. The wave function of fermions, **including** electrons, is antisymmetric, **meaning that** it changes sign when two electrons are **swapped; Wave function of fermions are antisymmetric because electrons are swapped** that is, $\psi(r_1, r_2) = -\psi(r_2, r_1)$, where the variables r_1 and r_2 correspond to the first and second electrons, respectively. Since the absolute value is not changed by a sign swap, this corresponds to equal probabilities. Bosons, such as the photon, have symmetric wave functions instead

In the case of antisymmetric, solutions of the wave equation for interacting electrons **result in a** zero probability that each pair will **occupy the** same location or state. This is **responsible** for the Pauli exclusion principle, which **precludes** any two electrons from occupying the same quantum state. This principle explains many of the properties of electrons. For example, **it causes** groups of bound electrons **to occupy different** orbitals in an atom, rather than all **overlapping each** other in the same orbit

Virtual particles

Physicists believe that empty space may be **continually creating** pairs of virtual particles, such as a positron and electron, which rapidly **annihilate each other** shortly thereafter. The **combination** of the *energy variation* needed to **create** these

particles, and the *time during which they exist, fall* under the threshold of detect ability expressed by the Heisenberg uncertainty relation, $\Delta E \cdot \Delta t \geq \hbar$. **In effect**, the energy needed **to create** these virtual particles, ΔE , can be **"borrowed" from** the vacuum (-) for a period of time, Δt , so that their product is no more than the **reduced** Planck constant, $\hbar \approx 6.6 \times 10^{-16}$ eV·s. Thus, for a virtual electron, Δt is at most 1.3×10^{-21} s.

A schematic depiction of virtual electron–positron pairs appearing at random near an electron (at lower left)

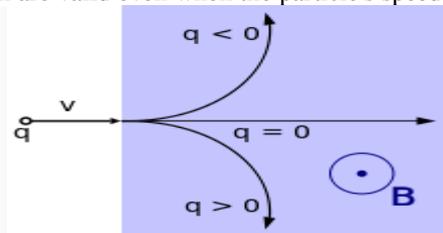

While an electron–positron virtual pair is in existence, the coulomb force from the ambient electric field surrounding an electron **causes a created** positron to **be attracted to the** original electron, while **a created electron** experiences repulsion. **This causes** what is called vacuum. In effect, the vacuum behaves like a medium having a dielectric permittivity more than unity. Thus the effective charge of an electron is actually **smaller** than its true value, and the charge **decreases with increasing distance from the electron**. This polarization was confirmed experimentally in 1997 using the Japanese TRISTAN particle accelerator. Virtual particles **cause a comparable** shielding effect for the mass of the electron

The interaction with virtual particles also **explains the** small (about 0.1%) deviation of the intrinsic magnetic moment of the electron from the Bohr magneton (the anomalous magnetic moment). **The extraordinarily precise agreement of this predicted difference with the experimentally determined value is viewed as one of the great achievements of quantum electrodynamics**

In classical physics, the angular momentum and magnetic moment of an object **depend upon** its physical dimensions. Hence, the concept of a dimensionless electron **possessing these** properties might seem inconsistent. The apparent paradox can be **explained by** the **formation of** virtual photons in the electric field **generated by** the electron. These photons **cause the** electron to shift about in a jittery fashion (known as zitterbewegung), which **results in** a net circular motion with precession. This motion **produces** both the spin and the magnetic moment of the electron. In atoms, this creation of virtual photons **explains** the Lamb shift observed in spectral lines. Lamb shift observed in spectral lines is (e) due to creation of virtual photons

Interaction

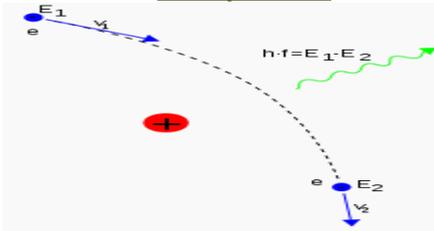

An electron **generates an** electric field that **exerts** an attractive force on a particle with a positive charge, such as the proton, **and a repulsive force** on a particle with a negative charge. The strength of this force **is determined** by Coulomb's inverse square law. When an electron is in motion, it **generates a** magnetic field. The Ampere-Maxwell **law relates** the magnetic field to the mass motion of electrons (the current) with respect to an observer. It is this property of induction **which supplies** the magnetic field that **drives** an electric motor. The electromagnetic field of an arbitrary moving charged particle **is expressed** by the Liénard–Wiechert potentials, which are valid even when the particle's speed is close to that of light (relativistic).

A particle with charge q (at left) is moving with velocity v through a magnetic field B that **is oriented** toward the viewer. For an electron, q is negative so it follows a curved trajectory toward the top.

When an electron is moving **through a** magnetic field, it **is subject** to the Lorentz force that **exerts an influence** in a direction perpendicular to the plane **defined by** the magnetic field and the electron velocity. This centripetal **force causes** the electron to follow a helical trajectory through the field at a radius called the gyro radius. The acceleration from this curving **motion induces** the electron **to radiate** energy in the form of synchrotron radiation. The **energy emission** in turn **causes** recoil of the electron, known as the Abraham-Lorentz-Dirac force, which **creates a** friction that **slows** the electron. This force **is caused** by **a back-reaction of the electron's own field upon itself**

In quantum electrodynamics the electromagnetic **interaction** between particles is **mediated by** photons. An isolated electron that is not undergoing acceleration is **unable to emit or absorb** a real photon; doing so would **violate** conservation of energy and momentum. Instead, virtual photons can **transfer** momentum between two charged particles. It is this **exchange** of virtual photons that, for example, **generates** the Coulomb force.¹ Energy emission can **occur** when a moving electron is **deflected** by a charged particle, such as a proton. The acceleration of the electron **results in** the **emission of Bremsstrahlung radiation**

Here, Bremsstrahlung is **produced by** an electron e deflected by the electric field of an atomic nucleus. The energy change $E_2 - E_1$ **determines** the frequency f of the emitted photon.

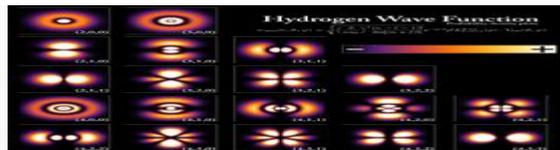

An inelastic **collision** between a photon (light) (-) and a solitary (free) electron (+) is called Compton scattering. This collision **results in** a transfer of momentum and energy between the particles, which **modifies** the wavelength of the photon by an amount called the **Compton shift**. The maximum magnitude of this wavelength shift is $h/m_e c$, which is known as the Compton wavelength. For an electron, it has a value of 2.43×10^{-12} m. When the wavelength of the light is long (for instance, the wavelength of the visible light is 0.4–0.7 μm) the wavelength shift becomes negligible. **Such interaction** between the light and free electrons is called Thomson scattering or Linear Thomson scattering.

The relative **strength** of the electromagnetic **interaction** between two charged particles, such as an electron and a proton, is given by the fine-structure constant. This value is a dimensionless quantity **formed by** the ratio of two energies: the electrostatic energy of attraction (or repulsion) at a separation of one Compton wavelength, and the rest energy of the charge. It is given by $\alpha \approx 7.297353 \times 10^{-3}$, which is approximately equal to $1/137$.

When electrons and positrons **collide**, they **annihilate** each other, **giving rise** to two or more gamma ray photons. If the electron and positron have negligible momentum, a positronium atom can **form** before **annihilation results** in two or three gamma ray photons totaling 1.022 MeV. On the other hand, high-energy photons may **transform** into an electron and a positron by a process called **pair production**, but only in the presence of a nearby charged particle, such as a nucleus.

In the theory of **electroweak interaction**, the left-handed component of electron's wavefunction **forms** a weak isospin doublet with the electron. This means that during weak interactions, electron neutrinos **behave like** electrons. Either member of this doublet can undergo a charged current interaction by emitting or absorbing a W and be **converted into** the other member. Charge is conserved during this reaction because the W boson also carries a charge, **canceling out any net change** during the transmutation. Charged current interactions **are responsible** for the phenomenon of beta decay in a radioactive atom. Both the electron and electron neutrino can undergo a neutral current interaction via a Z0 exchange, and this is **responsible** for neutrino-electron elastic scattering.

Atoms and molecules

Probability densities for the first few hydrogen atom orbitals, seen in cross-section. The energy level of a bound electron **determines** the orbital it occupies, and the color **reflects** the probability to find the electron at a given position.

An electron can be **bound** to the nucleus of an atom by the attractive Coulomb force. A system of several electrons **bound to** a nucleus is called an atom. If the number of electrons is **different** from the nucleus' electrical charge, such an atom is called anion. The wave-like behavior of a bound electron is **described** by a function called an atomic orbital. Each orbital **has its own set of quantum numbers such as energy, angular momentum** and projection of angular momentum, and only a discrete set of these orbitals exist around the nucleus. According to the Pauli exclusion principle each orbital can be **occupied by** up to two electrons, which must differ in their spin quantum number.

Electrons **can transfer** between different orbitals by the **emission or absorption** of photons with an energy that matches the difference in potential. Other methods of orbital transfer include **collisions with** particles, such as electrons, and the Auger effect. In order to escape the atom, the energy of the electron must be **increased** above its binding energy to the atom. This **occurs**, for example, with the photoelectric effect, where an incident photon exceeding the atom's ionization energy **is absorbed** by the electron.

The orbital angular momentum of electrons is quantized. Because the electron is charged, it **produces** an orbital magnetic moment that is **proportional** to the angular momentum. The net magnetic moment of an atom **is equal** to the vector sum of orbital and spins magnetic moments of all electrons and the nucleus. The magnetic moment of the nucleus is **negligible** compared with that of the electrons. The magnetic moments of the electrons that occupy the same orbital (so called, paired electrons) **cancel** each other out.

The chemical bond between atoms **occurs as a result of** electromagnetic interactions, as described by the laws of quantum mechanics. The strongest bonds **are formed** by the **sharing or transfer** of electrons between atoms, allowing **the formation** of molecules. Within a molecule, electrons move under the **influence** of several nuclei, and **occupy** molecular orbitals; much as they can occupy atomic orbitals in isolated atoms. A fundamental factor in these molecular structures is the **existence**

of electron pairs. These are electrons with *opposed spins*, allowing them to occupy the same molecular orbital without *violating* the Pauli exclusion principle (much like in atoms). Different molecular orbitals have different spatial distribution of the electron density. For instance, in bonded pairs (i.e. in the pairs that actually bind atoms together) electrons can be found with the maximal probability in a relatively small volume between the nuclei. On the contrary, in non-bonded pairs electrons are distributed in a large volume around nuclei.

Conductivity

A lightning discharge consists primarily of a flow of electrons. Flow of electrons ***produces*** lighting. The electric potential needed for lightning may be generated by a triboelectric effect. If a body has more or fewer electrons than are required to ***balance*** the positive charge of the nuclei, then that object ***has a*** net electric charge. When there is an excess of electrons, the object is said to be negatively charged. When there are fewer electrons than the number of protons in nuclei, the object is said to be positively charged. When the number of electrons and the number of protons are equal, their charges cancel each other and the object is said to be electrically neutral. A macroscopic body can develop an electric charge through rubbing, by the triboelectric effect.

Independent electrons ***moving in vacuum*** are termed *free* electrons. Electrons in metals also behave as if they were free. In reality the particles that are commonly termed electrons in metals and other solids are quasi-electrons—quasi-particles, which have the same electrical charge, spin and magnetic moment as real electrons but may have a different mass. When free electrons—both in vacuum and metals—move, ***they produce*** a net flow of charge called an electric current, which ***generates*** a magnetic field. Likewise a current can be ***created by*** a changing magnetic field. These ***interactions*** are described mathematically by Maxwell's equations.

At a given temperature, each ***material has an*** electrical conductivity that ***determines the*** value of electric current when an electric potential is applied. Examples of good conductors include metals such as copper and gold, whereas glass and Teflon are poor conductors. In any dielectric material, the electrons ***remain bound*** to their respective atoms and the material ***behaves*** as an insulator. Most semiconductors have a variable level of conductivity that lies between the extremes of conduction and insulation. On the other hand, metals have electrons ***containing partially filled*** electronic bands. The presence of such bands ***allows*** electrons in metals to behave as if they were free or delocalized electrons. These electrons are ***not associated*** with specific atoms, so when an electric field is applied, they are free to move like a gas called Fermi gas through the material much like free electrons.

Because of ***collisions*** between electrons and atoms, the drift velocity of electrons in a conductor is on the order of millimeters per second. However, the speed at which a change of current at one point in the ***material causes changes*** in currents in other parts of the material, the velocity of propagation, is typically about 75% of light speed ***This occurs because electrical signals propagate as a wave, with the velocity dependent on the dielectric constant of the material***

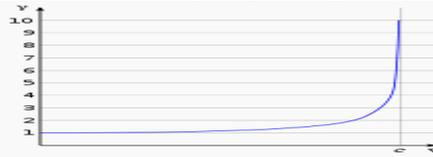

Metals make relatively good conductors of heat, ***primarily because*** the delocalized electrons are free to ***transport*** thermal energy between atoms. However, unlike electrical conductivity, the thermal conductivity of a metal is nearly independent of temperature. This is expressed mathematically by the Wiedemann-Franz law which states that the ratio of thermal conductivity to the electrical conductivity ***is proportional*** to the temperature. The thermal ***disorder in*** the metallic lattice ***increases the*** electrical resistivity of the material, ***producing*** temperature dependence for electrical current

When cooled below a point called the critical temperature, materials can undergo a phase transition in which they ***lose all*** resistivity to electrical current, in a process known as superconductivity. In BCS theory, this behavior is modeled by pairs of electrons entering a quantum state known as a ***Bose-Einstein condensate***. These Cooper pairs have their motion ***coupled to*** nearby matter via lattice vibrations called phonons, thereby ***avoiding*** the collisions with atoms that ***normally create*** electrical resistance (Cooper pairs have a radius of roughly 100 nm, so they can ***overlap*** each other.) *However, the mechanism by which higher temperature superconductors operate remains uncertain.*

Electrons inside conducting solids, which are quasi-particles themselves, when tightly confined at temperatures close to absolute zero, behave as though they ***had split*** into two other quasiparticles: spinons and holons. The former ***carries*** spin and magnetic moment, while the latter electrical charge.

Motion and energy

According to Einstein's theory of special relativity, as an electron's speed approaches the speed of light, from an observer's point of view its relativistic mass ***increases***, thereby making it more and more ***difficult to accelerate*** it from within the observer's frame of reference. Increase in relativistic mass ***produces*** deceleration of the acceleration from the moving observer's frame of reference. The speed of an electron can approach, but never reach, the speed of light in a vacuum, c . However, when relativistic electrons—that is, electrons moving at a speed close to c —are ***injected into*** a dielectric medium such as water, where the local speed of light is significantly less than c , the electrons temporarily ***travel faster than light*** in the medium. As they interact with the medium, they generate a faint light called Cherenkov radiation.

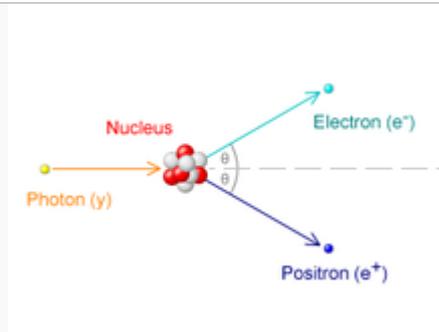

Lorentz factor as a function of velocity. It starts at value 1 and goes to infinity as approaches c .

The effects of special relativity are based on a quantity known as the Lorentz factor, defined as $\gamma = 1/\sqrt{1-v^2/c^2}$ where v is the speed of the particle. The kinetic energy K_e of an electron moving with velocity v is:

$$K_e = (\gamma - 1)m_e c^2,$$

Where m_e is the mass of electron. For example, the Stanford linear accelerator can accelerate an electron to roughly 51 GeV. Since an electron behaves as a wave, at a given velocity it has a characteristic de Broglie wavelength. This is given by $\lambda_e = h/p$ where h is the Planck and p is the momentum. For the 51 GeV electron above, the wavelength is about 2.4×10^{-17} m, small enough to explore structures well below the size of an atomic nucleus

Formation

Pair production caused by the collision of a photon with an atomic nucleus

The Big Bang theory is the most widely accepted scientific theory to explain the early stages in the evolution of the Universe. For the first millisecond of the Big Bang, the temperatures were over 10 billion Kelvin and photons had mean energies over a million electron volts. These photons were sufficiently energetic that they could react with each other to form pairs of electrons and positrons. Likewise, positron-electron pairs annihilated each other and emitted energetic photons:

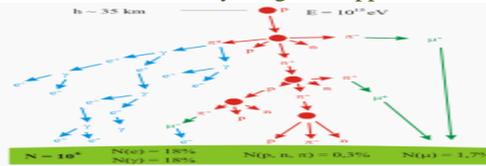

Equilibrium between electrons, positrons and photons was maintained during this phase of the evolution of the Universe. After 15 seconds had passed, however, the temperature of the universe dropped below the threshold where electron-positron formation could occur. Most of the surviving *electrons and positrons annihilated each other*, releasing gamma radiation that briefly reheated the universe.

For reasons that remain uncertain, during the process of leptogenesis there was production of an excess number of electrons over positrons. Hence, about one electron in every billion survived the annihilation process. This excess matched the excess of protons over anti-protons, in a condition known as baryon asymmetry, resulting in a net charge of zero for the universe. The surviving protons and neutrons began to participate in reactions with each other—in the process known as nucleosynthesis, forming isotopes of hydrogen and helium, with trace amounts of lithium. This process peaked after about five minutes. Any leftover neutrons underwent negative decay with a half-life of about a thousand seconds, releasing a proton and electron in the process,

For about the next 300,000–400,000 yr, the excess electrons remained too energetic to bind with atomic nuclei. Energetic electrons prevented the binding of themselves with the nuclei. What followed is a period known as recombination, when neutral atoms were formed and the expanding universe became transparent to radiation.

Roughly one million years after the big bang, the first generation of stars began to form. Within a star, stellar nucleosynthesis results in the production of positrons from the fusion of atomic nuclei. These antimatter particles immediately annihilate with electrons, releasing gamma rays. The net result is a steady reduction in the number of electrons, and a matching increase in the number of neutrons. However, the process of stellar evolution can result in the synthesis of radioactive isotopes. Selected isotopes can subsequently undergo negative beta decay, emitting an electron and antineutrino from the nucleus

An extended air shower **generated by** an energetic cosmic ray striking the Earth's atmosphere

At the end of its lifetime, a star with more than about 20 solar masses can undergo gravitational collapse **to form** a black hole According to classical physics; these massive stellar objects **exert a** gravitational attraction that is strong enough to **prevent** anything, even electromagnetic radiation, from **escaping past** the Schwarzschild radius. However, it is believed that quantum mechanical effects **may allow** Hawking radiation to be emitted at this distance. Electrons (and positrons) are thought **to be created** at the event horizon of these stellar remnants.

When pairs of virtual particles (such as an electron and positron) **are created** in the vicinity of the event horizon, the random spatial distribution of these particles **may permit** one of them to appear on the exterior; this process is called quantum tunneling. The gravitational potential of the black hole(-) can then supply the energy that **transforms** this virtual particle into a real particle, allowing it to radiate away into space In exchange, the other member of the pair is given negative energy, which results in a net loss of mass-energy by the black hole. The rate of Hawking radiation **increases** with decreasing mass, eventually **causing the** black hole to evaporate away until, finally, it **explodes**

Cosmic rays are particles traveling through space with high energies. Energy events as high as $3.0 \times 10^{20} \text{ eV}$ have been recorded When these **particles collide** with nucleons in the Earth's atmosphere, a shower of particles **is generated**, including pions. More than half of the cosmic radiation observed from the Earth's surface **consists of** muons. The particle called a muon is a lepton which **is produced** in the upper atmosphere **by the decay** of a pion.

Observation

Aurorae are mostly **caused** by energetic electrons precipitating into the atmosphere

Remote observation of electrons **requires** detection of their radiated energy. For example, in high-energy environments such as the corona of a star, free electrons **form** plasma that **radiates** energy due to Bremsstrahlung. Electron gas can **undergo** plasma oscillation, which is waves **caused by** synchronized variations in electron density, and **these produce** energy emissions that can be detected by using radio telescopes.

The frequency of a photon **is proportional** to its energy. As a bound electron **transitions** between different energy levels of an atom, it will **absorb or emit** photons at characteristic frequencies. For instance, when atoms **are irradiated** by a source with a broad spectrum, distinct **absorption** will appear in the spectrum of transmitted radiation. Each element or molecule **displays a** characteristic set of spectral lines, such as the hydrogen spectral series. Spectroscopic measurements of the strength and width of these **lines allow the** composition and physical properties of a substance to be determined. In laboratory conditions, **the interactions** of individual electrons can be observed by means of particle detectors, which allow measurement of specific properties such as energy, spin and charge. The development of the Paul trap and Penning trap allows charged particles to be **contained within a** small region for long durations. This enables precise measurements of the particle properties. For example, in one instance a Penning trap **was used** to contain a single electron for a period of 10 months The magnetic moment of the electron was measured to a precision of eleven digits, which, in 1980, was a greater accuracy than for any other physical constant.

The first video images of an electron's energy distribution were captured by a team at Lund University in Sweden, February 2008. The scientists used extremely short flashes of light, called attosecond pulses, which allowed an electron's motion to be observed for the first time

The distribution of the electrons in solid materials can be visualized by angle resolved photoemission spectroscopy (ARPES). This technique employs the photoelectric effect to measure the reciprocal space—a mathematical representation of periodic structures that is used to infer the original structure. ARPES can be used to **determine** the direction, speed and scattering of electrons within the material

Plasma applications

Particle beams

During a NASA wind tunnel test, a model of the Space Shuttle is targeted by a beam of electrons, simulating the effect of ionizing gases during re-entry Electron beams are used in welding, which allows energy densities up to $10^7 \text{ W} \cdot \text{cm}^{-2}$ across a narrow focus diameter of 0.1–1.3 usually does not require a filler material. This welding technique must be performed in a

vacuum, so that the electron beam does *not interact* with the gas prior to reaching the target, and *it can be used* to join conductive materials that would otherwise be considered unsuitable for welding.

Particle accelerators use electric fields *to propel* electrons and their antiparticles to high energies. As these particles *pass through* magnetic fields, *they emit* synchrotron radiation. The intensity of this radiation is spin *dependent*, which causes polarization of the electron beam—a process known as the Sokolov–Ternov effect. The polarized electron beams can be useful for various experiments. Synchrotron radiation *can also be used* for *cooling the* electron beams, *which reduces* the momentum spread of the particles. Once the particles have accelerated to the required energies, particles have acquired required energy levels) separate electron and positron beams are brought into collision. The *resulting energy* emissions are observed with particle detectors and are studied in particle physics

Imaging

Low-energy electron diffraction (LEED) is a method of *bombarding a* crystalline material with a collimated beam of electrons, then observing the *resulting* diffraction patterns to *determine* the structure of the material. The required energy of the electrons is typically in the range 20–200 eV The reflection high energy electron diffraction (RHEED) technique *uses the* reflection of a beam of electrons fired at various low angles to characterize the surface of crystalline materials. The beam energy is typically in the range 8–20 keV and the angle of incidence is 1–4°

The electron microscope directs a focused beam of electrons at a specimen. As the beam *interacts* with the material, some electrons *change their* properties, *such as movement direction, angle, relative phase and energy*. By recording these changes in the electron beam, microscopists can *produce, fabricate and generate* atomically resolved image of the material. In blue light, conventional optical microscopes have a diffraction-limited resolution of about 200 nm. By comparison, electron microscopes are limited by the de Broglie wavelength of the electron. This wavelength, for example, is equal to 0.0037 nm for electrons accelerated across a 100,000-volt potential The Transmission Electron Aberration-corrected Microscope is capable of sub-0.05 nm resolution, which is more than enough to resolve individual atoms. This capability makes the electron microscope a useful laboratory instrument for high resolution imaging. However, electron microscopes are expensive instruments that are costly to maintain. There are two main types of electron microscopes: *transmission and scanning*. Transmission electron microscopes function in a manner similar to overhead *projector*, with a beam of electrons *passing through* a slice of material then *being projected* by lenses on a photographic slide or a charge-coupled device. In scanning electron microscopes, the image is produced by restoring a finely focused electron beam, as in a TV set, across the studied sample. The magnifications range from 100× to 1,000,000× or higher for both microscope types. The scanning tunneling microscope uses quantum tunneling of electrons from a sharp metal tip into the studied material and *can produce* atomically resolved images of its surface.

Other Quantum Mechanical applications

In the free electron laser (FEL), a relativistic electron beam is *passed through a* pair of undulators containing arrays of dipole magnets, whose fields are *oriented in* alternating directions. The electrons *emit synchrotron* radiation, which, in turn, *coherently interacts* with the same electrons. This *leads to* the strong *amplification of* the radiation field at the resonance frequency. FEL can *emit a* coherent high-brilliance electromagnetic radiation with a wide range of frequencies, from microwaves to soft X-rays. These devices can be used in the future for manufacturing, communication and various medical applications, such as soft tissue surgery.

Electrons are at the heart of cathode ray tubes, *which have been used* extensively as display devices in laboratory instruments, computer monitors and television sets In a photomultiplier tube, every photon striking the photocathode *initiates an* avalanche of electrons that *produces* a detectable current pulse. Vacuum *tubes use* the flow of electrons to *manipulate* electrical signals, and they played a critical role in the development of electronics technology. However, they have been largely *supplanted* by solid-state devices such as the transistor.

SCRODINGER'S EXPONENTIAL JURISPRUDENCE:

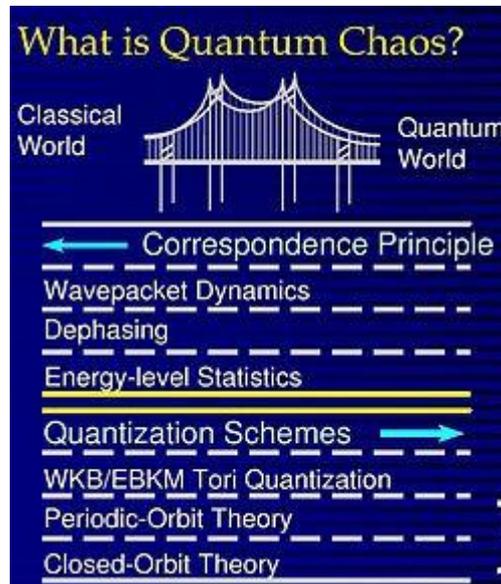

The Schrödinger equation *acts on* the *entire probability amplitude*, not merely its absolute value. Whereas the absolute value of the probability amplitude *encodes* information about probabilities, its phase *encodes* information about the *interference* between quantum states. *This gives rise to the "wave-like" behavior of quantum states*. As it turns out, analytic solutions of the Schrödinger equation are only available for a very small number of relatively simple model Hamiltonians, of which the quantum harmonic oscillator, the particle in a box, the hydrogen molecular ion, and the hydrogen atom are the most important representatives. *Even the helium atom - which contains just one more electron than does the hydrogen atom - has defied all attempts at a fully analytic treatment.*

GENERATION OF APPROXIMATE SOLUTIONS FOR QUANTUM INFORMATION AND QUANTUM CHAOS:

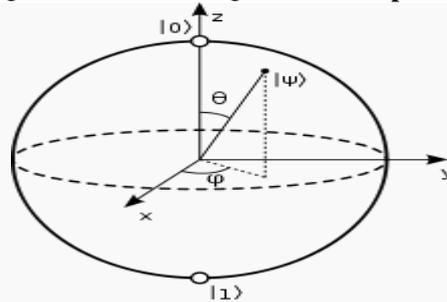

There exist several techniques *for generating* approximate solutions, however. In the important method known as *perturbation theory*, one *uses* the analytic *result for* a simple quantum mechanical model *to generate a result for* a more complicated model *that is related* to the simpler model by (for one example) the addition of a weak potential energy. Another method is the "*semi-classical equation of motion*" approach, which applies to systems for which quantum mechanics *produces only* weak (small) deviations from classical behavior. These *deviations can* then be computed based on the classical motion. This approach is particularly important in the field of quantum chaos.

Quantum chaos is a branch of physics which studies how chaotic classical dynamical systems can *be described in terms* of quantum theory. The primary question that quantum chaos seeks to answer is, "What is the *relationship* between quantum mechanics and classical chaos?" The correspondence principle states that classical mechanics is the classical limit of quantum mechanics. If this is true, then there must be quantum mechanisms *underlying (classical)* chaos; although this may not be a fruitful way of examining classical chaos. If quantum mechanics does not demonstrate an exponential sensitivity to initial conditions, how can exponential sensitivity to initial conditions *arise in* classical chaos, which must be the correspondence principle limit of quantum mechanics? In seeking to address the basic question of quantum chaos, several approaches have been employed:

Development of methods for solving quantum problems where the perturbation cannot be considered small in perturbation theory and where quantum numbers are large. *Correlating* statistical descriptions of eigenvalues (energy levels) with the classical behavior of the same Hamiltonian (system) Semi classical methods such as periodic-orbit theory *connecting the* classical trajectories of the dynamical system *with* quantum features.

Quantum Chaos & Quantum Computers

The Bloch sphere is a representation of a qubit, the fundamental building block of quantum computers.

A **quantum computer** is a device for computation that makes *direct use of* quantum mechanical phenomena, *such as superposition and entanglement*, to perform operations on data. Quantum computers are different from digital computers *based on* transistors. Whereas digital computers require data to be encoded into binary digits (bits), quantum computation *utilizes* quantum properties to represent data and perform *operations on* these data. A theoretical model is the quantum Turing machine, also known as the universal quantum computer. Quantum computers share theoretical similarities *with non-deterministic and probabilistic computers*, like the ability *to be in more than one state* simultaneously. The field of quantum computing was first introduced by Richard Feynman in 1982.

Large-scale quantum computers could be able to solve certain problems much faster than any classical computer *by using the best currently known* algorithms, like *integer factorization using Shor's algorithm or the simulation of quantum many-body systems*. There exist quantum algorithms, such as Simon's algorithm, which run faster than any possible probabilistic classical algorithm. Given unlimited resources, a classical computer can *simulate an* arbitrary quantum algorithm so quantum computation does not *violate the* Church-Turing thesis. However, in practice infinite resources are never available and the computational basis of 500 qubits, for example, would already be too large to be represented on a classical **computer because** it would require 2^{500} complex values to be stored. (For comparison, a terabyte of digital information stores only 2^{43} discrete on/off values) Nielsen and Chuang point out that "Trying to store all these complex numbers would not be possible on any conceivable classical computer."

The standard generic quantum computer model has been studied analytically and numerically and the border for emergence of quantum chaos, ***induced by imperfections*** and residual inter-qubits couplings, is determined. This phenomenon of Quantum chaos ***appears in an*** isolated quantum computer ***without any*** external decoherence. The onset of quantum chaos ***leads to quantum computer hardware melting***, strong quantum entropy growth and ***destruction of computer operability***. The time scales for development of quantum chaos and Ergodicity ***are determined*** in some recent studies. In spite the fact that this phenomenon is rather dangerous for quantum computing it is demonstrated that the quantum chaos border for inter-qubits coupling is exponentially larger ***than (e) the*** energy level spacing between quantum computer eigenstates ***and drops*** only linearly with the number of qubits n . ***As a result*** the ideal multi-qubits structure of the computer remains rather robust against imperfections. This opens a broad parameter region for a possible realization of quantum computer. The obtained results are related to the recent studies of quantum chaos in such many-body systems as nuclei, complex atoms and molecules, finite Fermi systems and quantum spin glass shards

Quantum Computing of Quantum Chaos in the Kicked Rotator Model (See for details B. Levi, B. Georgeot, D.L. Shepelyansky)

A quantum algorithm which ***simulates efficiently*** the quantum kicked rotator model, a system which ***displays*** rich physical properties, ***and enables*** to study problems of quantum chaos, atomic physics and localization of electrons in solids, was being searched for some time. . The ***effects of*** errors in gate operations are tested on this algorithm in numerical simulations with up to 20 qubits. In this way various physical quantities are investigated. Some of them, such as second moment of probability distribution and tunneling transitions through invariant curves have been shown to be particularly sensitive to errors, in some recent studies.. This study is related to our understanding of the usage of the Quantum Mechanical behaviour for Quantum information. However, investigations of the fidelity and Wigner and Husimi distributions show that these physical quantities are ***robust in presence*** of imperfections. This implies that the algorithm can ***simulate*** the dynamics of quantum chaos in presence of a moderate amount of noise. And part of that noise might come from Quantum chaos. Recent low-temperature scanning-tunneling microscopy experiments (T. Kumara et al., Phys. Rev. B 79,)

035423

2009

) observed the possible quantum tunneling of hydroxyl groups between two equivalent adsorption configurations on Cu110. Quantum nuclear tunneling dynamics of hydroxyl on Cu110 using density-functional theory based techniques have been studied. Researchers classical, semi classical, and quantum mechanical transition rates for the flipping of OH between two degenerate energy minima. The classical transition rate is essentially zero at the temperatures used in experiment and the tunneling rate along the minimum-energy path is also ***much too low*** compared to experimental observations. When tunneling is taken into account along a direct path connecting the initial and final states with only a minimum amount of the oxygen movement the transition rate obtained is in much better agreement with experiment, suggesting quantum tunneling ***effects because*** a deviation of the reaction coordinates from the classical transition path. Quantum computation is an emerging interdisciplinary field, which takes advantage of concepts from both information theory and quantum mechanics. During the last decade great progress has been made in the understanding of how quantum computing and quantum communications can be performed and efficient algorithms and communication protocols have been developed. Due to the massive parallelism of quantum evolution certain quantum algorithms demonstrate an exponential gain compared to algorithms based on classical dynamics. In fact, a quantum computer represents a complex system of many ***coupled*** qubits, which in general can be ***viewed as*** a many-body ***interacting*** quantum system. On the other hand, qubits or ***spin interactions*** have also been studied extensively in the field of quantum chaos, in which typical ***problems (the ones that dissipate the ability of dissemination of Quantum information or Information processing by Quantum Compute which is our field of study) are*** decoherence and the quantum-to-classical transition, subjects that are also essential for any realistic implementation of a quantum computer. . Theory of quantum-computer algorithms, error-***correcting codes***, decoherence and quantum chaos ***effects*** in the exponentially large ***Hilbert space*** of quantum computers are vital for the ultimate technological success of quantum computation.

Quantum Chaos and Quantum Computer/Computing

Quantum chaos

Classical chaos refers to the ***sensitive dependence*** on initial condition which is commonly found in nonlinear systems. In quantum mechanics, the ***trajectory loses*** its significance completely. Moreover the Schrodinger equation is a linear equation leaving no room for chaos. The ***correspondence principle, on the other hand, demand(e)s the utilization of the principle*** that in the semi-classical regime, namely, at length scale large compared with the de Broglie wavelength, ***quantum mechanics continuously develops into classical mechanics***. Therefore, at first glance, the name of ***quantum chaos seems self-contradictory***. After several years debate, now people commonly accept that ***quantum chaos*** refers to the study of quantum mechanical behavior of the systems whose ***classical counterparts*** are chaotic. This field has been very active in last two decades. Three manifestation of chaos in quantum systems have been studied so far.

Quantum Manifestation of Classical Chaos : Energy level spacing statistics

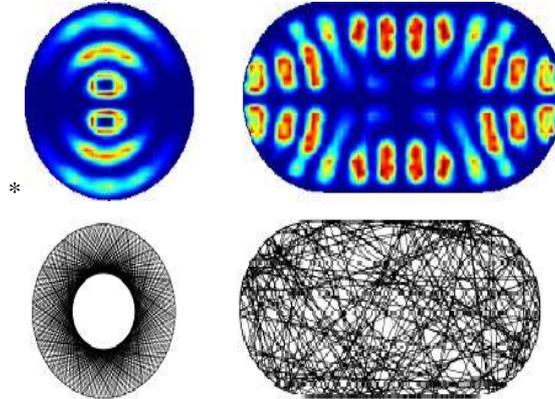

Energy level statistics has some universal features in the semi classical limit. It has been ***conjectured*** that level fluctuations ***depend only on*** general space-time symmetry and they are as predicted by the Random Matrix Theory [R]. For instance, the energy level spacing statistics in circular billiard (representing integrable systems) is Poisson distribution, whereas that in

stadium (or Sinai) billiard (representing chaotic systems with time reversal symmetry) has Wigner distribution. For a generic (mixed) system -neither complete chaotic nor complete integrable the energy level.

Quantum Manifestation of Classical Chaos II: statistical properties of stationary wavefunctions and Quantum Tunneling:

Along with eigenenergies, wavefunctions are also used to probe quantum fingerprints and signatures of classical chaos. Usually wavefunctions provide more information about the dynamics than eigenenergies. In fact, it is the space structure of wavefunction that determines the properties of spectral statistics such as level repulsion (in chaotic systems) and/or clustering (in integrable systems) etc. So far the only proved theorem about the eigenfunctions is Shnirelman's theorem. It agrees with the conjecture of Berry and Voros that the probability density of most eigenstates of a chaotic billiard approaches a uniform distribution. It also agrees with the Porter-Thomas distribution of RMT. Numerical studies of a large number of high-lying eigenstates of billiards have confirmed the Gaussian distribution of local wave functions.

Quantum Manifestation of Classical Chaos III: Dynamical evolution of states in Quantum Information:

One of the most important discoveries in quantum chaos is the *dynamical localization*, namely the quantum interference effects suppress the classical diffusive process (in phase space) which may take place in classical systems under external periodic perturbations. It has been shown by many physicists and computer scientists that the dynamical localization can be mapped to the *Anderson localization* for electrons in 1d systems with random impurity. This fact bridges Two different fields Quantum Chaos and Solid State Physics. Dynamical localization has been confirmed in several experiments such as Rydberg atom in a microwave field and an atom moving in a modulated standing wave

- Wave function structure and statistics in quantum billiard,
- Quantitative study of scars (wavefunction localization along the unstable classical periodic orbit) in far semi-classical limit.
- Energy level statistics and wave functions in mixed systems.
- Dynamical localization in quantum billiards.
- Semi-classical propagator for chaotic quantum systems.
- Semi-classical analysis of correlation functions in chaotic eigenstates. (g) Quantum chaos in non-KAM systems.

Quantum fidelity (quantum Loschmidt's echo) and chaos in Quantum Information:

The definition of classical chaos - sensitive dependence on initial condition - loses its meaning in quantum mechanics, because the unitarity properties of quantum mechanics, namely, the overlap between two evolving wave functions - a natural indicator of distance between them is preserved with time, hence there is no divergence. An alternative definition of chaos the sensitive dependence on perturbation - has been suggested recently. This new definition is meaningful both in classical and quantum mechanics. Classically, even for Small perturbation, one generically expects rapid divergence when the systems are chaotic, as the perturbation, i.e. the difference between equations of motion, soon introduces a small displacement between the trajectories. Quantum mechanically, the overlap between the wave functions begins at unity, and then decays with time, and the rate of this decay is equivalent to a measure of the sensitivity of quantum evolution to perturbations in the equation of motion - which can be used as a signature of quantum chaos.

Quantum mechanics as a statistical theory (For details see. E. Moyal)

An attempt is made by some computer scientists and theoretical physicists that quantum mechanics is a statistical theory, or more exactly as a form of non-deterministic statistical dynamics. Distribution functions of the complete set of dynamical variables specifying a mechanical system (phase-space distributions), which are fundamental in any form of statistical dynamics, could be expressed in terms of the wave vectors of quantum theory. This is shown to be equivalent to specifying a theory of functions of non-commuting operators, and may hence be considered as an interpretation of *quantum kinematics*. In

the second part, the laws governing the transformation with time of these phase-space distributions are derived from the equations of motion of *quantum dynamics* and found to be of the required form for a dynamical stochastic process. It is also shown that these phase-space transformation equations can be used as an alternative to the Schrödinger equation in the solution of quantum mechanical problems, such as the evolution with time of wave packets, *collision problems and the calculation of transition probabilities in perturbed systems*; an approximation method is derived for this purpose. *Quantum statistics*, deals with the phase-space distribution of members of large assemblies, with a view to applications of quantum mechanics to kinetic theories of matter. Recently, investigation has been carried out in the crossover of the quantum Loschmidt's echo (or fidelity) from the golden rule regime to the perturbation-independent exponential decay regime by using the kicked top model

$$M(t) = |\langle \Phi_0 | \exp(iHt) \exp(-iH_0t) | \Phi_0 \rangle|^2.$$

Where H is a perturbed Hamiltonian from H₀ which is chaotic. It is shown that the deviation of the perturbation independent decay of the averaged fidelity from the Lyapunov decay results from quantum fluctuations in individual fidelity, which is caused by the coherence in the initial coherent states. With an averaging procedure suppressing the quantum fluctuations effectively, the perturbation-independent decay is found to be close to the Lyapunov decay. This obviously means that the dissipation in quantum information sticks to the axiomatic predications of both Lyapunov decay and the Theory Of Classification.

Quantum Computer, Quantum Information, Dynamic Thermalization, Quantum Ergodicity, Theory of Classification, Quantum Mechanical process and Quantum Computing

In classical mechanics, chaos severely limits the operation of a reversible computer. Any uncertainty in the initial conditions is magnified exponentially by chaotic dynamics, rendering the outcome of the computation unpredictable. This is why practical computational scheme are irreversible. A quantum computer does not have this option. It relies on the reversible unitary evolution of entangled quantum mechanical states, which does not tolerate dissipation. On the other hand, the exponential gain of quantum computing is due to exponentially large size of Hilbert space which grows exponentially with the number of qubits which are the basis of quantum computers. In order to perform logical operations in quantum computers, these qubits should be coupled. As a consequence, quantum computers represent many body systems with interaction. Similar systems have been recently studied in the field of quantum chaos with applications to different many body systems such as nuclei, complex atoms, quantum dots and quantum spin glasses. It had been found that a sufficiently strong coupling leads to the emergence of quantum Ergodicity and dynamical (internal) thermalization. In this regime the systems eigenstates become very complex and strongly different from the eigenstates of non interacting many body systems. At first glance, one would expect this regime to appear when the coupling is comparable with the spacing between multiparticles levels. This naïve estimate would give an absurdly strong restriction for the coupling strength and therefore a too severe limitation for the realization of quantum computers. This raises the question:

- What limitations quantum chaos might pose on quantum computing?
- What restrictions of quantum chaos might pose on quantum error correction?
- Whether the suppression of quantum chaos (dynamical localization) improve the fidelity for recovery from errors of decoherence.

Mathematically equivalent formulations of quantum mechanical behaviour and Quantum Information

Oldest and most commonly used formulations is the "transformation theory" proposed by the late Cambridge theoretical physicist Paul Dirac, which unifies and generalizes the two earliest formulations of quantum mechanics - matrix mechanics (invented by Werner Heisenberg) and wave mechanics (invented by Erwin Schrödinger). In Matrix formulation, the instantaneous state of a quantum system encodes the probabilities of its *measurable properties*, or "observables". Examples of observables include energy, position, momentum, and angular momentum. These are the factors that play a vital role in the classification scheme of our paper. Observables can be either continuous (e.g., the position of a particle) or discrete (e.g., the energy of an electron bound to a hydrogen atom) An alternative formulation of quantum mechanics is Feynman's path integral formulation, in which a quantum-mechanical amplitude is considered as equivalent to as a sum over all possible histories between the initial and final states. This is the quantum-mechanical counterpart of the *action principle* in classical mechanics.

Quantum Mechanical Behaviour, DIRAC Equation, Quantum Information and its Interactions with other scientific theories

The rules of quantum mechanics are fundamental. They assert that the state space of a system is a Hilbert space, and that observables of that system are operators acting on that space - although they do not tell us which Hilbert space or which operators. (In physics, particularly in quantum physics, a system observable is a property of the system state that can be determined by some sequence of physical operations. For example, these operations might involve submitting the system to various electromagnetic fields and eventually reading a value off some gauge. In systems governed by classical mechanics,

any experimentally observable value can be shown to be given by a real-valued function on the set of all possible system states. Physically meaningful observables must also satisfy transformation laws which relate observations performed by different observers in different frames of reference. These transformation laws are automorphism of the state space that is bijective transformations which preserve some mathematical property.)

These can be chosen appropriately in order to obtain a quantitative description of a quantum system. An important guide for making these choices is the correspondence principle, which states that the predictions of quantum mechanics reduce to those of ,become equal to classical mechanics when a system moves to higher energies or - equivalently - larger quantum numbers, i.e. whereas a single particle exhibits a degree of randomness, in systems incorporating millions of particles averaging takes over and, at the high energy limit, the statistical probability of random behaviour approaches zero. In other words, classical mechanics is simply a quantum mechanics of large systems. This "high energy" limit is known as the classical or correspondence limit. One can even start from an established classical model of a particular system, then attempt to guess the underlying quantum model that would give rise to the classical model in the correspondence limit. When quantum mechanics was originally formulated, it was applied to models whose correspondence limit was non-relativistic classical mechanics. For instance, the well-known model of the quantum harmonic oscillator uses an explicitly non-relativistic expression for the kinetic energy of the oscillator, and is thus a quantum version of the classical harmonic oscillator.

Early attempts to merge quantum mechanics with special relativity involved the replacement of the Schrödinger equation with a covariant equation such as the Klein-Gordon equation or the Dirac equation. The Dirac bispinor is represented by four ionic internal states, and position and momentum of the Dirac particle are associated with the respective ionic variables. Simulation of the simplified 1 + 1 case, requiring the manipulation of only two internal levels and one motional degree of freedom. Moreover, relevant quantum-relativistic effects, like the Zitterbewegung and Klein's paradox, the transition from massless to massive fermions, and the relativistic and nonrelativistic limits, via the tuning of controllable experimental parameters. Dirac equation, describes the behaviour of fermions, and predicted the existence of antimatter

While these theories were successful in explaining many experimental results, they had certain unsatisfactory qualities stemming from their neglect of the relativistic creation and annihilation of particles. A fully relativistic quantum theory required the development of quantum field theory, which applies quantization to a field (rather than a fixed set of particles). The first complete quantum field theory, quantum electrodynamics, provides a fully quantum description of the electromagnetic interaction. The full apparatus of quantum field theory is often unnecessary for describing electrodynamic systems. A simpler approach, one that has been employed since the inception of quantum mechanics, is to treat charged particles as quantum mechanical objects being acted on by a classical electromagnetic field. For example, the elementary quantum model of the hydrogen atom describes the electric field of the hydrogen atom using a classical $-e^2/(4\pi \epsilon_0 r)$ Coulomb potential. This "semi-classical" approach fails if quantum fluctuations in the electromagnetic field play an important role, such as in the emission of photons by charged particles.

Quantum field theories for the strong nuclear force and the weak nuclear force have also been developed. The quantum field theory of the strong nuclear force is called quantum chromodynamics, and describes the interactions of sub nuclear particles such as quarks and gluons. The weak nuclear force and the electromagnetic force were unified, in their quantized forms, into a single quantum field theory (known as electroweak theory), by the physicists Abdus Salam, Sheldon Glashow and Steven Weinberg. It has proven difficult to construct quantum models of gravity, the remaining fundamental force. Semi-classical approximations are workable, and have led to predictions such as Hawking. However, the formulation of a complete theory of quantum gravity is hindered by apparent incompatibilities between general relativity (the most accurate theory of gravity currently known) and some of the fundamental assumptions of quantum theory. The resolution of these incompatibilities is an area of active research, and theories such as String Theory are among the possible candidates for a future theory of quantum gravity. Classical mechanics has also been extended into the complex domain, with complex classical mechanics exhibiting behaviors similar to quantum mechanics.

Quantum Chaos and Quantum Information:

Predictions of quantum mechanics have been verified experimentally to an extremely high degree of accuracy. According to the correspondence principle between classical and quantum mechanics, all objects obey the laws of quantum mechanics, and classical mechanics is just an approximation for large systems of objects (or a statistical quantum mechanics of a large collection of particles). The laws of classical mechanics thus follow from the laws of quantum mechanics as a statistical average at the limit of large systems or large quantum numbers. However, chaotic systems do not have good quantum numbers, and quantum chaos studies the relationship between classical and quantum descriptions in these systems. Maintaining coherence in Quantum Computers. (W. G. Unruh) is an important phenomenon that has to be addressed with for the efficient functioning of a Quantum Computer. The effect of the inevitable coupling to external degrees of freedom of a quantum computer are examined, by various Physicists (See Unruh). It is found that for quantum calculations (in which the maintenance of coherence over a large number of states is important), not only must the coupling be small but the time taken in the quantum calculation must be less than the thermal time scale, Quantum computers to be more efficient in certain problems involves having the computer be placed in the coherent superposition of a very large number (exponential in L) of "classical states", and having the outputs interfere in such a way that there is a very high probability that on the appropriate reading of the output, one would obtain the required answer. One is replacing exponentiality in time with exponentiality in quantum coherence. This requires that the computer be able to maintain the coherence during the course of the calculation.

The **constraints** placed on the ability to maintain this coherence in the face of coupling to external heat baths. Landauer has long emphasized the necessity of examining **the effect of** both imperfections and of the coupling **to** the external world of any realistic device on the ability of quantum computers to realize their promise. For longer times the condition on the strength of the coupling to the external world becomes much more stringent. Quantum coherence is an essential difference between classical and quantum theories, and is illustrated by the Einstein-Podolsky-Rosen paradox. Quantum interference **involves adding together probability amplitudes**, whereas classical "waves" infer that there is an adding **together of intensities**. For microscopic bodies, the extension of the system is much smaller than the **coherence length**, which gives rise to long-range entanglement and other nonlocal phenomena that are characteristic of quantum systems. Quantum coherence is not typically evident at macroscopic scales - although an exception to this rule **can occur at** extremely low temperatures (i.e. approaching absolute zero), when quantum behavior can manifest itself on more macroscopic scales (see macroscopic quantum phenomena, Bose-Einstein condensate, and Quantum machine).

Many macroscopic properties of a classical system are a direct **consequence** of the quantum behavior of its parts. For example, the stability of bulk matter (which consists of atoms and molecules which **would quickly collapse under** electric forces alone), the rigidity of solids, and the mechanical, thermal, chemical, optical and magnetic properties of matter **are all results** of the interaction of electric charges under the rules of quantum mechanics. While the seemingly "exotic" behavior of matter **posited by** quantum mechanics and relativity theory **become more apparent** when dealing with particles of extremely small size or velocities approaching the speed of light, the laws of classical Newtonian physics remain accurate in predicting the behavior of the vast majority of "large" objects (on the order of the size of large molecules or bigger) at velocities much smaller than the velocity of light.

Emergence of Quantum Chaos in Quantum Computer Core and How to manage it has been discussed by B. Georgeot and D. L. Shepelyansky. Generic quantum computer model, **describes a** realistic isolated quantum computer **with fluctuations** in individual qubit energies and residual short-range inter-qubit **couplings**. In the limit where the fluctuations and couplings **are small** compared to one-qubit energy spacing the spectrum **has a** band structure and **a renormalized** Hamiltonian **is obtained** which describes the eigenstate properties inside one band. The studies are concentrated on the central band of the computer ("core") with the highest density of states. **Above a** critical inter-qubit coupling strength, quantum chaos **sets in, leading to** quantum Ergodicity of the computer eigenstates. In this regime the ideal qubit structure **disappears**, the eigenstates **become** complex and the operability of the computer are quickly **destroyed**. Quantum chaos border **decreases** only linearly with the number of qubits n , although the spacing between multi-qubit states **drops** exponentially with n . The investigation of time-evolution in the quantum computer **shows that** in the quantum chaos regime, an ideal (noninteracting) state quickly **disappears** and exponentially many states **become** mixed after a short chaotic time scale for which the dependence on system parameters **is determined**. **Below the** quantum chaos border an ideal state can survive for long times and can **be used** for computation. The **results show** that a broad parameter region **does exist** where the efficient operation of a quantum computer is possible. Quantum computers **have problem in** simulation of common quantum systems, since the computation time **grows** exponentially with the number of quantum particles. Therefore for such problems it is natural to **envision a** computer composed from quantum elements (qubits) which **operate** according to the laws of quantum mechanics. In any case, such devices will be in a sense unavoidable since the technological progress **leads to** chips of smaller and smaller size which will eventually reach the quantum scale. At present a quantum computer is viewed as a system of n qubits (two-level quantum systems), with the possibility of **switching on and off a coupling between them**. The operation of such computers **is based** on reversible unitary transformations in the Hilbert space whose dimension $N_H = 2^n$ is exponentially large in n . It has been shown that all unitary operations can be realized with two-qubit transformations. This makes necessary the existence of **a coupling** between qubits. Any quantum algorithm will be a sequence of such fundamental transformations, which form the basis of new quantum logic. Shor constructed a quantum algorithm which is **exponentially faster** than the classical ones. It was also shown by Grover that the searching of an item in a long list is parametrically much faster on a quantum computer. The recent development of error correcting codes showed that a certain amount of noise due to external coupling **could be tolerable** in the operation of a quantum computer. All these exciting developments motivated a great body of experimental proposals to effectively realize such a quantum computer. They include ion traps, nuclear magnetic resonance systems, nuclear spins with **interaction controlled** electronically or by laser pulses, quantum dots, Cooper pair boxes optical lattices and electrons floating on liquid helium. **As a result**, a two-qubit gate has been experimentally realized with cold ions, and the Grover algorithm has been performed for three qubits made from nuclear spins in a molecule. However, to have a quantum computer competitive with a classical one will require a much larger number of qubits. For example, the minimal number of qubits for which Shor's algorithm will become useful is of the order of $n = 1000$. Serious **obstacle to** the physical realization of such computers is the quantum decoherence due to the couplings with the external world **which gives** a finite lifetime to the excited state of a given qubit. **The effects** of decoherence and laser pulse shape broadening were numerically simulated in the context of Shor's algorithm, and shown to be quite important for the operability of the computer. However, in a number of physical proposals, for example nuclear spins in two-dimensional semiconductor structures, the relaxation time due to this decoherence process can be many orders of magnitude **larger than** the time required for the gates operation, so that there are hopes to manage this obstacle. Obstacle to the physical realization of quantum computers that was not stressed up to now. This problem arises even if the decoherence time is infinite and the system is **isolated/decoupled** from the external world. Indeed, even **in the absence** of decoherence there are always imperfections in physical systems. **Due to that the** spacing between the two states of each qubit will have fluctuations in some finite detuning interval δ . Also, some residual static

interaction J between qubits will be unavoidably present (inter-qubit coupling is required to operate the gates). Extensive studies of many-body **interacting systems** such as nuclei, complex atoms, quantum dots and quantum spin glasses have shown that generically in such **systems the interaction leads to** quantum chaos characterized by Ergodicity of the eigenstates and level spacing statistics as in Random Matrix Theory (RMT). In a sense the interaction **leads to** dynamical thermalization **without** coupling to an external thermal bath. If the quantum computer were in such a regime, its operability would be effectively **destroyed** since the noninteracting multi-qubit states representing the quantum register states **will be eliminated** by quantum ergodicity. In this respect, it is important to stress that unavoidably the residual interaction J **will be much larger than** the energy spacing Δ_n between adjacent eigenstates of the quantum computer. Indeed the residual interaction J is relatively small so that all NH computer eigenenergies are **distributed in an** energy band of size $\Delta E \sim n\Delta_0$, where Δ_0 is the average energy distance between the two levels of one qubit and n is the total number of qubits in the computer. **By changing the** electrostatic gate potential, the effective electron mass can **be modified up** to a factor of two. In the quantum computer the quantum **chaos sets in only for** couplings J exponentially stronger than Δ_n . In fact, it was shown that the critical coupling J_c for the transition to quantum chaos **decreases** only linearly with the number of qubits n (for short-range inter-qubit coupling): a broad parameter region where a quantum computer can be operated below the quantum chaos border, **exists** when noninteracting multi-qubit states are **very close** to the exact quantum computer eigenstates. Details the **transition to** chaos and how **it effects** the time evolution of the system. **The effects** of **residual interaction** in the presence or absence of fine fluctuations of individual qubit energy spacing are also analyzed in great detail.

Relativity and quantum Information and Quantum machine:

Quantum mechanics, information theory, and relativity theory are the basic foundations of theoretical physics. The acquisition of information from a quantum system **is the interface of** classical and quantum physics. Essential tools for its description are Kraus matrices and positive operator valued measures (POVMs). Special relativity **imposes severe restrictions** on the transfer of information between distant systems. Quantum entropy is not a Lorentz covariant concept. Lorentz transformations of reduced density matrices for entangled **systems may not be completely** positive maps. Quantum field theory, which is necessary for a consistent description of interactions, implies a fundamental trade-off between detector reliability and localizability. General relativity produces new, counterintuitive effects, in particular when black holes (or more generally, event horizons) are involved. Most of the current concepts in quantum information theory may then require a reassessment

The fundamental properties of quantum information and its applications to computing and cryptography have been greatly illuminated by considering information-theoretic tasks that are provably possible or impossible within non-relativistic quantum mechanics. I describe here a general framework for defining tasks within (special) relativistic quantum theory and illustrate it with examples from relativistic quantum cryptography and relativistic distributed quantum computation. The framework gives a unified description of all tasks previously considered and also defines a large class of new questions about the properties of quantum information in relation to Minkowski causality. It offers a way of exploring interesting new fundamental tasks and applications, and also highlights the scope for a more systematic understanding of the fundamental information-theoretic properties of relativistic quantum theory.

Entanglement generation in relativistic quantum fields and corresponding Quantum Computation. (See Nicolai Friis, Ivette Fuentes)

A general, analytic recipe is to compute the entanglement **that is generated** between arbitrary, discrete modes of bosonic quantum fields by **Bogoliubov transformations**. One setup allows the complete characterization of the quantum **correlations in all** Gaussian field states. Additionally, it holds for all Bogoliubov transformations. These are commonly **applied in** quantum optics **for the description** of squeezing operations, **relate** the mode decompositions of observers in different regions of curved spacetimes, and **describe** observers moving along non-stationary trajectories. Physicists have focused on a quantum optical example in a cavity quantum electrodynamics setting: **an uncharged scalar field within a cavity provides a** model for an optical resonator, in which **entanglement is created** by **non-uniform acceleration**. Amount of generated entanglement can be **magnified** by initial single-mode squeezing. Applications to quantum fields in curved spacetimes, such as an expanding universe, are also discussed. in many studies.

There exists an intimate **relationship** between quantum mechanics, information theory, and relativity theory. Taken together these are the foundations of present-day theoretical physics, and their interrelationship is an essential part of the theory. The acquisition of information from a quantum system by an observer **occurs at the** interface of classical and quantum physics. Many a author have reviewed the essential tools needed to describe this interface, i.e., Kraus matrices and positive-operator-valued measures. They then discuss how special relativity **imposes** severe (e) **restrictions** on the **transfer of information between distant systems and the implications of the fact that quantum entropy is not a Lorentz-covariant concept**. This leads to a discussion of how it comes about that Lorentz transformations of reduced density matrices for entangled systems may not be completely positive maps. Quantum field theory is, of course, necessary for a consistent description of interactions. Its structure implies a fundamental **tradeoff** between detector reliability **and** localizability. Moreover, general relativity **produces new and counterintuitive effects**, particularly when black holes (or, more generally, event horizons) are involved. In this more general context some authors discuss how most of the current concepts in quantum information theory may require a reassessment. How relativistic effects (-) can be **exploited** to improve quantum information tasks, (+) a key topic of immense technological importance already today and more so for the next decades. The vantage point of these investigations is that the world is fundamentally both quantum and relativistic, and that these facts are immensely useful for the design of communication devices that are absolutely safe from eavesdropping, and of quantum computers that can quickly perform difficult computational tasks which overwhelm any classically imaginable computer. Indeed, impressive technological

achievements and promises have already been derived from taking seriously solely the quantum aspects of matter: quantum cryptography and communication have become a technical reality in recent years, but the practical construction of a quantum computer still requires understanding better how to efficiently store, manipulate and read information, without prohibitively large disturbances from the environment. Throwing relativity into the equation fundamentally changes the entire game, as I could show in a series of research papers, one of which was featured in a generally accessible Science article highlighting my work (Cho, Science 2005). I propose to push this exciting line of theoretical research to the point where relativistic effects in quantum information theory can be exploited technologically. Far from yielding only quantitative corrections, relativity **plays a dominant role** in the qualitative behaviour of many physical systems used to implement quantum information tasks in the laboratory. The prototypical example is provided by any system involving light, be it for the transmission or manipulation of quantum information. There is no such thing as a **non-relativistic approximation** to light quanta, so-called photons, since these always travel at the speed of light. While relativistic quantum theory, commonly known as quantum field theory, is a very well studied subject in foundational particle physics, research in **quantum information theory** selectively focused almost exclusively on those aspects one can study without relativity. Thus both unexpected obstacles (such as a relativistic **degradation** of quantum entanglement) and unimagined possibilities for quantum information theory (such as improved **quantum cryptography** and **hypersensitive quantum** measurement devices) have gone unnoticed. , Indeed, the impact of such research extends beyond *pure quantum information theory*, and applications to foundational questions in cosmology and black hole physics have been found. Over the past few years, a new field of high research intensity has emerged, known as **Relativistic Quantum Information (RQI)**. The field of RQI aims to understand the **relationship** between special and general relativity, and quantum information. In particular, so-called **quantum entanglement bits (e-bits)** are **a necessary resource** in all of **quantum communication and quantum computation**. One of the key goals of the field of RQI is to develop a theory of e-bits in realistic spacetimes described by Lorentzian manifolds. This offers exciting new challenges because it combines **information theory with quantum theoretic and general relativistic questions**. Deep questions concerning the **relationship** between information processing and the structure of spacetime are considered. Phenomena of relativistic quantum information, for example, use quantum communication with satellite-based instruments or **Berry's phase tests of the Unruh effect**.

Recently, there has been increased interest in understanding entanglement and quantum communication in black hole spacetimes and in using quantum information techniques to address questions in gravity. Studies on **relativistic entanglement** show the emergence of conceptually important **qualitative differences** to a non-relativistic treatment. For instance, entanglement was found to be an observer-dependent property that changes from the perspective of accelerated observers moving in flat spacetime. Relativistic quantum information theory uses well-known tools coming from quantum information and quantum optics to study quantum effects provoked by gravity to learn information about the spacetime. We can take advantage of our knowledge **about quantum correlations** and **effects produced** by the **gravitational interaction** to set the basis for experimental proposals ultimately aiming at **finding corrections due** to quantum gravity effects, too mild to be directly observed.

Quantum theory and **general relativity** are famously at loggerheads. Their mathematical languages are different and conceptual bases are discordant, if not outright conflicting. For more than sixty years this conceptual gap and scant experimental evidence has been preventing **unification of** the two theories. At the close of the last century a seemingly unrelated development of quantum information theory helped to unriddle some of the long-standing conceptual problems in quantum mechanics. While originally discussed in terms of **non-relativistic quantum mechanics**, recent years have seen increasing research interest and activities in placing quantum information in a more rigorous framework of **quantum field theory in** curved spacetimes. As a matter of fact, information theory is often appealed to in black hole physics and gravitational theories, particularly in relation to **the information loss paradox** and the **holographic principle**. **A relationship of "R" and "QI" is twofold**. On the one hand, **quantum field theory** is an **instrumental** tool in proposed designs of **quantum computing and communication**, and to comprehend the meaning and possibilities of **quantum non-locality**, and **entanglement in the quantum vacuum**. On the other hand, what "R" entails in RQI is perhaps best captured by what a relativist does traditionally: encompassing special and general relativity, geometry and topology (of spacetime and gauge fields), quantum field theory in curved spacetime and quantum gravity

Black hole information paradox and Quantum Machine:

The **black hole information paradox results** from the combination of quantum mechanics and general relativity. It suggests that physical INFORMATION could permanently **disappear in a** black hole, **allowing** many physical states **to evolve into** the same state. Loss of information in a black hole **produces** evolution of many physical states in to the same state Or, in other words, evolution of many physical states in to single state must **utilize** the loss of physical information in black hole..This is controversial because it violates a commonly assumed tenet of science—that *in principle* complete information about a physical system at one point in time should **determine** its state at any other time A fundamental postulate of quantum

mechanics is that complete information about a **system is encoded** in its wave function. The evolution of the wave function is **determined(e) by** a unitary operator. And unitarity **implies** that information is conserved in the quantum sense.

There are two main principles in play: **quantum determinism, and reversibility**. Quantum determinism means that given a present wave function, its future changes are uniquely **determined by** the evolution operator. Reversibility refers to the fact that the evolution operator **has an** inverse, meaning that the past wave functions are similarly unique. The combination of the two means that information must always be preserved.

Starting in the mid 1970's, Stephen Hawking and Jacob Bekenstein put forward theoretical arguments based on general relativity and quantum that appeared to be inconsistent with information conservation. Specifically, Hawking's calculations indicated that black hole evaporation via Hawking radiation **does not** preserve information. Today, many physicists believe that the holographic principle (specifically the AdS/CFT duality) **demonstrates that** Hawking's conclusion was incorrect, and that information is in fact preserved. In 2004 Hawking himself conceded a bet he had made, agreeing that black hole evaporation does in fact preserve information. Black hole evaporation **produces** the conservation and preservation of information. Conservation and preservation of information is attributable and ascribable to the entropic entecote of (e) Black hole evaporation.

Einstein himself is well known for rejecting some of the claims of quantum mechanics. While clearly contributing to the field, he did not accept many of the more "philosophical consequences and interpretations" of quantum mechanics, such as the **lack of deterministic** causality. He is famously quoted as saying, in response to this aspect, "My God does not play with dice". He also had difficulty with the assertion that a single subatomic particle **can occupy** numerous areas of space at one time. However, he was also the first to notice some of the apparently exotic **consequences of** entanglement, and **used** them to formulate the Einstein-Podolsky-Rosen paradox in the hope of showing that quantum mechanics had unacceptable implications. This was 1935, but in 1964 it was shown by John Bell (see Bell inequality) that - although Einstein was correct in identifying seemingly **paradoxical implications** of quantum mechanical non locality - these implications could be experimentally tested. Alain Aspect's initial experiments in 1982, and many subsequent experiments since, have definitively verified quantum entanglement.

According to the paper of J. Bell and the Copenhagen interpretation - the common interpretation of quantum mechanics by physicists since 1927 - and contrary to Einstein's ideas, quantum mechanics was **not**, at the same time:

EPR EXPERIMENT, QUANTUM STATES, QUANTUM COMPUTATION, QUANTUM ENTANGLEMENT:

The Einstein-Podolsky-Rosen paradox shows in any case that there exist experiments by which one can measure the state of one particle and instantaneously **change the** state of its entangled partner - although the two particles can be an arbitrary distance apart. However, **this effect** does **not violate** causality, since **no transfer of** information happens. Quantum entanglement forms the **basis** of quantum cryptography, which is used in high-security commercial applications in banking and government.

Gravity **is negligible** in many areas of particle physics, so that **unification between** general relativity and quantum mechanics is not an urgent issue in those particular applications. However, the lack of a correct theory of **quantum gravity** is an important issue in cosmology and the search by physicists for an elegant "Theory of Everything" (TOE). Consequently, resolving the inconsistencies between both theories has been a major goal of 20th and 21st century physics. Many prominent physicists, including Stephen Hawking, have labored for many years in the attempt to discover a theory underlying **everything**. This TOE would combine not only the different models of subatomic physics, but also derive the four fundamental forces of nature - the strong force, electromagnetism, the weak force, and gravity - from a single force or phenomenon. While Stephen Hawking was initially a believer in the Theory of Everything, after considering Gödel's Incompleteness Theorem, he has concluded that one is not obtainable, and has stated so publicly in his lecture "Gödel and the End of Physics" (2002). One of the leading authorities continuing the search for a coherent TOE is Edward Witten, a theoretical physicist who formulated the groundbreaking M-theory, which is an attempt at describing the super symmetrical based string theory. **M-theory posits** that our apparent 4-dimensional spacetime is, in reality, actually an 11-dimensional spacetime containing 10 spatial dimensions and 1 time dimension, although 7 of the spatial dimensions are - at lower energies - **completely "compactified" (or** infinitely curved) and not readily **amenable to** measurement or probing.

ATTEMPTS AT UNIFIED THEORY AND ITS IMPLICATIONS ON QUANTUM COMPUTING:

The quest **to unify the** fundamental forces through quantum mechanics is still ongoing. Quantum electrodynamics (or "quantum electromagnetism"), which is currently (in the perturbative regime at least) the most accurately tested physical theory¹ has been successfully merged with the weak nuclear force into the electroweak force and work is currently being done to merge the electroweak and strong force into the electro strong force. Current predictions state that at around 10^{14} GeV the three aforementioned forces are fused into a single unified field,^[37] Beyond this "grand unification," it is speculated that it may be possible to merge gravity with the other three gauge symmetries, expected to occur at roughly 10^{19} GeV. However — and while special relativity is parsimoniously incorporated into quantum electrodynamics — the expanded general relativity, currently the best theory describing the gravitation force, has not been fully incorporated into quantum theory.

Albert Einstein, himself one of the founders of quantum theory, disliked this **loss of determinism in measurement**. Einstein held that there should be a theory underlying quantum mechanics and, consequently, that the present theory was incomplete. He produced a series of objections to the theory, the most famous of which has become known as the Einstein-Podolsky-

Rosen paradox. John Bell showed that this "EPR" paradox led to experimentally testable differences between quantum mechanics and local realistic theories. Experiments have been performed confirming the accuracy of quantum mechanics, **thereby demonstrating that** the physical world cannot be described by any local realistic theory. The *Bohr-Einstein debates* provide a vibrant critique of the Copenhagen Interpretation from an epistemological point of view.

The *Everett many-worlds interpretation*, formulated in 1956, holds that *all* the possibilities described by quantum theory *simultaneously* occur in a multiverse composed of mostly **independent parallel universes**. This is not accomplished by introducing some "new axiom" to quantum mechanics, but on the contrary, **by removing** the axiom of the **collapse of the wave packet**. All of the possible consistent states of the measured system and the measuring apparatus (including the observer) are present in a *real* physical - not just formally mathematical, as in other interpretations - **quantum superposition**. Such a superposition of consistent state **combinations of different** systems is called an entangled state. While the multiverse is deterministic, we perceive non-deterministic behavior **governed** by probabilities, **because** we can observe only the universe (i.e., the consistent state contribution to the aforementioned superposition) that we, as observers, inhabit. Everett's interpretation is perfectly **consistent with John** Bell's experiments and makes them intuitively understandable. However, according to the theory of quantum decoherence, these "parallel universes" **will never be accessible to us**. The inaccessibility can be understood as follows: once a measurement is done, the measured system **becomes entangled** with *both* the physicist who measured it *and* a huge number of other particles, some of which are photons flying away at the speed of light towards the other end of the universe. In order to prove that the wave function **did not collapse**, one would have to bring *all* these particles back and measure them again, together with the system that was originally measured. Not only is this completely impractical, but even if one *could* theoretically do this, it would **destroy any evidence that the original measurement took place** (to include the physicist's memory).

Quantum mechanics had enormous success in explaining many of the features of our world. The **individual behaviors** of the subatomic particles that make up all forms of matter (electrons, protons, neutrons, photons, and others) can often **only be satisfactorily described** using quantum mechanics. Quantum mechanics has **strongly influenced** string theories, candidates for a *Theory of Everything* (see *reductionism*), and the **multiverse hypotheses**.

QUANTUM TUNELLING, QUANTUM COHERENCE, AND QUANTUM MACHINE

Quantum Tunneling of Magnetization and Related Phenomena in Molecular Materials (SEE Dante Gatteschi dRoberta Sessoli)

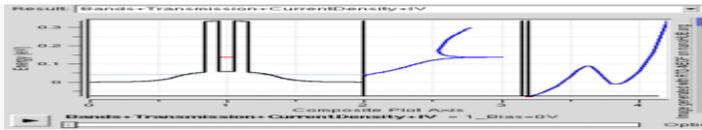

The fields in which chemistry may have a fundamental role are increasing in number, and it is becoming more and more difficult (though stimulating) for synthetic chemists to cope with requests of new compounds with highly sophisticated properties. The movement from simplicity to complexity in molecular chemistry is one which cannot be stopped, and supramolecular chemistry is just one clear example of that. The last few years have seen the opening of many new research fields in which molecular materials have been forced, through chemical ingenuity, to acquire properties which are associated with classic inorganic materials. Perhaps the most convincing evidence for this has been the development of purely organic materials, which behave as conductors and superconductors. In addition, organic materials, because of their photorefractive and nonlinear-optical properties, are now even used to make lasers. Magnetism is certainly one of the fundamental properties of matter, inextricably associated with electrical properties. One of the main difficulties in developing molecule-based magnets is that bulk magnetism is intrinsically a three-dimensional (3D) property in that only if a 3D lattice of interacting magnetic centers is assembled may the material show spontaneous magnetization below a critical temperature. The problem with molecular materials is that the design of genuine 3D connected lattices is not obvious, because the intrinsic low symmetry of the individual molecules tends to favor 1D or 2D arrangements. Here the difference between molecular magnets and conductors is striking, because for conductors exciting properties can be found even if 1D arrangements of individual molecules are obtained in the solid state. However, this has not scared the synthetic chemists and genuine room-temperature molecule based magnets are now available. The difficulties in forming 3D magnets with molecular materials have been turned into advantages when it was realized that oligonuclear compounds, comprising a large, but finite, number of magnetic centers may have unique magnetic properties which have made them almost ideal systems for observing quantum size effects in magnets.

The magnetic centers can be transition-metal or rare-earth ions, or even organic radicals. The observation of quantum phenomena in mesoscopic matter provides, in principle, confirmation to the so-called Copenhagen interpretation, which assumes that there is a continuous transition from the field of small objects, where quantum mechanics is required, to macroscopic objects, where classical physics operates well. Materials the properties of which are intermediate between classical and quantum nature, or where there is coexistence of the two, may be used for completely new types of devices. A particularly interesting field is that of **quantum computing**, where information can be handled taking advantage of quantum Tunneling. Molecules comprising a large number of coupled paramagnetic centers are attracting much interest because they may show properties which are intermediate between those of simple paramagnets and classical bulk magnets and provide unambiguous evidence of quantum size effects in magnets. To date, two cluster families usually referred to as Mn₁₂ and Fe₈, have been used to test theories. However, it is reasonable to predict that other classes of molecules will be discovered which have similar or superior properties. To do this it is necessary that synthetic chemists have a good understanding of the correlation between the structure and properties of the molecules, for this it is necessary that concepts such as **quantum tunneling, quantum coherence, quantum oscillations are understood**. In fact it gives rise to magnetic hysteresis, which is one condition for storing information in a particle. Under this respect therefore Mn₁₂ac behaves like a classical magnet. However, it is still small enough to also show large quantum effects. In fact Mn₁₂ac, and other molecules which have since

been investigated, provide the best examples to date of the observation of quantum effects, such as the tunneling of the magnetization, in magnets. These molecules are now often called TMsingle-molecule magnets]

The interactions with the environment will tend to localize the particles, because the interactions will make one well more TMattractive] than the other (that is, reduce the energy of one of the wells). In the case of strong coupling with the environment, which means that this interaction is much larger than the tunnel splitting, the particle will stay localized in one of the two wells, and will not tunnel. For intermediate coupling the particle can tunnel, but jumping incoherently from one well to the other. This means that one particle will tunnel, and localize for some time in the other well, and then tunnel again, but in an irregular way. The third case is that of weak coupling when the tunnel splitting is large compared to the interaction with the environment, and the particle oscillates coherently between the two minima. The conditions for observing coherent tunneling are severe. Evidence for coherent tunneling is the observation of energy absorption at a frequency corresponding to the tunnel splitting. In the above experiment of calyx a peak was observed in the proton-spin lattice-relaxation rate at a field corresponding to the tunneling frequency of 35 MHz

Quantum mechanics is also critically important for understanding how individual atoms combine covalently to form molecules. Relativistic quantum mechanics can, in principle, mathematically describe most of chemistry. Quantum mechanics can also provide quantitative insight into ionic and covalent bonding processes by explicitly showing which molecules are energetically favorable to which others, and the magnitudes of the energies involved. Furthermore, most of the calculations performed in modern computational chemistry rely on quantum mechanics.

A working mechanism of a resonant tunneling diode device, based on the (e)phenomenon of quantum tunneling through potential barriers

A great deal of modern technological inventions operates at a scale where quantum effects are significant. Examples include the laser, the transistor (and thus the microchip), the electron microscope, and magnetic resonance imaging (MRI). The study of semiconductors led to the invention of the diode and the transistor, which are indispensable parts of modern electronics systems and devices.\

SIMULATION OF THE REALITY-IS THIS WORLD SIMULATED BY A GIANT QUANTUM COMPUTER?

A Quantum-Digital Universe (See Giacomo Mauro D'Ariano)

Can Reality be simulated by a huge Quantum Computer? Do we believe that Reality is made of something more than interacting quantum systems? The idea that the whole Physics is ultimately quantum computation; strong quantum version of the Church-Turing hypothesis well synthesized by the Wheeler's coinage it from bit is very appealing. It is theoretically very parsimonious and curmudgeonly- an Occam razor's quality-guaranteed description of the world. But, if this is the case, then we need to understand the entire Physics as emergent(e) from the quantum computation. Universe (=) is a Quantum Field. Particles are(=) just states of the Field: they can be created and (e)&(eb)annihilated. We have indeed a beautiful Grand Unified Field Theory, and we are looking forward to see the Higg's boson at the LHC.

But what is the Quantum Field made of? Ultimately, Quantum Field is (e)made of quantum systems that are interacting,(each Quantum system located at a different position in space). Quantum field is((e)) a continuum. But is Reality actually continuous? We don't know: but it looks easier to think to Reality or Objective Reality and in fact the Subjective experience as a continuum. Now, suppose that this is not the case, namely Reality is (e&eb)ultimately discrete, and the continuum is only a mathematical fiction. Then, what else are out there more than interacting quantum systems? Is it space? No, space is "nothingness". Is it Relativity? No, that's not a "thing": Or is it? Can it not be classified based on the tensorial entities it is made of for a particle or set of particles it is meant of? That despite the fact that the 'theory' is a 'generalization' one; it is a way of looking at things. We thus come to the conclusion that Reality is made(e) only of "interacting quantum systems", and this is (=)precisely what we call a quantum computer; the interacting quantum states. David Deutsch in his seminal paper Quantum theory, the Church-Turing principle and the universal quantum computer rephrased the Church-Turing hypothesis as a truly physical principle. In short: every piece of physical reality can be perfectly 'simulated' by a quantum computer. But now: what is the difference between Reality and its simulation? Reality is indistinguishable from its simulation implies then it is its simulation. But how would you know that a situation is simulation or the Objective Reality. If you are followed by Supari Mafia, Crime Syndicates, hoodlum mugger aggregates, raucous ribaldry congregates, loutish, jeerish elements, the veritable string ray sachrochusus imperators, herrenvolk sandhurst lucubration cormorants, that cause traffic jams, create havoc in the neighborhood with the connivance and contrivance of the neighbours, or some hundred vehicles are parked at your door; somebody is keeping vigil while' casually' sitting in the park. Then? It is here consciousness comes in. Consciousness of what exactly the truth is comes from 'knowing'. How would you 'know'? From the subjective experiences of the past. That you are the victim. So it is 'consciousness' that produces 'objective reality' Next paper exactly deals with this: 'Consciousness' and 'Objective reality'; and 'consciousness' and 'Subjective experience' 'The Universe is really a huge quantum computer: the computational universe of Seth Lloyd .But we have more than that. Quantum Theory is (=)ultimately a "theory of information", an idea that has been hanging around for many years since the Wheeler's it from bit, and which has been also recently proved mathematically. Therefore, if we adopt the Deutsch's Church-Turing principle, the notion of Information becomes(e) the new big paradigm for Physics. And Physics can be classified based on the theoretical

parameters that are involved in a Theory; notwithstanding 'generalizationalness' of the theory. Take for example Heisenberg's Principle of Uncertainty. Can we not have positions and momentums that are different to different particles? That the product is always less than $h/2$ does not mean there cannot be total quantum of 'positions and momentums' of the particles or for that matter there cannot be 'total gravitational field'. The scientific approach behind the computational paradigm. The Informationalism can be ultimately regarded as a new scientific approach, very close to the spirit of Niels Bohr and the Copenhagen school. Far from being speculative, the approach is truly operational, namely everything must be defined by a precise procedure—ultimately in terms of accurate quantum measurements. The real entities are the events, facts of the world describable by the basic language obeying the rules of predicate logic (the "facts" of Wittgenstein's Tractatus). Formulating a Theory of the observed (or potentially observable) events means **building up a network** of input-output connections between them. In a causal theory these connections are causal links: Quantum Theory is exactly a theory of this kind. Translating these terms into computer-programming language, the events are the subroutines, and the **causal links** are the registers where information is written and read. Like "Transfer Scrolls" in the Bank. Total conservation and preservation of assets and liabilities does not mean that there cannot be individual debits and credits. In fact individual debits and credits are conserved; then the summary sheets of each department is conserved; then the General Ledger which gives the double entries of 'inflow' and 'outflow' are recorded gives the total quantum of energy transformed from one to another is recorded. This 'General Ledger' is the "General Theory Of Every Thing" the Quantum Mechanical Operations, Relativistic operations, or nonoperationability of accounts themselves which are taken in to consideration also but in such a case there are no inflows and out flows. Translating into physical terms: the links are the systems and the events are the transformations. There absolutely is no difference except in that there might not be (?) 'Interest' in the energy transactions or for that matter Nature might not be making any "Profit" out of each transaction. But still all these "inflow" terms are given 'Account Heads' and are 'invoked' and 'revoked' based on the concomitant and corresponding "Debits and Credits"; Whenever it is eschewed then there shall be no "transactions" under this head. It is in the light of the foregoing consideration the word or notion of "event" must be regarded as truly primordial: events **do not (e(eb)) happen** in spacetime, **they(eb) build-up** space-time. Stated in other words: space-time is **our(e&eb) way of organizing** events. The idea of deriving the geometry of space-time from apurely "causal structure"(this is the source) has been also hanging around for more than two decades after Raphael Sorkin opened the causal sets program.

A portion of a quantum circuit (left) and its causal network representation (right). The hexagon (and the corresponding circle on the right) represents a tile which allows to recover the whole circuit upon translation. This is the equivalent of a Physical Law. Physicists often identify Theory with Reality, but Theory is only our way to **connect** phenomena, **to relate** input with an output. Input and output are linked through cascades of local interactions, namely events that involve only a finite number of systems. In the quantum computer the subroutines (the potential events) are the unitary transformations of the gates, and the causal links are the quantum systems—the so-called qubits. In Fig. 1 a piece of quantum circuit is represented. The gate(box) performing the unitary transformation A reads information from two input registers (wires) which in turn are the output of two gates performing the unitary B, and so forth. What is a Physical Law in this causal-network framework? It is a piece of network—a set of events (gates) along with causal links (wires) connecting them—by translating which we can build up the whole unbounded periodic network, corresponding to our supposition that the law is true everywhere and ever. Such representation of the physical law contains only its logical essence, stripped of the "conventional" part (e. g. the conventionality of simultaneity the informational paradigm is a huge change of ontology: there is no stuff that supports the qubits, but **stuff itself is made(e) of** qubits! This is a change of perspective that is hard to swallow. Those who strongly believe in the reality of space-time with "objects" inside it in. Another objection is that, once we have the computer, we still need to provide it with the software. True: but this is the same challenge of grand unification of quantum field theory, and here at least we have a simple common "programmable" background, and we may hope to find unification in new kinds of principles, related e. g. to the topological nature of the network. The principles must be simple: the software must be simple. But the computational grand-unification, being naturally a lattice theory, would also have the great bonus of avoiding all problems due to the continuum which plague quantum field theory (ultraviolet divergences, the Feynman path integral, nonlocalizability of measurements, and many more). On the other hand, the digital theory will likely miss some of the simplicity of the continuum, whence finding easy ways to interpolate digital with analog must have top priority. Recovering the whole Physics as emergent from the quantum information processing is a large program: we need to build up a complete dictionary that translates all physical notions into information-theoretic words. And we want more than that: we want to know if the digital character of Reality is experimentally detectable at some scale. Spacetime, a physical notion, **can(e) emerge from the** quantum computation, and how the quantum-digital nature of Reality **leads to physical (eb)consequences** that are in-principle detectable. Current quantum field theory is indeed a kind of "thermodynamic" limit, valid at the Fermi scale, of a deeper theory that holds at the Planck scale, where the quantum **field is replaced** by a giant quantum computer. We'll see that the free-flow of quantum information is described by digital version of the Dirac equation and **this also provides** informational interpretations for inertial mass and Planck constant. At the same time, the notion of Hamiltonian is emerging, and, the quantum field **can be eliminated** in favor of pure qubits. Some of these ideas for the moment plainly work in one space dimension, and are only a starting point: later in the paper we will see routes to be explored for larger space dimensions. The free flow of information is the Dirac equation. One striking feature of the computational paradigm is that Lorentz covariance is a free bonus. As a matter of fact, Lorentz covariance must **emerge(e) from** the computation if this is able to simulate "Reality". And, the Dirac equation turns out to be just the freedom of quantum informations mentioned, we will restrict to one space dimension, and incorporation of larger dimensions later. In the quantum computer information can flow in a fixed direction only at the maximum speed of one-gate-per-step. In the digital world there is no physical unit: **time and space are measured by counting, and the digital-analog conversion factors**

will be given by a time τ expressed in seconds and length a expressed in meters, which can be interpreted as the minimal space distance and time-distance between events, respectively. We may think to as providing the Planck scale, namely 0.1 mm compared to an electron as huge as an entire galaxy! In analog units, the maximal speed is then given by $c = a/\tau$. Mathematically information flow in the two directions by the two field operators.

Various present and future specialized applications of magnets require monodisperse, small magnetic particles, and the discovery of molecules that can function as Nanoscale magnets was an important development in this regard. These molecules act as single-domain magnetic particles that, below their blocking temperature, **exhibit** magnetization hysteresis, a classical property of macroscopic magnets. Such 'single-molecule magnets' (SMMs)⁴ straddle the interface between classical and quantum mechanical behaviour because they also display quantum tunnelling of magnetization^{5,6} and quantum phase interference⁷. Quantum tunnelling of magnetization can be advantageous for some potential applications of SMMs, for example, in providing the quantum superposition of states required for quantum computing⁸. However, it is a disadvantage in other applications, such as information storage, where it would lead to information loss. Thus it is important to both understand **and control** the quantum properties of SMMs. Here we report a supramolecular SMM dimer in which antiferromagnetic coupling between the two components results in quantum behaviour different from that of the individual SMMs. Our experimental observations and theoretical analysis suggest a means of tuning the quantum tunnelling of magnetization in SMMs. This system may also prove useful for studying quantum tunnelling of relevance to mesoscopic antiferromagnets. Researchers are currently seeking robust methods of **directly manipulating** quantum states. Efforts are being made to more fully **develop** quantum cryptography, which will **theoretically allow** guaranteed secure transmission of information. A more distant goal is the development of quantum computers, which are expected to perform certain computational tasks exponentially faster than classical computers. Another active research topic is quantum teleportation, which deals with techniques to transmit quantum information over arbitrary distances

QUANTUM COMPUTATION AND PAULI'S EXCLUSION PRINCIPLE:

What is quantum computing? Alan Turing thought about this in 1936 with regard (implicitly) to classical mechanics, and gave the world the paradigm classical computer: the Turing machine. In a trivial sense, everything is a quantum computer. (A pebble **is a** quantum computer **for calculating** the constant-position function - you get the idea.) And of course, today's computers exploit quantum *effects* (like electrons tunneling through barriers) to help do the right thing and do it fast. For that matter, both the computer and the pebble **exploit a** quantum effect - **the "Pauli exclusion principle"**, which **holds(e) up** ordinary matter against collapse by bringing about the kind of degeneracy we call chemistry - just to remain stable solid objects. But quantum computing is much more than that.

The most exciting really new feature of quantum computing is **quantum parallelism**. A quantum system is in general not in *one* "classical state", but in a "quantum state" consisting (crudely speaking) of a **superposition of many(e&eb) classical or classical-like** states. This superposition is not just a figure of speech, covering up our ignorance of which classical-like state it's "really" in. But actually you need the whole superposition to get the time evolution right. The system *really is* in some sense in all the classical-like states at once! If the superposition can be protected from unwanted entanglement **with its** environment (known as *decoherence*), a quantum computer can **output results dependent on details** of *all* its classical-like states. This is quantum parallelism - parallelism on a serial machine. And if that wasn't enough, machines that would already, in architectural terms, qualify as parallel can benefit from quantum parallelism too -

QUANTUM TUNELLING AND QUANTUM MACHINE:.

Physicists Andrew Cleland and John Martinis from the University of California at Santa Barbara and their colleagues designed the machine -- a tiny metal paddle of semiconductor, visible to the naked eye -- and coaxed it into dancing with a quantum groove. First, they cooled the paddle until it reached its "ground state," or the lowest energy state permitted by the laws of quantum mechanics (a goal long-sought by physicists). Then they raised the widget's energy by a single quantum to produce a purely quantum-mechanical state of motion. They even managed to put the gadget in both states at once, so that it literally vibrated a little and a lot at the same time -- a bizarre phenomenon allowed by the weird rules of quantum mecha space with a complex metric permitted by quantum cosmology is given; two regions, one containing no closed causal curve and one containing closed time like curves, are separated by a complex region. Through quantum tunneling one can travel from one region to the other. The vacuum polarization stress-energy tensor converges everywhere so the space is stable. This challenges Hawking's chronology protection conjecture and highlights on building a time machine.

Superpositional quantum computation

Superpositional quantum computations **exploit the(e) fact** that a coherent quantum state is a **superposition(e&eb)** of n distinct states, α_i , each weighted by some complex scalar α_i . Under certain conditions, this quantum state decoheres, and the particle adopts one of the α_i as its determinate state, with a probability that is determined by the ratios of the α_i . The idea proposed in [Feynman, 1982] and developed in, e.g., [Deutsch, 1985], is that if such superpositional states were used to implement the states of a computer, then **various registers or memory locations** in the computer would not be conventional bits with a determinate value of 1 or 0, but would instead be quantum bits - *qubits* - which are superpositions of both the 0 and 1 values.

A key advantage to this would be that n qubits **could (e)be used** to perform 2^n computations in parallel, one computation for **each (e&eb)combination** of values of the superposed states. However, there are two principal difficulties **in (e)exploiting** this proposal. First, there is the problem of maintaining the coherence (=superpositionality) of a qubit while performing computations on it: the danger is that the kind of physical processes necessary to implement the relevant bit operations are

such that they would cause the quantum state to collapse or decohere. But even supposing one can perform such operations while maintaining the coherence of the qubit, there is still the difficulty of exploiting the superpositionality of the qubit in a way that can perform effective computational work.

The only specific idea of how this can be done was proposed by Shor [Shor, 1994]. Shor describes how to initialize a superpositional quantum state with a random number x and a number n to be factored into primes. He then describes how to transform(e&eb) that state into another which is such that the probability distribution of the measurements of the state is a simple function of a number r which is a reliable guide to the prime factors of n . A few collapses, then, of this system allows one to calculate r and thus factorize n . If this algorithm could be implemented in a real quantum computational system, one could then produce the prime factors of large (e.g., 159-digit) numbers in seconds. Since current cryptography technology relies on the fact that such numbers would take a single computer many years to factor, Shor's algorithm has generated much interest in quantum computation. However, it has proven difficult to generalize this exploitation of the qubit to other applications. The general problem of how to use a superpositional state to do computational work remains. Quantum tunneling is vital to the operation of many devices - even in the simple light switch, as otherwise the electrons in the electric current could not penetrate the potential barrier made up of a layer of oxide. Memory chips found in USB drives(e) use quantum tunneling to(e) erase their memory cells.

BLACK BODY RADIATION QUANTUM COMPUTATION

Hawking radiation is black body radiation that is predicted to be emitted by black holes, due to quantum effects near the event horizon. It is named after the physicist Stephen Hawking, who provided a theoretical argument for its existence in 1974, and sometimes also after the physicist Jacob Bekenstein who predicted that black holes should have a finite, non-zero temperature and entropy. Hawking's work followed his visit to Moscow in 1973 where Soviet scientists Yakov Zeldovich and Alexei Starobinsky showed him that according to the quantum mechanical uncertainty principle, rotating black holes should create and emit particles. Hawking radiation reduces the mass and the energy of the black hole and is therefore also known as **black hole evaporation**. Because of this, black holes that lose more mass than they gain through other means are expected to shrink and ultimately vanish. Micro black holes (MBHs) are predicted to be larger net emitters of radiation than larger black holes and should shrink and dissipate faster.

Quantum coherence and nonlocality were long regarded as primary(eb) manifestations of the counterintuitive nature of quantum theory. They are now also coming to be recognized as a potentially(e) valuable resource for information processing and communication. In contact with its environment, a quantum system can(e) lose its ability to (eb)exhibit coherence and nonlocality. The process responsible for *this transition* to effectively classical behavior is known as decoherence. While shedding new light on the origins of "the classical" decoherence makes difficult to take advantage of the full potential offered by the quantum in communication and, especially, in computation. A challenge for physics is therefore to understand more thoroughly the reasons for decoherence and to devise means to preserve(e&eb) it. The discovery by Peter Shor that quantum computers can factor large numbers much more efficiently than their classical counterparts has brought the whole field to the limelight. In quantum computers coherence must e(e&eb)be preserved throughout the calculation. The notion of quantum operations, reversible measurement and the information theoretic notions are described extensively in literature demonstrates how quantum communication can be done without (e) requiring energy extending the analogous classical result. Generalisation of the quantum factoring algorithm. Zalka demonstrates how a quantum computer can be utilized(e) for efficiently simulating quantum mechanical systems. Cleve et al., identify common pattern of quantum algorithms. Quantum information is extremely fragile. Not only there is little energy between the states $|0\rangle$ and $|1\rangle$ but any superpositions are also allowed. Superpositions with the different phase s have the same energy and therefore become exceedingly fragile. This fragility has been thought to imply the demise of quantum computers. Fortunately quantum error correction codes have been discovered thus giving hope that it may be possible to build quantum computers robust against imperfections. The third part of these proceedings deals with errors and quantum error correction. Paz and Zurek analyze the effect of errors on the factoring algorithm. Knill et al. introduce error correction and demonstrate an accuracy threshold theorem. A similar theorem is also proved and analyzed by Preskill. Finally, all these theoretical constructions would be like sand castles if it would not be possible to build quantum computers. Wineland gives a review of the ion trap quantum computer. Walther surveys single atom experiments in cavities and traps. And finally Gershenfeld et al. analyze a new system to realize a quantum computer: Nuclear Magnetic Resonance. While quantum mechanics primarily applies to the atomic regimes of matter and energy, some systems exhibit quantum on a large scale - super fluidity, the frictionless flow of a liquid at temperatures near absolute, is one well-known example. Quantum theory also provides accurate descriptions for many previously unexplained phenomena, such as black body radiation and the stability of the orbitals of electrons in atoms. It has also given insight into the workings of many different biological systems, including receptors and protein structures Recent work on photosynthesis has provided evidence that quantum correlations play an essential role in this basic fundamental process of the plant kingdom. Even so, classical physics can often provide good approximations to results otherwise obtained by quantum physics, typically in circumstances with large numbers of particles or large quantum numbers.

Examples

Topological quantum computer

A **topological quantum computer** is a theoretical quantum computer that(e) employs two-dimensional quasiparticles called anyons, whose world lines cross(e&eb) over one another to form braids in a three-dimensional spacetime (i.e., one temporal plus two spatial dimensions). These braids form(eb) the logic gates that make(eb)

up the computer. The advantage of a quantum computer based (e)on quantum braids over using (e)trapped quantum particles is that the former is much more stable. The smallest perturbations can (e)cause a quantum particle to decohere and introduce errors in the computation, but such small perturbations do (e&e)not change the topological properties of the braids. This is like the effort required to cut a string and reattach the ends to form a different braid, as opposed to a ball (representing an ordinary quantum particle in four-dimensional spacetime) simply bumping into a wall. While the elements of a topological quantum computer originate in a purely mathematical realm, experiments in 2002 by Michael H. Freedman along with Zhenghan Wang, both with Microsoft, and Michael Larsen of Indiana University indicate these elements can be(e) created in the real world using semiconductors made of gallium arsenide near absolute zero and subjected to strong magnetic fields.

Anyons are quasiparticles in a two-dimensional space. Anyons are not strictly fermions or bosons, but do share the characteristic of fermions in that they cannot occupy the same state. Thus, the world lines of two anyons cannot e(e&e)cross or merge. This allows braids to be made that make up a particular circuit. In the real world, anyons form(e) from the excitations in an electron gas in a very strong magnetic field, and carry fractional units of magnetic flux in a particle-like manner. This phenomenon is called the fractional quantum Hall effect. The electron "gas" is sandwiched between two flat plates of gallium arsenide, which (e)create the two-dimensional space required for anyons, and is cooled(e) and subjected to intense transverse magnetic fields.

When anyons are(e&e) braided, the transformation of the quantum state of the system depends only on the topological class of the anyons' trajectories (which are classified according to the braid group). Therefore, the quantum information which is stored in the state of the system is(e(e&e) impervious to small errors in the trajectories. In 2005, Sankar Das Sarma, Michael Freedman, and Chetan Nayak proposed a quantum Hall device which would realize a topological qubit. In a key development for topological quantum computers, in 2005 Vladimir J. Goldman, Fernando E. Camino, and Wei Zhou were said to have created the first experimental evidence for using fractional quantum Hall effect to (e)create actual anyons, although others have suggested their results could be the product of phenomena not involving anyons. It should also be noted that nonabelian anyons, a species required for topological quantum computers, have yet to be experimentally confirmed.

Topological quantum computers are equivalent in computational power to other standard models of quantum computation, in particular to the quantum circuit model and to the quantum Turing machine model. That is, any of these models can efficiently simulate any of the others. Nonetheless, certain algorithms may be a more natural fit to the topological quantum computer model. For example, algorithms for evaluating the Jones polynomial were first developed in the topological model, and only later converted and extended in the standard quantum circuit model.

Topological Quantum Computations

To live up to its name, a topological quantum computer must(e) provide the unique computation properties promised by a conventional quantum computer design, which uses trapped quantum particles. Fortunately in 2002, Michael H. Freedman along with Zhenghan Wang, both with Microsoft, and Michael Larsen of Indiana University proved that a topological quantum computer can, in principle, perform any computation that a conventional quantum computer can do.

They found that conventional quantum computer device, given a flawless (error-free) operation of its logic circuits, will give a solution with an absolute level of accuracy, whereas a topological quantum computing device with flawless operation will(e) give the solution with only a finite level of accuracy. However, any level of precision for the answer can be obtained by adding more braid twists (e&e) of logic circuits to the topological quantum computer, in a simple linear relationship. In other words, a reasonable(+x) increase in elements (braid twists) can(e) achieve a high degree of accuracy in the answer. Actual computation [gates] is done(e) by edge states of fractional quantum Hall effect. This makes models one dimensional anyons important. In one space dimension anyons are defined algebraically.

Error correction and control

Even though quantum braids are inherently more(e) stable than trapped quantum particles, there is still a need to control(e&e) for error inducing(e) thermal fluctuations, which(e) produce random stray pairs of anyons which(e&e) interfere with adjoining braids. Controlling these errors is simply a matter of(e&e) separating the anyons to a distance where the rate of interfering strays drops(e) to near zero. Simulating the dynamics of a topological quantum computer may be a promising method of implementing fault-tolerant quantum computation even with a standard quantum information processing scheme. Raussendorf, Harrington, and Goyal have studied one model, with promising simulation results.

Free particle

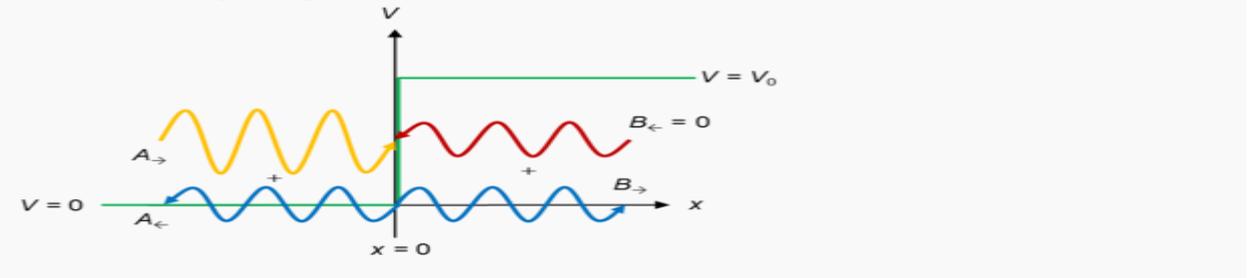

For example, consider a free particle. In quantum mechanics, there is wave-particle duality, so the properties of the particle can be described as the properties of a wave. Therefore, its quantum state can be represented as a wave of arbitrary shape and extending over space as a wave function. The position and momentum of the particle are observables. The Uncertainty Principle states that both the position and the momentum cannot simultaneously be measured with complete precision simultaneously. However, one can measure the position (alone) of a moving free particle, creating an eigenstate of position with a wavefunction that is very large (a Dirac delta) at a particular position x , and zero everywhere else. If one performs a position measurement on such a wavefunction, the resultant x will be obtained with 100% probability (i.e., with full certainty, or complete precision). This is called an

eigenstate of position - or, stated in mathematical terms, a *generalized position eigenstate (eigendistribution)*. If the particle is in an eigenstate of position, then its momentum is completely unknown. On the other hand, if the particle is in an eigenstate of momentum, then its position is completely unknown. In an eigenstate of momentum having a plane wave form, it can be shown that the wavelength is equal to h/p , where h is Planck's constant and p is the momentum of the eigenstate

3D confined electron wave functions for each eigenstate in a Quantum Dot. Here, rectangular and triangular-shaped quantum dots are shown. Energy states in rectangular dots are more 's-type' and 'p-type'. However, in a triangular dot, the wave functions are mixed due to confinement symmetry.

Step potential and Schrodinger's Equation:

Scattering at a finite potential step of height V_0 , shown in green. The amplitudes and direction of left- and right-moving waves are indicated. Yellow is the incident wave, blue are reflected and transmitted waves, red does not occur $> V_0$ for this figure.

The potential in this case is given by:

$$V(x) = \begin{cases} 0, & x < 0, \\ V_0, & x \geq 0. \end{cases}$$

The solutions are superpositions of left- and right-moving waves:

$$\psi_1(x) = \frac{1}{\sqrt{k_1}} \left(A_{\rightarrow} e^{ik_1x} + A_{\leftarrow} e^{-ik_1x} \right) \quad x < 0$$

$$\psi_2(x) = \frac{1}{\sqrt{k_2}} \left(B_{\rightarrow} e^{ik_2x} + B_{\leftarrow} e^{-ik_2x} \right) \quad x > 0$$

where the wave vectors are related to the energy via

$$k_1 = \sqrt{2mE/\hbar^2}, \text{ and}$$

$$k_2 = \sqrt{2m(E - V_0)/\hbar^2}$$

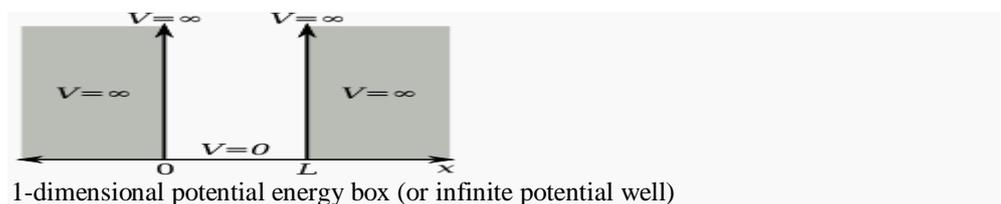

and the coefficients A and B are determined from the boundary conditions and by imposing a continuous derivative on the solution.

Each term of the solution can be interpreted as an incident, reflected, or transmitted component of the wave, allowing the calculation of transmission and reflection coefficients. In contrast to classical mechanics, incident particles with energies higher than the size of the potential step are still partially reflected.

Rectangular potential barrier

This is a model for the quantum tunneling effect, which has important applications to modern devices such as flash memory and the scanning tunneling microscope.

Particle in a box

The particle in a one-dimensional potential energy box is the most simple example where restraints lead to the quantization of energy levels. The box is defined as having zero potential energy everywhere *inside* a certain region, and infinite potential energy everywhere *outside* that region. For the one-dimensional case in the x direction, the time-independent Schrödinger equation can be written as

$$-\frac{\hbar^2}{2m} \frac{d^2\psi}{dx^2} = E\psi.$$

Writing the differential operator

$$\hat{p}_x = -i\hbar \frac{d}{dx}$$

the previous equation can be seen to be evocative of the classic kinetic energy analogue

$$\frac{1}{2m} \hat{p}_x^2 = E$$

with E as the energy for the state ψ , which in this case coincides with the kinetic energy of the particle.

The general solutions of the Schrödinger equation for the particle in a box are:

$$\psi(x) = Ae^{ikx} + Be^{-ikx} \quad E = \frac{\hbar^2 k^2}{2m}$$

or, from Euler's formula,

$$\psi(x) = C \sin kx + D \cos kx.$$

The presence of the walls of the box determines the values of C , D , and k . At each wall ($x = 0$ and $x = L$), $\psi = 0$. Thus when $x = 0$,

$$\psi(0) = 0 = C \sin 0 + D \cos 0 = D$$

and so $D = 0$. When $x = L$,

$$\psi(L) = 0 = C \sin kL.$$

C cannot be zero, since this would conflict with the Born interpretation. Therefore, $\sin kL = 0$, and so it must be that kL is an integer multiple of π . And additionally,

$$k = \frac{n\pi}{L} \quad n = 1, 2, 3, \dots$$

The quantization of energy levels follows from this constraint on k , since

$$E = \frac{\hbar^2 \pi^2 n^2}{2mL^2} = \frac{n^2 h^2}{8mL^2}.$$

Finite potential well

This is the generalization of the infinite potential well problem to potential wells of finite depth.

Harmonic oscillator

Some trajectories of a harmonic oscillator (i.e. a ball attached to a spring) in classical mechanics (A-B) and quantum mechanics (C-H). In quantum mechanics, the position of the ball is represented by a wave (called the wavefunction), with the real part shown in blue and the imaginary shown in red. Some of the trajectories (such as C, D, E, and F) are standing waves (or "stationary states"). Each standing-wave frequency is proportional to a possible energy of the oscillator. This "energy quantization" does not occur in classical physics, where the oscillator can have *any* energy.

As in the classical case, the potential for the quantum harmonic oscillator is given by:

$$V(x) = \frac{1}{2} m\omega^2 x^2$$

This problem can be solved either by solving the Schrödinger equation directly, which is not trivial, or by using the more elegant "ladder method", first proposed by Paul Dirac. The eigenstates are given by:

$$\psi_n(x) = \sqrt{\frac{1}{2^n n!}} \cdot \left(\frac{m\omega}{\pi \hbar}\right)^{1/4} \cdot e^{-\frac{m\omega x^2}{2\hbar}} \cdot H_n\left(\sqrt{\frac{m\omega}{\hbar}} x\right), \quad n = 0, 1, 2, \dots$$

where H_n are the Hermite polynomials:

$$H_n(x) = (-1)^n e^{x^2} \frac{d^n}{dx^n} (e^{-x^2})$$

and the corresponding energy levels are

$$E_n = \hbar\omega \left(n + \frac{1}{2} \right)$$

This is another example which illustrates the quantization of energy for bound states.

Quantum coherence and Quantum Computation:

In quantum mechanics, all objects have wave-like properties (see de Broglie waves). For instance, in Young's Double-slit experiment electrons can be used in the place of light waves. Each electron's wave-function goes through both slits, and hence has two separate split-beams that contribute to the intensity pattern on a screen. According to standard wave theory [Fresnel, Huygens] these two contributions give rise to an intensity pattern of bright bands due to constructive interference, interlaced with dark bands due to destructive interference, on a downstream screen. (Each split-beam, by itself, generates a diffraction pattern with less noticeable, more widely spaced dark and light bands.) This ability to interfere and diffract is related to coherence (classical or quantum) of the wave. The association of an electron with a wave is unique to quantum theory.

The effect of the inevitable coupling to external degrees of freedom of a quantum computer are extensively examined. It is found that for quantum calculations (in which the maintenance of coherence over a large number of states is important), not only must the coupling ***be small but the*** time taken in the quantum calculation ***must be less than*** the thermal time scale, \hbar/kBT . For longer times the condition on the strength of the coupling to the external world becomes much more stringent.

When the incident beam is represented by a quantum pure state, the split beams downstream of the two slits are represented as a superposition of the pure states representing each split beam. (This has nothing to do with two particles or Bell's inequalities) relevant to an entangled state: a 2-body state, a kind of coherence between two 1-body states.) The quantum description of imperfectly coherent paths is called a mixed state. A perfectly coherent state has a density matrix (also called the "statistical operator") that is a projection onto the pure coherent state, while a mixed state is described by a classical probability distribution for the pure states that make up the mixture.

Large-scale (macroscopic) quantum coherence leads to novel phenomena, the so-called macroscopic quantum phenomena. For instance, the laser, superconductivity, and superfluidity are examples of highly coherent quantum systems, whose effects are evident at the macroscopic scale. The macroscopic quantum coherence (Off-Diagonal Long-Range Order, ODLRO) [Penrose & Onsager (1957), C. N. Yang (1962)] for laser light, and super fluidity, is related to first-order (1-body) coherence/ODLRO, while superconductivity is related to second-order coherence/ODLRO. (For fermions, such as electrons, only even orders of coherence/ODLRO are possible.) Super fluidity in liquid He4 is related to a partial Bose-Einstein condensate. Here, the condensate portion is described by a multiply occupied single-particle state. [e.g., Cummings & Johnston (1966)]

On the other hand, the Schrödinger's cat thought experiment highlights the fact that quantum coherence cannot be arbitrarily applied to macroscopic situations. In order to have a quantum superposition of dead and alive cat, one needs to have pure states associated with aliveness and pure states associated with death, which are then superposed. Given the problem of defining death (absence of EEG, heartbeat,) it is hard to imagine a set of quantum parameters that could be used in constructing such superposition. In any case, this is not a good topic for a description of quantum coherence. [Ref.: Fresnel, Huygens, R. Glauber (1963)]

Regarding the occurrence of quantum coherence at a macroscopic level, it is interesting to note that the classical electromagnetic field exhibits macroscopic quantum coherence. The most obvious example is carrier signals for radio and TV. They satisfy Glauber's quantum description of coherence.

CONSERVATION LAWS AND QUANTUM COMPUTATION(INFORMATION)

The Wigner-Araki-Yanase theorem shows that conservation laws ***limit (e)*** the accuracy of measurement. Ozawa generalized the argument to show that conservation laws ***limit (e) the*** accuracy of quantum logic operations. A rigorous lower bound was obtained of the error probability of any physical realization of the controlled-NOT gate ***under the(e) constraint*** that the computational basis is represented by a component of spin and that physical implementations ***obey e(e&eb) the*** angular momentum conservation law. The lower bound ***is shown to be*** inversely proportional to the number of ancilla qubits or the strength of the external control field. Since the discovery of Shor's algorithm, physical realization of quantum computers is one of the major topics in physics. One of the formidable ***obstacles to(e) the*** realization of quantum computers is the decoherence induced by the environment. The theory of quantum error correction and the theory of fault-tolerant quantum computing have been developed to ***overcome*** this difficulty. One of the main achievements of this field is the threshold theorem: Provided the noise in individual quantum gates ***is below a certain(e) threshold*** it is possible to efficiently perform an arbitrarily large quantum computing. However, the threshold is rather demanding and the problem turns to whether there is any fundamental limit for implementing quantum gates. Recently, Lloyd and Ng have discussed how fundamental constants ***provide limits (e)on*** speed and memory of quantum computers. MASANAO OZAWA proposed another approach based on conservation laws. If we consider the ultimate performance of computing allowed by the laws of physics, elementary quantum gates should be isolated and small, so that the corresponding unitary operators should satisfy fundamental symmetries, or conservation laws. From this point of view, it is likely that the degree of conflict with a conservation law ***depends on the*** nature of its logic to be performed and that the imperfection can be ***reduced by*** increasing the size of implementation. However, no serious investigation has ever taken place. Ozawa model takes qubits as spin 1/2 objects and investigate the quantum limit ***induced by the*** angular momentum conservation law. He shows that although the

SWAP gate has no conflict with the conservation law, the controlled-NOT gate, which is one of the universal quantum logic gates, cannot be implemented by any 2-qubit rotationally invariant unitary operation within error probability $1/16$. Thus, to obtain more accuracy, we need to blow up the unitary operation to an ancilla system. Then, the size of an implementation of the quantum gate is defined as the total number of qubits in the computational basis and the ancilla.

Conservation-law-induced quantum limits for physical (e&eb)realizations of the quantum NOT gate

In recent investigations, it has been found that conservation laws generally lead(eb) to precision limits on quantum computing. Lower bounds of the error probability have been obtained for various logic operations from the commutation relation between the noise operator and the conserved quantity or from the recently developed universal uncertainty principle for the noise-disturbance trade-off in general measurements. However, the problem of obtaining the precision limit to realizing the quantum NOT gate has eluded a solution from these approaches. Tokishiro Karasawa* and Masanao Ozawa† developed a method for this problem based on analyzing the trace distance between the output state from the realization under consideration and the one from the ideal gate. Using the mathematical apparatus of orthogonal polynomials, they(eb) obtained a general lower bound on the error probability for the(eb&e) realization of the quantum NOT gate in terms of the number of qubits in the control system under conservation of the total angular momentum of the computational qubit plus the control system along the direction(e) used to encode the computational basis. The lower bound turns out to be more stringent than one might expect from previous results. Their method is expected to lead to more accurate estimates for physical realizations of various types of quantum computations under conservation laws and to contribute to related problems such as the accuracy of programmable quantum processors.

Conservation Laws, Uncertainty Relations, and Quantum Limits of Measurements

The uncertainty relation between the noise operator and the conserved quantity leads(eb) to a bound on the accuracy of general measurements. The bound extends the assertion by Wigner, Araki, and Yanase that conservation laws limit the (e)accuracy of “repeatable,” or “nondisturbing,” measurements to general measurements, and improves the one previously obtained by Yanase for spin measurements. The bound represents an obstacle to making a small quantum computer. It was found that conservation laws put a(e) limit on measurements of quantum mechanical observables. In 1960, Araki and Yanase proved the following assertion known as the Wigner-Araki-Yanase (WAY) theorem: Observables which do not commute with bounded additive conserved quantities have(e) no “exact” measurements. Subsequently, Yanase found a bound for the accuracy of measurements of the x component of spin in terms of the “size” of the apparatus, where the size is characterized by the mean square of the z component of the angular momentum. Yanase and Wigner concluded from this result that in order to increase the accuracy of spin measurement one ha(e)s to use a very large measuring apparatus. In the WAY theorem, for a measurement to be “exact” the following two conditions are(eb) required to be satisfies:

- (i) the Born statistical formula (BSF) and
- (ii) The repeatability hypothesis (RH), asserting that, if an observable is measured twice in succession in a system, then we obtain the same value each time.

Yanase’s bound does not assume the RH. Instead, a condition, to be referred to as Yanase’s condition, is assumed that the probe observable, the observable in the apparatus to be measured after the measuring interaction, commutes with the conserved quantity, to ensure the measurability of the probe observable. Elaborating the suggestions given by Stein and Shimony, Ohira and Pearle constructed a simple measuring interaction that satisfies the conservation law and the BSF, assuming the precise probe measurement, but does not satisfy the RH. Based on their model, Ohira and Pearle claimed that it is possible to have an accurate measurement of the spin component regardless of the size of the apparatus, if the RH is abandoned. However, their model does not satisfy Yanase’s condition, so that the problem remains as to the measurability of the probe observable. Yanase’s argument, however, assumes a large (but of variable size) measuring apparatus having the continuous angular momentum from the beginning for technical reasons and concludes that accurate measurement requires(e) a very large apparatus. To avoid a circular argument, a rigorous derivation without such an assumption is still demanded. Moreover, Wigner pointed out the necessity for generalizing the bound to general quantum systems other than +spin systems, as well as including all additive conservation laws. In order to accomplish the suggested generalization, a new approach to the problem is proposed by Ozawa based on uncertainty relation between the conserved quantity and the noise operator, defined as the difference between the post-measurement probe and the measured quantity. We obtain a bound for the mean-square error of general measuring interactions imposed by any additive conservation laws without assuming the RH. This bound also clarifies the trade-off between the size and the commutativity of the noise operator with the conserved quantity, unifying the suggestion by WAY and others and the one suggested by Ohira and Pearle. For spin measurements, this bound with Yanase’s condition leads to a tight bound for the error probability of spin measurement, which improves Yanase’s bound.

Quantum decoherence

Protection of Quantum Information Encoded in Decoherence Free States against Exchange Errors (See Daniel A. Lidar, David Bacon, Julia Kempe and K. Birgitta Whaley) calls for Decoherence Sub spaces The exchange interaction between identical qubits in a quantum information processor gives (eb)rise to unitary two-qubit errors. Decoherence free subspaces (DFSs) for collective decoherence undergo Pauli errors under exchange, which however do not take the decoherence Free states outside of the DFS. In order to protect DFSs against these errors it is sufficient to employ a recently proposed concatenated DFS-quantum error correcting code scheme [D.A. Lidar, D. Bacon and K.B. Whaley, Phys. Rev. Lett. 82, 4556 (1999)].

Preserving e & eb the coherence of quantum states and **controlling e & eb their** unitary evolution is one of the fundamental goals of Quantum Information Processing. When the system Hamiltonian is invariant under particle permutations, the exchange operator E_{ij} interchanging particles i and j is a constant of the motion, and definite symmetry of a state will be conserved. Models of quantum computers based on identical bosons or fermions must of course respect this elementary requirement. It was pointed out in a recent paper that active quantum error correcting codes (QECCs) designed to **correct e & eb independent** single-qubit errors, will **fail e for** identical particles in the presence of exchange errors. The reason is that exchange acts as a two-qubit error which has the same effect as a simultaneous bit flip on two different qubits. Of course, QECCs dealing explicitly with multiple-qubit errors are also available, so that exchange errors can readily be dealt with provided one accepts longer code words than are needed to deal with single-qubit errors. For example, in Ref. [2] a nine-qubit code is presented **which can e & eb correct** all single-qubit errors and all Pauli exchange errors. This is to be compared with the five-qubit "perfect" code which protects (only) against all single-qubit errors. While the nine-qubit code is longer than the "perfect" code, it is shorter than a code **required to e protect** against all two-qubit errors. A different error model which has been considered by several authors is that in which qubits undergo collective, rather than independent errors. The underlying physics of this model has a rich history: it dates back at least to Dicke's quantum optics work on super radiance of atoms **coupled e & eb to a** radiation field, **where it eb arose** in the consideration of systems confined to a region whose linear dimensions are small compared to the shortest wavelength of the field. The model was later treated extensively by Agarwal in the context of spontaneous emission. It was only recently realized, however, that in the collective decoherence model **there eb exist** large decoherence-free subspaces (DFSs), which are "quiet" Hilbert subspaces in which no environmentally-induced errors **occur** at eb all. Such subspaces offer **a passive e protection** against decoherence. Collective decoherence is an assumption **about the e manner** in which the environment couples to the system: instead of independent errors, as assumed in the active QECC approach, one assumes that errors are strongly correlated, in the sense that all qubits can be permuted without affecting the coupling between system and bath. This is clearly a very strong assumption, and it may not hold exactly in a realistic system-bath coupling scenario. To deal with this limitation, it has been shown recently how DFSs can be stabilized in the presence of errors that perturb the exact permutation symmetry, by concatenating DFSs with QECCs. Concatenation is a general technique that is useful for achieving fault tolerant quantum computation and trades stability of quantum information for the price of longer code words. Effect of exchange errors on DFSs for collective decoherence. These errors are fundamentally different from those induced by the system-bath coupling, since they originate entirely from the internal system Hamiltonian. It is shown that by use of the very same concatenation scheme (which was designed originally to deal with system-bath induced errors), a DFS can be stabilized in the presence of exchange errors as well. DFS is invariant under such errors, and conclude that concatenation with a QECC can generally stabilize DFSs against exchange.

In quantum mechanics, **quantum decoherence** is **the e loss of** coherence or ordering of the phase angles between the components of a system in a quantum superposition. **A eb consequence** of this dephasing **leads eb to** classical or probabilistically additive behavior. Quantum decoherence gives **the appearance** of wave function collapse (the **reduction e of** the physical possibilities into a single possibility as seen by an observer) and justifies the framework and intuition of classical physics as an acceptable approximation: decoherence is the mechanism by which the classical limit emerges out of a quantum starting point and **it determines** the location of the quantum-classical boundary. Decoherence **occurs eb when** a system **interacts e & eb with its environment** in a thermodynamically irreversible way. **This e prevents** different elements in the quantum superposition of the system+environment's wavefunction from interfering with each other. Decoherence has been a subject of active research since the 1980s

Decoherence can be viewed as **the e loss of** information from a system into the environment (often modeled as a heat bath) since every system is loosely coupled with the energetic state of its surroundings. Viewed in isolation, the system's dynamics are non-unitary (although the combined system plus environment evolves in a unitary fashion). Thus the dynamics of the system alone are irreversible. As with any coupling, entanglements are **generated eb between** the system and environment, which **have e & eb the effect of** sharing quantum information with—or **transferring it** to—the surroundings.

Decoherence does **not generate** actual wave function collapse. It only provides an explanation for the **appearance** of the wavefunction collapse, as the quantum nature of the system **"leaks" $-$ & $+$** into the environment. That is, components of the wavefunction **are e & eb decoupled** from a coherent system, and acquire phases from their immediate surroundings. In other words, wave function acquires phase (+) from the environment (-) A total superposition of the global or universal wavefunction still exists (and remains coherent at the global level), but its ultimate fate remains an interpretational issue. Specifically, decoherence does not attempt to explain the measurement problem. Rather, decoherence provides an explanation for the transition of the system to a mixture of states that seem to correspond to those states observers perceive. Moreover, our observation tells us that this mixture looks like a proper quantum ensemble in a measurement situation, as we observe that measurements lead to the "realization" of precisely one state in the "ensemble".

Decoherence represents a challenge for the practical realization of quantum computers, since they are expected to rely heavily on the undisturbed evolution of quantum coherences. Simply put; they require that coherent states be preserved and that decoherence is managed, in order to actually perform quantum computation.

Mechanisms

To examine how decoherence operates, an "intuitive" model is presented. The model requires some familiarity with quantum theory basics. Analogies are made between visualisable classical phase spaces and Hilbert spaces. A more rigorous

derivation in Dirac notation shows how decoherence destroys interference effects and the "quantum nature" of systems. Next, the density matrix approach is presented for perspective.

Phase space picture

An N -particle system can be represented in non-relativistic quantum mechanics by a wavefunction, $\psi(x_1, x_2, \dots, x_N)$. This has analogies with the classical phase space. A classical phase space contains a real-valued function in $6N$ dimensions (each particle contributes 3 spatial coordinates and 3 momenta). Our "quantum" phase space conversely contains a complex-valued function in a $3N$ dimensional space. The position and momenta do not commute but can still inherit much of the mathematical structure of a Hilbert space. Aside from these differences, however, the analogy holds.

Different previously-isolated, non-interacting systems occupy different phase spaces. Alternatively we can say they occupy different, lower-dimensional subspaces in the phase space of the joint system. The *effective* dimensionality of a system's phase space is the number of *degrees of freedom* present which—in non-relativistic models—is 6 times the number of a system's *free* particles. For a macroscopic system this will be a very large dimensionality. When two systems (and the environment would be a system) start to interact, though, their associated state vectors are no longer constrained to the subspaces. Instead the combined state vector time-evolves a path through the "larger volume", whose dimensionality is the sum of the dimensions of the two subspaces. A square (2-d surface) extended by just one dimension (a line) forms a cube. The cube has a greater volume, in some sense, than its component square and line axes. The extent two vectors interfere with each other is a measure of how "close" they are to each other (formally, their overlap or Hilbert space scalar product together) in the phase space. When a system couples to an external environment, the dimensionality of, and hence "volume" available to, the joint state vector increases enormously. Each environmental degree of freedom contributes an extra dimension.

Marcos Saraceno, in his paper represents both the states and the evolution of a quantum computer in phase space using the discrete Wigner function. Properties of the phase space representation of quantum algorithms are studied by many authors: apart from analyzing important examples, such as the Fourier Transform and Grover's search, the conditions for the existence of a direct correspondence between quantum and classical evolutions in phase space. Wigner function in a given phase space point could be measured by means of a tomographic method that, itself, can be interpreted as a simple quantum algorithm. Quantum mechanics can be formulated in phase space, the natural arena of classical physics. For this we can use the Wigner function, which is a distribution enabling to represent quantum states and temporal evolution in the classical phase space scenario. Generalization of the familiar Wigner representation of quantum mechanics to the case of a system with a finite, N -dimensional, Hilbert space. Phase space representation of both the states and the evolution of a quantum computer, has been investigated by various researchers..

One can ask if there are potential advantages in(e) using a phase space representation for a quantum computer. The use of this(e) approach is quite widespread in various areas of physics (such as quantum optics, and has been fruitful, for example, in analyzing issues concerning the classical limit of quantum mechanics. In answering the above question one should have in mind that a quantum algorithm can be simply thought of as a quantum map acting in a Hilbert space of finite dimensionality (a quantum map should be simply thought of as a unitary operator that is applied successively to a system. Therefore, any algorithm is clearly amenable to a phase space representation. Whether this representation will be useful or not will depend on properties of the algorithm. Specifically, algorithms become interesting in the large N limit (i.e. when operating on many qubits). For a quantum map this is the semi classical limit where regularities may arise in connection with its classical behavior. Unraveling these regularities, when they exist, becomes an important issue which can be naturally accomplished in a phase space representation. This representation may be useful to analyze some classes of algorithms. Moreover, the phase space approach may allow one to establish contact between the vast literature on quantum maps (dealing with their construction, the study of their semi classical properties, etc) and that of quantum algorithms. This, in turn, may provide hints to develop new algorithms and ideas for novel physics simulations. As a first application of these ideas several properties of quantum algorithms in phase space were studied by Marcos; Scientists analyzed under what circumstance it is possible to establish a direct classical analogue for a quantum algorithm (exhibiting interesting examples of this kind, such as the Fourier transform and other examples which naturally arise in studies of quantum maps). Marcos et al. have shown that, quite surprisingly, Grover's search algorithm can be represented in phase space and interpreted as a simple quantum map. To define Wigner functions for discrete systems various attempts can be found in the literature. Most notably, Wootters proposes a definition that has all the desired properties only when N is a prime number. His phase space is an $N \times N$ grid (if N is prime) and a Cartesian product of spaces corresponding to prime factors of N in the general case

The original system's wavefunction can be expanded arbitrarily as a sum of elements in a quantum superposition. Each expansion corresponds to a projection of the wave vector onto a basis. The bases can be chosen at will. Let us choose any expansion where the resulting elements interact with the environment in an element-specific way. Such elements will—with overwhelming probability—be rapidly separated from each other by their natural unitary time evolution along their own independent paths. After a very short interaction, there is almost no chance of any further interference. The process is effectively irreversible. The different elements effectively become "lost" from each other in the expanded phase space created by coupling with the environment; in phase space, this decoupling is monitored through the Wigner quasi-probability distribution. The original elements are said to have decohered. The environment has effectively selected out those expansions or decompositions of the original state vector that decohere (or lose phase coherence) with each other. This is called "environmentally-induced-super selection", or einselection. The decohered elements of the system no longer

exhibit quantum interference between each other, as in a double-slit experiment. Any elements that decohere from each other via environmental interactions are said to be quantum entangled with the environment. The converse is not true: not all entangled states are decohered from each other.

Any measuring device or apparatus acts as an environment since, at some stage along the measuring chain, it has to be large enough to be read by humans. It must possess a very large number of hidden degrees of freedom. In effect, the interactions may be considered to be quantum measurements. As a result of an interaction, the wave functions of the system and the measuring device become entangled with each other. Decoherence happens when different portions of the system's wavefunction become entangled in different ways with the measuring device. For two einselected elements of the entangled system's state to interfere, both the original system and the measuring in both elements device must significantly overlap, in the scalar product sense. If the measuring device has many degrees of freedom, it is *very* unlikely for this to happen.

As a consequence, the system behaves as a classical statistical ensemble of the different elements rather than as a single coherent quantum superposition of them. From the perspective of each ensemble member's measuring device, the system appears to have irreversibly collapsed onto a state with a precise value for the measured attributes, relative to that element.

Dirac notation

Using the Dirac notation, let the system initially be in the state $|\psi\rangle$ where

$$|\psi\rangle = \sum_i |i\rangle \langle i|\psi\rangle$$

where the $|i\rangle$ s form an einselected basis (environmentally induced **selected** eigen basis^[4]); and let the environment initially be in the state $|\epsilon\rangle$. The vector basis of the total combined system and environment can be formed by tensor multiplying the basis vectors of the subsystems together. Thus, before any interaction between the two subsystems, the joint state can be written as:

$$|before\rangle = \sum_i |i\rangle |\epsilon\rangle \langle i|\psi\rangle.$$

where $|i\rangle |\epsilon\rangle$ is shorthand for the tensor product: $|i\rangle \otimes |\epsilon\rangle$. There are two extremes in the way the system can interact with its environment: either (1) the system loses its distinct identity and merges with the environment (e.g. photons in a cold, dark cavity get converted into molecular excitations within the cavity walls), or (2) the system is not disturbed at all, even though the environment is disturbed (e.g. the idealized non-disturbing measurement). In general an interaction is a mixture of these two extremes, which we shall examine:

System absorbed by environment

If the environment absorbs the system, each element of the total system's basis interacts with the environment such that:

$$|i\rangle |\epsilon\rangle \text{ evolves into } |\epsilon_i\rangle$$

and so

$$|before\rangle \text{ evolves into } |after\rangle = \sum_i |\epsilon_i\rangle \langle i|\psi\rangle$$

where the unitarity of time-evolution demands that the total state basis remains orthonormal and in particular their scalar or inner products with each other vanish, since $\langle i|j\rangle = \delta_{ij}$:

$$\langle \epsilon_i | \epsilon_j \rangle = \delta_{ij}$$

This orthonormality of the environment states is the defining characteristic required for einselection.

System not disturbed by environment

This is the idealized measurement or undisturbed system case in which each element of the basis interacts with the environment such that:

$$|i\rangle |\epsilon\rangle \text{ evolves into the product } |i, \epsilon_i\rangle = |i\rangle |\epsilon_i\rangle$$

i.e. the system disturbs the environment, but is itself *undisturbed* by the environment.

and so:

$$|before\rangle \text{ evolves into } |after\rangle = \sum_i |i, \epsilon_i\rangle \langle i|\psi\rangle$$

where, again, unitarity demands that:

$$\langle i, \epsilon_i | j, \epsilon_j \rangle = \langle i|j\rangle \langle \epsilon_i | \epsilon_j \rangle = \delta_{ij} \langle \epsilon_i | \epsilon_j \rangle = \delta_{ij}$$

and *additionally* decoherence requires, by virtue of the large number of hidden degrees of freedom in the environment, that

$$\langle \epsilon_i | \epsilon_j \rangle \approx \delta_{ij}$$

As before, this is the defining characteristic for decoherence to become einselection. The approximation becomes more exact as the number of environmental degrees of freedom affected increases.

Note that if the system basis $|i\rangle$ were not an einselected basis then the last condition is trivial since the disturbed environment is not a function of i and we have the trivial disturbed environment basis $|\epsilon_j\rangle = |\epsilon'\rangle$. This would correspond to the system basis being degenerate with respect to the environmentally-defined-measurement-observable. For a complex environmental interaction (which would be expected for a typical macro scale interaction) a non-einselected basis would be hard to define.

DIRAC FORMALISM AND QUANTUM COMPUTER:

G. Benenti et al, modeled an isolated quantum computer as a two-dimensional lattice of qubits (spin halves) with fluctuations in individual qubit energies and residual short-range inter-qubit couplings. In the limit when fluctuations and couplings are small compared to the one-qubit energy spacing, the spectrum has a band structure and the quantum computer core (central band) with the highest density of states. Above a critical inter-qubit coupling strength, quantum chaos sets in, leading to quantum Ergodicity of eigenstates in an isolated quantum computer. The onset of chaos results in the interaction induced dynamical thermalization and the occupation numbers well described by the Fermi-Dirac distribution. This thermalization **destroys the** noninteracting qubit structure and sets serious requirements for the quantum computer operability.

The key ingredient of a quantum computer is that it can simultaneously follow all of the computation paths corresponding to the distinct classical inputs and **produce** a state which **depends on the** interference of these paths. **As a result**, some computational tasks can be performed much more efficiently than on a classical computer. Shor constructed a quantum algorithm **which performs large** number factorization into prime factors exponentially faster than any known classical algorithm. It was also shown by Grover that the search of an item in an unstructured list **can be done with a** square root speedup over any classical algorithm. These results motivated a great body of experimental proposals for a construction of a realistic quantum computer. At present, quantum gates were **realized with** cold ions and the Grover algorithm **was performed** for three qubits made from nuclear spins in a molecule. For proper operation ability, it is essential for the quantum computer to remain **coherent** during the computation process. Hence, a serious obstacle to its physical realization is the quantum decoherence due to the coupling with the external world. In spite of that, in certain physical proposals, for example nuclear spins in two-dimensional semiconductor structures, the decoherence time can be many orders of magnitude **larger than the time** required for the gate operations. **As a result**, one can analyze the operation of an isolated quantum computer **decoupled** from the external world. However, even if the quantum computer is isolated from the external world and the decoherence time is infinite, a proper operation ability of the computer is not guaranteed. As a matter of fact, one has to face a many-body **problem for a system** of n interacting qubits (two level systems): any computer operation { a unitary transformation in the Hilbert space of size $NH = 2^n$ } can **be decomposed** into two-qubit gates such as controlled-NOT and single qubit rotations. Due to the unavoidable **presence of imperfections**, the spacing between the two states of each qubit **fluctuates** in some detuning interval. Also, some residual **interaction** between qubits necessarily remains when the **two-qubit coupling is used** to operate the gates. In an isolated quantum computer was modeled as a qubit lattice with fluctuations in individual qubit energies and residual short-range inter-qubit couplings. Similarly to previous studies of interacting many-body systems **such as nuclei, clusters, complex atoms, quantum dots, and quantum spin glasses**, the **interaction leads to** quantum chaos characterized by Ergodicity of the eigenstates and level spacing statistics as in Random Matrix Theory. The transition to chaos takes place when strength is of the order of the energy spacing between directly coupled states. This border is exponentially larger than the energy level spacing in a quantum computer.

This means that a strong enough **interaction plays the role** of a heat bath, thus **leading to** dynamical Thermalization for an isolated system. In such a regime, a quantum computer eigenstate is composed by an exponentially large (with n) number of noninteracting multiqubit states representing the quantum register states. **As a result**, exponentially many states of the computation basis **are mixed** after a chaotic time scale and the computer operability **is destroyed**. We note that the dynamical thermalization has been discussed in other many-body interacting systems. **The dependence of the** critical coupling for the onset of dynamical thermalization on the number of qubits. Illustration of the equivalence between the chaos border and the thermalization border is also shown by Benenti.

CONDENSED MATTER AND QUANTUM COMPUTATION A BRIEF OVERLOOK OF THE WORK DONE:

•Christoph Kloeffer and Daniel Loss: Prospects for Spin-Based Quantum Computing

•Experimental and theoretical progress toward quantum computation with spins in quantum dots (QDs) is reviewed, with particular focus on QDs formed in GaAs heterostructures, on nanowire-based QDs, and on self-assembled QDs. We report on a remarkable evolution of the field where decoherence, one of the main(e) challenges for realizing quantum computers, no longer seems to be the stumbling block it had originally been considered. General concepts, relevant quantities, and basic requirements for spin-based quantum computing are explained; opportunities and challenges of spin-orbit interaction and nuclear spins are reviewed.

•Cotunneling in the 5/2 fractional quantum Hall regime: Robert Zielke, Bernd Braunecker, and Daniel Loss.

•Cotunneling in the 5/2 fractional quantum Hall regime allows to test the Moore-Read wave function, proposed for this regime, and to probe the nature of the fractional charge carriers. Cotunneling current for electrons that tunnel between two quantum Hall edge states via(e&eb) a quantum dot and for quasiparticles with fractional charges $e/4$ and $e/2$ that tunnel via

an antidot. While electron cotunneling is strongly suppressed(e), the quasiparticle tunneling shows(eb) signatures characteristic for the Moore-Read state. Cotunneling between Laughlin states, lead to the fact that electron-transport between Moore-Read states and the one between Laughlin states at filling factor 1/3 have identical voltage dependences.

•Non-abelian Majoranas and braiding in inhomogeneous spin ladders Fabio L. Pedrocchi, Suhas Gangadharaiah (Bhopal), Stefano Chesi (Montreal), and Daniel Loss.

An inhomogeneous open spin ladder, related to the Kitaev honeycomb model, which can be tuned between topological and non-topological phases. In extension of Lieb's theorem, it has been shown numerically that the ground state of the spin ladder is either vortex-free or vortex-full. At the phase-boundaries single Majorana states emerge which are proven to be robust against local perturbations and to obey non-abelian braiding statistics. It is also shown that a network of spin ladders provides a promising platform for topological quantum computing.

•Majorana qubit decoherence by quasiparticle poisoning Diego Rainis and Daniel Loss.Phys. Rev. B 85, 174533 (2012);

•Consideration is given to the problem of quasiparticle poisoning in a nanowire-based realization of a Majorana qubit, where a spin-orbit-coupled semiconducting wire is placed on top of a (bulk) superconductor. By making use of recent experimental data exhibiting evidence of a low-temperature residual nonequilibrium quasiparticle population in superconductors, it is shown by means of analytical and numerical calculations that the dephasing time due to the tunneling of quasiparticles into the nanowire may be problematically short to allow(eb) for qubit manipulation.

•Effect of strain on(e&eb) hyperfine-induced hole-spin decoherence in quantum dots Franziska Maier and Daniel Loss.Phys. Rev. B 85, 195323 (2012);

•Theoretical consideration is given prominence to the effect(e&eb) of strain on the spin dynamics of a single heavy hole (HH) confined to a self-assembled quantum dot and interacting with the surrounding nuclei via hyperfine interaction. Confinement and strain hybridize(e&eb) the HH states, which show(eb) an exponential decay for a narrowed nuclear spin bath. For different strain configurations within the dot, the dependence of the spin decoherence time T_2 on external parameters is shifted and the nonmonotonic dependence of the peak is altered. Application of external strain yields(eb) considerable shifts in the dependence of T_2 on external parameters. It is found that external strain affects (e&eb)mostly the effective hyperfine coupling strength of the conduction band (CB), indicating(eb) that the CB admixture of the hybridized HH states plays a(e&eb) crucial role in the sensitivity of T_2 on strain.

•High threshold error correction for the surface code (James R. Wootton and Daniel Loss).

•An algorithm is presented for error correction in the surface code quantum memory. This is shown to correct depolarizing noise up to a threshold error rate of 18.5%, exceeding previous results and coming close to the upper bound of 18.9%. The time complexity of the algorithm is found to be sub-exponential, offering a significant speed-up over brute force methods and allowing efficient error correction for codes of realistic sizes.

Kevin A. van Hoogdalem and Daniel Loss.Phys. Rev. B 85, 054413 (2012);

Motivated by potential applications in spintronics, the study concentrates on frequency dependent spin transport in noninteracting one-dimensional spin chains. A system is proposed that behaves as a capacitor for the spin degree of freedom. It consists of a spin chain with two impurities a distance d apart. We find that at low energy (frequency) the impurities flow to strong coupling, thereby effectively cutting (e) the chain into three parts, with the middle island containing (e) a discrete number of spin excitations. At finite frequency spin transport through the system increases. Authors find a strong dependence of the finite frequency characteristics both on the anisotropy of the spin chain and the applied magnetic field. A method is proposed to measure the finite-frequency conductance in this system.

Electric-Field Induced Majorana Fermions in Armchair Carbon Nanotubes Jelena Klinovaja, Suhas Gangadharaiah, and Daniel Loss.Phys. Rev. Lett. 108, 196804 (2012)

Authors' consider theoretically an armchair carbon nanotube (CNT) in the presence of an electric field and in contact with an s-wave superconductor. It is shown that the proximity effect (e&eb) opens (eb)up superconducting gaps in the CNT of different strengths for the exterior and interior branches of the two Dirac points. For strong proximity induced (eb) superconductivity the interior gap can be of the p-wave type, while the exterior gap can be tuned (e&eb) by the electric field to be of the s-wave type. Such a setup supports a single Majorana bound state at each end of the CNT. In the case of weak proximity induced superconductivity, the gaps in both branches are of the p-wave type. However, the temperature can be chosen in such a way that the smallest gap is effectively closed. Using renormalization group techniques authors' show that the Majorana bound states exist (eb) even after taking into (e) account electron-electron interactions.

Thin-Film Magnetization Dynamics on the Surface of a Topological Insulator Yaroslav Tserkovnyak (UCLA) and Daniel Loss.Phys. Rev. Lett. 108, 187201 (2012);

Authors theoretically study the magnetization dynamics of a thin ferromagnetic film exchange-coupled with a surface of a strong three-dimensional topological insulator. Focus is on the role of electronic zero modes associated with domain walls (DW's) and other topological textures in the magnetic film. Thermodynamically reciprocal hydrodynamic equations of motion are derived for the DW responding to electronic spin torques, on the one hand, and fictitious electromotive forces in the electronic chiral mode fomented by the DW, on the other. An experimental realization illustrating this physics is proposed based on a ferromagnetic strip, which cuts the topological insulator surface into two gapless regions. In the presence of a ferromagnetic DW, a chiral mode transverse to the magnetic strip acts as a dissipative interconnect, which is itself a dynamic object that controls (and, inversely, responds to) the magnetization dynamics.

Singlet-triplet splitting in double quantum dots due to spin orbit and hyperfine interactions Dimitrije Stepanenko, Mark Rudner (Harvard), Bertrand I. Halperin (Harvard), and Daniel Loss.Phys. Rev. B 85, 075416 (2012);

Authors' analyze the low-energy spectrum of a two-electron double quantum dot under a potential bias in the presence of an external magnetic field. Focus is on the regime of spin (e)blockade, taking into account the spin-orbit interaction (e&eb) and hyperfine coupling(e&eb) of electron and nuclear spins. Starting from a model for two interacting electrons in a double dot, authors' derive an effective two-level Hamiltonian in the vicinity of an avoided crossing between singlet and triplet levels, which are(e&eb) coupled by the spin-orbit and hyperfine interactions. Also, authors' evaluate the level splitting at the anticrossing, and show that it depends on a variety of parameters including the spin-orbit coupling strength, the orientation of the external magnetic field relative to an internal spin-orbit axis, the potential detuning of the dots, and the difference between hyperfine fields in the two dots. They provide a formula for the splitting in terms of the spin-orbit length, the hyperfine fields in the two dots, and the double dot parameters such as tunnel coupling and Coulomb energy. This formula should prove useful for extracting spin-orbit parameters from transport or charge sensing experiments in such systems. Authors identify a parameter regime where the spin-orbit and hyperfine terms can become of comparable strength, and discuss how this regime might be reached.

Incoherent dynamics in the toric code subject to disorderBeat Roethlisberger, James R. Wootton, Robert M. Heath (Leeds), Jiannis K. Pachos (Leeds), and Daniel Loss.Phys. Rev. A 85, 022313 (2012).

Authors' numerically study the *effects(e&eb) of two* forms of quenched disorder on the anyons of the toric code. Firstly, a new class of codes based on random lattices of stabilizer operators is presented, and shown to be superior to the standard square lattice toric code for certain forms of biased noise. It is further argued that these codes are close to optimal, in that they tightly reach the upper bound of error thresholds beyond which no correctable CSS codes can exist. Additionally, they study the classical motion of anyons in toric codes with randomly distributed onsite potentials. In the presence of repulsive long-range interaction between the anyons, a surprising increase with disorder strength of the lifetime of encoded states is reported and explained by an entirely incoherent mechanism. Finally, the coherent transport of the anyons in the presence of both forms of disorder is investigated, and a significant suppression of the anyon motion is found.

Rashba spin orbit interaction in a quantum wire superlattice(Gunnar Thorgilsson (Reykjavik), J. Carlos Egues (Sao Carlos), Daniel Loss, and Sigurdur I. Erlingsson (Reykjavik).Phys. Rev. B 85, 045306 (2012); Phys. Rev. B 85, 039904(E) (2012);

In this work authors' study the effects of a longitudinal periodic potential on a parabolic quantum wire defined in a two-dimensional electron gas with Rashba spin-orbit interaction. For an infinite wire superlattice we find, by direct diagonalization, that the energy gaps are shifted away from the usual Bragg planes due to the Rashba spin-orbit interaction. Interestingly, results show that the location of the band gaps in energy can be controlled via the strength of the Rashba spin-orbit interaction. Authors' have also calculated the charge conductance through a periodic potential of a finite length via the non-equilibrium Green's function method combined with the Landauer formalism. We find dips in the conductance that correspond well to the energy gaps of the infinite wire superlattice. From the infinite wire energy dispersion, is derived an equation relating the location of the conductance dips as a function of the (gate controllable) Fermi energy to the Rashba spin-orbit coupling strength. It is proposed that the strength of the Rashba spin-orbit interaction can be extracted via a charge conductance measurement.

Localized end states in density modulated quantum wires and ringsSuhas Gangadharaiah, Luka Trifunovic, and Daniel Loss.Phys. Rev. Lett. 108, 136803 (2012);

Authors' study finite quantum wires and rings in the presence of a charge-density wave gap induced by a periodic modulation of the chemical potential. We show that the Tamm-Shockley bound states emerging at the ends of the wire are stable against weak disorder and interactions, for discrete open chains and for continuum systems. The low-energy physics can be mapped onto the Jackiw-Rebbi equations *describing* massive Dirac fermions and bound end states. They treat *interactions via* the continuum model and show that they increase the charge gap and further localize the end states. The electrons placed in the two localized states on the opposite ends of the wire can interact via exchange interactions and this setup can be used as a double quantum dot hosting spin qubits. The existence of these states could be experimentally detected through the presence of an unusual 4π Aharonov-Bohm periodicity in the spectrum and persistent current as a function of the external flux.

Long-distance spin-spin coupling via floating gatesKoji Sato (UCLA), Daniel Loss, and Yaroslav Tserkovnyak (UCLA).

Authors' theoretically study tunneling of Cooper pairs from an s-wave superconductor into two semiconductor quantum wires with strong spin-orbit interaction under magnetic field, which approximate helical Luttinger liquids. The entanglement of electrons within a Cooper pair can be detected by the electric current cross correlations in the wires. By *controlling the* relative orientation of the wires, either lithographically or mechanically, on the substrate, the *current correlations* can be tuned, as dictated by the initial spin entanglement. This proposal of a spin-to-charge readout of quantum correlations is alternative to a recently proposed utilization of the quantum spin Hall insulator. Subtle Coriolis force, earth's differential heating, Poincare Kelvin Functional are some of the factors that get affected by the phenomenon.

Strong Spin-Orbit Interaction and Helical Hole States in Ge/Si NanowiresCarbon nanotubes in electric and magnetic fields.Jelena Klinovaja, Manuel J. Schmidt, Bernd Braunecker, and Daniel Loss.Phys. Rev. B 84, 085452 (2011);

Authors' derive an effective low-energy theory for metallic (armchair and nonarmchair) single-wall nanotubes in the presence of an electric field perpendicular to the nanotube axis, and in the presence of magnetic fields, taking into account spin-orbit interactions and screening effects on the basis of a microscopic tight-binding model. The *interplay* between electric field and spin-orbit interaction allows us to *tune* armchair nanotubes into a helical conductor in both Dirac valleys. Metallic nonarmchair nanotubes are gapped by the surface curvature, yet helical conduction modes can be restored in one of

the valleys by a magnetic field along the nanotube axis. Furthermore, authors' discuss electric dipole spin resonance in carbon nanotubes, and find that the Rabi frequency shows a pronounced dependence on the momentum along the nanotube.

Loss of interference and the transition from quantum to classical

The utility of decoherence lies in its application to the analysis of probabilities, before and after environmental interaction, and in particular to the vanishing of quantum interference terms after decoherence has occurred. If we ask what is the probability of observing the system making a transition or quantum leap from ψ to ϕ **before** ψ has interacted with its environment, then application of the Born probability rule states that the transition probability is the modulus squared of the scalar product of the two states:

$$prob_{before}(\psi \rightarrow \phi) = |\langle \psi | \phi \rangle|^2 = \left| \sum_i \psi_i^* \phi_i \right|^2 = \sum_i |\psi_i^* \phi_i|^2 + \sum_{ij; i \neq j} \psi_i^* \psi_j \phi_j^* \phi_i$$

where $\psi_i = \langle i | \psi \rangle$, $\psi_i^* = \langle \psi | i \rangle$ and $\phi_i = \langle i | \phi \rangle$ etc.

Terms appear in the expansion of the transition probability above which involve $i \neq j$; these can be thought of as representing *interference* between the different basis elements or quantum alternatives. This is a purely quantum effect and represents the non-additivity of the probabilities of quantum alternatives.

To calculate the probability of observing the system making a quantum leap from ψ to ϕ **after** ψ has interacted with its environment, then application of the Born probability rule states we must sum over all the relevant possible states of the environment, E_i , before squaring the modulus:

$$prob_{after}(\psi \rightarrow \phi) = \sum_j |\langle after | \phi, \epsilon_j \rangle|^2 = \sum_j \left| \sum_i \psi_i^* \langle i, \epsilon_i | \phi, \epsilon_j \rangle \right|^2 = \sum_j \left| \sum_i \psi_i^* \langle i | \phi \rangle \langle \epsilon_i | \epsilon_j \rangle \right|^2$$

The internal summation vanishes when we apply the decoherence / einselection condition $\langle \epsilon_i | \epsilon_j \rangle \approx \delta_{ij}$ and the formula simplifies to:

$$prob_{after}(\psi \rightarrow \phi) \approx \sum_j |\psi_j^* \langle j | \phi \rangle|^2 = \sum_i |\psi_i^* \phi_i|^2$$

If we compare this with the formula we derived before the environment introduced decoherence we can see that the effect of decoherence has been to move the summation sign \sum_i from inside of the modulus sign to outside. As a result all the cross-or quantum interference-terms:

$$\sum_{ij; i \neq j} \psi_i^* \psi_j \phi_j^* \phi_i$$

have vanished from the transition probability calculation. The decoherence has irreversibly converted quantum behaviour (additive probability amplitudes) to classical behaviour (additive probabilities). In terms of density matrices, the loss of interference effects corresponds to the diagonalization of the "environmentally traced over" density matrix.

Density matrix approach

The effect of decoherence on density matrices is essentially the decay or rapid vanishing of the off-diagonal elements of the partial trace of the joint system's density matrix, i.e. the trace, with respect to *any* environmental basis, of the density matrix of the combined system *and* its environment. The decoherence irreversibly converts the "averaged" or "environmentally traced over" density matrix from a pure state to a reduced mixture; it is this that gives the *appearance* of wavefunction collapse. Again this is called "environmentally-induced-super selection", or einselection. The advantage of taking the partial trace is that this procedure is indifferent to the environmental basis chosen.

The density matrix approach has been combined with the Bohmian approach to yield a *reduced trajectory approach*, taking into account the system reduced density matrix and the influence of the environment.^[7]

Operator-sum representation

Consider a system S and environment (bath) B, which are closed and can be treated quantum mechanically. Let \mathcal{H}_S and \mathcal{H}_B be the system's and bath's Hilbert spaces, respectively. Then the Hamiltonian for the combined system is

$$\hat{H} = \hat{H}_S \otimes \hat{I}_B + \hat{I}_S \otimes \hat{H}_B + \hat{H}_I$$

where \hat{H}_S , \hat{H}_B are the system and bath Hamiltonians, respectively, and \hat{H}_I is the interaction Hamiltonian between the system and bath, and \hat{I}_S , \hat{I}_B are the identity operators on the system and bath Hilbert spaces, respectively. The time-evolution of the density operator of this closed system is unitary and, as such, is given by

$$\rho_{SB}(t) = \hat{U}(t) \rho_{SB}(0) \hat{U}^\dagger(t)$$

where the unitary operator is $\hat{U} = e^{\frac{-i\hat{H}t}{\hbar}}$. If the system and bath are not entangled initially, then we can write $\rho_{SB} = \rho_S \otimes \rho_B$. Therefore, the evolution of the system becomes

$$\rho_{SB}(t) = \hat{U}(t)[\rho_S(0) \otimes \rho_B(0)]\hat{U}^\dagger(t).$$

The system-bath interaction Hamiltonian can be written in a general form as

$$\hat{H}_I = \sum_i \hat{S}_i \otimes \hat{B}_i,$$

where $\hat{S}_i \otimes \hat{B}_i$ is the operator acting on the combined system-bath Hilbert space, and \hat{S}_i, \hat{B}_i are the operators that act on the system and bath, respectively. This coupling of the system and bath is the cause of decoherence in the system alone. To see this, a partial trace is performed over the bath to give a description of the system alone:

$$\rho_S(t) = Tr_B[\hat{U}(t)[\rho_S(0) \otimes \rho_B(0)]\hat{U}^\dagger(t)].$$

$\rho_S(t)$ is called the *reduced density matrix* and gives information about the system only. If the bath is written in terms of its set of orthogonal basis kets, that is, if it has been initially diagonalized then Computing the partial trace with respect to this (computational) basis gives:

$$\rho_S(t) = \sum_l \hat{A}_l \rho_S(0) \hat{A}_l^\dagger$$

where $\hat{A}_l, \hat{A}_l^\dagger$ are defined as the **Kraus operators** and are represented as

$$\hat{A}_l = \sqrt{a_j} \langle k | \hat{U} | j \rangle.$$

This is known as the **operator-sum representation (OSR)**. A condition on the Kraus operators can be obtained by using the fact that $Tr(\rho_S(t)) = 1$; this then gives

$$\sum_l \hat{A}_l^\dagger \hat{A}_l = \hat{I}_S.$$

This restriction determines if decoherence will occur or not in the OSR. In particular, when there is more than one term present in the sum for $\rho_S(t)$ then the dynamics of the system will be non-unitary and hence decoherence will take place.

Semi group approach

A more general consideration for the existence of decoherence in a quantum system is given by the **master equation**, which determines how the density matrix of the *system alone* evolves in time. This uses the Schrödinger picture, where evolution of the *state* (represented by its density matrix) is considered. The master equation is:

$$\rho'_S(t) = \frac{-i}{\hbar} [\tilde{\mathbf{H}}_S, \rho_S(t)] + L_D [\rho_S(t)]$$

where $\tilde{\mathbf{H}}_S = \mathbf{H}_S + \Delta$ is the system Hamiltonian, \mathbf{H}_S , along with a (possible) unitary contribution from the bath, Δ and L_D is the **Lindblad decohering term**. The Lindblad decohering term is represented as

$$L_D [\rho_S(t)] = \frac{1}{2} \sum_{\alpha, \beta=1}^M b_{\alpha\beta} ([\mathbf{F}_\alpha, \rho_S(t) \mathbf{F}_\beta^\dagger] + [\mathbf{F}_\alpha \rho_S(t), \mathbf{F}_\beta^\dagger]).$$

In quantum mechanics, **quantum decoherence** is the loss of coherence or ordering of the phase angles between the components of a system in a quantum superposition. A consequence of this dephasing (eb) leads to classical or probabilistically additive behavior. Quantum decoherence gives the appearance of wave function collapse (the reduction of the physical possibilities into a single possibility as seen by an observer) and justifies the framework and intuition of classical physics as an acceptable approximation: decoherence is the mechanism by which the classical limit emerges (eb) out of a quantum starting point and it determines the location of the quantum-classical boundary. Decoherence occurs when a system interacts with its environment in a thermodynamically irreversible way. This prevents different elements in the quantum superposition of the system+environment's wavefunction from interfering with each other. Decoherence has been a subject of active research since the 1980s.

Decoherence can be viewed as the loss of information from a system into the environment (often modeled as a heat bath) since every system is loosely coupled with the energetic state of its surroundings. Viewed in isolation, the system's dynamics are non-unitary (although the combined system plus environment evolves in a unitary fashion).^[3] Thus the

dynamics of the system alone are irreversible. As with any coupling, entanglements are generated between the system and environment, which have the effect of sharing quantum information with—or transferring it to—the surroundings.

Decoherence does not generate *actual* wave function collapse. It only provides an explanation for the *appearance* of the wavefunction collapse, as the quantum nature of the system "leaks" into the environment. That is, components of the wavefunction are decoupled from a coherent system, and acquire phases from their immediate surroundings. A total superposition of the global or universal wavefunction still exists (and remains coherent at the global level), but its ultimate fate remains an interpretational issue. Specifically, decoherence does not attempt to explain the measurement problem. Rather, decoherence provides an explanation for the transition of the system to a mixture of states that seem to correspond to those states observers perceive. Moreover, our observation tells us that this mixture looks like a proper quantum ensemble in a measurement situation, as we observe that measurements lead to the "realization" of precisely one state in the "ensemble".

Decoherence represents a challenge for the practical realization of quantum computers, since they are expected to rely heavily on the undisturbed evolution of quantum coherences. Simply put; they require that coherent states be preserved and that decoherence is managed, in order to actually perform quantum computation.

Mechanisms

To examine how decoherence operates, an "intuitive" model is presented. The model requires some familiarity with quantum theory basics. Analogies are made between visualisable classical phase spaces and Hilbert spaces. A more rigorous derivation in Dirac notation shows how decoherence destroys interference effects and the "quantum nature" of systems. Next, the density matrix approach is presented for perspective.

Phase space picture

An N -particle system can be represented in non-relativistic quantum mechanics by a wavefunction, $\psi(x_1, x_2, \dots, x_N)$. This has analogies with the classical phase space. A classical phase space contains a real-valued function in $6N$ dimensions (each particle contributes 3 spatial coordinates and 3 momenta). Our "quantum" phase space conversely contains a complex-valued function in a $3N$ dimensional space. The position and momenta do not commute but can still inherit much of the mathematical structure of a Hilbert space. Aside from these differences, however, the analogy holds.

Different previously-isolated, non-interacting systems occupy different phase spaces. Alternatively we can say they occupy different, lower-dimensional subspaces in the phase space of the joint system. The *effective* dimensionality of a system's phase space is the number of *degrees of freedom* present which—in non-relativistic models—is 6 times the number of a system's *free* particles. For a macroscopic system this will be a very large dimensionality. When two systems (and the environment would be a system) start to interact, though, their associated state vectors are no longer constrained to the subspaces. Instead the combined state vector time-evolves a path through the "larger volume", whose dimensionality is the sum of the dimensions of the two subspaces. A square (2-d surface) extended by just one dimension (a line) forms a cube. The cube has a greater volume, in some sense, than its component square and line axes. The extent two vectors interfere with each other is a measure of how "close" they are to each other (formally, their overlap or Hilbert space scalar product together) in the phase space. When a system couples to an external environment, the dimensionality of, and hence "volume" available to, the joint state vector increases enormously. Each environmental degree of freedom contributes an extra dimension.

The original system's wavefunction can be expanded arbitrarily as a sum of elements in a quantum superposition. Each expansion corresponds to a projection of the wave vector onto a basis. The bases can be chosen at will. Let us choose any expansion where the resulting elements interact with the environment in an element-specific way. Such elements will—with overwhelming probability—be rapidly separated from each other by their natural unitary time evolution along their own independent paths. After a very short interaction, there is almost no chance of any further interference. The process is effectively irreversible. The different elements effectively become "lost" from each other in the expanded phase space created by coupling with the environment; in phase space, this decoupling is monitored through the Wigner quasi-probability distribution. The original elements are said to have *decohered*. The environment has effectively selected out those expansions or decompositions of the original state vector that decohere (or lose phase coherence) with each other. This is called "environmentally-induced-super selection", or einselection The decohered elements of the system no longer exhibit quantum interference between each other, as in a double-slit experiment. Any elements that decohere from each other via environmental interactions are said to be quantum entangled with the environment. The converse is not true: not all entangled states are decohered from each other.

Any measuring device or apparatus acts as an environment since, at some stage along the measuring chain, it has to be large enough to be read by humans. It must possess a very large number of hidden degrees of freedom. In effect, the interactions may be considered to be quantum measurements. As a result of an interaction, the wave functions of the system and the measuring device become entangled with each other. Decoherence happens when different portions of the system's wavefunction become entangled in different ways with the measuring device. For two einselected elements of the entangled system's state to interfere, both the original system and the measuring in both elements device must significantly overlap, in the scalar product sense. If the measuring device has many degrees of freedom, it is *very* unlikely for this to happen.

As a consequence, the system behaves as a classical statistical ensemble of the different elements rather than as a single coherent quantum superposition of them. From the perspective of each ensemble member's measuring device, the system appears to have irreversibly collapsed onto a state with a precise value for the measured attributes, relative to that element.

Dirac notation

Using the Dirac notation, let the system initially be in the state $|\psi\rangle$ where

$$|\psi\rangle = \sum_i |i\rangle \langle i|\psi\rangle$$

where the $|i\rangle$ s form an einselected basis (environmentally induced selected eigen basis); and let the environment initially be in the state $|\epsilon\rangle$. The vector basis of the total combined system and environment can be formed by tensor multiplying the basis vectors of the subsystems together. Thus, before any interaction between the two subsystems, the joint state can be written as:

$$|before\rangle = \sum_i |i\rangle |\epsilon\rangle \langle i|\psi\rangle.$$

where $|i\rangle |\epsilon\rangle$ is shorthand for the tensor product: $|i\rangle \otimes |\epsilon\rangle$. There are two extremes in the way the system can interact with its environment: either (1) the system loses its distinct identity and merges with the environment (e.g. photons in a cold, dark cavity get converted into molecular excitations within the cavity walls), or (2) the system is not disturbed at all, even though the environment is disturbed (e.g. the idealized non-disturbing measurement). In general an interaction is a mixture of these two extremes, which we shall examine:

System absorbed by environment

If the environment absorbs the system, each element of the total system's basis interacts with the environment such that:

$$|i\rangle |\epsilon\rangle \text{ evolves into } |\epsilon_i\rangle$$

and so

$$|before\rangle \text{ evolves into } |after\rangle = \sum_i |\epsilon_i\rangle \langle i|\psi\rangle$$

where the unitarity of time-evolution demands that the total state basis remains orthonormal and in particular their scalar or inner products with each other vanish, since $\langle i|j\rangle = \delta_{ij}$:

$$\langle \epsilon_i | \epsilon_j \rangle = \delta_{ij}$$

This orthonormality of the environment states is the defining characteristic required for einselection.

System not disturbed by environment

This is the idealized measurement or undisturbed system case in which each element of the basis interacts with the environment such that:

$$|i\rangle |\epsilon\rangle \text{ evolves into the product } |i, \epsilon_i\rangle = |i\rangle |\epsilon_i\rangle$$

i.e. the system disturbs the environment, but is itself *undisturbed* by the environment.

and so:

$$|before\rangle \text{ evolves into } |after\rangle = \sum_i |i, \epsilon_i\rangle \langle i|\psi\rangle$$

where, again, unitarity demands that:

$$\langle i, \epsilon_i | j, \epsilon_j \rangle = \langle i|j\rangle \langle \epsilon_i | \epsilon_j \rangle = \delta_{ij} \langle \epsilon_i | \epsilon_j \rangle = \delta_{ij}$$

and *additionally* decoherence requires, by virtue of the large number of hidden degrees of freedom in the environment, that

$$\langle \epsilon_i | \epsilon_j \rangle \approx \delta_{ij}$$

As before, this is the defining characteristic for decoherence to become einselection.¹The approximation becomes more exact as the number of environmental degrees of freedom affected increases.

Note that if the system basis $|i\rangle$ were not an einselected basis then the last condition is trivial since the disturbed environment is not a function of i and we have the trivial disturbed environment basis $|\epsilon_j\rangle = |\epsilon'\rangle$. This would correspond to the system basis being degenerate with respect to the environmentally-defined-measurement-observable. For a complex environmental interaction (which would be expected for a typical macro scale interaction) a non-einselected basis would be hard to define.

Loss of interference and the transition from quantum to classical

The utility of decoherence lies in its application to the analysis of probabilities, before and after environmental interaction, and in particular to the vanishing of interference terms after decoherence has occurred. If weak what is the probability of

observing the system making a transition or quantum leap from ψ to **before** ψ has interacted with its environment, then application of the Born probability rule states that the transition probability is the modulus squared of the scalar product of the two states:

$$prob_{before}(\psi \rightarrow \phi) = |\langle \psi | \phi \rangle|^2 = \left| \sum_i \psi_i^* \phi_i \right|^2 = \sum_i |\psi_i^* \phi_i|^2 + \sum_{ij; i \neq j} \psi_i^* \psi_j \phi_j^* \phi_i$$

where $\psi_i = \langle i | \psi \rangle$, $\psi_i^* = \langle \psi | i \rangle$ and $\phi_i = \langle i | \phi \rangle$ etc.

Terms appear in the expansion of the transition probability above which involve $i \neq j$; these can be thought of as representing *interference* between the different basis elements or quantum alternatives. This is a purely quantum effect and represents the non-additivity of the probabilities of quantum alternatives.

To calculate the probability of observing the system making a quantum leap from ψ to ϕ **after** ψ has interacted with its environment, then application of the Born probability rule states we must sum over all the relevant possible states of the environment, E_i , before squaring the modulus:

$$prob_{after}(\psi \rightarrow \phi) = \sum_j |\langle after | \phi, \epsilon_j \rangle|^2 = \sum_j \left| \sum_i \psi_i^* \langle i, \epsilon_i | \phi, \epsilon_j \rangle \right|^2 = \sum_j \left| \sum_i \psi_i^* \langle i | \phi \rangle \langle \epsilon_i | \epsilon_j \rangle \right|^2$$

The internal summation vanishes when we apply the decoherence / einselection condition $\langle \epsilon_i | \epsilon_j \rangle \approx \delta_{ij}$ and the formula simplifies to:

$$prob_{after}(\psi \rightarrow \phi) \approx \sum_j |\psi_j^* \langle j | \phi \rangle|^2 = \sum_i |\psi_i^* \phi_i|^2$$

If we compare this with the formula we derived before the environment introduced decoherence we can see that the effect of decoherence has been to move the summation sign \sum_i from inside of the modulus sign to outside. As a result all the cross-or quantum interference-terms:

$$\sum_{ij; i \neq j} \psi_i^* \psi_j \phi_j^* \phi_i$$

have vanished from the transition probability calculation. The decoherence has irreversibly converted quantum behaviour (additive probability amplitudes) to classical behaviour (additive probabilities)

In terms of density matrices, the loss of interference effects corresponds to the diagonalization of the "environmentally traced over" density matrix.

Density matrix approach

The effect of decoherence on density matrices is essentially the decay or rapid vanishing of the off-diagonal elements of the partial trace of the joint system's density matrix, i.e. the trace, with respect to *any* environmental basis, of the density matrix of the combined system *and* its environment. The decoherence irreversibly converts the "averaged" or "environmentally traced over"¹ density matrix from a pure state to a reduced mixture; it is this that gives the *appearance* of wavefunction collapse. Again this is called "environmentally-induced-super selection", or einselection. The advantage of taking the partial trace is that this procedure is indifferent to the environmental basis chosen.

The density matrix approach has been combined with the Bohmian approach to yield a *reduced trajectory approach*, taking into account the system reduced density matrix and the influence of the environment.¹

Operator-sum representation

Consider a system S and environment (bath) B, which are closed and can be treated quantum mechanically. Let \mathcal{H}_S and \mathcal{H}_B be the systems and bath's Hilbert spaces, respectively. Then the Hamiltonian for the combined system is

$$\hat{H} = \hat{H}_S \otimes \hat{I}_B + \hat{I}_S \otimes \hat{H}_B + \hat{H}_I$$

where \hat{H}_S , \hat{H}_B are the system and bath Hamiltonians, respectively, and \hat{H}_I is the interaction Hamiltonian between the system and bath, and \hat{I}_S , \hat{I}_B are the identity operators on the system and bath Hilbert spaces, respectively. The time-evolution of the density operator of this closed system is unitary and, as such, is given by

$$\rho_{SB}(t) = \hat{U}(t) \rho_{SB}(0) \hat{U}^\dagger(t)$$

where the unitary operator is $\hat{U} = e^{\frac{-i\hat{H}t}{\hbar}}$. If the system and bath are not entangled initially, then we can write $\rho_{SB} = \rho_S \otimes \rho_B$. Therefore, the evolution of the system becomes

$$\rho_{SB}(t) = \hat{U}(t)[\rho_S(0) \otimes \rho_B(0)]\hat{U}^\dagger(t).$$

The system-bath interaction Hamiltonian can be written in a general form as

$$\hat{H}_I = \sum_i \hat{S}_i \otimes \hat{B}_i,$$

where $\hat{S}_i \otimes \hat{B}_i$ is the operator acting on the combined system-bath Hilbert space, and \hat{S}_i, \hat{B}_i are the operators that act on the system and bath, respectively. This coupling of the system and bath is the cause of decoherence in the system alone. To see this, a partial trace is performed over the bath to give a description of the system alone:

$$\rho_S(t) = \text{Tr}_B[\hat{U}(t)[\rho_S(0) \otimes \rho_B(0)]\hat{U}^\dagger(t)].$$

$\rho_S(t)$ is called the *reduced density matrix* and gives information about the system only. If the bath is written in terms of its set of orthogonal basis kets, that is, if it has been

$$\rho_B(0) = \sum_j a_j |j\rangle \langle j|.$$

Semi group approach

A more general consideration for the existence of decoherence in a quantum system is given by the **master equation**, which determines how the density matrix of the *system alone* evolves in time. This uses the Schrödinger picture, where evolution of the *state* (represented by its density matrix) is considered. The master equation is:

$$\rho'_S(t) = \frac{-i}{\hbar} [\tilde{\mathbf{H}}_S, \rho_S(t)] + L_D [\rho_S(t)]$$

where $\tilde{\mathbf{H}}_S = \mathbf{H}_S + \Delta$ is the system Hamiltonian, \mathbf{H}_S , along with a (possible) unitary contribution from the bath, Δ and L_D is the **Lindblad decohering term**. They are basis operators for the M-dimensional space of bounded operators that act on the system Hilbert space \mathcal{H}_S -these are the **error generators**-and $b_{\alpha\beta}$ represent the elements of a positive semi-definite Hermitian matrix-these matrix elements characterize the decohering processes and, as such, are called the **noise parameters**.^[8] The semi group approach is particularly nice, because it distinguishes between the unitary and decohering(non-unitary) processes, which is not the case with the OSR. In particular, the non-unitary dynamics are represented by L_D , whereas the unitary dynamics of the state are represented by the usual Heisenberg commutator. Note that when $L_D[\rho_S(t)] = 0$, the dynamical evolution of the system is unitary. The conditions for the evolution of the system density matrix to be described by the master equation are:

QUANTUM MECHANICAL BEHAVIOUR ATOMISM (DISAMBIGUATION) AND THEORY OF CLASSIFICATION OF QUANTUM MECHANICAL BEHAVIOUR:

Dirac equation as the basic formalism of quantum mechanics, representations of Dirac matrices, covariant realization of the Dirac equation, interpretation of negative energies, Foldy-Wouthuysen transformation, Klein's paradox, spherically symmetric interactions and a treatment of the relativistic hydrogen atom, etc., and also provides excellent additional treatments of a variety of other relevant topics. The monograph contains an extensive treatment of the Lorentz and Poincare groups and their representations. The author discusses in depth Lie algebraic and projective representations, covering groups, and Mackey's theory and Wigner's realization of induced representations. A careful classification of external fields with respect to their behavior under Poincare transformations is supplemented by a basic account of self-adjointness and spectral properties of Dirac operators. A state-of-the-art treatment of relativistic scattering theory based on a time-dependent approach originally due to Enss is presented. An excellent introduction to quantum electrodynamics in external fields is provided. Various appendices containing further details, notes on each chapter commenting on the history involved and

referring to original research papers and further developments in the literature, and a bibliography covering all relevant monographs and over 500 articles on the subject, complete this text.

atom

An illustration of the helium atom, depicting the nucleus (pink) and the electron cloud distribution (black). The nucleus (upper right) in helium-4 is in reality spherically symmetric and closely resembles the electron cloud, although for more complicated nuclei this is not always the case. The black bar is one angstrom (10^{-10} m or 100 pm).

Classification

Smallest recognized division of a chemical element

Properties

Mass range: * 1.67×10^{-27} to 4.52×10^{-25} kg

Electric charge: *zero (neutral), or ion charge

Diameter range: *62 pm (He) to 520 pm (Cs) ([data page](#))

Components: *Electrons and a compact nucleus of protons and neutrons

The **atom** is a basic unit of matter that consists of a dense central nucleus surrounded by a cloud of negatively charged electrons. The atomic nucleus contains a mix of positively charged protons and electrically neutral neutrons (except in the case of hydrogen-1, which is the only stable nuclide with no neutrons). The electrons of an atom are bound to the nucleus by the electromagnetic force. Likewise, a group of atoms can remain bound to each other, forming a molecule. An atom containing an equal number of protons and electrons is electrically neutral, otherwise it has a positive charge if there are fewer electrons (electron deficiency) or negative charge if there are more electrons (electron excess). A positively or negatively charged atom is known as an ion. An atom is classified according to the number of protons and neutrons in its nucleus: the number of protons determines the chemical element, and the number of neutrons determines the isotope of the element.

The name atom comes from the Greek ἄτομος (*atomos*, "indivisible") from ἀ- (*a-*, "not") and τέμνω (*temnō*, "I cut"),^[2] which means uncuttable, or indivisible, something that cannot be divided further. The concept of an atom as an indivisible component of matter was first proposed by early Indian and Greek philosophers. In the 17th and 18th centuries, chemists provided a physical basis for this idea by showing that certain substances could not be further broken down by chemical methods. During the late 19th and early 20th centuries, physicists discovered subatomic components and structure inside the atom, thereby demonstrating that the 'atom' was divisible. The principles of quantum mechanics were used to successfully model the atom.

Atoms are minuscule objects with proportionately tiny masses. Atoms can only be observed individually using special instruments such as the scanning tunneling microscope. Over 99.94% of an atom's mass is concentrated in the nucleus,^[note 1] with protons and neutrons having roughly equal mass. Each element has at least one isotope with an unstable nucleus that can undergo radioactive decay. This can result in a transmutation that changes the number of protons or neutrons in a nucleus.^[6] Electrons that are bound to atoms possess a set of stable energy levels, or orbitals, and can undergo transitions between them by absorbing or emitting photons that match the energy differences between the levels. The electrons determine the chemical properties of an element, and strongly influence an atom's magnetic properties.

History

Atomism

The concept that matter is composed of discrete units and cannot be divided into arbitrarily tiny quantities has been around for millennia, but these ideas were founded in abstract, philosophical reasoning rather than experimentation and empirical observation. The nature of atoms in philosophy varied considerably over time and between cultures and schools, and often had spiritual elements. Nevertheless, the basic idea of the atom was adopted by scientists thousands of years later because it elegantly explained new discoveries in the field of chemistry.

References to the concept of atoms date back to ancient Greece and India. In India, the Ājīvika, Jain, and Cārvāka schools of atomism may date back to the 6th century BCE. The Nyaya and Vaisheshika schools later developed theories on how atoms combined into more complex objects. In the West, the references to atoms emerged in the 5th century BCE with Leucippus, whose student, Democritus, systematized his views. In approximately 450 BCE, Democritus coined the term *atomos* (Greek: ἄτομος), which means "uncuttable" or "the smallest indivisible particle of matter". Although

the Indian and Greek concepts of the atom were based purely on philosophy, modern science has retained the name coined by Democritus

Corpuscularianism is the postulate, expounded in the 13th-century by the alchemist Pseudo-Geber (Geber), sometimes identified with Paul of Taranto, that all physical bodies possess an inner and outer layer of minute particles or corpuscles. Corpuscularianism is similar to the theory of atomism, except that where atoms were supposed to be indivisible, corpuscles could in principle be divided. In this manner, for example, it was theorized that mercury could penetrate into metals and modify their inner structure. Corpuscularianism stayed a dominant theory over the next several hundred years.

In 1661, natural philosopher Robert Boyle published *The Sceptical Chymist* in which he argued that matter was composed of various combinations of different "corpuscles" or atoms, rather than the classical elements of air, earth, fire and water.^[13] During the 1670s Corpuscularianism was used by Isaac Newton in his development of the corpuscular theory of light. Further progress in the understanding of atoms did not occur until the science of chemistry began to develop. In 1789, French nobleman and scientific researcher Antoine Lavoisier discovered the law of conservation of mass and defined an element as a basic substance that could not be further broken down by the methods of chemistry.¹

In 1805, English instructor and natural philosopher John Dalton used the concept of atoms to explain why elements always react in ratios of small whole numbers (the law of multiple proportions) and why certain gases dissolved better in water than others. He proposed that each element consists of atoms of a single, unique type, and that these atoms can join together to form chemical compounds.^{[16][17]} Dalton is considered the originator of modern atomic theory

Dalton's atomic hypothesis did not specify the size of atoms. Common sense indicated they must be very small, but nobody knew how small. Therefore it was a major landmark when in 1865 Johann Josef Loschmidt's measured the size of the molecules that make up air.

An additional line of reasoning in support of particle theory (and by extension atomic theory) began in 1827 when botanist Robert Brown used a microscope to look at dust grains floating in water and discovered that they moved about erratically—a phenomenon that became known as "Brownian motion". J. Desaulx suggested in 1877 that the phenomenon was caused by the thermal motion of water molecules, and in 1905 Albert Einstein produced the first mathematical analysis of the motion. French physicist Jean Perrin used Einstein's work to experimentally determine the mass and dimensions of atoms, thereby conclusively verifying Dalton's atomic theory

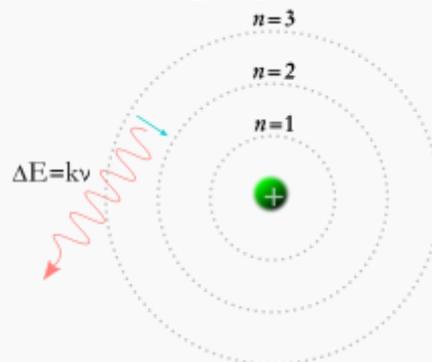

In 1869, building upon earlier discoveries by such scientists as Lavoisier, Dmitri Mendeleev published the first functional periodic table.^[23] The table itself is a visual representation of the periodic law, which states that certain chemical properties of elements repeat periodically when arranged by atomic number.

Subcomponents and quantum theory

The physicist J. J. Thomson, through his work on cathode rays in 1897, discovered the electron, and concluded that they were a component of every atom. Thus he overturned the belief that atoms are the indivisible, ultimate particles of matter. Thomson postulated that the low mass, negatively charged electrons were distributed throughout the atom, possibly rotating in rings, with their charge balanced by the presence of a uniform sea of positive charge. This later became known as the plum pudding model.

In 1909, Hans Geiger and Ernest Marsden, under the direction of physicist Ernest Rutherford, bombarded a sheet of gold foil with alpha rays—by then known to be positively charged helium atoms—and discovered that a small percentage of these particles were deflected through much larger angles than was predicted using Thomson's proposal. Rutherford interpreted the gold foil experiment as suggesting that the positive charge of a heavy gold atom and most of its mass was concentrated in a nucleus at the center of the atom—the Rutherford model

While experimenting with the products of radioactive decay, in 1913 radio chemist Frederick Soddy discovered that there appeared to be more than one type of atom at each position on the periodic table. The term isotope was coined by Margaret Todd as a suitable name for different atoms that belong to the same element. J.J. Thomson created a technique for separating atom types through his work on ionized gases, which subsequently led to the discovery of stable isotopes.

A Bohr model of the hydrogen atom, showing an electron jumping between fixed orbits and emitting a photon of energy with a specific frequency

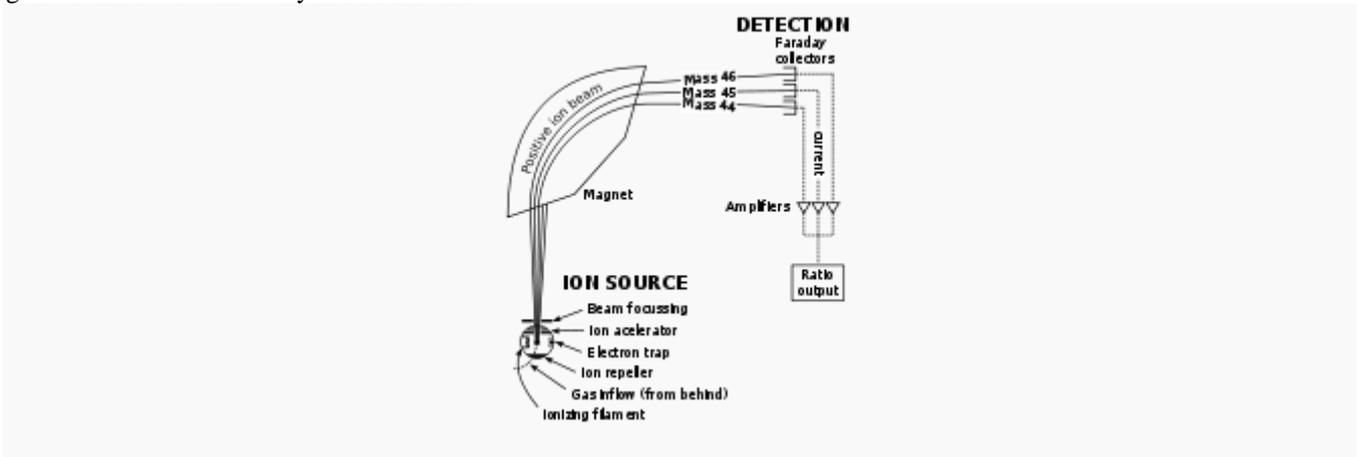

Meanwhile, in 1913, physicist Niels Bohr suggested that the electrons were confined into clearly defined, quantized orbits, and could jump between these, but could not freely spiral inward or outward in intermediate states. An electron must absorb or emit specific amounts of energy to transition between these fixed orbits. When the light from a heated material was passed through a prism, it produced a multi-colored spectrum. The appearance of fixed lines in this spectrum was successfully explained by these orbital transitions.

Later in the same year Henry Moseley provided additional experimental evidence in favor of Niels Bohr's theory. These results refined Ernest's and Antonius Van den Broek's model, which proposed that the atom contains in its nucleus a number of positive nuclear that is equal to its (atomic) number in the periodic table. Until these experiments, atomic number was not known to be a physical and experimental quantity. That it is equal to the atomic nuclear charge remains the accepted atomic model today

Chemical bonds between atoms were now explained, by Gilbert Newton Lewis in 1916, as the interactions between their constituent electrons.²¹ As the chemical properties of the elements were known to largely repeat themselves according to the periodic law, in 1919 the American chemist Irving Langmuir suggested that this could be explained if the electrons in an atom were connected or clustered in some manner. Groups of electrons were thought to occupy a set of electron shells about the nucleus

The Stern–Gerlach experiment of 1922 provided further evidence of the quantum nature of the atom. When a beam of silver atoms was passed through a specially shaped magnetic field, the beam was split based on the direction of an atom's angular momentum, or spin. As this direction is random, the beam could be expected to spread into a line. Instead, the beam was split into two parts, depending on whether the atomic spin was oriented up or down.

In 1924, Louis de Broglie proposed that all particles behave to an extent like waves. In 1926, Erwin Schrödinger used this idea to develop a mathematical model of the atom that described the electrons as three-dimensional waveforms rather than point particles. A consequence of using waveforms to describe particles is that it is mathematically impossible to obtain precise values for both the position and momentum of a particle at the same time; this became known as the uncertainty principle, formulated by Werner Heisenberg in 1926. In this concept, for a given accuracy in measuring a position one could only obtain a range of probable values for momentum, and vice versa. This model was able to explain observations of atomic behavior that previous models could not, such as certain structural and spectral patterns of atoms larger than hydrogen. Thus, the planetary model of the atom was discarded in favor of one that described atomic orbital zones around the nucleus where a given electron is most likely to be observed

The development of the mass spectrometer allowed the exact mass of atoms to be measured. The device uses a magnet to bend the trajectory of a beam of ions, and the amount of deflection is determined by the ratio of an atom's mass to its charge. The chemist Francis William Aston used this instrument to show that isotopes had different masses. The atomic mass of these isotopes varied by integer amounts, called the whole number rule. The explanation for these different isotopes awaited the discovery of the neutron, a neutral-charged particle with a mass similar to the proton, by the physicist James Chadwick in 1932. Isotopes were then explained as elements with the same number of protons, but different numbers of neutrons within the nucleus.

Fission, high-energy physics and condensed matter

NUCLEAR FISSION AND QUANTUM CHIPS:

The following dissemination of the information on the News Paper report(See references for further details):

Current technology uses ultraviolet light to (e)create the fine features in computer chips in a process called photolithography, which involves projecting the image of a mask onto a light-sensitive material, then chemically etching the resulting pattern.

New nanolithography will be needed to continue advances in computer technology and to extend Moore's law, an unofficial rule stating that the number of transistors on integrated circuits, or chips, doubles about every 18 months.

"We can't make devices much smaller using conventional lithography, so we have to find ways of creating beams having more narrow wavelengths," said Ahmed Hassanein, the Paul L. Wattelet Professor of Nuclear Engineering and head of Purdue's School of Nuclear Engineering.

The new plasma-based lithography under development generates "extreme ultraviolet" light having a wavelength of 13.5 nanometers, less than one-tenth the size of current lithography, Hassanein said.

Nuclear engineers and scientists at Purdue and the U.S. Department of Energy's Argonne National Laboratory are working to improve the efficiency of two techniques for producing the plasma: One approach uses a laser and the other "discharge-produced" method uses an electric current.

"In either case, only about 1 to 2 percent of the energy spent is converted into plasma," Hassanein said. "That conversion efficiency means you'd need greater than 100 kilowatts of power for this lithography, which poses all sorts of engineering problems. We are involved in optimizing conversion efficiency - reducing the energy requirements - and solving various design problems for the next-generation lithography."

Findings are detailed in a research paper scheduled to appear in the October-December 2009 issue of the *Journal of Micro/Nanolithography, MEMS, and MOEMS*. The paper was written by Hassanein, senior research scientist Valeryi Sizyuk, computer analyst Tatyana Sizyuk, and research assistant professor Sivanandan Harilal, all in the School of Nuclear Engineering.

Critical to the research is a computer simulation, called HEIGHTS -- for high-energy interaction with general heterogeneous target systems -- developed by Hassanein's team. Computations for a single HEIGHTS simulation using Argonne supercomputers can take several months to finish, said Hassanein, a former Argonne senior scientist who led work there to develop HEIGHTS.

The laser method creates plasma by heating xenon, tin or lithium. The plasma produces high-energy packets of light, photons, of extreme ultraviolet light.

Plasma is a partially ionized gas like material that conducts electricity. Because of this electrical conductivity, researchers are able to use magnetic fields to shape and control plasmas, forming beams, filaments and other structures. In experimental fusion reactors, magnetic fields are used to keep plasma-based nuclear fuel from touching the metal walls of the containment vessel, enabling the plasma to be heated to the extreme temperatures required to maintain fusion reactions.

HEIGHTS simulate the entire process of the plasma evolution: the laser interacting with the target, and the target evaporating, ionizing and turning into plasma. The simulation also shows what happens when the magnetic forces "pinch" the plasma cloud into a smaller diameter spot needed to generate the photons.

Findings in the paper detail the laser-produced plasma beams, showing that simulations match data from laboratory experiments recently built at Purdue, Hassanein said. One design challenge stems from the fact that lenses absorb the photons that make up light, meaning they cannot be used to focus the beam. Instead, mirrors are used in the design. However, plasma condenses on the mirrors, reducing their reflectivity and limiting the efficiency of the process.

"We are trying to help find innovative ways of producing these photons, optimizing the production and mitigating the effects of the plasma on the mirrors," Hassanein said. "So we are trying to improve the entire system."

The simulation tool combines computations in plasma physics, radiation transport, atomic physics, plasma-material interactions and magneto hydrodynamics, or what happens when a target is heated, melts and turns into a plasma.

In 1938, the German chemist Otto Hahn, a student of Rutherford, directed neutrons onto uranium atoms expecting to get transuranium elements. Instead, his chemical experiments showed barium as a product. A year later, Lise Meitner and her nephew Frisch verified that Hahn's result were the first experimental *nuclear fission*.¹ In 1944, Hahn received the Nobel prize in chemistry. Despite Hahn's efforts, the contributions of Meitner and Frisch were not recognized

In the 1950s, the development of improved particle accelerators and particle detectors allowed scientists to study the impacts of atoms moving at high energies.^[44] Neutrons and protons were found to be hadrons, or composites of smaller particles called quarks. Standard models of nuclear physics were developed that successfully explained the properties of the nucleus in terms of these sub-atomic particles and the forces that govern their interactions

Components

Subatomic particles

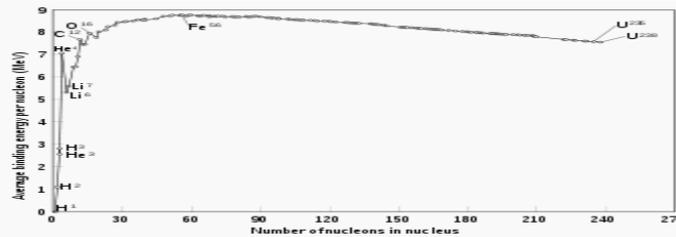

Though the word *atom* originally denoted a particle that cannot be cut into smaller particles, in modern scientific usage the atom is composed of various subatomic particles. The constituent particles of an atom are the electron, the proton and the neutron. However, the hydrogen-1 atom has no neutrons and a positive hydrogen ion has no electrons.

The electron is by far the least massive of these particles at 9.11×10^{-31} kg, with a negative electrical charge and a size that is too small to be measured using available techniques.¹ Protons have a positive charge and a mass 1,836 times that of the electron, at 1.6726×10^{-27} kg, although this can be reduced by changes to the energy binding the proton into an atom. Neutrons have no electrical charge and have a free mass of 1,839 times the mass of electrons, or 1.6929×10^{-27} kg. Neutrons and protons have comparable dimensions—on the order of 2.5×10^{-15} m—although the 'surface' of these particles is not sharply defined.

In the Standard Model of physics, both protons and neutrons are composed of elementary particles called quarks. The quark belongs to the fermion group of particles, and is one of the two basic constituents of matter—the other being the lepton, of

which the electron is an example. There are six types of quarks, each having a fractional electric charge of either $+\frac{2}{3}$ or $-\frac{1}{3}$. Protons are composed of two up quarks and one down quark, while a neutron consists of one up quark and two down quarks. This distinction accounts for the difference in mass and charge between the two particles. The quarks are held together by the strong nuclear force, which is mediated by gluons. The gluon is a member of the family of gauge bosons, which are elementary particles that mediate physical forces.

Nucleus

The binding energy needed for a nucleon to escape the nucleus, for various isotopes

All the bound protons and neutrons in an atom make up a tiny atomic nucleus, and are collectively called nucleons. The radius of a nucleus is approximately equal to $1.07 \sqrt[3]{A} \text{ fm}$, where A is the total number of nucleons¹. This is much smaller than the radius of the atom, which is on the order of 10^5 fm . The nucleons are bound together by a short-ranged attractive potential called the residual strong force. At distances smaller than 2.5 fm this force is much more powerful than the electrostatic force that causes positively charged protons to repel each other.^[52]

Atoms of the same element have the same number of protons, called the atomic number. Within a single element, the number of neutrons may vary, determining the isotope of that element. The total number of protons and neutrons determine the nuclide. The number of neutrons relative to the protons determines the stability of the nucleus, with certain isotopes undergoing radioactive decay.

The neutron and the proton are different types of fermions. The Pauli exclusion principle is a mechanical effect that prohibits identical fermions, such as multiple protons, from occupying the same quantum physical state at the same time. Thus every proton in the nucleus must occupy a different state, with its own energy level, and the same rule applies to all of the neutrons. This prohibition does not apply to a proton and neutron occupying the same quantum state

For atoms with low atomic numbers, a nucleus that has a different number of protons than neutrons can potentially drop to a lower energy state through a radioactive decay that causes the number of protons and neutrons to more closely match. As a result, atoms with roughly matching numbers of protons and neutrons are more stable against decay. However, with increasing atomic number, the mutual repulsion of the protons requires an increasing proportion of neutrons to maintain the stability of the nucleus, which modifies this trend. Thus, there are no stable nuclei with equal proton and neutron numbers above atomic number $Z = 20$ (calcium); and as Z increases toward the heaviest nuclei, the ratio of neutrons per proton required for stability increases to about 1.5.^[54]

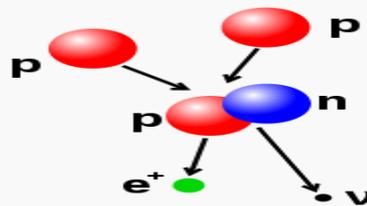

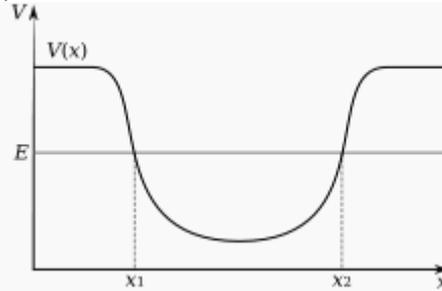

Illustration of a nuclear fusion process that forms a deuterium nucleus, consisting of a proton and a neutron, from two protons. A positron (e^+)—an antimatter electron—is emitted along with an electron neutrino.

The number of protons and neutrons in the atomic nucleus can be modified, although this can require very high energies because of the strong force. Nuclear fusion occurs when multiple atomic particles join to form a heavier nucleus, such as through the energetic collision of two nuclei. For example, at the core of the Sun protons require energies of 3–10 keV to overcome their mutual repulsion—the coulomb barrier—and fuse together into a single nucleus. Nuclear fission is the opposite process, causing a nucleus to split into two smaller nuclei—usually through radioactive decay. The nucleus can also be modified through bombardment by high energy subatomic particles or photons. If this modifies the number of protons in a nucleus, the atom changes to a different chemical element.¹ If the mass of the nucleus following a fusion reaction is less than the sum of the masses of the separate particles, then the difference between these two values can be emitted as a type of usable energy (such as a gamma ray, or the kinetic energy of a beta particle), as described by Albert Einstein's mass-energy equivalence formula, $E = mc^2$, where m is the mass loss and c is the speed of light. This deficit is part of the binding energy of the new nucleus, and it is the non-recoverable loss of the energy that causes the fused particles to remain together in a state that requires this energy to separate.^[58]

The fusion of two nuclei that create larger nuclei with lower atomic numbers than iron and nickel—a total nucleon number of about 60—is usually an exothermic process that releases more energy than is required to bring them together.^[59] It is this

energy-releasing process that makes nuclear fusion in stars a self-sustaining reaction. For heavier nuclei, the binding energy per nucleon in the nucleus begins to decrease. That means fusion processes producing nuclei that have atomic numbers higher than about 26, and atomic masses higher than about 60, is an endothermic process. These more massive nuclei can not undergo an energy-producing fusion reaction that can sustain the hydrostatic equilibrium of a star.^[54]

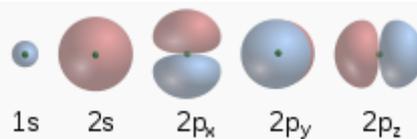

Electron cloud, Electron Configuration, Atomic Orbital:

A potential well, showing, according to classical mechanics, the minimum energy $V(x)$ needed to reach each position x . Classically, a particle with energy E is constrained to a range of positions between x_1 and x_2 .

The electrons in an atom are attracted to the protons in the nucleus by the electromagnetic force. This force binds the electrons inside an electrostatic potential well surrounding the smaller nucleus, which means that an external source of energy is needed for the electron to escape. The closer an electron is to the nucleus, the greater the attractive force. Hence electrons bound near the center of the potential well require more energy to escape than those at greater separations.

Electrons, like other particles, have properties of both a particle and a wave. The electron cloud is a region inside the potential well where each electron forms a type of three-dimensional standing wave—a wave form that does not move relative to the nucleus. This behavior is defined by an atomic orbital, a mathematical function that characterises the probability that an electron appears to be at a particular location when its position is measured.^[60] Only a discrete (or quantized) set of these orbitals exist around the nucleus, as other possible wave patterns rapidly decay into a more stable form.^[61] Orbitals can have one or more ring or node structures, and they differ from each other in size, shape and orientation.¹

Wave functions of the first five atomic orbitals. The three 2p orbitals each display a single angular node that has an orientation and a minimum at the center.

Each atomic orbital corresponds to a particular energy level of the electron. The electron can change its state to a higher energy level by absorbing a photon with sufficient energy to boost it into the new quantum state. Likewise, through spontaneous emission, an electron in a higher energy state can drop to a lower energy state while radiating the excess energy as a photon. These characteristic energy values, defined by the differences in the energies of the quantum states, are responsible for atomic spectral lines.^[61]

The amount of energy needed to remove or add an electron—the electron binding energy—is far less than the binding energy of nucleons. For example, it requires only 13.6 eV to strip a ground-state electron from a hydrogen atom,^[63] compared to 2.23 million eV for splitting a deuterium nucleus.^[64] Atoms are electrically neutral if they have an equal number of protons and electrons. Atoms that have either a deficit or a surplus of electrons are called ions. Electrons that are farthest from the nucleus may be transferred to other nearby atoms or shared between atoms. By this mechanism, atoms are able to bond into molecules and other types of chemical compounds like ionic and covalent network crystals.^[65]

Properties

Nuclear properties-Stable Isotopes, List of Nuclides and List of Elements by Isotopes:

By definition, any two atoms with an identical number of protons in their nuclei belong to the same chemical element. Atoms with equal numbers of protons but a different number of neutrons are different isotopes of the same element. For example, all hydrogen atoms admit exactly one proton, but isotopes exist with no neutrons (hydrogen-1, by far the most common form,^[66] also called protium), one neutron (deuterium), two neutrons (tritium) and more than two neutrons. The known elements form a set of atomic numbers, from the single proton element hydrogen up to the 118-proton element ununoctium.^[67] All known isotopes of elements with atomic numbers greater than 82 are radioactive.^{[68][69]}

About 339 nuclides occur naturally on Earth,^[70] of which 255 (about 75%) have not been observed to decay, and are referred to as "stable isotopes". However, only 90 of these nuclides are stable to all decay, even in theory. Another 165 (bringing the total to 255) have not been observed to decay, even though in theory it is energetically possible. These are also formally classified as "stable". An additional 33 radioactive nuclides have half-lives longer than 80 million years, and are long-lived

enough to be present from the birth of the solar system. This collection of 288 nuclides are known as primordial nuclides. Finally, an additional 51 short-lived nuclides are known to occur naturally, as daughter products of primordial nuclide decay (such as radium from uranium), or else as products of natural energetic processes on Earth, such as cosmic ray bombardment (for example, carbon-14).^{[71][note 2]}

For 80 of the chemical elements, at least one stable isotope exists. As a rule, there is only a handful of stable isotopes for each of these elements, the average being 3.2 stable isotopes per element. Twenty-six elements have only a single stable isotope, while the largest number of stable isotopes observed for any element is ten, for the element tin. Elements 43, 61, and all elements numbered 83 or higher have no stable isotopes.^{[72][page needed]}

Stability of isotopes is affected by the ratio of protons to neutrons, and also by the presence of certain "magic numbers" of neutrons or protons that represent closed and filled quantum shells. These quantum shells correspond to a set of energy levels within the shell model of the nucleus; filled shells, such as the filled shell of 50 protons for tin, confers unusual stability on the nuclide. Of the 255 known stable nuclides, only four have both an odd number of protons *and* odd number of neutrons: hydrogen-2 (deuterium), lithium-6, boron-10 and nitrogen-14. Also, only four naturally occurring, radioactive odd-odd nuclides have a half-life over a billion years: potassium-40, vanadium-50, lanthanum-138 and tantalum-180m. Most odd-odd nuclei are highly unstable with respect to beta decay, because the decay products are even-even, and are therefore more strongly bound, due to nuclear pairing effects.^{[72][page needed]}

Mass Number Of an Atom:

The large majority of an atom's mass comes from the protons and neutrons that make it up. The total number of these particles (called "nucleons") in a given atom is called the mass number. The mass number is a simple whole number, and has units of "nucleons." An example of use of a mass number is "carbon-12," which has 12 nucleons (six protons and six neutrons).

The actual mass of an atom at rest is often expressed using the unified atomic mass unit (u), which is also called a dalton (Da). This unit is defined as a twelfth of the mass of a free neutral atom of carbon-12, which is approximately 1.66×10^{-27} kg.^[73] Hydrogen-1, the lightest isotope of hydrogen and the atom with the lowest mass, has an atomic weight of 1.007825 u.^[74] The value of this number is called the atomic mass. A given atom has an atomic mass approximately equal (within 1%) to its mass number times the mass of the atomic mass unit. However, this number will not be an exact whole number except in the case of carbon-12 (see below)^[75] The heaviest stable atom is lead-208,^[68] with a mass of 207.9766521 u.^[76]

As even the most massive atoms are far too light to work with directly, chemists instead use the unit of moles. One mole of atoms of any element always has the same number of atoms (about 6.022×10^{23}). This number was chosen so that if an element has an atomic mass of 1 u, a mole of atoms of that element has a mass close to one gram. Because of the definition of the unified atomic mass unit, each carbon-12 atom has an atomic mass of exactly 12 u, and so a mole of carbon-12 atoms weighs exactly 0.012 kg.^{[73][page needed]}

Shape and size-The Atomic Radius:

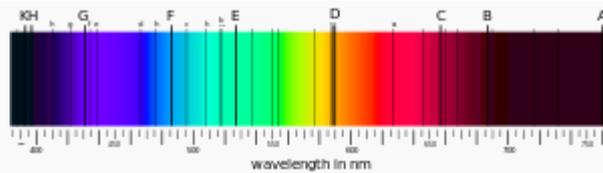

Atoms lack a well-defined outer boundary, so their dimensions are usually described in terms of an atomic radius. This is a measure of the distance out to which the electron cloud extends from the nucleus. However, this assumes the atom to exhibit a spherical shape, which is only obeyed for atoms in vacuum or free space. Atomic radii may be derived from the distances between two nuclei when the two atoms are joined in a chemical bond. The radius varies with the location of an atom on the atomic chart, the type of chemical bond, the number of neighboring atoms (coordination number) and a quantum mechanical property known as spin.^[77] On the periodic table of the elements, atom size tends to increase when moving down columns, but decrease when moving across rows (left to right).^[78] Consequently, the smallest atom is helium with a radius of 32 pm, while one of the largest is caesium at 225 pm.^[79]

When subjected to external fields, like an electrical field, the shape of an atom may deviate from that of a sphere. The deformation depends on the field magnitude and the orbital type of outer shell electrons, as shown by group-theoretical considerations. Aspherical deviations might be elicited for instance in crystals, where large crystal-electrical fields may occur at low-symmetry lattice sites. Significant ellipsoidal deformations have recently been shown to occur for sulfur ions in pyrite-type compounds.^[81]

Atomic dimensions are thousands of times smaller than the wavelengths of light (400–700 nm) so they can not be viewed using an optical microscope. However, individual atoms can be observed using a scanning tunneling microscope. To visualize the minuteness of the atom, consider that a typical human hair is about 1 million carbon atoms in width.^[82] A single drop of water contains about 2 sextillion (2×10^{21}) atoms of oxygen, and twice the number of hydrogen atoms.^[83] A single carat diamond with a mass of 2×10^{-4} kg contains about 10 sextillion (10^{22}) atoms of carbon.^[note 3] If an apple were magnified to the size of the Earth, then the atoms in the apple would be approximately the size of the original apple.^[84]

Radioactive decay

specific energy levels appear as distinct bands in the electromagnetic spectrum. Each element has a characteristic spectrum that can depend on the nuclear charge, sub shells filled by electrons, the electromagnetic interactions between the electrons and other factors

An example of absorption lines in a spectrum

When a continuous spectrum of energy is passed through a gas or plasma, some of the photons are absorbed by atoms, causing electrons to change their energy level. Those excited electrons that remain bound to their atom spontaneously emit this energy as a photon, traveling in a random direction, and so drop back to lower energy levels. Thus the atoms behave like a filter that forms a series of dark absorption bands in the energy output. (An observer viewing the atoms from a view that does not include the continuous spectrum in the background, instead sees a series of emission lines from the photons emitted by the atoms.) Spectroscopic measurements of the strength and width of spectral lines allow the composition and physical properties of a substance to be determined.

Close examination of the spectral lines reveals that some display a fine structure splitting. This occurs because of spin-orbit coupling, which is an interaction between the spin and motion of the outermost electron. When an atom is in an external magnetic field, spectral lines become split into three or more components; a phenomenon called the Zeeman effect. This is caused by the interaction of the magnetic field with the magnetic moment of the atom and its electrons. Some atoms can have multiple electron configurations with the same energy level, which thus appear as a single spectral line. The interaction of the magnetic field with the atom shifts these electron configurations to slightly different energy levels, resulting in multiple spectral lines. The presence of an external electric field can cause a comparable splitting and shifting of spectral lines by modifying the electron energy levels, a phenomenon called the Stark effect.

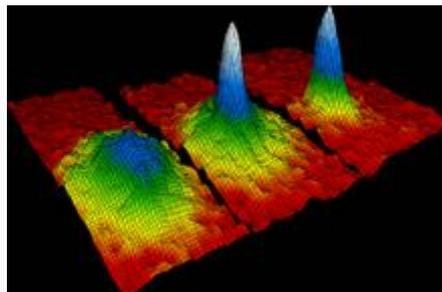

If a bound electron is in an excited state, an interacting photon with the proper energy can cause stimulated emission of a photon with a matching energy level. For this to occur, the electron must drop to a lower energy state that has an energy difference matching the energy of the interacting photon. The emitted photon and the interacting photon then move off in parallel and with matching phases. That is, the wave patterns of the two photons are synchronized. This physical property is used to make lasers, which can emit a coherent beam of light energy in a narrow frequency band

Valence and bonding behavior

The outermost electron shell of an atom in its uncombined state is known as the valence shell, and the electrons in that shell are called valence electrons. The number of valence electrons determines the bonding behavior with other atoms. Atoms tend to chemically react with each other in a manner that fills (or empties) their outer valence shells. For example, a transfer of a single electron between atoms is a useful approximation for bonds that form between atoms with one-electron more than a filled shell, and others that are one-electron short of a full shell, such as occurs in the compound sodium chloride and other chemical ionic salts. However, many elements display multiple valences, or tendencies to share differing numbers of electrons in different compounds. Thus, chemical bonding between these elements takes many forms of electron-sharing that are more than simple electron transfers. Examples include the element carbon and the organic compounds

The chemical elements are often displayed in a periodic table that is laid out to display recurring chemical properties, and elements with the same number of valence electrons form a group that is aligned in the same column of the table. (The horizontal rows correspond to the filling of a quantum shell of electrons.) The elements at the far right of the table have their outer shell completely filled with electrons, which results in chemically inert elements known as the noble gases.

STATE OF MATTER AND PHASE OF MATTER FOR CLASSIFICATION OF QUANTUM MECHANICAL BEHAVIOUR:

Snapshots illustrating the formation of a Bose–Einstein condensate

Quantities of atoms are found in different states of matter that depend on the physical conditions, such as temperature and pressure. By varying the conditions, materials can transition between solids, liquids, gases and

plasmas Within a state, a material can also exist in different phases. An example of this is solid carbon, which can exist as graphite or diamond.

At temperatures close to absolute zero, atoms can form a Bose–Einstein condensate, at which point quantum mechanical effects, which are normally only observed at the atomic scale, become apparent on a macroscopic scale This super-cooled collection of atoms then behaves as a single super atom, which may allow fundamental checks of quantum mechanical behavior.

The scanning tunneling microscope is a device for viewing surfaces at the atomic level. It uses the quantum tunneling phenomenon, which allows particles to pass through a barrier that would normally be insurmountable. Electrons tunnel through the vacuum between two planar metal electrodes, on each of which is an adsorbed atom, providing a tunneling-current density that can be measured. Scanning one atom (taken as the tip) as it moves past the other (the sample) permits plotting of tip displacement versus lateral separation for a constant current. The calculation shows the extent to which scanning-tunneling-microscope images of an individual atom are visible. It confirms that for low bias, the microscope images the space-averaged dimensions of the electron orbitals across closely packed energy levels—the Fermi level local density of states

An atom can be ionized by removing one of its electrons. The electric charge causes the trajectory of an atom to bend when it passes through a magnetic field. The radius by which the trajectory of a moving ion is turned by the magnetic field is determined by the mass of the atom. The mass spectrometer uses this principle to measure the mass-to-charge ratio of ions. If a sample contains multiple isotopes, the mass spectrometer can determine the proportion of each isotope in the sample by measuring the intensity of the different beams of ions. Techniques to vaporize atoms include inductively coupled plasma atomic emission spectroscopy and inductively coupled plasma mass spectrometry, both of which use a plasma to vaporize samples for analysis

A more area-selective method is electron energy loss spectroscopy, which measures the energy loss of an electron beam within a transmission when it interacts with a portion of a sample. The atom-probe tomograph has sub-nanometer resolution in 3-D and can chemically identify individual atoms using time-of-flight mass spectrometry

Spectra of excited states can be used to analyze the atomic composition of distant stars. Specific light wavelengths contained in the observed light from stars can be separated out and related to the quantized transitions in free gas atoms. These colors can be replicated using a gas-discharge lamp containing the same element Helium was discovered in this way in the spectrum of the Sun 23 years before it was found on Earth.

Origin and current state

Atoms form about 4% of the total energy density of the observable universe, with an average density of about 0.25 atoms/m^3 . Within a galaxy such as the Milky Way, atoms have a much higher concentration, with the density of matter in the interstellar medium (ISM) ranging from 10^5 to 10^9 atoms/m^3 . The Sun is believed to be inside the Local Bubble, a region of highly ionized gas, so the density in the solar neighborhood is only about 10^3 atoms/m^3 Stars form from dense clouds in the ISM, and the evolutionary processes of stars result in the steady enrichment of the ISM with elements more massive than hydrogen and helium. Up to 95% of the Milky Way's atoms are concentrated inside stars and the total mass of atoms forms about 10% of the mass of the galaxy. (The remainder of the mass is an unknown dark matter.)

Nucleosynthesis

Stable protons and electrons appeared one second after the Big Bang. During the following three minutes, Big Bang nucleosynthesis produced most of the helium, lithium, and deuterium in the universe, and perhaps some of the beryllium and boron. The first atoms (complete with bound electrons) were theoretically created 380,000 years after the Big Bang—an epoch called recombination, when the expanding universe cooled enough to allow electrons to become attached to nuclei. Since the Big Bang, which produced no carbon, atomic nuclei have been combined in stars through the process of nuclear fusion to produce more of the element helium, and (via the triple alpha process) the sequence of elements from carbon up to iron. Isotopes such as lithium-6, as well as some beryllium and boron are generated in space through cosmic ray spallation. This occurs when a high-energy proton strikes an atomic nucleus, causing large numbers of nucleons to be ejected. Elements heavier than iron were produced in supernovae through the r-process and in AGB stars through the s-process, both of which involve the capture of neutrons by atomic nuclei. Elements such as lead formed largely through the radioactive decay of heavier elements.¹

Earth

Most of the atoms that make up the Earth and its inhabitants were present in their current form in the nebula that collapsed out of a molecular cloud to form the Solar System. The rest are the result of radioactive decay, and their relative proportion can be used to determine the age of the Earth through radiometric dating. Most of the helium in the crust of the Earth (about 99% of the helium from gas wells, as shown by its lower abundance of helium-3) is a product of alpha decay.

There are a few trace atoms on Earth that were not present at the beginning (i.e., not "primordial"), nor are results of radioactive decay. Carbon-14 is continuously generated by cosmic rays in the atmosphere. Some atoms on Earth have been artificially generated either deliberately or as by-products of nuclear reactors or explosions Of the transuranic elements—those with atomic numbers greater than 92—only plutonium and neptunium occur naturally on Earth. Transuranic elements have radioactive lifetimes shorter than the current age of the Earth and thus identifiable quantities of these elements have

long since decayed, with the exception of traces of plutonium-244 possibly deposited by cosmic dust. Natural deposits of plutonium and neptunium are produced by neutron capture in uranium ore

The Earth contains approximately 1.33×10^{50} atoms. In the planet's atmosphere, small numbers of independent atoms of noble gases exist, such as argon and neon. The remaining 99% of the atmosphere is bound in the form of molecules, including carbon Dioxide and diatomic oxygen and nitrogen. At the surface of the Earth, atoms combine to form various compounds, including water, salt, silicates and oxides. Atoms can also combine to create materials that do not consist of discrete molecules, including crystals and liquid or solid metals. This atomic matter forms networked arrangements that lack the particular type of small-scale interrupted order associated with molecular matter

Rare and theoretical forms

While isotopes with atomic numbers higher than lead (82) are known to be radioactive, an "island of stability" has been proposed for some elements with atomic numbers above 103. These super heavy elements may have a nucleus that is relatively stable against radioactive decay. The most likely candidate for a stable super heavy atom, unbihexium, has 126 protons and 184 neutrons.

Each particle of matter has a corresponding antimatter particle with the opposite electrical charge. Thus, the positron is a positively charged antielectron and the antiproton is a negatively charged equivalent of a proton. When a matter and corresponding antimatter particle meet, they annihilate each other. Because of this, along with an imbalance between the number of matter and antimatter particles, the latter are rare in the universe. (The first causes of this imbalance are not yet fully understood, although the baryogenesis theories may offer an explanation.) As a result, no antimatter atoms have been discovered in nature. However, in 1996, antihydrogen, the antimatter counterpart of hydrogen, was synthesized at the CERN laboratory in Geneva. Other exotic atoms have been created by replacing one of the protons, neutrons or electrons with other particles that have the same charge. For example, an electron can be replaced by a more massive muon, forming a muonic atom. These types of atoms can be used to test the fundamental predictions of physics

QUANTUM MECHANICAL BEHAVIOUR: SYSTEMAL IMPLICATIONS:

ASSUMPTIONS:

- a) QUANTUM MECHANICAL BEHAVIOURS are classified into three categories;
 - 1) Category 1 **OF QUANTUM MECHANICAL BEHAVIOUR CONCOMITANT TO QUANTUM COMPUTATION CLASSIFICATION IN CATEGORY 1**
 - 2) Category 2 (second interval) **OF QUANTUM MECHANICAL BEHAVIOUR CONCOMITANT TO QUANTUM COMPUTATION CLASSIFICATION IN CATEGORY 2**
 - 3) Category 3 **OF QUANTUM MECHANICAL BEHAVIOUR CONCOMITANT TO QUANTUM COMPUTATION CLASSIFICATION IN CATEGORY 3**

In this connection, it is to be noted that there is no sacrosanct time scale as far as the above pattern of classification is concerned. Any operationally feasible scale with an eye on the classification of **QUANTUM MECHANICAL BEHAVIOUR CONCOMITANT TO QUANTUM COMPUTATION CLASSIFICATION IN Categories 1, 2, and 3** would be in the fitness of things. For category 3. "Over and above" nomenclature could be used to encompass a wider range of CATEGORICAL CONSTITUENTS. Similarly, a "less than" scale for category 1 can be used. The speed of growth of **QUANTUM MECHANICAL BEHAVIOUR CONCOMITANT TO QUANTUM COMPUTATION CLASSIFICATION IN CATEGORY 1** proportional to the total amount of **QUANTUM MECHANICAL BEHAVIOUR CONCOMITANT TO QUANTUM COMPUTATION CLASSIFICATION IN CATEGORY 2** In essence the accentuation coefficient in the model is representative of the constant of proportionality between **QUANTUM MECHANICAL BEHAVIOUR CONCOMITANT TO QUANTUM COMPUTATION CLASSIFICATION IN CATEGORY** under category 1 and category 2. This assumptions is made to foreclose the necessity of addition of one more variable, that would render the systemic equations unsolvable

DISSIPATION OF QUANTUM MECHANICAL BEHAVIOUR:

The dissipation in all the three categories is attributable to the following two phenomenon : **Aging phenomenon:** The aging process leads to transference of the **QUANTUM MECHANICAL BEHAVIOUR CONCOMITANT TO QUANTUM COMPUTATION CLASSIFICATION IN CATEGORY 1** to the next category, **Depletion phenomenon:** Complete destruction of say quantum entanglement For detailed exposition see essay at the end.*

NOTATION :

G_{36} : **QUANTUM MECHANICAL BEHAVIOUR CONCOMITANT TO QUANTUM COMPUTATION CLASSIFICATION IN CATEGORY**

G_{37} : **OF QUANTUM MECHANICAL BEHAVIOUR CONCOMITANT TO QUANTUM COMPUTATION CLASSIFICATION IN CATEGORY 2**

G_{38} : **QUANTUM MECHANICAL BEHAVIOUR CONCOMITANT TO QUANTUM COMPUTATION CLASSIFICATION IN CATEGORY 3**

$(a_{36})^{(7)}, (a_{37})^{(7)}, (a_{38})^{(7)}$: Accentuation coefficients

$(a'_{36})^{(7)}, (a'_{37})^{(7)}, (a'_{38})^{(7)}$: Dissipation coefficients*

FORMULATION OF THE SYSTEM :

In the light of the assumptions stated in the foregoing, we infer the following:-

The growth speed in category 1 is the sum of a accentuation term $(a_{36})^{(7)}G_{37}$ and a dissipation term $-(a'_{36})^{(7)}G_{36}$, the amount of dissipation taken to be proportional to the **QUANTUM MECHANICAL BEHAVIOUR CONCOMITANT TO QUANTUM COMPUTATION CLASSIFICATION IN CATEGORY**

(a) The growth speed in category 2 is the sum of two parts $(a_{37})^{(7)}G_{36}$ and $-(a'_{37})^{(7)}G_{37}$ the inflow from the category 1 dependent on the total amount standing in that category.

The growth speed in category 3 is equivalent to $(a_{38})^{(7)}G_{37}$ and $-(a'_{38})^{(7)}G_{38}$ dissipation ascribed only to depletion phenomenon.*

*
*

$$\frac{dG_{36}}{dt} = (a_{36})^{(7)}G_{37} - (a'_{36})^{(7)}G_{36} \quad *1$$

$$\frac{dG_{37}}{dt} = (a_{37})^{(7)}G_{36} - (a'_{37})^{(7)}G_{37} \quad *2$$

$$\frac{dG_{38}}{dt} = (a_{38})^{(7)}G_{37} - (a'_{38})^{(7)}G_{38} \quad *3$$

$$(a_i)^{(7)} > 0, \quad i = 36, 37, 38 \quad *4$$

$$(a'_i)^{(7)} > 0, \quad i = 36, 37, 38 \quad *5$$

$$(a_{37})^{(7)} < (a'_{36})^{(7)} \quad *6$$

$$(a_{38})^{(7)} < (a'_{37})^{(7)} \quad *7$$

We can rewrite *

$$\frac{dG_{36}}{(a_{36})^{(7)}G_{37} - (a'_{36})^{(7)}G_{36}} = dt \quad *8$$

$$\frac{dG_{37}}{(a_{37})^{(7)}G_{36} - (a'_{37})^{(7)}G_{37}} = dt \quad *9$$

Or we write a single equation as *

$$\frac{dG_{36}}{(a_{36})^{(7)}G_{37} - (a'_{36})^{(7)}G_{36}} = \frac{dG_{37}}{(a_{37})^{(7)}G_{36} - (a'_{37})^{(7)}G_{37}} = \frac{dG_{38}}{(a_{38})^{(7)}G_{37} - (a'_{38})^{(7)}G_{38}} = dt \quad *10$$

The equality of the ratios in equation (10) remains unchanged in the event of multiplication of numerator and denominator by a constant factor.*

For constant multiples α, β, γ all positive we can write equation (10) as*

$$\frac{\alpha dG_{36}}{\alpha((a_{36})^{(7)}G_{37} - (a'_{36})^{(7)}G_{36})} = \frac{\beta dG_{37}}{\beta((a_{37})^{(7)}G_{36} - (a'_{37})^{(7)}G_{37})} = \frac{\gamma dG_{38}}{\gamma((a_{38})^{(7)}G_{37} - (a'_{38})^{(7)}G_{38})} = dt \quad *14$$

The general solution of the **SYSTEM OF QUANTUM MECHANICAL BEHAVIOUR CONCOMITANT TO QUANTUM COMPUTATION CLASSIFICATION IN CATEGORY** can be written in the form *

$\alpha_i G_i + \beta_i G_i + \gamma_i G_i = C_i e_i^{\lambda_i t}$ Where $i = 36, 37, 38$ and C_{36}, C_{37}, C_{38} are arbitrary constant coefficients.*

THERE ARE MANY ILLUSTRATIONS AND EXAMPLES UNDER THIS HEAD THAT CAN BE DISCUSSED WHERE THE QUANTUM ENTANGLEMENT STABILITY OR INSTABILITY PERSISTS OR NOT AND ITS WIDE RANGING AMPLITUDINAL RAMIFICATIONS THEREOF:

Quantum entanglement at Nano Scale:

More often than not, issues of Quantum Entanglement theory, quantum molecular entanglement in nano-scale, quantum coherence in delocalized bond structures and quantum entanglement in Nanoscale dot- systems are interlinked to each other. One of most peculiar properties of Quantum Physics is focused on the Entanglement that get the possibility to built up special quantum shared states based on delocalized electron's field. In fact Entanglement permits **to (e&eb)change** the degree of localization of quantum/wave particles ;in fact also during a spatial separation of pair wise electrons quantum entanglement **generate(eb) a new** partial localized conjugate-systems of bonding atoms. The entanglement activity **can (eb)evolve in** strength and in coherence of simultaneity properties of mixed delocalized states and/or in the successive decay to localized single states in function of some noises (temperature and other interferences) that **dis-entangled the stability** in the time-scale of the simultaneity co-existence of entangled states . To investigate on the properties innovation of entanglement effects good experimental information **can be (eb)obtained** looking at the **spectrum of emission induced by lasers and measured in Femto-seconds** (Femto-chemistry *). In fact this fast-method of investigation can give information observed exactly what happens at the molecular level during a chemical reaction. So that ultrafast molecular dynamics in future can permit to deeply understand **the effect(e&eb) of** entangled hybridization of electron's field (in some way similar to the metallic bond) caused by the over position of electron orbitals **create(eb) the** molecular bonding in the nano-scale dimension.

Stability of atomic clocks based (e)on entangled atoms

Under this head, many authors have shown that the stability and instability of quantum evolution are analyzed in the interaction of a two-level atom with a quantized-field mode in an ideal cavity with allowance for photon recoil, which is the basic model of cavity QED. It is shown that the Jaynes-Cammings quantum dynamics **can be unstable** in the *regime of the*

random walk of the atom in the quantized field of a standing wave in the absence of any interaction with the environment. This **instability is manifested** in large fluctuations of the quantum entropy, which correlate with a classical-chaos measure, the maximum Lyapunov exponent, and in the exponential sensitivity of the fidelity of the quantum states **of the strongly coupled** atom-field system to small variations of resonance detuning. Numerical experiments reveal the **sensitivity of the atomic population inversion to the initial conditions** and to **correlation between** the quantum and classical degrees of freedom of the atom.

Stability in atomic clocks:

Effect(e&eb) of realistic noise sources for an atomic clock consisting of a local oscillator that is actively **locked to a** spin-squeezed (entangled) ensemble of N atoms. Use of entangled states **can lead (eb) to an** improvement of the long-term stability of the clock when the measurement **is(e) limited by** decoherence associated with instability of the local oscillator combined with fluctuations in the atomic ensemble's Bloch vector. Atomic states with a moderate degree of entanglement **yield (eb) the** maximal clock stability, resulting in an improvement that scales as $N^{1/6}$ compared to the atomic shot noise level. Quantum entanglement is the basis for many of the proposed applications of quantum information science. The experimental implementation of these ideas is challenging since entangled states are easily **destroyed(e) (by** decoherence. To evaluate the potential usefulness of entanglement it is therefore essential to include a realistic description of noise in experiments of interest. Although decoherence is commonly analyzed in the context of simple models, practical sources of noise often **possess(e) a** non-trivial frequency spectrum, and enter through a variety of different physical processes. **Effect(e&eb) of** realistic decoherence processes and noise sources in an atomic clock that is actively **locked(e&eb) to a** spin-squeezed (entangled) ensemble of atoms. The performance of an atomic clock can be characterized by **its frequency accuracy and stability**. Accuracy refers to the frequency offset from the ideal value, whereas stability **describes** the fluctuations around, and drift away from the average frequency. To improve the **long-term clock stability**, it has been suggested **to (e)use** entangled atomic ensembles, in the **presence of** realistic decoherence and noise. In practice, an atomic clock operates **by (e&eb)locking the** frequency of a local oscillator (L.O.) **to the** transition frequency between two levels in an atom. This locking is achieved by a spectroscopic measurement determining the L.O. frequency offset $\delta\omega$ from the atomic resonance, followed by a feedback Mechanism which steers the L.O. frequency so as to null the mean frequency offset. The problem of frequency control thus **combines** elements of **quantum parameter estimation theory** and **control of stochastic systems via feedback**. The spectroscopic measurement of the atomic transition frequency is typically **achieved** through Ramsey spectroscopy, in which the atoms are illuminated by two short, near-resonant pulses from the local oscillator, **separated by a** long period of free evolution, referred to as the Ramsey time T . During the free evolution the atomic state and the L.O. acquire a relative phase difference $\delta\phi = \delta\omega T$, which is subsequently **determined** by a projection measurement. If a long time T is used, then Ramsey spectroscopy provides a very sensitive measurement of the L.O. frequency offset $\delta\omega$. Situation IS relevant to trapped particles, such as atoms in an optical lattice or trapped ions. In this situation, the optimal value of T **is(eb) determined by** atomic decoherence (**caused by** imperfections in the experimental setup) which **therefore(eb) determines the** ultimate performance of the clock. Using a simple noise model it was shown that entanglement **provides(eb) little gain** in spectroscopic sensitivity in the presence of atomic decoherence. In essence, random fluctuations in the phase of the atomic coherence **cause(eb) a** rapid smearing of the error contour. In practice, the Stability of atomic clocks is often **limited(e) primarily by** fluctuations of the L.O. Atomic dephasing **and(e) the use of** entangled states **can (eb)lead to a** significant improvement in clocks. Pracy, Disclaimer, Terms & Conditions, and Copyright Inf

Large scale effective Theory for cosmological bounces(See for details Martin Bojowald)*

An exactly solvable bounce model in loop quantum cosmology is identified which serves as a perturbative basis for realistic bounce scenarios. Its bouncing solutions are derived analytically, demonstrating why recent numerical simulations **robustly led to** smooth bounces under the assumption **of semi classicality**. Several **effects(e&eb)**, easily **included in a** perturbative analysis, can **however(e&eb) change this** smoothness. The effective theory is not only applicable to such situations where a numerical technique become highly involved but also allows one to discuss conceptual issues. For instance, consequences of the notoriously difficult physical inner product can be implemented at the effective level. This indicates that even physical predictions from full quantum gravity **can be (e)obtained from** perturbative effective equations.

Using Lagrange–Poincare stability analysis and some catastrophe theory classification of singularities, we analyze the two-slit experiments of quantum physics. It is shown that assuming micro-spacetime to be a **Fuzzy Kähler-like manifold $K(\epsilon^{(c)})$** with an **inbuilt** wave–particle duality, **one of the two slits is always(e&eb) unstable**. Consequently, the faintest interference **with the experiment** is sufficient to **break the** symmetry of “equilibrium” and **leads (eb) to what is perceived** on the other side of the quantum-classical interface as a wave collapse.

Black strings and p-branes are (e&eb) unstable (Ruth Gregory)

Investigation is on the evolution of small perturbations around black strings and branes which are low energy solutions of string theory. For simplicity we focus attention on the zero charge case and show that there are unstable modes for a range of time frequency and wavelength in the extra $10-D$ dimensions. These perturbations can be stabilized if the extra dimensions are compactified to a scale smaller than the minimum wavelength for which instability occurs and thus will not affect large astrophysical black holes in four dimensions. We comment on the implications of this result for the cosmic censorship hypothesis.

*

Supposing $G_i(0) = G_i^0(0) > 0$, and denoting by λ_i the characteristic roots of the system, it easily results that

1. If $(a'_{36})^{(7)}(a'_{37})^{(7)} - (a_{36})^{(7)}(a_{37})^{(7)} > 0$ all the components of the solution, i.e all the three parts of the **OF QUANTUM MECHANICAL BEHAVIOUR CONCOMITANT TO QUANTUM COMPUTATION CLASSIFICATION IN CATEGORY 1** tend to zero, and the solution is stable with respect to the initial data.

2. If $(a'_{36})^{(7)}(a'_{37})^{(7)} - (a_{36})^{(7)}(a_{37})^{(7)} < 0$ and $(\lambda_{37} + (a'_{36})^{(7)})G_{36}^0 - (a_{36})^{(7)}G_{37}^0 \neq 0, (\lambda_{37} < 0)$, the first two components of the solution tend to infinity as $t \rightarrow \infty$, and $G_{38} \rightarrow 0$, i.e. The category 1 and category 2 parts grows to infinity, whereas the third part category 3 tends to zero.

3. If $(a'_{36})^{(7)}(a'_{37})^{(7)} - (a_{36})^{(7)}(a_{37})^{(7)} < 0$ and $(\lambda_{37} + (a'_{36})^{(7)})G_{36}^0 - (a_{36})^{(7)}G_{37}^0 = 0$ Then all the three parts tend to zero, but the solution is not stable i.e. at a small variation of the initial values of G_i , the corresponding solution tends to infinity.*

*

From the above stability analysis we infer the following:

1.The adjustment process is stable in the sense that the system converges to equilibrium.2.The approach to equilibrium is a steady one, and there exists progressively diminishing oscillations around the equilibrium point3.Conditions 1 and 2 are independent of the size and direction of initial disturbance7.The actual shape of the time path system is determined by efficiency parameter, the strength of the response of the portfolio in question, and the initial disturbance5.Result 3 warns us that we need to make an exhaustive study of the behavior of any case in which generalization derived from the model do not hold6.Growth studies as the one in the extant context are related to the systemic growth paths with full employment of resources that are available in question,

Traveling wave analysis of semiconductor lasers: modulation responses, mode stability and quantum mechanical treatment of noise spectra is an example of the system in which stability analysis could be conducted. A traveling wave analysis of a general class of semiconductor lasers, which includes multisession DFB/DBR lasers and gain-coupled DFB lasers. The analysis leads to new semi analytic expressions for the small-signal IM and FM modulation responses, the intensity and FM noise spectra, and the line width. The expressions are given in terms of solutions to four coupled linear homogeneous differential equations and can easily be evaluated numerically. Derivation of a stability parameter σ , for which $\sigma < 0$ indicates that the model is unstable with respect to small-scale fluctuations. The noise spectra are derived from semiclassical calculations as well as from calculations based on quantized fields, and there are limitations of the semiclassical approach. The formalism of the quantum mechanical treatment has a built-in relationship between the relative intensity noise and the noise of the injection current. This relationship is discussed and illustrated by numerical examples by various authors extensively in literature.

Carlton M. Caves and G. J. Milburn have studied Quantum-mechanical model for continuous position measurements, which is another example of the Quantum Mechanical Behaviour and Dissipation where Stability Analysis could be carried out..They present an idealized model for a sequence of position measurements, and then take an appropriate limit in which the measurements become continuous. The measurements lead to fluctuations without systematic dissipation, and they rapidly destroy off-diagonal terms in the position basis; thus the pointer basis is position. A modification of the model incorporates systematic dissipation via a feedback mechanism; in the modified model there is no decay of off-diagonal coherence in the position basis.

Igamberdiev A.U. is another author who has studied the Prigogine's dissipative structures and has analyzed the stability processes thereof. In Quantum mechanical properties of biosystems: A framework for complexity, structural stability, and transformations is provided by the author. Internal quantum non-demolition measurements are inherent for biological organization and determine the essential features of living systems. Low energy dissipation in these measurements provided by slow conformational relaxation of biomacromolecular complexes (regarded as measuring devices) is the main precondition of enzyme operation and information transfer determining the steady non-equilibrium state of biosystems. The presence of an internal formal description inside a biosystems, expressed in genetic structures (developmental program), is a consequence of its quantum properties. Incompleteness of this formal description provides the possibility of the generation of new functional relations and interconnections inside the system. This is a logical precondition of an evolutionary process. The quantum mechanical uncertainty that underlies the appearance of bifurcations is considered to be the main physical foundation of complication and irreversible transformation of biosystems. It provides a framework for temporal and spatial characteristics of the biosystems. The logic of such a framework derives from Aristotle, as in his philosophy we find the analysis of fundamental irreversibility and self determination of the living processes.

Quantum properties of biosystems structures was studied by, Pattee (1968) and Rosen (1977) concluded that its logic should reveal an internal resemblance to the logic of quantum mechanical measurement, in which a non-formal process of mapping physical events into symbols takes place. Biological molecular complexes are operational structures put in correspondence

with other molecules and processes. These considerations give a theoretical framework for a description of the complexity, **structural stability and transformations of living systems**. Quantum measurement is connected with low energy dissipation in the case where the relaxation period of a macroscopic oscillator (t^*) is many times larger than the time interval of measurement (t'). Minimal energy dissipation in quantum measurement is calculated. *

QUANTUM COMPUTER:

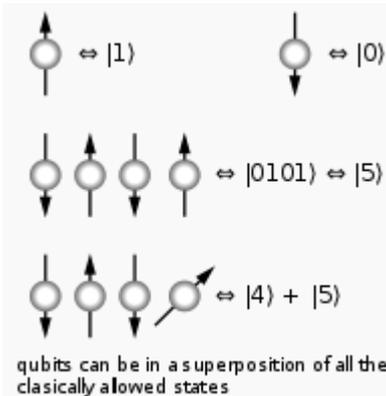

Quantum computer is a device for computation that makes **direct use of** quantum mechanical phenomena, such as **superposition and entanglement**, to perform operations on data. Quantum computers are different from digital computers based on transistors. Whereas digital computers require data to be encoded into binary digits (bits), quantum computation **utilizes** quantum properties to represent data and perform operations on these data. A theoretical model is the **Quantum Turing machine**, also known as the universal quantum computer. Quantum computers share theoretical similarities with non-deterministic and probabilistic computers, like the ability to be in more than one state simultaneously. The field of quantum computing was first introduced by Richard Feynman in 1982.

Although quantum computing is still in its infancy, experiments have been carried out in which quantum computational operations were executed on a very small number of qubits (quantum bits). Both practical and theoretical research continues, and many national government and military funding agencies support quantum computing research to develop quantum computers for both civilian and national security purposes, such as cryptanalysis.

Large-scale quantum computers could be able to solve certain problems much faster than any classical computer by using the best currently known algorithms, like integer factorization using Shor's algorithm or the simulation of quantum many-body systems. There exist quantum algorithms, such as Simon's algorithm, which run faster than any possible probabilistic classical algorithm. Given unlimited resources, a classical computer can simulate an arbitrary quantum algorithm so quantum **computation does not violate** the Church. However, in practice infinite resources are never available and the computational basis of 500 qubits, for example, would already be too large to be represented on a classical computer because it would require 2^{500} complex values to be stored. (For comparison, a terabyte of digital information stores only 2^{43} discrete on/off values) Nielsen and Chuang point out that "Trying to store all these complex numbers would not be possible on any conceivable classical computer."

Bits vs. qubits

A quantum computer with a given number of qubits is fundamentally different from a classical computer composed of the same number of classical bits. For example, to represent the state of an n -qubit system on a classical computer would require the storage of 2^n complex coefficients. Although this fact may seem to indicate that qubits **can hold** exponentially more information than their classical counterparts, care must be taken not to **overlook the fact** that the qubits are only in a probabilistic **superposition of all** of their states. This means that when the final state of the qubits is measured, they will only be found in one of the possible configurations they were in before measurement. Moreover, it is incorrect to think of the qubits as only being in one particular state before measurement since the fact that they were in **a superposition** of states before the measurement was made directly affects the possible outcomes of the computation.

Qubits are made up of controlled particles and the means of control (e.g. devices that trap particles and switch them from one state to another) For example: Consider first a classical computer that operates on a three-bit register. The state of the computer at any time is a probability distribution over the $2^3 = 8$ different three-bit strings 000, 001, 010, 011, 100, 101, 110, 111. If it is a deterministic computer, then it is in exactly one of these states with probability 1. However, if it is a probabilistic computer, then there is a possibility of it being in any *one* of a number of different states. We can **describe this** probabilistic state by eight nonnegative numbers A, B, C, D, E, F, G, H (where A = probability computer is in state 000, B = probability computer is in state 001, etc.). There is **a restriction** that these probabilities sum to 1.

The state of a three-qubit quantum computer is similarly described by an eight-dimensional vector (a, b, c, d, e, f, g, h) , called a **ket**. However, instead of adding to one, the sum of the *squares* of the coefficient magnitudes, $|a|^2 + |b|^2 + \dots + |h|^2$, must equal one. Moreover, the coefficients are complex numbers. Since the probability amplitudes of the states are represented with complex numbers, the phase between any two states is a meaningful parameter, which is a key difference between quantum computing and probabilistic classical computing.^[8]

If you measure the three qubits, you will observe a three-bit string. The probability of measuring a given string is the squared magnitude of that string's coefficient (i.e., the probability of measuring 000 = $|a|^2$, the probability of measuring 001 = $|b|^2$, etc.). Thus, measuring a quantum state described by complex coefficients (a, b, \dots, h) gives the classical probability distribution ($|a|^2, |b|^2, \dots, |h|^2$) and we say that the quantum state "**collapses**" to a classical state **as a result of making** the measurement.

Note that an eight-dimensional vector can be specified in many different ways depending on what basis is chosen for the space. The basis of bit strings (e.g., 000, 001, and 111) is known as the computational basis. Other possible bases are unit-length, orthogonal vectors and the eigenvectors of the Pauli-x operator. **Ket notation** is often used to make the choice of basis explicit. For example, the state (a, b, c, d, e, f, g, h) in the computational basis can be written as:

$$a|000\rangle + b|001\rangle + c|010\rangle + d|011\rangle + e|100\rangle + f|101\rangle + g|110\rangle + h|111\rangle$$

where, e.g., $|010\rangle = (0, 0, 1, 0, 0, 0, 0, 0)$

Assumptions:

Category 1 **QUANTUM COMPUTER(INFORMATION) CORRESPONDING TO THE QUANTUM MECHANICAL BEHAVIOUR STRATIFIED IN THE CORRESPONDING CATEGORY1**

Category 2 **QUANTUM COMPUTER(INFORMATION) CORRESPONDING TO THE QUANTUM MECHANICAL BEHAVIOUR STRATIFIED IN THE CORRESPONDING CATEGORY 2**

Category 3 **QUANTUM COMPUTER(INFORMATION) CORRESPONDING TO THE QUANTUM MECHANICAL BEHAVIOUR STRATIFIED IN THE CORRESPONDING CATEGORY 3***

The speed of growth of **QUANTUM COMPUTER (INFORMATION) CORRESPONDING TO THE QUANTUM MECHANICAL BEHAVIOUR STRATIFIED IN THE CORRESPONDING CATEGORY** is a linear function of the in category 2 at the time of reckoning. As before the accentuation coefficient that characterizes the speed of growth in category 1 is the proportionality factor between balance in category 1 and category 2. The dissipation coefficient in the growth model is attributable to two factors passage of time and DETRITION DUE TO Quantum Information (For examples please see Hawking Radiation essays and others at the end written in the form of epilogue to substantiate the factors that are used in the paper. Nevertheless, one instantaneous example that comes to mind is the following:

Quantum engineering via dissipation is an example of dissipation of Quantum Information. Due to the ongoing miniaturization of devices, one of the central challenges of the 21st century's technology will be to handle **quantum effects** at the Nanoscale. A first fundamental paradigm shift happened in the mid '90s when it was realized that quantum effects, which from the traditional point of view put fundamental limits on the possible miniaturization, could be exploited to do information theoretic tasks impossible with classical devices. The main obstacle in building such quantum devices however is the **occurrence of** decoherence, by which coherence within the quantum device gets **degraded due** to the **coupling with** the environment. In second proposal, a second paradigm shift was resorted to, by demonstrating that one can actually **take advantage of** decoherence if engineered in a smart way. The central focus will be the study of quantum processes driven by **dissipation**, and investigations whether quantum coherence and the associated applications can actually be **driven(eb) by** decoherence. The main tools that we plan to use to achieve that goal **originate from** the theory of quantum entanglement. The timing of this innovative project is actually perfect as the field of entanglement theory is just mature enough to pursue the ambitious goals stated in this proposal.

The main objectives of this proposal are:

(1)To set up a rigorous mathematical framework for studying fixed points and convergence rates of dissipative processes;(2)To investigate how highly entangled quantum states arising in strongly correlated quantum systems or in a quantum information theoretic context can be created by dissipative processes;(3)To study quantum devices powered by dissipation such as quantum memories and quantum Metropolis devices;(4)To use such devices to come up with novel ways for implementing quantum computation in the presence of decoherence(Decoherence dissipates Quantum entanglement)(5)To study non-equilibrium phase transitions driven by dissipation and associated to that new possible phases of matter.

J. Hassel, H. Seppa, P. Helisto studied the RSFQ devices with selective dissipation for quantum information processing. They study the possibility to use frequency dependent damping in RSFQ circuits as means to **reduce** dissipation and **consequent** decoherence in RSFQ/qubit circuits. They also show that stable RSFQ operation can be achieved **by shunting** the **Josephson junctions** with an $\text{\$R\$}$ circuit instead of a plain resistor. A presentation of derived criteria for the stability of such an arrangement, and discuss the **effect** on decoherence and the optimization issues. We also design a simple flux generator aimed at manipulating flux qubits.

Robust edge states and non-Abelian excitations are another example of the Dissipation of Quantum information that occurs in systems be it natural or human made ,The trademark of topological states of matter, with promising applications such as 'topologically protected' quantum memory and computing. So far, topological phases have been exclusively discussed in a Hamiltonian context. Here we show that such phases and the associated topological protection and phenomena also emerge in open quantum systems with engineered dissipation. The specific system studied here is a quantum wire of spinless atomic fermions in an optical lattice coupled to a bath. The key feature of the dissipative dynamics described by a Lindblad master equation is the existence of Majorana edge modes, representing a non-local decoherence-free subspace. The isolation of the

edge states is enforced by a dissipative gap in the p -wave paired bulk of the wire. We describe dissipative non-Abelian braiding operations within the Majorana subspace, and illustrate the insensitivity to imperfections. Topological protection is granted by a non-trivial winding number of the system density matrix

In the following we discuss some salient points and cardinal aspects of the Quantum Dissipation which is an important phenomenon in Quantum Computers:

Motivation

The goal of *dissipative quantum mechanics* or 'quantum dissipation theory' is to formulate microscopic theories of irreversible behaviour of quantum systems. Simply speaking, one would like to understand processes like, e.g., *friction* or 'damping' on a microscopic level. This requires at least two things: 'friction' means that physical objects interact with each other, i.e., we need to talk about interactions. Furthermore, this occurs as a function of time for systems which are usually out of equilibrium, i.e., we need to talk about dynamics.

A further, more ambitious goal is to better understand the relation between microscopic and macroscopic theories, e.g., the relation between mechanics (classical or quantum) and statistical mechanics (again classical or quantum).

Already in classical (Newtonian) mechanics, the description of irreversible behaviour is a non-trivial problem. One can often introduce dissipation into microscopic equations by adding phenomenological terms, such as the velocity-dependent

damping term $\gamma \dot{x}(t)$ ($\gamma > 0$) in the damped (forced) harmonic oscillator,

$$\ddot{x}(t) + \gamma \dot{x}(t) + \omega^2 x(t) = f(t).$$

1)

In this example, one of the goals would be to derive this equation and to actually calculate γ from an underlying microscopic theory.

Other examples (some of these are very tough, some not so tough problems):

- What is the spontaneous photon emission rate of an atom in vacuum?
- What is the electrical resistance of a (small or large) piece of metal at very low temperatures?
- How does a Laser work?
- What is the typical time after which a given realisation of a qubit (a quantum two-level system as realised in, e.g., a linear ion trap, the charge or magnetic flux in superconducting junctions, the electron charge or spin in semiconductor quantum dots, the nuclear spin etc.) fails to operate in the desired manner?

Origin of Dissipation, System-Bath Theories

The most successful approach to quantum dissipation has been the use of *System-Bath Theories*, which will be the main topic of this chapter. The main idea is the following:

STEP 1: we divide the 'world' into two parts: a) the part we are really interested in (for example, all the conduction band electrons in a piece of metal), and b) the part we are not so much interested in (for example, all the rest of the metal). This splitting obviously is a choice that depends on what we want to describe/calculate

STEP 2: Call these two parts 'system' and 'reservoir', identify the interaction between system and reservoir, and then derive an effective theory for the Example

Single oscillator ('system') with angular frequency ω_0 , mass M , position x , coupled to $N \gg 1$ oscillators ('reservoir') with angular frequencies ω_i , masses m_i , position x_i , coupling of the form $c_i x_i x$ via position coordinates.

The coupling leads to an effective dynamics of the system oscillator governed by the sum of many eigenmodes with eigenfrequencies. This sum is determined by the coupling constants c_i . For finite N , this is just a problem of coupled

oscillators, and the motion of the system oscillator must therefore be periodic with a (large) period T . The time T after which the entire system returns back to its initial starting point is called *Poincaré* time.

$$t \ll T \quad p$$

The key point now is: 1. For times $t \ll T$, the effective dynamics of the system (x and p of the system oscillator) very much resembles the dynamics we would expect from a *damped* system: a sum of many oscillatory terms with 'nearly

$$t \ll T$$

random' coefficients decays as a function of time t . 2. In most known cases, T is very, very large ('larger than the age of the universe'). This means that one can safely neglect the periodic 'Poincaré return' of the system.

Formal Splitting

The basic idea in microscopic theories of dissipation is a decomposition of a total system into a system S and a reservoir part R or B , 'bath'. The (Hamiltonian) dynamics of the total system is reversible, but the dynamics of the system S is

$$t \ll T$$

effectively not reversible for times $t \ll T$.

In this lecture, we formulate these ideas for quantum systems. The Hilbert space of the total system is defined by the tensor product

$$\mathcal{H}_{\text{total}} = \mathcal{H}_S \otimes \mathcal{H}_B. \quad \text{***}(2)$$

The Hamiltonian of the total system is defined as

$$H_{\text{total}} \equiv H \equiv H_S + H_{SB} + H_B \quad \text{***}(3)$$

Here and in the following, we will mostly discuss *time-independent* Hamiltonians. Time-dependent

$$H = H(t)$$

Hamiltonians can be treated

Overview

1. 'Simple' Systems with *few* degrees of freedom: typically quantum optics systems, atoms, few-level systems, cavity modes.

- Weak coupling approximation: Master Equation (Born and Markov Approximation)
- Damped harmonic oscillator.
- Solution methods: phase-space methods (P -representation etc.).
- Solution methods: quantum trajectories.
- Correlation Functions, Quantum Regression Theorem.
- Beyond weak coupling approximation: Feynman-Vernon influence functional (path integral) theories; R. P. Feynman, F. L. Vernon, Ann. Phys. (N.Y.) **24**, 118 (1963). Non-exponential decay laws at low temperatures.
- Exact solution of damped harmonic oscillator.
- Spin-Boson Problem, Two-Level System.
- Non-Markovian versus Markovian, Lindblad versus non-Lindblad.
- 'Non-standard' methods.

2. Systems with *many* degrees of freedom: typically condensed matter systems, electrons + phonons (particle statistics).

- Quasiclassical kinetic theories, Boltzmann equation.
- Quantum Many-Body Non-Equilibrium Methods. (Keldysh) Greens Function Methods, quantum Boltzmann equation.

In this chapter, we will concentrate on 1. ('Simple' Systems with *few* degrees of freedom). Also, not discussed in detail in this lecture are

- Nakajima-Zwanzig theories, Mori projection operator theories. These give a more formal approach towards system-bath theories.
- 'Early approaches' such as Wigner-Weisskopf theory of spontaneous emission.
- ...

Generally speaking, quantum dissipation can be regarded as a subfield of non-equilibrium quantum statistics/ non-equilibrium many-body theory. d as well but require additional techniques (e.g., Floquet theory for period time-dependence; adiabatic theorems for slow time-dependence).

Interaction Picture

We define an interaction picture by writing

$$H \equiv H_0 + V, \quad H_0 \equiv H_S + H_B, \quad V \equiv H_{SB} \tag{4}$$

with the Hamiltonian H_0 describing the time evolution of the uncoupled system and bath, and the perturbation V describing the interaction H_{SB} .

We define $\chi(t)$ as the total density matrix (system + bath) which obeys the Liouville-von-Neumann equation ,

$$\frac{d}{dt}\chi(t) = -i[H, \chi(t)] \rightsquigarrow \chi(t) = e^{-iHt}\chi(t=0)e^{iHt}, \tag{5}$$

where we start with the initial condition $\chi(t=0)$ at time $t=0$. In the interaction picture,

$$\tilde{\chi}(t) \equiv e^{iH_0t}\chi(t)e^{-iH_0t} \tag{6}$$

$$\tilde{A}(t) \equiv e^{iH_0t}Ae^{-iH_0t}. \tag{7}$$

The equation of motion for the density operator in the interaction picture becomes

$$\begin{aligned} \frac{d}{dt}\tilde{\chi}(t) &= i[H_0, \tilde{\chi}(t)] + e^{iH_0t}\frac{d}{dt}\chi(t)e^{-iH_0t} \\ &= i[H_0, \tilde{\chi}(t)] - ie^{iH_0t}[H, \chi(t)]e^{-iH_0t} \\ &= i[H_0, \tilde{\chi}(t)] - ie^{iH_0t}[H_0 + V, \chi(t)]e^{-iH_0t} \\ &= i[H_0, \tilde{\chi}(t)] - i[H_0 + \tilde{V}(t), \tilde{\chi}(t)] \\ &= -i[\tilde{V}(t), \tilde{\chi}(t)]. \end{aligned} \tag{8}$$

In integral form, this can be written as

$$\tilde{\chi}(t) = \chi(t=0) - i \int_0^t dt' [\tilde{V}(t'), \tilde{\chi}(t')] \tag{9}$$

which we insert into Eq. (7.8) to obtain

$$\frac{d}{dt} \tilde{\chi}(t) = -i [\tilde{V}(t), \chi(t=0)] - \int_0^t dt' [\tilde{V}(t), [\tilde{V}(t'), \tilde{\chi}(t')]] \tag{10}$$

Up t Effective Density Matrix of the System

$t > 0$

We wish to obtain an equation of motion for the *effective density matrix of the system* at time

$$\rho(t) \equiv \text{Tr}_B [\chi(t)] \tag{11}$$

This object is sufficient to calculate expectation values of *system operators* A_S :

$$\begin{aligned} \langle A_S \rangle_t &\equiv \text{Tr}_{\text{total}} [\chi(t) A_S] \\ &= \text{Tr}_S [\text{Tr}_B \chi(t)] A_S = \text{Tr}_S [\rho(t) A_S] \end{aligned} \tag{12}$$

Now use

$$\begin{aligned} \text{Tr}_B [\tilde{\chi}(t)] &= \text{Tr}_B e^{iH_0 t} \chi(t) e^{-iH_0 t} \\ &= e^{iH_S t} (\text{Tr}_B e^{iH_B t} \chi(t) e^{-iH_B t}) e^{-iH_S t} = e^{iH_S t} \rho(t) e^{-iH_S t} \\ &\equiv \tilde{\rho}(t) \end{aligned} \tag{13}$$

Note that the interaction picture $\rho(t) \leftrightarrow \tilde{\rho}(t)$ involves only the free *System Hamiltonian* H_S and not H_0 ,

$$\tilde{\rho}(t) \equiv e^{iH_S t} \rho(t) e^{-iH_S t} \tag{14}$$

Using

$$\tilde{A}_S(t) \equiv e^{iH_0 t} A_S e^{-iH_0 t} = e^{iH_S t} A_S e^{-iH_S t} \tag{15}$$

for system operators, one has

$$\langle A_S \rangle_t = \text{Tr}_S [\tilde{\rho}(t) \tilde{A}_S(t)] = \text{Tr}_S [\rho(t) A_S(t)] \tag{16}$$

Assumption (factorising initial condition):

$$\chi(t=0) = R_0 \otimes \rho(t=0) \tag{18}$$

$$R_0 \equiv \text{Tr}_S[\chi(t=0)], \quad \rho(t=0) \equiv \text{Tr}_B[\chi(t=0)].$$

This *factorisation assumption* is key to most of the results that follow. Its validity has been discussed and criticised in the past (see Weiss book for further references). Some of the issues are:

- Does the factorisation assumption only affect transient or also the long-time behaviour of the density matrix?
- Are there exactly solvable models where these issues can be clarified?

A theoretical formulation of time-evolution for arbitrary initial condition is sometimes possible: 'preparation function' (exact solution of dissipative quantum oscillator; Grabert, Ingold et al); generalisation of many-body Keldysh GF (three-by-three matrix instead of two-by-two matrix, M. Wagner).

Born Approximation

In the interaction picture,

$$\tilde{\chi}(t') = R_0 \otimes \tilde{\rho}(t=0) \text{ to zeroth order in } V. \tag{19}$$

The Born approximation in the equation of motion Eq.(7.17) consists in

$$\tilde{\chi}(t') \approx R_0 \otimes \tilde{\rho}(t') \tag{20}$$

Born approximation

This means one assumes that for all times $t' > 0$, the total density matrix remains a product of the initial bath density matrix R_0 and the system density matrix $\tilde{\rho}(t')$. Intuitively, one argues that this is justified when the bath is 'very large' and the coupling H_{SB} 'weak', so that the back-action of the system onto the bath can be neglected. In practice, one usually assumes a thermal equilibrium for the bath,

$$R_0 = \frac{e^{-\beta H_B}}{\text{Tr} e^{-\beta H_B}}, \tag{21}$$

thermal equilibrium bath,

where $\beta = 1/k_B T$ with T the bath equilibrium temperature.

Remark: A more detailed analysis of the Born approximation and alternative approximations can be done within the framework of the *Projection Operator formalism*.

Within the Born approximation, with Eq. (7.20), (7.18), and (7.17), one obtains a *closed integro-differential equation* for the reduced density operator $\tilde{\rho}(t)$ of the system in the interaction picture,

$$\frac{d}{dt} \tilde{\rho}(t) = -i \text{Tr}_B [\tilde{V}(t), R_0 \otimes \tilde{\rho}(t=0)] - \int_0^t dt' \text{Tr}_B [\tilde{V}(t), [\tilde{V}(t'), R_0 \otimes \tilde{\rho}(t')]].$$

*** (22)

Remark: Eq.(7.22) is exact up to second order in the perturbation V : set $\tilde{\rho}(t') = \rho(0)$ on the r.h.s. of Eq.(7.22).

Since $\tilde{\rho}(t')$ in the double commutator on the r.h.s. of Eq.(7.22) depends on V , Eq.(7.22) is to infinite order in V though not exact. Diagrammatically this corresponds to a summation of an infinite series of diagrams. It is non-trivial to make this statement more precise, but roughly speaking these diagrams contain certain vertex corrections as can be seen from the fact that $\rho(t)$ is a density matrix and not a wave function.

Motivation: telegraphic fluorescence (driven spontaneous emission) of single atoms

Example single V-systems: two upper levels 1 (fast spontaneous emission) and 2 (slow spontaneous emission), one lower level 0 driven by two lasers. Transition $0 \rightarrow 2$ traps the system in 2 for a long time. Resonance fluorescence intensity $I(t)$ therefore exhibits jumps: 'telegraphic fluorescence' with random switching between bright and dark periods. Aim: calculate distribution of dark periods.

Length T_D of dark period can be simply calculated from the density matrix element ρ_{22}

$$T_D^{-1} = \dot{\rho}_{22}(t=0), \quad \rho_{22} = 0, \quad \text{*(138)}$$

where the derivative is calculated from the underlying equation of motion (Master equation). However, the calculation of other, more complicated quantities related to the description of telegraphic fluorescence turns out to be technically complicated within the Master equation formalism. Example: 'exclusive probability' $P_0(t)$ that, after an emission at time $t = 0$, no other photon has been emitted in the time interval $[0, t]$.

- Some people raise 'objections' against the traditional Master equation approach: the density operator describes *ensembles* of quantum systems and is therefore inappropriate to describe *single* quantum systems such as a single ion in an ion trap. However, these objections are unjustified; as long as one sticks with the probabilistic interpretation of Quantum Mechanics, the density operator description is perfectly valid for a *single* quantum system.
- 'Single quantum systems' can not only be realised in ion traps, but also in 'artificial atoms' and 'artificial molecules' (solid state based quantum dots, superconducting charge or flux qubits). These will be discussed in a later chapter.

QUANTUM COMPUTER AND QUANTUM MECHANICAL BEHAVIOUR- A DUAL SYSTEM ANALYSIS

Various present and future specialized applications of magnets require monodisperse, small magnetic particles, and the discovery of molecules that can function as Nanoscale magnets was an important development in this regard^{1,2,3}. These molecules act as single-domain magnetic particles that, below their blocking temperature, exhibit magnetization hysteresis, a classical property of macroscopic magnets. Such 'single-molecule magnets' (SMMs)⁴ straddle the interface between classical and quantum mechanical behaviour because they also display quantum tunnelling of magnetization^{5,6} and quantum phase interference⁷. Quantum tunnelling of magnetization can be advantageous for some potential applications of SMMs, for example, in providing the quantum superposition of states required for quantum computing⁸. However, it is a disadvantage in other applications, such as information storage, where it would lead to information loss. Thus it is important to both understand and control the quantum properties of SMMs. Here we report a supramolecular SMM dimer in which antiferromagnetic coupling between the two components results in quantum behaviour different from that of the individual SMMs. Our experimental observations and theoretical analysis suggest a means of tuning the quantum tunnelling of magnetization in SMMs. This system may also prove useful for studying quantum tunnelling of relevance to mesoscopic antiferromagnets.

he Possibilities of Quantum Computing

The special properties of qubits will allow quantum computers to work on millions of computations at once, while desktop PCs can typically handle minimal simultaneous computations. For example, a single 250-qubit state contains more bits of information than there are atoms in the universe.

These properties will have wide-spread implications foremost for the field of data encryption where quantum computers could factor very large numbers like those used to decode and encode sensitive information.

"The quantum computing work we are doing shows it is no longer just a brute force physics experiment. It's time to start creating systems based on this science that will take computing to a new frontier," says IBM scientist Matthias Steffen,

manager of the IBM Research team that's focused on developing quantum computing systems to a point where it can be applied to real-world problems.

Other potential applications for quantum computing may include searching databases of unstructured information, performing a range of optimization tasks and solving previously unsolvable mathematical problems.

How Quantum Computing Works

The most basic piece of information that a typical computer understands is a bit. Much like a light that can be switched on or off, a bit can have only one of two values: "1" or "0". For qubits, they can hold a value of "1" or "0" as well as both values at the same time. Described as superposition, this is what allows quantum computers to perform millions of calculations at once.

One of the great challenges for scientists seeking to harness the power of quantum computing is controlling or removing quantum decoherence – the creation of errors in calculations caused by interference from factors such as heat, electromagnetic radiation, and materials defects. To deal with this problem, scientists have been experimenting for years to discover ways of reducing the number of errors and of lengthening the time periods over which the qubits retain their quantum mechanical properties. When this time is sufficiently long, error correction schemes become effective making it possible to perform long and complex calculations.

There are many viable systems that can potentially lead to a functional quantum computer. IBM is focusing on using superconducting qubits that will allow a more facile transition to scale up and manufacturing.

IBM has recently been experimenting with a unique "three dimensional" superconducting qubit (3D qubit), an approach that was initiated at Yale University. Among the results, the IBM team has used a 3D qubit to extend the amount of time that the qubits retain their quantum states up to 100 microseconds – an improvement of 2 to 4 times upon previously reported records. This value reaches just past the minimum threshold to enable effective error correction schemes and suggests that scientists can begin to focus on broader engineering aspects for scalability.

3D" superconducting qubit device where a qubit (about 1mm in length) is suspended in the center of the cavity on a small Sapphire chip. The cavity is formed by closing the two halves, and measurements are done by passing microwave signals to the connectors. Despite the apparent large feature size (the cavity is about 1.5 inches wide) for this single qubit demonstration, the team believes it is possible to scale such a system to hundreds or thousands of qubits.

A picture of IBM's "3D" superconducting qubit device where a qubit (about 1mm in length) is suspended in the center of the cavity on a small Sapphire chip. The cavity is formed by closing the two halves, and measurements are done by passing microwave signals to the connectors. Despite the apparent large feature size (the cavity is about 1.5 inches wide) for this single qubit demonstration, the team believes it is possible to scale such a system to hundreds or thousands of qubits.

In separate experiments, the group at IBM also demonstrated a more traditional "two-dimensional" qubit (2D qubit) device and implemented a two-qubit logic operation – a controlled-NOT (CNOT) operation, which is a fundamental building block of a larger quantum computing system. Their operation showed a 95 percent success rate, enabled in part due to the long coherence time of nearly 10 microseconds. These numbers are on the cusp of effective error correction schemes and greatly facilitate future multi-qubit experiments.

Imagine a computer whose memory is exponentially larger than its apparent physical size; a computer that can manipulate an exponential set of inputs simultaneously; a computer that computes in the twilight zone of Hilbert space. You would be thinking of a quantum computer. Relatively few and simple concepts from quantum mechanics are needed to make quantum computers a possibility. The subtlety has been in learning to manipulate these concepts. Is such a computer an inevitability or will it be too difficult to build?

Quantum Mechanics can be used to improve computation. Our challenge: solving an exponentially difficult problem for a conventional computer---that of factoring a large number. As a prelude, there are standard tools of computation, universal gates and machines. These ideas are then applied first to classical, dissipation less computers and then to quantum computers. A schematic model of a quantum computer is described as well as some of the subtleties in its programming. The Shor algorithm for efficiently factoring numbers on a quantum computer is presented in two parts: the quantum procedure within the algorithm and the classical algorithm that calls the quantum procedure. The mathematical structure in factoring which makes the Shor algorithm possible has been studied widely by many authors.. .

Let us start by describing the problem at hand: factoring a number N into its prime factors (e.g., the number **51688** may be

$$2^3 \times 7 \times 13 \times 71$$

decomposed as). A convenient way to quantify how quickly a particular algorithm may solve a problem is to ask how the number of steps to complete the algorithm scales with the size of the "input" the algorithm is fed.

$$\log N$$

For the factoring problem, this input is just the number N we wish to factor; hence the length of the input is . (The base of the logarithm is determined by our numbering system. Thus a base of **2** gives the length in binary; a base of **10** in decimal.) 'Reasonable' algorithms are ones which scale as some small-degree polynomial in the input size (with a degree of perhaps **2** or **3**).

On conventional computers the best known factoring algorithm runs

$$O(\exp[(64/9)^{1/3}(\ln N)^{1/3}(\ln \ln N)^{2/3}])$$

in $\log N$ steps. This algorithm, therefore, scales exponentially with the

input size $\log N$.

For instance, in 1994 a 129 digit number (known as RSA129) was successfully factored using this algorithm on approximately 1600 workstations scattered around the world; the entire factorization took eight months. Using this to estimate the prefactor of the above exponential scaling, we find that it would take roughly 800,000 years to factor a 250 digit number with the same computer power; similarly, a 1000 digit number would require 10^{25} years (significantly longer than the age of the universe). The difficulty of factoring large numbers is crucial for public-key cryptosystems, such as ones used by banks. There, such codes rely on the difficulty of factoring numbers with around 250 digits.

$$O((\log N)^{2+\epsilon})$$

Recently, an algorithm was developed for factoring numbers on a quantum computer which runs in steps where ϵ is small. This is roughly quadratic in the input size, so factoring a 1000 digit number with such an algorithm would require only a few million steps. The implication is that public key cryptosystems based on factoring may be breakable.

To give you an idea of how this exponential improvement might be possible, we review an elementary quantum mechanical experiment that demonstrates where such power may lie hidden. The two-slit experiment is prototypic for observing quantum mechanical behavior: A source emits photons, electrons or other particles that arrive at a pair of slits. These particles undergo unitary evolution and finally measurement. We see an interference pattern, with both slits open, which wholly vanishes if either slit is covered. In some sense, the particles pass through both slits in parallel. If such unitary evolution were to represent a calculation (or an operation within a calculation) then the quantum system would be performing computations in parallel. Quantum parallelism comes for free. The output of this system would be given by the constructive interference among the parallel computations.

The traditional management skills of planning, organizing, directing and controlling are inadequate in the fast-paced, constantly changing, highly complex world of twenty-first century organizations. Concepts from quantum mechanics and chaos theory as metaphors for a new management skill set can enable managers to actualize more of their leadership potential. The seven quantum skills are ancient and futuristic, scientific and spiritual, simple and complex. Together they form a model that balances the traditional left-brain management skills with new skills that more fully utilize both hemispheres of the brain. As managers master these skills, they transcend the limitations of mechanistic, deterministic, reductionistic thinking and become authentic change masters, changing themselves and their organizations at depth.

Quantum computing (For details see Andrew Steane A. M. Steane, Reports on Progress in Physics, vol 61, pp 117-173 (1998)).

The subject of quantum computing brings together ideas from classical information theory, computer science, and quantum physics. This review aims to summarize not just quantum computing, but the whole subject of quantum information theory. It turns out that information theory and quantum mechanics fit together very well. In order to explain their relationship, the review begins with an introduction to classical information theory and computer science, including Shannon's theorem, error correcting codes, Turing machines and computational complexity. The principles of quantum mechanics are then outlined, and the EPR experiment described. The EPR-Bell correlations and quantum entanglement in general, form the essential new ingredient which distinguishes quantum from classical information theory, and, arguably, quantum from classical physics. Basic quantum information ideas are described, including key distribution, teleportation, data compression, quantum error correction, the universal quantum computer and quantum algorithms. The common theme of all these ideas is the use of quantum entanglement as a computational resource. Experimental methods for small quantum processors are briefly sketched, concentrating on ion traps, high Q cavities, and NMR. The review concludes with an outline of the main features of quantum information physics, and avenues for future research.

The science of physics seeks to ask, and find precise answers to, basic questions about why nature is as it is. Historically, the fundamental principles of physics have been concerned with questions such as "what are things made of?" and "why do things move as they do?" In his *Principia*, Newton gave very wide-ranging answers to some of these questions. By showing that the same mathematical equations could describe the motions of everyday objects and of planets, he showed that an everyday object such as a tea pot is made of essentially the *same sort of stuff* as a planet: the motions of both can be described in terms of their mass and the forces acting on them. Nowadays we would say that both move in such a way as to conserve energy and momentum. In this way, physics allows us to abstract from nature concepts such as energy or momentum which always obey fixed equations, although the same energy might be expressed in many different ways: for example, an electron in the large electron-positron collider at CERN, Geneva, can have the same kinetic energy as a slug on a lettuce leaf.

Another thing which can be expressed in many different ways is *information*. For example, the two statements "the quantum computer is very interesting" and "l'ordinateur quantique est tres interessant" have something in common, although they share no words. The thing they have in common is their *information* content. Essentially the same information could be expressed in many other ways, for example by substituting numbers for letters in a scheme such as $a \rightarrow 97$, $b \rightarrow 98$, $c \rightarrow 99$ and so on, in which case the English version of the above statement becomes 116 104 101 32 113 117 97 110 116 117 109... . It is very significant that information can be expressed in different ways without losing its essential nature, since this leads to the possibility of the automatic manipulation of information: a machine need only be able to manipulate quite simple things like integers in order to do surprisingly powerful information processing, from document preparation to differential calculus, even to translating between human languages. We are familiar with this now, because of the ubiquitous computer, but even fifty years ago such a widespread significance of automated information processing was not foreseen.

However, there is one thing that all ways of expressing information must have in common: they all use real physical things to do the job. Spoken words are conveyed by air pressure fluctuations, written ones by arrangements of ink molecules on paper, even thoughts depend on neurons (Landauer 1991). The rallying cry of the information physicist is "no information without physical representation!" Conversely, the fact that information is insensitive to exactly how it is expressed, and can be freely translated from one form to another, makes it an obvious candidate for a fundamentally important role in physics, like energy and momentum and other such abstractions. However, until the second half of this century, the precise mathematical treatment of information, especially information processing, was undiscovered, so the significance of information in physics was only hinted at in concepts such as entropy in thermodynamics. It now appears that information may have a much deeper significance. Historically, much of fundamental physics has been concerned with discovering the fundamental particles of nature and the equations which describe their motions and interactions. It now appears that a different programme may be equally important: to discover the ways that nature allows, and prevents, information to be expressed and manipulated, rather than particles to move. For example, the best way to state exactly what can and cannot travel faster than light is to identify information as the speed-limited entity. In quantum mechanics, it is highly significant that the state vector must not contain, whether explicitly or implicitly, more information than can meaningfully be associated with a given system. Among other things this produces the wavefunction symmetry requirements which lead to Bose Einstein and Fermi Dirac statistics, the periodic structure of atoms, and so on.

Historically, the concept of information in physics does not have a clear-cut origin. An important thread can be traced if we consider the paradox of Maxwell's demon of 1871 (Fig. 1) (see also Brillouin 1956). Recall that Maxwell's demon is a creature that opens and closes a trap door between two compartments of a chamber containing gas, and pursues the subversive policy of only opening the door when fast molecules approach it from the right, or slow ones from the left. In this way the demon establishes a temperature difference between the two compartments without doing any work, in violation of the second law of thermodynamics, and consequently permitting a host of contradictions.

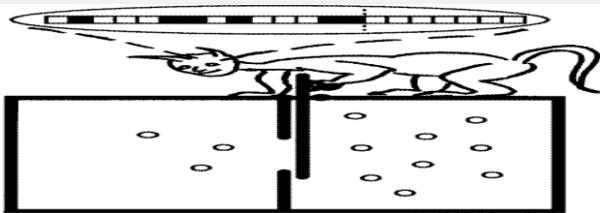

Fig. 1. Maxwell's demon. In this illustration the demon sets up a pressure difference by only raising the partition when more gas molecules approach it from the left than from the right. This can be done in a completely reversible manner, as long as the demon's memory stores the random results of its observations of the molecules. The demon's memory thus gets hotter. The irreversible step is not the acquisition of information, but the loss of information if the demon later clears its memory.

A number of attempts were made to exorcise Maxwell's demon (see Bennett 1987), such as arguments that the demon cannot gather information without doing work, or without disturbing (and thus heating) the gas, both of which are untrue. Some were tempted to propose that the 2nd law of thermodynamics could indeed be violated by the actions of an "intelligent being." It was not until 1929 that Leo Szilard made progress by reducing the problem to its essential components, in which the demon need merely identify whether a single molecule is to the right or left of a sliding partition, and its action allows a simple heat engine, called Szilard's engine, to be run. Szilard still had not solved the problem, since his analysis was unclear about whether or not the act of measurement, whereby the demon learns whether the molecule is to the left or the right, must involve an increase in entropy.

A definitive and clear answer was not forthcoming, surprisingly, until a further fifty years had passed. In the intermediate years digital computers were developed, and the physical implications of information gathering and processing were

carefully considered. The thermodynamic costs of elementary information manipulations were analyzed by Landauer and others during the 1960s (Landauer 1961, Keyes and Landauer 1970), and those of general computations by Bennett, Fredkin, Toffoli and others during the 1970s (Bennett 1973, Toffoli 1980, Fredkin and Toffoli 1982). It was found that almost anything can in principle be done in a reversible manner, i.e. with no entropy cost at all (Bennett and Landauer 1985). Bennett (1982) made explicit the relation between this work and Maxwell's paradox by proposing that the demon can indeed learn where the molecule is in Szilard's engine without doing any work or increasing any entropy in the environment, and so obtain useful work during one stroke of the engine. However, the information about the molecule's location must then be present in the demon's memory (Fig. 1). As more and more strokes are performed, more and more information gathers in the demon's memory. To complete a thermodynamic cycle, the demon must *erase* its memory, and it is during this erasure operation that we identify an increase in entropy in the environment, as required by the 2nd law. This completes the essential physics of Maxwell's demon; further subtleties are discussed by Zurek (1989), Caves (1990), and Caves, Unruh and Zurek (1990).

The thread we just followed was instructive, but to provide a complete history of ideas relevant to quantum computing is a formidable task. Our subject brings together what are arguably two of the greatest revolutions in twentieth-century science, namely quantum mechanics and information science (including computer science). The relationship between these two giants is illustrated in Figure 2.

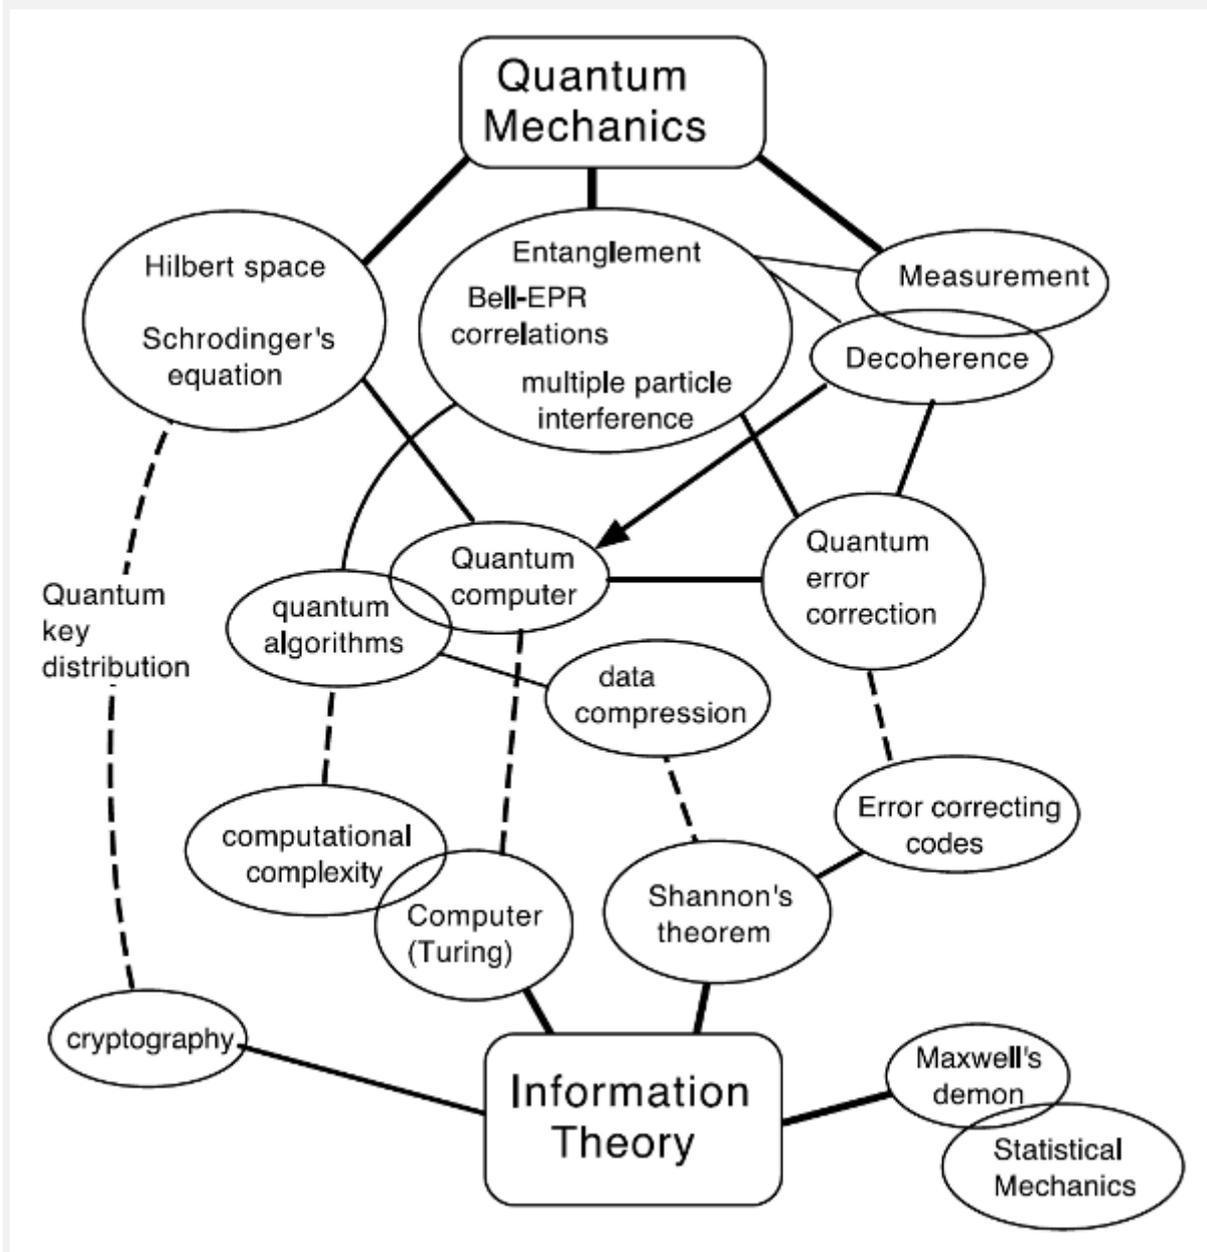

Fig. 2. Relationship between quantum mechanics and information theory. This diagram is not intended to be a definitive statement, the placing of entries being to some extent subjective, but it indicates many of the connections discussed in the article.

Classical information theory is founded on the definition of information. A warning is in order here. Whereas the theory tries to capture much of the normal meaning of the term 'information', it can no more do justice to the full richness of that term in everyday language than particle physics can encapsulate the everyday meaning of 'charm'. 'Information' for us will be an abstract term. Much of information theory dates back to seminal work of Shannon in the 1940's (Slepian 1974). The observation that information can be translated from one form to another is encapsulated and quantified in Shannon's noiseless coding theorem (1948), which quantifies the resources needed to store or transmit a given body of information. Shannon also considered the fundamentally important problem of communication in the presence of noise, and established Shannon's main theorem which is the central result of classical information theory. Error-free communication even in the presence of noise is achieved by means of 'error-correcting codes', and their study is a branch of mathematics in its own right. Indeed, the journal *IEEE Transactions on Information Theory* is almost totally taken up with the discovery and analysis of error-correction by coding. Pioneering work in this area was done by Golay (1949) and Hamming (1950).

The foundations of computer science were formulated at roughly the same time as Shannon's information theory, and this is no coincidence. The father of computer science is arguably Alan Turing (1912-1954), and its prophet is Charles Babbage (1791-1871). Babbage conceived of most of the essential elements of a modern computer, though in his day there was not the technology available to implement his ideas. A century passed before Babbage's Analytical Engine was improved upon when Turing described the Universal Turing Machine in the mid 1930s. Turing's genius (see Hodges 1983) was to clarify exactly what a calculating machine might be capable of, and to emphasise the role of programming, i.e. software, even more than Babbage had done. The giants on whose shoulders Turing stood in order to get a better view were chiefly the mathematicians David Hilbert and Kurt Gödel. Hilbert had emphasized between the 1890s and 1930s the importance of asking fundamental questions about the nature of mathematics. Instead of asking "is this mathematical proposition true?" Hilbert wanted to ask "is it the case that every mathematical proposition can in principle be proved or disproved?" This was unknown, but Hilbert's feeling, and that of most mathematicians, was that mathematics was indeed complete, so that conjectures such as Goldbach's (that every even number can be written as the sum of two primes) could be proved or disproved somehow, although the logical steps might be as yet undiscovered.

Gödel destroyed this hope by establishing the existence of mathematical propositions which were undecidable, meaning that they could be neither proved nor disproved. The next interesting question was whether it would be easy to identify such propositions. Progress in mathematics had always relied on the use of creative imagination, yet with hindsight mathematical proofs appear to be automatic, each step following inevitably from the one before. Hilbert asked whether this 'inevitable' quality could be captured by a 'mechanical' process. In other words, was there a universal mathematical method, which would establish the truth or otherwise of every mathematical assertion? After Gödel, Hilbert's problem was re-phrased into that of establishing decidability rather than truth, and this is what Turing sought to address.

In the words of Newman, Turing's bold innovation was to introduce 'paper tape' into symbolic logic. In the search for an automatic process by which mathematical questions could be decided, Turing envisaged a thoroughly mechanical device, in fact a kind of glorified typewriter (Fig. 3). The importance of the Turing machine (Turing 1936) arises from the fact that it is sufficiently complicated to address highly sophisticated mathematical questions, but sufficiently simple to be subject to detailed analysis. Turing used his machine as a theoretical construct to show that the assumed existence of a mechanical means to establish decidability leads to a contradiction. In other words, he was initially concerned with quite abstract mathematics rather than practical computation. However, by seriously establishing the idea of automating abstract mathematical proofs rather than merely arithmetic, Turing greatly stimulated the development of general purpose information processing. This was in the days when a "computer" was a person doing mathematics.

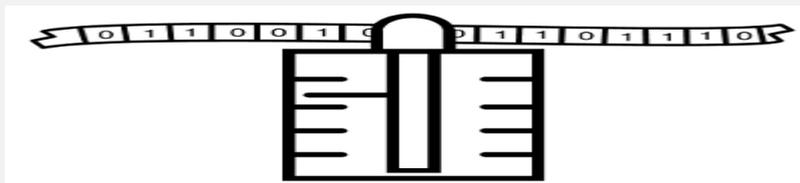

Fig. 3. The Turing Machine. This is a conceptual mechanical device which can be shown to be capable of efficiently simulating all classical computational methods. The machine has a finite set of internal states, and a fixed design. It reads one binary symbol at a time, supplied on a tape. The machine's action on reading a given symbol s depends only on that symbol and the internal state G . The action consists in overwriting a new symbol s' on the current tape location, changing state to G' , and moving the tape one place in direction d (left or right). The internal construction of the machine can therefore be specified by a finite fixed list of rules of the form $(s, G \rightarrow s', G', d)$. One special internal state is the 'halt' state: once in this state the machine ceases further activity. An input 'programme' on the tape is transformed by the machine into an output result printed on the tape.

Modern computers are neither Turing machines nor Babbage engines, though they are based on broadly similar principles, and their computational power is equivalent (in a technical sense) to that of a Turing machine. I will not trace their development here, since although this is a wonderful story, it would take too long to do justice to the many people involved.

Let us just remark that all of this development represents a great improvement in speed and size, but does not involve any change in the essential idea of what a computer is, or how it operates. Quantum mechanics raises the possibility of such a change, however.

Quantum mechanics is the mathematical structure which embraces, in principle, the whole of physics. We will not be directly concerned with gravity, high velocities, or exotic elementary particles, so the standard non-relativistic quantum mechanics will suffice. The significant feature of quantum theory for our purpose is not the precise details of the equations of motion, but the fact that they treat quantum amplitudes, or state vectors in a Hilbert space, rather than classical variables. It is this that allows new types of information and computing.

There is a parallel between Hilbert's questions about mathematics and the questions we seek to pose in quantum information theory. Before Hilbert, almost all mathematical work had been concerned with establishing or refuting particular hypotheses, but Hilbert wanted to ask what general type of hypothesis was even amenable to mathematical proof. Similarly, most research in quantum physics has been concerned with studying the evolution of specific physical systems, but we want to ask what general type of evolution is even conceivable under quantum mechanical rules.

The first deep insight into quantum information theory came with Bell's 1964 analysis of the paradoxical thought-experiment proposed by Einstein, Podolsky and Rosen (EPR) in 1935. Bell's inequality draws attention to the importance of correlations between separated quantum systems which have interacted (directly or indirectly) in the past, but which no longer influence one another. In essence his argument shows that the degree of correlation which can be present in such systems exceeds that which could be predicted on the basis of *any* law of physics which describes particles in terms of classical variables rather than quantum states. Bell's argument was clarified by Bohm (1951, also Bohm and Aharonov 1957) and by Clauser, Holt, Horne and Shimony (1969), and experimental tests were carried out in the 1970s (see Clauser and Shimony (1978) and references therein). Improvements in such experiments are largely concerned with preventing the possibility of any interaction between the separated quantum systems, and a significant step forward was made in the experiment of Aspect, Dalibard and Roger (1982), (see also Aspect 1991) since in their work any purported interaction would have either to travel faster than light, or possess other almost equally implausible qualities.

The next link between quantum mechanics and information theory came about when it was realized that simple properties of quantum systems, such as the unavoidable disturbance involved in measurement, could be put to practical use, in *quantum cryptography* (Wiesner 1983, Bennett *et al.* 1982, Bennett and Brassard 1984; for a recent review see Brassard and Crepeau 1996). Quantum cryptography covers several ideas, of which the most firmly established is quantum key distribution. This is an ingenious method in which transmitted quantum states are used to perform a very particular communication task: to establish at two separated locations a pair of identical, but otherwise random, sequences of binary digits, without allowing any third party to learn the sequence. This is very useful because such a random sequence can be used as a cryptographic key to permit secure communication. The significant feature is that the principles of quantum mechanics guarantee a type of conservation of quantum information, so that if the necessary quantum information arrives at the parties wishing to establish a random key, they can be sure it has not gone elsewhere, such as to a spy. Thus the whole problem of compromised keys, which fills the annals of espionage, is avoided by taking advantage of the structure of the natural world.

While quantum cryptography was being analyzed and demonstrated, the quantum computer was undergoing a quiet birth. Since quantum mechanics underlies the behaviour of all systems, including those we call classical ("even a screwdriver is quantum mechanical", Landauer (1995)), it was not obvious how to conceive of a distinctively quantum mechanical computer, i.e. one which did not merely reproduce the action of a classical Turing machine. Obviously it is not sufficient merely to identify a quantum mechanical system whose evolution could be interpreted as a computation; one must prove a much stronger result than this. Conversely, we know that classical computers can simulate, by their computations, the evolution of any quantum system... with one reservation: no classical process will allow one to prepare separated systems whose correlations break the Bell inequality. It appears from this that the EPR-Bell correlations are the quintessential quantum-mechanical property (Feynman 1982).

In order to think about computation from a quantum-mechanical point of view, the first ideas involved converting the action of a Turing machine into an equivalent reversible process, and then inventing a Hamiltonian which would cause a quantum system to evolve in a way which mimicked a reversible Turing machine. This depended on the work of Bennett (1973; see also Lecerf 1963) who had shown that a universal classical computing machine (such as Turing's) could be made reversible while retaining its simplicity. Benioff (1980, 1982) and others proposed such Turing-like Hamiltonians in the early 1980s. Although Benioff's ideas did not allow the full analysis of quantum computation, they showed that unitary quantum evolution is at least as powerful computationally as a classical computer.

A different approach was taken by Feynman (1982, 1986) who considered the possibility not of universal computation, but of universal *simulation* -- i.e. a purpose-built quantum system which could simulate the *physical behaviour* of any other. Clearly, such a simulator would be a universal computer too, since any computer must be a physical system. Feynman gave arguments which suggested that quantum evolution could be used to compute certain problems more efficiently than any

classical computer, but his device was not sufficiently specified to be called a computer, since he assumed that any interaction between adjacent two-state systems could be 'ordered', without saying how.

In 1985 an important step forward was taken by Deutsch. Deutsch's proposal is widely considered to represent the first blueprint for a quantum computer, in that it is sufficiently specific and simple to allow real machines to be contemplated, but sufficiently versatile to be a universal quantum simulator, though both points are debatable. Deutsch's system is essentially a line of two-state systems, and looks more like a register machine than a Turing machine (both are universal classical computing machines). Deutsch proved that if the two-state systems could be made to evolve by means of a specific small set of simple operations, then *any* unitary evolution could be produced, and therefore the evolution could be made to simulate that of any physical system. He also discussed how to produce Turing-like behaviour using the same ideas.

Deutsch's simple operations are now called quantum 'gates', since they play a role analogous to that of binary logic gates in classical computers. Various authors have investigated the minimal class of gates which are sufficient for quantum computation.

The two questionable aspects of Deutsch's proposal are its efficiency and realisability. The question of efficiency is absolutely fundamental in computer science, and on it the concept of 'universality' turns. A *universal* computer is one that not only can reproduce (i.e. simulate) the action of any other, but can do so without running too slowly. The 'too slowly' here is defined in terms of the number of computational steps required: this number must not increase exponentially with the size of the input. Deutsch's simulator is not universal in this strict sense, though it was shown to be efficient for simulating a wide class of quantum systems by Lloyd (1996). However, Deutsch's work has established the concepts of quantum networks (Deutsch 1989) and quantum logic gates, which are extremely important in that they allow us to think clearly about quantum computation.

In the early 1990's several authors (Deutsch and Jozsa 1992, Berthiaume and Brassard 1992, Bernstein and Vazirani 1993) sought computational tasks which could be solved by a quantum computer more efficiently than *any* classical computer. Such a quantum algorithm would play a conceptual role similar to that of Bell's inequality, in defining something of the essential nature of quantum mechanics. Initially only very small differences in performance were found, in which quantum mechanics permitted an answer to be found with certainty, as long as the quantum system was noise-free, where a probabilistic classical computer could achieve an answer 'only' with high probability. An important advance was made by Simon (1994), who described an efficient quantum algorithm for a (somewhat abstract) problem for which no efficient solution was possible classically, even by probabilistic methods. This inspired Shor (1994) who astonished the community by describing an algorithm which was not only efficient on a quantum computer, but also addressed a central problem in computer science: that of factorizing large integers.

Shor discussed both factorization and discrete logarithms, making use of a quantum Fourier transform method discovered by Coppersmith (1994) and Deutsch. Further important quantum algorithms were discovered by Grover (1997) and Kitaev (1995).

Just as with classical computation and information theory, once theoretical ideas about computation had got under way, an effort was made to establish the essential nature of quantum information -- the task analogous to Shannon's work. The difficulty here can be seen by considering the simplest quantum system, a two-state system such as a spin half in a magnetic field. The quantum state of a spin is a continuous quantity defined by two real numbers, so in principle it can store an infinite amount of classical information. However, a measurement of a spin will only provide a single two-valued answer (spin up/spin down) -- there is no way to gain access to the infinite information which appears to be there, therefore it is incorrect to consider the information content in those terms. This is reminiscent of the renormalization problem in quantum electrodynamics. How much information can a two-state quantum system store, then? The answer, provided by Jozsa and Schumacher (1994) and Schumacher (1995), is *one two-state system's worth!* Of course Schumacher and Jozsa did more than propose this simple answer, rather they showed that the two-state system plays the role in quantum information theory analogous to that of the bit in classical information theory, in that the quantum information content of *any* quantum system can be meaningfully measured as the minimum number of two-state systems, now called quantum bits or qubits, which would be needed to store or transmit the system's state with high accuracy.

Let us return to the question of realisability of quantum computation. It is an elementary, but fundamentally important, observation that the quantum interference effects which permit algorithms such as Shor's are extremely fragile: the quantum computer is ultra-sensitive to experimental noise and impression. It is not true that early workers were unaware of this difficulty; rather their first aim was to establish whether a quantum computer had any fundamental significance at all. Armed with Shor's algorithm, it now appears that such a fundamental significance is established, by the following argument: either nature does allow a device to be run with sufficient precision to perform Shor's algorithm for large integers (greater than, say, a googol which is 1 followed by 100 zeroes) or there are fundamental natural limits to precision in real systems. Both eventualities represent an important insight into the laws of nature.

At this point, ideas of quantum information and quantum computing come together. For, a quantum computer can be made much less sensitive to noise by means of a new idea which comes directly from the marriage of quantum mechanics with classical information theory, namely *quantum error correction*. Although the phrase 'error correction' is a natural one and was used with reference to quantum computers prior to 1996, it was only in that year that two important papers, of Calderbank and Shor, and independently Steane, established a general framework whereby quantum information processing can be used to combat a very wide class of noise processes in a properly designed quantum system. Much progress has since been made in generalizing these ideas (Knill and Laflamme 1997, Ekert and Macchiavello 1996, Bennett *et al.* 1996b, Gottesman 1996, Calderbank *et al.* 1997). An important development was the demonstration by Shor (1996) and Kitaev (1996) that correction can be achieved even when the corrective operations are themselves imperfect. Such methods lead to a general concept of 'fault tolerant' computing, of which a helpful review is provided by Preskill (1997).

If, as seems almost certain, quantum computation will only work in conjunction with quantum error correction, it appears that the relationship between quantum information theory and quantum computers is even more intimate than that between Shannon's information theory and classical computers. Error correction does not in itself guarantee accurate quantum computation, since it cannot combat all types of noise, but the fact that it is possible at all is a significant development.

A computer which only exists on paper will not actually perform any computations, and in the end the only way to resolve the issue of feasibility in quantum computer science is to build a quantum computer. To this end, a number of authors proposed computer designs based on Deutsch's idea, but with the physical details more fully worked out (Teich *et al.* 1988, Lloyd 1993, Berman *et al.* 1994, DiVincenzo 1995b). The great challenge is to find a sufficiently complex system whose evolution is nevertheless both coherent (i.e. unitary) and controllable. It is not sufficient that only some aspects of a system should be quantum mechanical, as in solid-state 'quantum dots', or that there is an implicit assumption of unfeasible precision or cooling, which is often the case for proposals using solid-state devices. Cirac and Zoller (1995) proposed the use of a linear ion trap, which was a significant improvement in feasibility, since heroic efforts in the ion trapping community had already achieved the necessary precision and low temperature in experimental work, especially the group of Wineland who demonstrated cooling to the ground state of an ion trap in the same year (Diedrich *et al.* 1989, Monroe *et al.* 1995). More recently, Gershenfeld and Chuang (1997) and Cory *et al.* (1996,1997) have shown that nuclear magnetic resonance (NMR) techniques can be adapted to fulfill the requirements of quantum computation, making this approach also very promising. Other recent proposals of Privman *et al.* (1997) and Loss and DiVincenzo (1997) may also be feasible.

As things stand, no quantum computer has been built, nor looks likely to be built in the author's lifetime, if we measure it in terms of Shor's algorithm, and ask for factoring of large numbers. However, if we ask instead for a device in which quantum information ideas can be explored, then only a few quantum bits are required, and this will certainly be achieved in the near future. Simple two-bit operations have been carried out in many physics experiments, notably magnetic resonance, and work with three to ten qubits now seems feasible. Notable recent experiments in this regard are those of Brune *et al.* (1994), Monroe *et al.* (1995b), Turchette *et al.* (1995) and Mattle *et al.* (1996).

STABILITY AND INSTABILITY OF QUANTUM INFORMATION:

Stability Diagram of a Few-Electron Triple Dot

Individual and coupled quantum dots containing one or two electrons have been realized and are regarded as components for future quantum information circuits. Mapping out has been done several authors(see references) out experimentally the stability diagram of the few electron triple dot system, the electron configuration map as a function of the external tuning parameters, and reveal experimentally for the first time the existence of quadruple points, a signature of the three dots being in resonance. In the vicinity of these quadruple points we observe a duplication of charge transfer transitions related to charge and spin reconfigurations triggered by changes in the total electron occupation number. These(e&eb) results are relevant for future quantum mechanical engineering applications within both quantum information and quantum cellular automata (QCA) architectures. A comparison between single quantum dots and real atoms confirms both analogous and dissimilar properties. Atomic-like shell structure and Hund's rules govern both systems. The very different energy scale of the artificial atom, however, manifests itself in novel interaction phenomena which have no analogue in real atoms, such as singlet triplet transitions and spin texture arrangements of electrons. The tunability of these devices makes them promising candidates for future quantum information applications as well as for fundamental studies of quantum molecular effects, and for exploiting nanospintronic functionalities

Stability, Gain, and Robustness in Quantum Feedback Networks (For details see C. D'Helon and M.R. James)

Problem of stability for quantum feedback networks, of quantum optics how stability of quantum feedback networks can be guaranteed using only simple gain inequalities for network components and algebraic relationships determined by the network. Quantum feedback networks are shown to be stable if the loop gain is less than one—this is an extension of the famous small gain theorem of classical control theory. Authors' illustrate the simplicity and power of the small gain approach with applications to important problems of robust stability and robust stabilization. Quantum feedback networks, stability, input-output stability, robustness, stabilization, quantum optics. Are all interrelated. Stable operation is a fundamental pre-requisite for the proper functioning of any technological system. Instability can cause some system variables to grow in magnitude without bound (or at least saturate or oscillate), with detrimental effects on performance and even damage. Consequently, methods for stability analysis and design have played an important role in the development of classical technologies. A significant early example was Watt's steam engine governor in the 1780's (subsequently analyzed by Maxwell in 1868), Indeed, one of the chief applications of feedback (but by no means the only application) is to stabilize systems that would otherwise be unstable. A striking example of this is the X29 plane, which has forward swept wings and requires the use of a stabilizing feedback control system. However, feedback per se does not guarantee stability: indeed, feedback can be "degenerative or regenerative—either stabilizing or destabilizing",. In particular, when interconnections of stable components include components with active elements, instability can occur (such as when a microphone is placed too close to a loudspeaker). An additional requirement of considerable practical importance is that stable operation be maintained in the presence of uncertainty (e.g., due to model error and approximation, altered operating conditions, etc.) and noise—this is a basic robustness requirement. Feedback is increasingly being used in the design of new technologies that include quantum components, In fact, a wide range of quantum technologies can be considered as networks of quantum and classical components which include cascade and feedback interconnections. Since these networks may include components that are active, e.g. optical amplifiers or classical amplifiers, questions of network stability are of considerable importance. Quantum input-output theory started developing in the 1980's, however general methods for stability analysis and design for quantum networks still do not apply to Theory of Quantum information

SOME STABILITY AND QUINTESSENTIAL REVIEWS ON QUANTUM COMPUTATION:

Loschmidt echoes (Tomaz Prosen, Thomas H. Seligman, Marko Znidaric

In this paper authors' investigate on the theoretical approach to quantum Loschmidt echoes, i.e. various properties of the so called echo dynamics -- the composition of forward and backward time evolutions generated by two slightly different Hamiltonians, such as the state autocorrelation function (fidelity) and the purity of a reduced density matrix traced over a subsystem (purity fidelity). Our main theoretical result is linear response formalism, expressing the fidelity and purity fidelity in terms of integrated time autocorrelation function of the generator of the perturbation. Surprisingly, this relation predicts that **the decay** of fidelity is the slower the faster the decay of correlations. In particular for a static (time-independent) perturbation, and for non-ergodic and non-mixing dynamics where asymptotic decay of correlations is absent, a qualitatively different and faster decay of fidelity is predicted on a time scale $1/\delta$ as opposed to mixing dynamics where the fidelity is found to decay exponentially on a time-scale $1/\delta^2$, where δ is a strength of perturbation. A detailed discussion of a semi-classical regime of small effective values of Planck constant is given where classical correlation functions can be used to predict quantum fidelity decay. Note that the correct and intuitively expected classical stability behavior is recovered in the classical limit, as the perturbation and classical limits do not commute. The theoretical results are demonstrated numerically for two models, the quantized kicked top and the multi-level Jaynes Cummings model. Method can for example be applied to the stability analysis of quantum computation and quantum information processing.

Towards scalable quantum information processing and quantum simulation with trapped ions(See Diedrich Leibfried)

Quantum information processing and experiments towards Quantum Information Processing (QIP) and Quantum Simulation (QS) with trapped ions are discussed. Most requirements for QIP and QS have been demonstrated in this system, with two big challenges remaining: Improving operation fidelity and scaling up to larger numbers of qubits. The architecture pursued by the Ion Stage Group at NIST is based on quantum information stored in long lived internal (hyperfine) states of the ions. We investigate the use of laser beams and microwave fields to induce both single-qubit rotations and multi-qubit gates mediated by the Coulomb interaction between ions. Moving ions through a multi-zone trap architecture allows for keeping the number of ions per zone small, while sympathetic cooling with a second ion species can remove energy and entropy from the system. After an introduction to these elements, I will discuss the current status of experiments and some future perspectives for QIP and QS as well as for other applications based on trapped ions.

Quantum circuits: from concept to future applications (Armand C. R. Niederberger)

Current experimental progress in quantum optics and nanophotonics is establishing a solid base for fascinating future applications. We may soon be able to create integrated circuits of nanophotonic components for ultra-low power and ultra-high speed optical switching. My theory seminar presents the methods with which we are currently studying photonic circuit models and discusses examples of circuits for classical photonic logic. Nanophotonics in general and the advantages of using optical interconnects over electronic interconnects in particular. Second, I present our high-level quantum hardware description language which links graphical circuit design tools with recent mathematical developments to describe open quantum optical networks, thus enabling scientists and engineers to simulate quantum circuits without having to deal with

the details of quantum optics. Third, author shows how to perform design optimization on nanophotonics circuits using adjoint calculus. This method is based on the use of Lagrange multipliers and drastically **reduces** the number of computations in parameter optimization and stability analysis.

Does a closed quantum system equilibrate? (Paolo Zanardi)

Author discusses the issue of whether and how we can make sense of the notion of **equilibration("convergence" to equilibrium)** for a large but finite quantum system with only internal degrees of freedom. (i.e., closed). It is illustrated that the results on equilibration of the Loschmidt echo in nearly-critical quantum many-body systems evolving unitarily.

Quantum wavelength conversion and transmission in opto mechanical systems(Lin Tian)

Optomechanical systems with strong light-matter interaction can be explored as an interface between photon modes of distinct wavelengths, e.g. an optical mode and a microwave mode. Authors' study transient and adiabatic schemes for cavity state conversion and for photon transmission in the optomechanical system. Author states that his results can be applied to various applications in optical quantum information processing, such as photon pulse generation and state manipulation, quantum repeaters, and conversion of information between different photon modes.

Protecting quantum gates from control noise (Constantin Brif)

External controls are necessary to enact quantum logic operations, and the inevitable **control** noise will **result in** gate errors in a realistic quantum circuit. Author investigates the robustness of quantum gates to random noise in an optimal control field, by utilizing properties of the quantum control landscape that relates the physical objective (in the present case, the quantum gate fidelity) to the applied controls. An approximate result obtained for the statistical expectation value of the gate fidelity in the weak noise regime is shown to be in excellent agreement with direct Monte Carlo sampling over noise process realizations for fidelity values relevant for practical quantum information processing. Using this approximate result, they demonstrate that maximizing the robustness to additive/multiplicative white noise **is equivalent to** minimizing the total control time/fluence. Also, a genetic optimization algorithm is **used to identify controls** with improved robustness to colored noise.

Exciton-Polariton Quantum Emulators (Na Young Kim)

Microcavity exciton-polaritons are hybrid light-matter quasi-particles **arising from** the mixed states between cavity photons and quantum well excitons. The inherent light matter duality **provides** experimental advantages: the stimulated scattering among interacting particles and the small effective mass ($\sim 10e-8$ times the hydrogen atom) **form** coherent condensate states at high temperatures (e.g. 4 K in GaAs and room temperature in GaN materials). In addition, the dynamics of exciton-polaritons are accessed by capturing the leaked photons out of the cavity due to the short lifetime. **Utilizing** coherence and open-dissipative nature of exciton-polariton condensates, we engineer a two-dimensional (2D) polariton-lattice system for investigating exotic quantum phase order. Via micro-photoluminescence measurements in both real and momentum spaces, authors' have observed d-orbital condensate states, vortex-antivortex phase order, massless Dirac dispersions in 2D square, honeycomb, and triangular lattices respectively. These results **demonstrate** that the polariton-lattice systems will be promising solid-state quantum emulators in the quest for better understanding strongly correlated materials and in the development of novel optoelectronic devices.

Benchmarking and Protecting Adiabatic Quantum Computation(Daniel Lidar)

How many bits does it take to track an open quantum system?

In general if one obtains information about an open quantum system by measuring its environment, that measurement will alter the future evolution of the system. However in the Markovian case this back-action is negligible and one can "track" the system i.e. assign it a (stochastically evolving) pure state at all times **without disturbing** its (deterministic) average evolution. In general this stochastic evolution **creates a** trajectory passing through infinitely many different pure states, even for a finite dimensional quantum system. Hence an infinite classical memory would be required to track such evolution. Here author shows that, for any ergodic master equation, there should **exist a** monitoring scheme (which in general must be adaptive) on the environment that can confine the system state to jumping between finitely many states, so that only a finitely large classical memory is required

Using symmetries to understand molecular devices and magnetic ad-atoms on substrates

Realizing a quantum transistor **built of** molecules or quantum dots has been one of the most ambitious challenges in nanotechnology. Even though remarkable progress has been made, being able to gate and **control** nanometer scale objects, as well to **interconnect** them to achieve scalability remains extremely difficult. Most experiments concern a single quantum dot or molecule, and they are made at ultra low temperature **to avoid** decoherence and tunnelling. Author proposes to use canonical transformations **to design** quantum devices that are **protected** by symmetry, and therefore, may be operational at high temperatures. We illustrate the idea with an example of a quantum transistor controlled by a gate electrode in a three terminal setup. They consider the **effects of** interactions, and we find that the same principles can be applied to design a device that could operate as an electrically controlled spin qubit. Author shows that similar but more sophisticated principles can be used to improve our understanding **of the effects of magnetic ad-atoms on substrates, such as** graphene.

Quantum Annealing with Superconducting Flux Qubits(Mark Jonson)

D-Wave Systems has implemented a processor based on Quantum Annealing, an algorithm for finding the ground state of a system of interacting spins. The technology is built on a superconducting chip composed of flux qubits that enable a quantum annealing algorithm, and digital components that apply programmable on-chip flux biases. In this presentation, author reviews Quantum Annealing, and then give a brief overview of the processor architecture. He also discusses a method for observing the system dynamics during the annealing process for a sample eight spin problem instance, and describe how the temperature dependence of these **dynamics(eb)** provides a signature of Quantum Annealing.*

QUANTUM MECHANICAL BEHAVIOUR AND QUANTUM COMPUTER

GOVERNING EQUATIONS

Quantum gravity (QG) is the field of theoretical physics which attempts to develop scientific models that unify quantum mechanics (describing three of the four known fundamental interactions) with general relativity (describing the fourth, gravity). It is hoped that development of such a theory would unify into a single mathematical framework all fundamental interactions and to describe all known observable interactions in the universe, at both subatomic and cosmological scales. Such a theory of quantum gravity would yield the same experimental results as ordinary quantum mechanics in conditions of weak gravity (gravitational potentials much less than c^2) and the same results as Einsteinian general relativity in phenomena at scales much larger than individual molecules (action much larger than reduced Planck's constant), but moreover be able to predict the outcome of situations where both quantum effects and strong-field gravity are important (at the Planck scale, unless large extra dimension conjectures are correct). If the theory of quantum gravity also achieves a grand unification of the other known interactions, it is referred to as a theory of everything (TOE).

Motivation for quantizing gravity comes from the remarkable success of the quantum theories of the other three fundamental interactions, and from experimental evidence suggesting that gravity can be made to show quantum effects. Although some quantum gravity theories such as string theory and other unified field theories (or 'theories of everything') attempt to unify gravity with the other fundamental forces, others such as loop quantum gravity make no such attempt; they simply quantize the gravitational field while keeping it separate from the other forces.

Observed physical phenomena can be described well by quantum mechanics or general relativity, without needing both. This can be thought of as due to an extreme separation of mass scales at which they are important. Quantum effects are usually important only for the "very small", that is, for objects no larger than typical molecules. General relativistic effects, on the other hand, show up mainly for the "very large" bodies such as collapsed stars. (Planets' gravitational fields, as of 2011, are well-described by linearised except for Mercury's perihelion precession; so strong-field effects—any effects of gravity beyond lowest nonvanishing order in ϕ/c^2 —have not been observed even in the gravitational fields of planets and main sequence stars). There is a lack of experimental evidence relating to quantum gravity, and classical physics adequately describes the observed effects of gravity over a range of 50 orders of magnitude of mass, i.e., for masses of objects from about 10^{-23} to 10^{30} kg.

Much of the difficulty in meshing these theories at all energy scales comes from the different assumptions that these theories make on how the universe works. Quantum field theory depends on particle fields embedded in the flat space-time of special relativity. General relativity models gravity as a curvature within space-time that changes as a gravitational mass moves. Historically, the most obvious way of combining the two (such as treating gravity as simply another particle field) ran quickly into what is known as the renormalization problem. In the old-fashioned understanding of renormalization, gravity particles would attract each other and adding together all of the interactions results in many infinite values which cannot easily be cancelled out mathematically to yield sensible, finite results. This is in contrast with quantum electrodynamics where, while the series still do not converge, **the interactions** sometimes evaluate to infinite results, but those are few enough in number to **be removable via renormalization**.

Effective field theories

Quantum gravity can be treated as an effective field theory. Effective quantum field theories come with some high-energy cutoff, beyond which we do not expect that the theory provides a good description of nature. The "infinities" then become large but finite quantities proportional to this finite cutoff scale, and correspond to processes that involve very high energies near the fundamental cutoff. These quantities can then be absorbed into an infinite collection **of coupling constants**, and at energies **well below** the fundamental cutoff of the theory, to any desired precision; only a finite number of **these coupling constants** need to be measured in order to make legitimate quantum-mechanical predictions. This same logic works just as well for the highly successful theory of low-energy pions as for quantum gravity. Indeed, the first quantum-mechanical corrections to graviton-scattering and Newton's law of gravitation have been explicitly computed (although they are so astronomically small that we may never be able to measure them). In fact, gravity is in many ways a much better quantum field theory than the Standard Model, since it appears to be valid all the way up to its cutoff at the Planck scale. (By comparison, the Standard Model is expected to start to break down above its cutoff at the much smaller scale of around 1000 GeV)

While confirming that quantum mechanics and gravity are indeed consistent at reasonable energies, it is clear that near or above the fundamental cutoff of our effective quantum theory of gravity (the cutoff is generally assumed to be of the order of the Planck scale), a new model of nature will be needed. Specifically, the problem of combining quantum mechanics and gravity becomes an issue only at very high energies, and may well require a totally new kind of model.

Quantum gravity theory for the highest energy scales

The general approach to deriving a quantum gravity theory that is valid at even the highest energy scales is to assume that such a theory will be simple and elegant and, accordingly, to study symmetries and other clues offered by current theories that might suggest ways **to combine them** into a comprehensive, **unified theory**. One problem with this approach is that it is unknown whether quantum gravity will actually conform to a simple and elegant theory, as it should resolve the dual conundrums of special relativity with regard to the uniformity of acceleration and gravity, and general relativity with regard to spacetime curvature.

Such a theory is required in order to understand problems involving the combination of very high energy and very small dimensions of space, such as the behavior of black holes, and the origin of the universe.

Quantum mechanics and general relativity**Gravity Probe B (GP-B) has measured spacetime curvature near Earth to test related models in application of Einstein's general theory of relativity.****The graviton**

At present, one of the deepest problems in theoretical physics is harmonizing the theory of general relativity, which describes gravitation, and applies to large-scale structures (stars, planets, galaxies), with quantum mechanics, which describes the other three fundamental forces acting on the atomic scale. This problem must be put in the proper context, however. In particular, contrary to the popular claim that quantum mechanics and general relativity are fundamentally incompatible, one can demonstrate that the structure of general relativity essentially follows inevitably from the quantum mechanics of interacting theoretical spin-2 massless particles (called gravitons).

While there is no concrete proof of the existence of gravitons, quantized theories of matter may necessitate their existence¹ Supporting this theory is the observation that all fundamental forces except gravity have one or more known messenger particles, leading researchers to believe that at least one most likely does exist; they have dubbed these hypothetical particles *gravitons*. Many of the accepted notions of a unified theory of physics since the 1970s, including string theory, superstring theory, M-theory, loop quantum gravity, all assume, and to some degree depend upon, the existence of the graviton. Many researchers view the detection of the graviton as vital to validating their work.

The dilaton

The dilaton made its first appearance in Kaluza–Klein theory, a five-dimensional theory that combined gravitation and electromagnetism. Generally, it appears in string theory. More recently, it has appeared in the lower-dimensional many-bodied gravity problem based on the field theoretic approach of Roman Jackiw. The impetus arose from the fact that complete analytical solutions for the metric of a covariant N -body system have proven elusive in General Relativity. To simplify the problem, the number of dimensions was lowered to $(I+1)$ namely one spatial dimension and one temporal dimension. **This model problem, known as $R=T$ theory (as opposed to the general $G=T$ theory)** was amenable to exact solutions in terms of a generalization of the Lambert W function. It was also found that the field equation governing the dilaton (derived from differential geometry) was the Schrödinger equation and consequently amenable to quantization. Thus, one had a theory which combined gravity, quantization and even the electromagnetic interaction, promising ingredients of a fundamental physical theory. It is worth noting that the outcome revealed a previously unknown and already existing *natural link* between general relativity and quantum mechanics. However, this theory needs to be generalized in $(2+1)$ or $(3+1)$ dimensions although, in principle, the field equations are amenable to such generalization as shown with the inclusion of a one-graviton process and yielding the correct Newtonian limit in d dimensions if a dilaton is included. However, it is not yet clear what the full field equation will govern the dilaton in higher dimensions. This is further complicated by the fact that gravitons can propagate in $(3+1)$ dimensions and consequently that would imply gravitons and dilatons exist in the real world. Moreover, detection of the dilaton is expected to be even more elusive than the graviton. However, since this approach allows for the combination of gravitational, electromagnetic and quantum effects, their coupling could potentially lead to a means of vindicating the theory, through cosmology and perhaps even *experimentally*.

Nonrenormalizability of gravity

General relativity, like electromagnetism, is a classical field theory. One might expect that, as with electromagnetism, there should be a corresponding quantum field theory. However, gravity is perturbatively nonrenormalizable. For a quantum field theory to be well-defined according to this understanding of the subject, it must be asymptotically free or asymptotically safe. The theory must be characterized by a choice of *finitely many* parameters, which could, in principle, be set by experiment. For example, in quantum electrodynamics, these parameters are the charge and mass of the electron, as measured at a particular energy scale. On the other hand, in quantizing gravity, there are *infinitely many independent parameters* (counterterm coefficients) needed to define the theory. For a given choice of those parameters, one could make sense of the theory, but since we can never do infinitely many experiments to fix the values of every parameter, we do not have a meaningful physical theory:

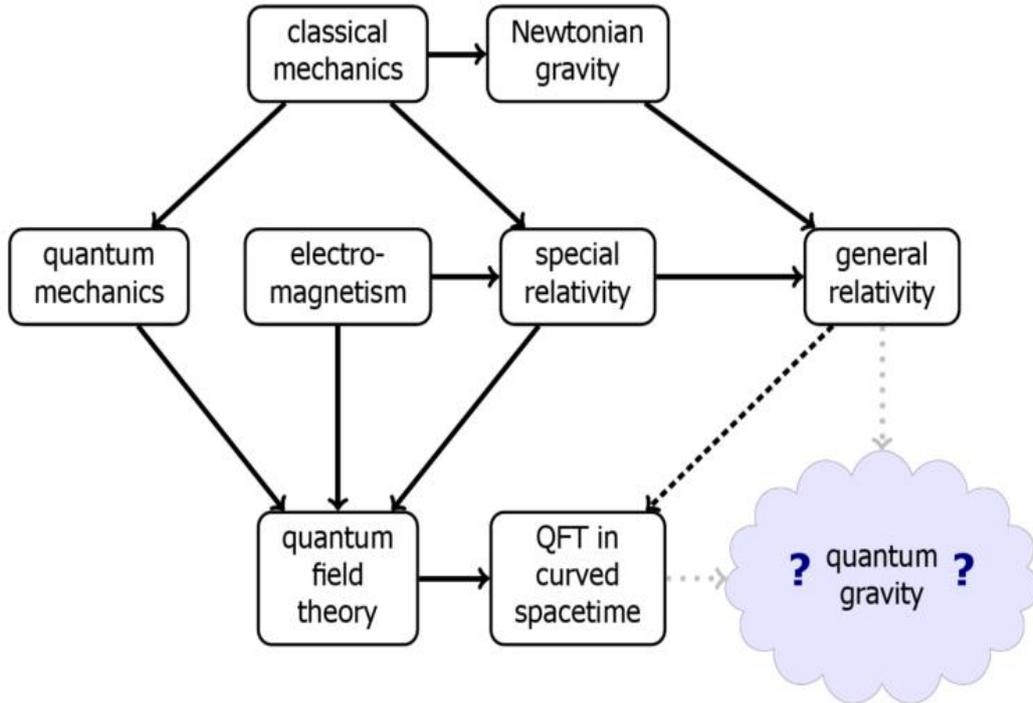

- At low energies, the logic of the renormalization group tells us that, despite the unknown choices of these infinitely many parameters, quantum gravity will reduce to the usual Einstein theory of general relativity.
- On the other hand, if we could probe very high energies where quantum effects take over, then *every one* of the infinitely many unknown parameters would begin to matter, and we could make no predictions at all.

As explained below, there is a way around this problem by treating QG as an effective field theory.

Any meaningful theory of quantum gravity that makes sense and is predictive at all energy scales must have some deep principle that reduces the infinitely many unknown parameters to a finite number that can then be measured.

- One possibility is that normal perturbation theory is not a reliable guide to the renormalizability of the theory, and that there really *is* a UV fixed point for gravity. Since this is a question of non-perturbative quantum field theory, it is difficult to find a reliable answer, but some people still pursue this option.
- Another possibility is that there are new symmetry principles that constrain the parameters and reduce them to a finite set. This is the route taken by string theory, where all of the excitations of the string essentially manifest themselves as new symmetries.

QUANTUM GRAVITY AS AN EFFECTIVE FIELD THEORY:

THE precise manner in which quantum-mechanical behaviour at the microscopic level underlies classical behaviour at the macroscopic level remains unclear, despite seventy years of theoretical investigation. Experimentally, the crossover between these regimes can be explored by looking for signatures of quantum-mechanical behaviour—such as tunneling—in macroscopic systems. Magnetic systems (such as small grains, spin glasses and thin films) are often investigated in this way because transitions between different magnetic states can be closely monitored. But transitions between states can be induced by thermal fluctuations, as well as by tunnelling, and definitive identification of macroscopic tunnelling events in these complex systems is therefore difficult. Here we report the results of low-temperature experiments on a single crystal composed of super-paramagnetic manganese clusters (Mn₁₂-ac), which clearly demonstrate the existence of quantum-mechanical tunnelling of the bulk magnetization. In an applied magnetic field, the magnetization shows hysteresis loops with a distinct 'staircase' structure: the steps occur at values of the applied field where the energies of different collective spin states of the manganese clusters coincide. At these special values of the field, relaxation from one spin state to another is enhanced above the thermally activated rate by the action of resonant quantum-mechanical tunnelling. These observations corroborate the results of similar experiments performed recently on a system of oriented crystallites made from a powdered sample.

Young's double slit experiment - Quantum mechanical behaviour

Young's double slit experiment represents the observation of an interference pattern consistent with a wave nature for objects that traverse the apparatus. This is emphasized in the figures 3 and 4

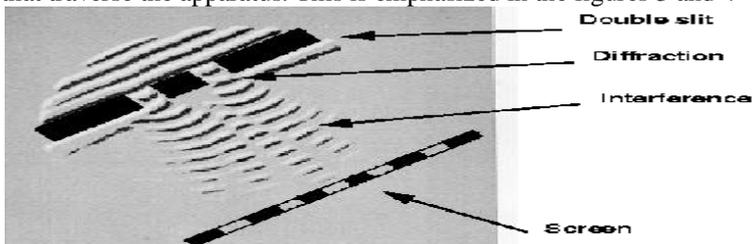

Figure 3: Young's double slit experiment with water waves.

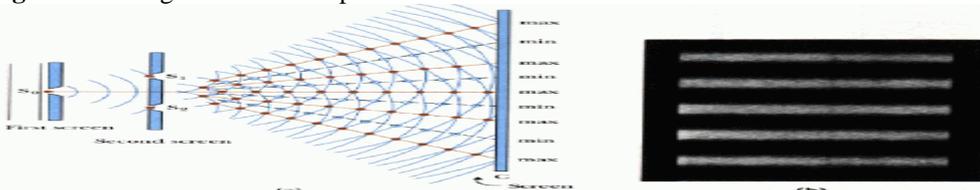

Figure 4: Young's double slit experiment, performed with either light or electrons leads to an interference pattern.

The diffraction and interference effects appear at first sight to be due to the beam of electrons, interfering with each other. However, the interference pattern still results even if only one electron traverses the apparatus at a time. In this case, the pattern is built up gradually from the statistically correlated impacts on many electrons arriving independently at the detection system. This effect is evidenced in figure 5.

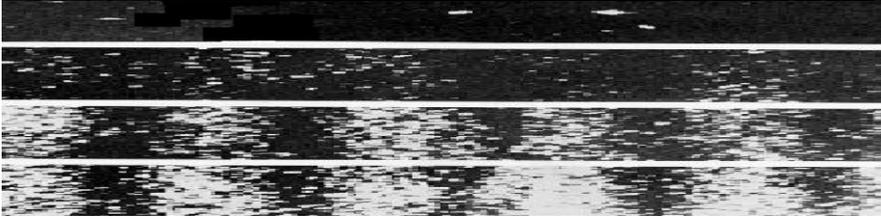

Figure 5: Young's double slit experiment, performed with electrons in such a way that only one electron is present in the apparatus at any one time.

We see that the electron must in some sense pass through both slits at once and then interfere with itself as it travels towards the detector. Young's double slit experiment has been performed many times in many different ways with electrons (and other particles). The inescapable conclusion is that each electron must be delocalized in both time and space over the apparatus.

Considering the analogies between Young's double slit experiment performed with water waves, electro-magnetic waves and with electrons, and considering the material of the foregoing section, we can now specify some properties for a new theory of mechanics, termed *wave mechanics*.

$$\Psi(\mathbf{r}, t)$$

1. There must be a wave function describing some fundamental property of matter. (We leave further physical interpretation of the wave function open to continuous debate through-out the course.)
2. As with the intensity pattern on the screen for water waves and light waves, the "observable" associated with the wave function indicating the probability of detection of the particle will be the intensity (square of the amplitude) of

$$|\Psi(\mathbf{r}, t)|^2 = \Psi(\mathbf{r}, t)\Psi^*(\mathbf{r}, t)$$

the wave. Mathematically, this is

$$\lambda = h/p$$

3. The wavelength in the wave function will be related to the de Broglie wavelength of the particle .
4. We would like to be able to proceed to develop a differential equation which would specify the time evolution of the wave function, consistent with the conservation of energy and momentum of physical systems.
5. The quantization of energy should arise in a natural way from this formalism, just as it does for other bounded systems that support oscillations.
6. Then we must develop the formalism to enable other observables than simple the probability of detection "position of the particle" to be determined. Examples would be the energy and momentum of the particle.
7. Note the judicious use of the word observable. The actual wave function itself has never yet been observed.

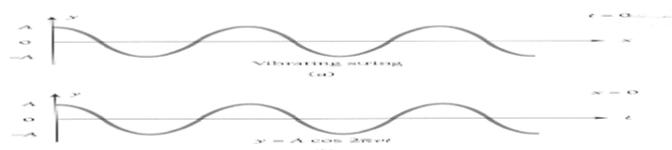

It is clear that an improved understanding of waves in physics is now necessary. To this end, some results from wave motion in physics are reviewed.

A transverse wave train, travelling on a string in the $+x$ -direction (as in figure 6) may be represented by

$$y(x, t) = A \cos 2\pi\nu \left(t - \frac{x}{v_p} \right) \tag{8}$$

where ν is the frequency of the wave and v_p is its *phase velocity*. The phase velocity is the velocity with which a point on the wave maintaining the same phase appears to be transported.

$$v_p = \lambda\nu \tag{9}$$

+x

Figure 6: A transverse wave train, travelling on a string in the +x-direction. It is more common to define the angular frequency (frequency in radians/sec rather than cycles/sec)

$$\omega = 2\pi\nu \quad (10)$$

and the wavenumber

$$k = \frac{2\pi}{\lambda} \quad (\text{by definition})$$

$$= \frac{\omega}{v_p} \quad (\text{substitution with the last two equations})$$

$$= \frac{|p|/\hbar}{\hbar} \quad (\text{using de Broglie's relation}) \quad (11)$$

$$\hbar = h/2\pi$$

where $\hbar = h/2\pi$. The wave equation for the wave moving in the +x-direction can now be written :

$$y(x, t) = A \cos(\omega t - kx) \quad (12)$$

In three dimensions, this equation would be

$$y(\mathbf{r}, t) = A \cos(\omega t - \mathbf{k} \cdot \mathbf{r}) \quad (13)$$

It turns out that in quantum mechanics, a particle will be described as a *wave packet*. By this, we mean a group of (usually infinitely many) waves which mutually interfere, creating a new wave form which exhibits some localization.

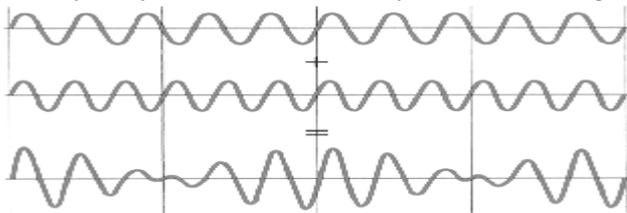

Figure 7: Two waves of nearly equal wave number combined coherently.

$$k \pm \Delta k$$

This can be illustrated by considering only two waves, of nearly equal wave number ($k \pm \Delta k$), and combining them coherently as in figure 7. Clearly, performing this process with many more waves would achieve a better localization of the wave packet, as illustrated in figure 8.

Figure 8: Localisation of a wave packet by combination of many waves.

We find that

$$y = A \cos[(\omega + \Delta\omega/2)t - (k + \Delta k/2)x] + A \cos[(\omega - \Delta\omega/2)t - (k - \Delta k/2)x]$$

... use trigonometric double angle formulae

$$= 2A \cos(\omega t - kx) \cos\left(\frac{\Delta\omega}{2}t - \frac{\Delta k}{2}x\right) \quad (14)$$

The combined wave train exhibits the phenomenon of "beats" as shown in figure 7 where an amplitude modulation envelope is superimposed on the original wave train. The amplitude modulation envelope will clearly have the frequency $\nu_g = \Delta\omega/\Delta k$, wave

number Δk and hence the velocity

$$v_g = \Delta\omega/\Delta k$$

The velocity of the localised group of waves (or beat) is known as the group velocity.

$$v_g = v \quad \text{and} \quad v_p = c^2/v \quad *(15)$$

This must be compared to the phase velocity of each wave train making up the wave packet

$$v_p = \frac{\omega}{k} \quad *(16)$$

$$v_g = v \quad \text{and} \quad v_p = c^2/v \quad *(17)$$

Thus the de Broglie wave group associated with a moving particle travels with the same velocity as the particle. The de Broglie waves in the packet have superluminal velocities, however, these do not represent the motion of the particle, and therefore the special relativity is not violated.

Finally, the form of the wave equation, yielding the above expression for a wave train is

$$y(x,t) = -iA \sin(\omega t - kx) \quad *(18)$$

We can verify that $y(x,t) = Ae^{-i(\omega t - kx)}$ is indeed a solution of the wave equation.

$$y(x,t) = -iA \sin(\omega t - kx)$$

Clearly $y(x,t) = Ae^{-i(\omega t - kx)}$ is also a solution of the wave equation. It follows that

$$y(x,t) = Ae^{-i(\omega t - kx)} \quad *(19)$$

is also a solution of the wave equation. This can be verified by direct substitution, or by exploiting the fact that any linear combination of solutions of the wave equation is itself a solution of the wave equation

$$e^{-i\theta} = \cos\theta - i \sin\theta$$

(Hint: .)

In fact a second order differential equation should have two constants of integration, which are determined by the boundary conditions of the specific problem. We can show that for the equation above, we could write

$$y(x,t) = A \cos(\omega t - kx) + B \sin(\omega t - kx) \quad *(20)$$

or

$$y(x,t) = C e^{-i(\omega t - kx)} + D e^{+i(\omega t - kx)} \quad *(21)$$

Also find the relationship between the two sets of coefficients. We will use the former set when discussing standing waves (like a guitar string), and the latter set when discussing travelling waves (like a ripple on a large pond)..

The differential system of this model is now *

$$\frac{dG_{36}}{dt} = (a_{36})^{(7)} G_{37} - [(a'_{36})^{(7)} + (a''_{36})^{(7)}(T_{37}, t)] G_{36} \quad *19$$

$$\frac{dG_{37}}{dt} = (a_{37})^{(7)} G_{36} - [(a'_{37})^{(7)} + (a''_{37})^{(7)}(T_{37}, t)] G_{37} \quad *20$$

$$\frac{dG_{38}}{dt} = (a_{38})^{(7)} G_{37} - [(a'_{38})^{(7)} + (a''_{38})^{(7)}(T_{37}, t)] G_{38} \quad *21$$

$$\frac{dT_{36}}{dt} = (b_{36})^{(7)} T_{37} - [(b'_{36})^{(7)} - (b''_{36})^{(7)}((G_{39}), t)] T_{36} \quad *22$$

$$\frac{dT_{37}}{dt} = (b_{37})^{(7)} T_{36} - [(b'_{37})^{(7)} - (b''_{37})^{(7)}((G_{39}), t)] T_{37}$$

*23

$$\frac{dT_{38}}{dt} = (b_{38})^{(7)}T_{37} - [(b'_{38})^{(7)} - (b''_{38})^{(7)}((G_{39}), t)]T_{38} \quad *24$$

$$+(a''_{36})^{(7)}(T_{37}, t) = \text{First augmentation factor}^*$$

$$-(b'_{36})^{(7)}((G_{39}), t) = \text{First detritions factor}^*$$

Where we suppose*

(A) $(a_i)^{(7)}, (a'_i)^{(7)}, (a''_i)^{(7)}, (b_i)^{(7)}, (b'_i)^{(7)}, (b''_i)^{(7)} > 0, \quad i, j = 36, 37, 38$

(B) The functions $(a''_i)^{(7)}, (b''_i)^{(7)}$ are positive continuous increasing and bounded.

Definition of $(p_i)^{(7)}, (r_i)^{(7)}$:

$$(a''_i)^{(7)}(T_{37}, t) \leq (p_i)^{(7)} \leq (\hat{A}_{36})^{(7)} \quad *25$$

$$(b''_i)^{(7)}(G, t) \leq (r_i)^{(7)} \leq (b'_i)^{(7)} \leq (\hat{B}_{36})^{(7)} \quad *26$$

(C) $\lim_{T_2 \rightarrow \infty} (a''_i)^{(7)}(T_{37}, t) = (p_i)^{(7)}$
 $\lim_{G \rightarrow \infty} (b''_i)^{(7)}((G_{39}), t) = (r_i)^{(7)}$

Definition of $(\hat{A}_{36})^{(7)}, (\hat{B}_{36})^{(7)}$: *27

Where $(\hat{A}_{36})^{(7)}, (\hat{B}_{36})^{(7)}, (p_i)^{(7)}, (r_i)^{(7)}$ are positive constants

and $i = 36, 37, 38$ *28

They satisfy Lipschitz condition:

$$|(a''_i)^{(7)}(T'_{37}, t) - (a''_i)^{(7)}(T_{37}, t)| \leq (\hat{k}_{36})^{(7)}|T'_{37} - T_{37}|e^{-(\hat{M}_{36})^{(7)}t} \quad *29$$

$$|(b''_i)^{(7)}((G_{39})', t) - (b''_i)^{(7)}((G_{39}), (T_{39}))| < (\hat{k}_{36})^{(7)}\|((G_{39}) - (G_{39})')\|e^{-(\hat{M}_{36})^{(7)}t} \quad *30$$

With the Lipschitz condition, we place a restriction on the behavior of functions $(a''_i)^{(7)}(T'_{37}, t)$ and $(a''_i)^{(7)}(T_{37}, t) \cdot (T'_{37}, t)$ and (T_{37}, t) are points belonging to the interval $[(\hat{k}_{36})^{(7)}, (\hat{M}_{36})^{(7)}]$. It is to be noted that $(a''_i)^{(7)}(T_{37}, t)$ is uniformly continuous. In the eventuality of the fact, that if $(\hat{M}_{36})^{(7)} = 7$ then the function $(a''_i)^{(7)}(T_{37}, t)$, the **first augmentation coefficient would be continuous**.*

Definition of $(\hat{M}_{36})^{(7)}, (\hat{k}_{36})^{(7)}$:

(D) $(\hat{M}_{36})^{(7)}, (\hat{k}_{36})^{(7)}$, are positive constants

$$\frac{(a_i)^{(7)}}{(\hat{M}_{36})^{(7)}}, \frac{(b_i)^{(7)}}{(\hat{M}_{36})^{(7)}} < 1 \quad *31$$

Definition of $(\hat{P}_{36})^{(7)}, (\hat{Q}_{36})^{(7)}$:

(E) There exists two constants $(\hat{P}_{36})^{(7)}$ and $(\hat{Q}_{36})^{(7)}$ which together with $(\hat{M}_{36})^{(7)}, (\hat{k}_{36})^{(7)}, (\hat{A}_{36})^{(7)}$ and $(\hat{B}_{36})^{(7)}$ and the constants $(a_i)^{(7)}, (a'_i)^{(7)}, (b_i)^{(7)}, (b'_i)^{(7)}, (p_i)^{(7)}, (r_i)^{(7)}, i = 36, 37, 38$, satisfy the inequalities

$$\frac{1}{(\hat{M}_{36})^{(7)}} [(a_i)^{(7)} + (a'_i)^{(7)} + (\hat{A}_{36})^{(7)} + (\hat{P}_{36})^{(7)} (\hat{k}_{36})^{(7)}] < 1$$

$$\frac{1}{(\hat{M}_{36})^{(7)}} [(b_i)^{(7)} + (b'_i)^{(7)} + (\hat{B}_{36})^{(7)} + (\hat{Q}_{36})^{(7)} (\hat{k}_{36})^{(7)}] < 1 \quad *32 \quad *33$$

Theorem 7: if the conditions (A)-(E) above are fulfilled, there exists a solution satisfying the conditions

Definition of $G_i(0), T_i(0)$:

$$G_i(t) \leq (\hat{P}_{36})^{(7)} e^{(\hat{M}_{36})^{(7)}t}, \quad \boxed{G_i(0) = G_i^0 > 0}$$

$$T_i(t) \leq (\hat{Q}_{36})^{(7)} e^{(\hat{M}_{36})^{(7)}t}, \quad \boxed{T_i(0) = T_i^0 > 0}$$

Proof:

Consider operator $\mathcal{A}^{(7)}$ defined on the space of sextuples of continuous functions $G_i, T_i: \mathbb{R}_+ \rightarrow \mathbb{R}_+$ which satisfy

$$G_i(0) = G_i^0, T_i(0) = T_i^0, G_i^0 \leq (\hat{P}_{36})^{(7)}, T_i^0 \leq (\hat{Q}_{36})^{(7)}, \quad *34$$

$$0 \leq G_i(t) - G_i^0 \leq (\hat{P}_{36})^{(7)} e^{(\hat{M}_{36})^{(7)}t} \quad *35$$

$$0 \leq T_i(t) - T_i^0 \leq (\hat{Q}_{36})^{(7)} e^{(\hat{M}_{36})^{(7)}t} \quad *36$$

By

$$\bar{G}_{36}(t) = G_{36}^0 + \int_0^t [(a_{36})^{(7)} G_{37}(s_{(36)}) - ((a'_{36})^{(7)} + a''_{36})^{(7)} (T_{37}(s_{(36)}), s_{(36)})] G_{36}(s_{(36)}) ds_{(36)} \quad *37$$

$$\bar{G}_{37}(t) = G_{37}^0 + \int_0^t [(a_{37})^{(7)} G_{36}(s_{(36)}) - ((a'_{37})^{(7)} + (a''_{37})^{(7)} (T_{37}(s_{(36)}), s_{(36)}))] G_{37}(s_{(36)}) ds_{(36)} \quad *38$$

$$\bar{G}_{38}(t) = G_{38}^0 + \int_0^t [(a_{38})^{(7)} G_{37}(s_{(36)}) - ((a'_{38})^{(7)} + (a''_{38})^{(7)} (T_{37}(s_{(36)}), s_{(36)}))] G_{38}(s_{(36)}) ds_{(36)} \quad *39$$

$$\bar{T}_{36}(t) = T_{36}^0 + \int_0^t [(b_{36})^{(7)} T_{37}(s_{(36)}) - ((b'_{36})^{(7)} - (b''_{36})^{(7)} (G(s_{(36)}), s_{(36)}))] T_{36}(s_{(36)}) ds_{(36)} \quad *40$$

$$\bar{T}_{37}(t) = T_{37}^0 + \int_0^t [(b_{37})^{(7)} T_{36}(s_{(36)}) - ((b'_{37})^{(7)} - (b''_{37})^{(7)} (G(s_{(36)}), s_{(36)}))] T_{37}(s_{(36)}) ds_{(36)} \quad *41$$

$$\bar{T}_{38}(t) = T_{38}^0 + \int_0^t [(b_{38})^{(7)} T_{37}(s_{(36)}) - ((b'_{38})^{(7)} - (b''_{38})^{(7)} (G(s_{(36)}), s_{(36)}))] T_{38}(s_{(36)}) ds_{(36)}$$

Where $s_{(36)}$ is the integrand that is integrated over an interval $(0, t)$ *42

(a) The operator $\mathcal{A}^{(7)}$ maps the space of functions satisfying 37,35,36 into itself. Indeed it is obvious that

$$G_{36}(t) \leq G_{36}^0 + \int_0^t [(a_{36})^{(7)} (G_{37}^0 + (\hat{P}_{36})^{(7)} e^{(\hat{M}_{36})^{(7)}s_{(36)}})] ds_{(36)} = (1 + (a_{36})^{(7)}t) G_{37}^0 + \frac{(a_{36})^{(7)} (\hat{P}_{36})^{(7)}}{(\hat{M}_{36})^{(7)}} (e^{(\hat{M}_{36})^{(7)}t} - 1) \quad *43$$

From which it follows that

$$(G_{36}(t) - G_{36}^0) e^{-(\hat{M}_{36})^{(7)}t} \leq \frac{(a_{36})^{(7)}}{(\hat{M}_{36})^{(7)}} \left[((\hat{P}_{36})^{(7)} + G_{37}^0) e^{-\left(\frac{(\hat{P}_{36})^{(7)} + G_{37}^0}{G_{37}^0}\right)} + (\hat{P}_{36})^{(7)} \right]$$

(G_i^0) is as defined in the statement of theorem 1 *44

Analogous inequalities hold also for $G_{37}, G_{38}, T_{36}, T_{37}, T_{38}$

It is now sufficient to take $\frac{(a_i)^{(7)}}{(\hat{M}_{36})^{(7)}}, \frac{(b_i)^{(7)}}{(\hat{M}_{36})^{(7)}} < 7$ and to choose

$(\hat{P}_{36})^{(7)}$ and $(\hat{Q}_{36})^{(7)}$ large to have

$$\frac{(a_i)^{(7)}}{(\hat{M}_{36})^{(7)}} \left[(\hat{P}_{36})^{(7)} + ((\hat{P}_{36})^{(7)} + G_j^0) e^{-\left(\frac{(\hat{P}_{36})^{(7)} + G_j^0}{G_j^0}\right)} \right] \leq (\hat{P}_{36})^{(7)} \quad *45$$

$$\frac{(b_i)^{(7)}}{(\hat{M}_{36})^{(7)}} \left[((\hat{Q}_{36})^{(7)} + T_j^0) e^{-\left(\frac{(\hat{Q}_{36})^{(7)} + T_j^0}{T_j^0}\right)} + (\hat{Q}_{36})^{(7)} \right] \leq (\hat{Q}_{36})^{(7)} \quad *46$$

In order that the operator $\mathcal{A}^{(7)}$ transforms the space of sextuples of functions G_i, T_i satisfying 37,35,36 into itself

The operator $\mathcal{A}^{(7)}$ is a contraction with respect to the metric

$$d\left(\left((G_{39})^{(1)}, (T_{39})^{(1)}\right), \left((G_{39})^{(2)}, (T_{39})^{(2)}\right)\right) = \sup_i \left\{ \max_{t \in \mathbb{R}_+} |G_i^{(1)}(t) - G_i^{(2)}(t)| e^{-(\hat{M}_{36})^{(7)}t}, \max_{t \in \mathbb{R}_+} |T_i^{(1)}(t) - T_i^{(2)}(t)| e^{-(\hat{M}_{36})^{(7)}t} \right\}$$

Indeed if we denote

Definition of $(\widetilde{G}_{39}), (\widetilde{T}_{39}) :$

$$((\widetilde{G}_{39}), (\widetilde{T}_{39})) = \mathcal{A}^{(7)}((G_{39}), (T_{39}))$$

It results

$$|\widetilde{G}_{36}^{(1)} - \widetilde{G}_i^{(2)}| \leq \int_0^t (a_{36})^{(7)} |G_{37}^{(1)} - G_{37}^{(2)}| e^{-(\widetilde{M}_{36})^{(7)}s_{(36)}} e^{(\widetilde{M}_{36})^{(7)}s_{(36)}} ds_{(36)} + *48$$

$$\int_0^t \{(a_{36}')^{(7)} |G_{36}^{(1)} - G_{36}^{(2)}| e^{-(\widetilde{M}_{36})^{(7)}s_{(36)}} e^{-(\widetilde{M}_{36})^{(7)}s_{(36)}} + (a_{36}'')^{(7)}(T_{37}^{(1)}, s_{(36)}) |G_{36}^{(1)} - G_{36}^{(2)}| e^{-(\widetilde{M}_{36})^{(7)}s_{(36)}} e^{(\widetilde{M}_{36})^{(7)}s_{(36)}} + *49$$

$$G_{36}^{(2)} | (a_{36}'')^{(7)}(T_{37}^{(1)}, s_{(36)}) - (a_{36}'')^{(7)}(T_{37}^{(2)}, s_{(36)}) | e^{-(\widetilde{M}_{36})^{(7)}s_{(36)}} e^{(\widetilde{M}_{36})^{(7)}s_{(36)}} ds_{(36)} *47$$

Where $s_{(36)}$ represents integrand that is integrated over the interval $[0, t]$

From the hypotheses it follows that:

$$|(G_{39})^{(1)} - (G_{39})^{(2)}| e^{-(\widetilde{M}_{36})^{(7)}t} \leq \frac{1}{(\widetilde{M}_{36})^{(7)}} ((a_{36})^{(7)} + (a_{36}')^{(7)} + (\widehat{A}_{36})^{(7)} + (\widehat{P}_{36})^{(7)} (\widehat{k}_{36})^{(7)}) d(((G_{39})^{(1)}, (T_{39})^{(1)}); (G_{39})^{(2)}, (T_{39})^{(2)}) *50$$

And analogous inequalities for G_i and T_i . Taking into account the hypothesis (37,35,36) the result follows

Remark 7: The fact that we supposed $(a_{36}'')^{(7)}$ and $(b_{36}'')^{(7)}$ depending also on t can be considered as not conformal with the reality, however we have put this hypothesis in order that we can postulate condition necessary to prove the uniqueness of the solution bounded by $(\widehat{P}_{36})^{(7)} e^{(\widetilde{M}_{36})^{(7)}t}$ and $(\widehat{Q}_{36})^{(7)} e^{(\widetilde{M}_{36})^{(7)}t}$ respectively of \mathbb{R}_+ .

If instead of proving the existence of the solution on \mathbb{R}_+ , we have to prove it only on a compact then it suffices to consider that $(a_i'')^{(7)}$ and $(b_i'')^{(7)}, i = 36,37,38$ depend only on T_{37} and respectively on (G_{39}) (and not on t) and hypothesis can be replaced by a usual Lipschitz condition.

*51

Remark 2: There does not exist any t where $G_i(t) = 0$ and $T_i(t) = 0$

$$G_i(t) \geq G_i^0 e^{-\int_0^t \{(a_i')^{(7)} - (a_i'')^{(7)}(T_{37}(s_{(36)}), s_{(36)})\} ds_{(36)}} \geq 0$$

$$T_i(t) \geq T_i^0 e^{-(b_i')^{(7)}t} > 0 \text{ for } t > 0 *52$$

Definition of $((\widetilde{M}_{36})^{(7)})_1, ((\widetilde{M}_{36})^{(7)})_2$ and $((\widetilde{M}_{36})^{(7)})_3 :$

Remark 3: if G_{36} is bounded, the same property have also G_{37} and G_{38} . indeed if

$$G_{36} < (\widetilde{M}_{36})^{(7)} \text{ it follows } \frac{dG_{37}}{dt} \leq ((\widetilde{M}_{36})^{(7)})_1 - (a_{37}')^{(7)} G_{37} \text{ and by integrating}$$

$$G_{37} \leq ((\widetilde{M}_{36})^{(7)})_2 = G_{37}^0 + 2(a_{37})^{(7)} ((\widetilde{M}_{36})^{(7)})_1 / (a_{37}')^{(7)}$$

In the same way, one can obtain

$$G_{38} \leq ((\widetilde{M}_{36})^{(7)})_3 = G_{38}^0 + 2(a_{38})^{(7)} ((\widetilde{M}_{36})^{(7)})_2 / (a_{38}')^{(7)}$$

If G_{37} or G_{38} is bounded, the same property follows for G_{36}, G_{38} and G_{36}, G_{37} respectively.

*53

Remark 7: If G_{36} is bounded, from below, the same property holds for G_{37} and G_{38} . The proof is analogous with the preceding one. An analogous property is true if G_{37} is bounded from below.

*54

Remark 5: If T_{36} is bounded from below and $\lim_{t \rightarrow \infty} ((b_i'')^{(7)}((G_{39})(t), t)) = (b_{37}')^{(7)}$ then $T_{37} \rightarrow \infty$.

Definition of $(m)^{(7)}$ and $\varepsilon_7 :$

Indeed let t_7 be so that for $t > t_7$

$$(b_{37})^{(7)} - (b'_i)^{(7)}((G_{39})(t), t) < \varepsilon_7, T_{36}(t) > (m)^{(7)}$$

*55

Then $\frac{dT_{37}}{dt} \geq (a_{37})^{(7)}(m)^{(7)} - \varepsilon_7 T_{37}$ which leads to

$$T_{37} \geq \left(\frac{(a_{37})^{(7)}(m)^{(7)}}{\varepsilon_7} \right) (1 - e^{-\varepsilon_7 t}) + T_{37}^0 e^{-\varepsilon_7 t} \text{ If we take } t \text{ such that } e^{-\varepsilon_7 t} = \frac{1}{2} \text{ it results}$$

$T_{37} \geq \left(\frac{(a_{37})^{(7)}(m)^{(7)}}{2} \right)$, $t = \log \frac{2}{\varepsilon_7}$ By taking now ε_7 sufficiently small one sees that T_{37} is unbounded. The same property holds for T_{38} if $\lim_{t \rightarrow \infty} (b''_{38})^{(7)}((G_{39})(t), t) = (b'_{38})^{(7)}$

We now state a more precise theorem about the behaviors at infinity of the solutions of equations 37 to 72

*

Behavior of the solutions of the system Quantum Information and Quantum mechanical Behaviour:

Theorem 2: If we denote and define

Definition of $(\sigma_1)^{(7)}, (\sigma_2)^{(7)}, (\tau_1)^{(7)}, (\tau_2)^{(7)}$:

(a) $(\sigma_1)^{(7)}, (\sigma_2)^{(7)}, (\tau_1)^{(7)}, (\tau_2)^{(7)}$ four constants satisfying

$$-(\sigma_2)^{(7)} \leq -(a'_{36})^{(7)} + (a'_{37})^{(7)} - (a''_{36})^{(7)}(T_{37}, t) + (a''_{37})^{(7)}(T_{37}, t) \leq -(\sigma_1)^{(7)}$$

$$-(\tau_2)^{(7)} \leq -(b'_{36})^{(7)} + (b'_{37})^{(7)} - (b''_{36})^{(7)}((G_{39}), t) - (b''_{37})^{(7)}((G_{39}), t) \leq -(\tau_1)^{(7)}$$

*56

57

and analogously

$$(\mu_2)^{(7)} = (u_0)^{(7)}, (\mu_1)^{(7)} = (u_1)^{(7)}, \text{ if } (u_0)^{(7)} < (u_1)^{(7)}$$

$$(\mu_2)^{(7)} = (u_1)^{(7)}, (\mu_1)^{(7)} = (\bar{u}_1)^{(7)}, \text{ if } (u_1)^{(7)} < (u_0)^{(7)} < (\bar{u}_1)^{(7)},$$

$$\text{and } (u_0)^{(7)} = \frac{T_{36}^0}{T_{37}^0}$$

$(\mu_2)^{(7)} = (u_1)^{(7)}, (\mu_1)^{(7)} = (u_0)^{(7)}$, if $(\bar{u}_1)^{(7)} < (u_0)^{(7)}$ where $(u_1)^{(7)}, (\bar{u}_1)^{(7)}$ are defined by 59 and 67 respectively

*68

69

70

Then the solution of the system Quantum Information(machine-Computer) and Quantum Mechanical Behaviour satisfies the inequalities

$$G_{36}^0 e^{((S_1)^{(7)} - (p_{36})^{(7)})t} \leq G_{36}(t) \leq G_{36}^0 e^{(S_1)^{(7)}t}$$

where $(p_i)^{(7)}$ is defined in the foregoing

*71

$$\frac{1}{(m_7)^{(7)}} G_{36}^0 e^{((S_1)^{(7)} - (p_{36})^{(7)})t} \leq G_{37}(t) \leq \frac{1}{(m_2)^{(7)}} G_{36}^0 e^{(S_1)^{(7)}t}$$

*72

$$\left(\frac{(a_{38})^{(7)} G_{36}^0}{(m_1)^{(7)} ((S_1)^{(7)} - (p_{36})^{(7)} - (S_2)^{(7)})} \left[e^{((S_1)^{(7)} - (p_{36})^{(7)})t} - e^{-(S_2)^{(7)}t} \right] + G_{38}^0 e^{-(S_2)^{(7)}t} \right) \leq G_{38}(t) \leq \frac{(a_{38})^{(7)} G_{36}^0}{(m_2)^{(7)} ((S_1)^{(7)} - (a'_{38})^{(7)})} \left[e^{(S_1)^{(7)}t} - e^{-(a'_{38})^{(7)}t} \right] + G_{38}^0 e^{-(a'_{38})^{(7)}t}$$

*73

$$T_{36}^0 e^{(R_1)^{(7)}t} \leq T_{36}(t) \leq T_{36}^0 e^{((R_1)^{(7)} + (r_{36})^{(7)})t}$$

*74

$$\frac{1}{(\mu_1)^{(7)}} T_{36}^0 e^{(R_1)^{(7)}t} \leq T_{36}(t) \leq \frac{1}{(\mu_2)^{(7)}} T_{36}^0 e^{((R_1)^{(7)} + (r_{36})^{(7)})t}$$

*75

$$\frac{(b_{38})^{(7)} T_{36}^0}{(\mu_1)^{(7)} ((R_1)^{(7)} - (b'_{38})^{(7)})} \left[e^{(R_1)^{(7)}t} - e^{-(b'_{38})^{(7)}t} \right] + T_{38}^0 e^{-(b'_{38})^{(7)}t} \leq T_{38}(t) \leq$$

$$\frac{(a_{38})^{(7)} T_{36}^0}{(\mu_2)^{(7)} ((R_1)^{(7)} + (r_{36})^{(7)} + (R_2)^{(7)})} \left[e^{((R_1)^{(7)} + (r_{36})^{(7)})t} - e^{-(R_2)^{(7)}t} \right] + T_{38}^0 e^{-(R_2)^{(7)}t}$$

*76

Definition of $(S_1)^{(7)}, (S_2)^{(7)}, (R_1)^{(7)}, (R_2)^{(7)}$:-

$$\text{Where } (S_1)^{(7)} = (a_{36})^{(7)}(m_2)^{(7)} - (a'_{36})^{(7)}$$

$$(S_2)^{(7)} = (a_{38})^{(7)} - (p_{38})^{(7)}$$

$$(R_1)^{(7)} = (b_{36})^{(7)}(\mu_2)^{(7)} - (b'_{36})^{(7)}$$

$$(R_2)^{(7)} = (b'_{38})^{(7)} - (r_{38})^{(7)} \quad *77$$

78

79

Proof From the sytemal equations of Quantum Information and Quantum Mechanical Behaviour, and the resultant equations we get:

$$\frac{dv^{(7)}}{dt} = (a_{36})^{(7)} - \left((a'_{36})^{(7)} - (a'_{37})^{(7)} + (a''_{36})^{(7)}(T_{37}, t) \right) - (a''_{37})^{(7)}(T_{37}, t)v^{(7)} - (a_{37})^{(7)}v^{(7)}$$

Definition of $v^{(7)}$:-

$$v^{(7)} = \frac{G_{36}}{G_{37}}$$

It follows

$$- \left((a_{37})^{(7)}(v^{(7)})^2 + (\sigma_2)^{(7)}v^{(7)} - (a_{36})^{(7)} \right) \leq \frac{dv^{(7)}}{dt} \leq - \left((a_{37})^{(7)}(v^{(7)})^2 + (\sigma_1)^{(7)}v^{(7)} - (a_{36})^{(7)} \right)$$

From which one obtains

Definition of $(\bar{v}_1)^{(7)}, (v_0)^{(7)}$:-

I. For $0 < \boxed{(v_0)^{(7)} = \frac{G_{36}^0}{G_{37}^0}} < (v_1)^{(7)} < (\bar{v}_1)^{(7)}$

$$v^{(7)}(t) \geq \frac{(v_1)^{(7)} + (C)^{(7)}(v_2)^{(7)} e^{[-(a_{37})^{(7)}(v_1)^{(7)} - (v_0)^{(7)}]t}}{1 + (C)^{(7)} e^{[-(a_{37})^{(7)}(v_1)^{(7)} - (v_0)^{(7)}]t}}, \quad \boxed{(C)^{(7)} = \frac{(v_1)^{(7)} - (v_0)^{(7)}}{(v_0)^{(7)} - (v_2)^{(7)}}$$

it follows $(v_0)^{(7)} \leq v^{(7)}(t) \leq (v_1)^{(7)}$ *80

81

In the same manner, we get

$$v^{(7)}(t) \leq \frac{(\bar{v}_1)^{(7)} + (\bar{C})^{(7)}(\bar{v}_2)^{(7)} e^{[-(a_{37})^{(7)}(\bar{v}_1)^{(7)} - (\bar{v}_2)^{(7)}]t}}{1 + (\bar{C})^{(7)} e^{[-(a_{37})^{(7)}(\bar{v}_1)^{(7)} - (\bar{v}_2)^{(7)}]t}}, \quad \boxed{(\bar{C})^{(7)} = \frac{(\bar{v}_1)^{(7)} - (v_0)^{(7)}}{(v_0)^{(7)} - (\bar{v}_2)^{(7)}}$$

From which we deduce $(v_0)^{(7)} \leq v^{(7)}(t) \leq (\bar{v}_1)^{(7)}$ *82

83

II. If $0 < (v_1)^{(7)} < (v_0)^{(7)} = \frac{G_{36}^0}{G_{37}^0} < (\bar{v}_1)^{(7)}$ we find like in the previous case,

$$(v_1)^{(7)} \leq \frac{(v_1)^{(7)} + (C)^{(7)}(v_2)^{(7)} e^{[-(a_{37})^{(7)}(v_1)^{(7)} - (v_2)^{(7)}]t}}{1 + (C)^{(7)} e^{[-(a_{37})^{(7)}(v_1)^{(7)} - (v_2)^{(7)}]t}} \leq v^{(7)}(t) \leq$$

$$\frac{(\bar{v}_1)^{(7)} + (\bar{C})^{(7)}(\bar{v}_2)^{(7)} e^{[-(a_{37})^{(7)}(\bar{v}_1)^{(7)} - (\bar{v}_2)^{(7)}]t}}{1 + (\bar{C})^{(7)} e^{[-(a_{37})^{(7)}(\bar{v}_1)^{(7)} - (\bar{v}_2)^{(7)}]t}} \leq (\bar{v}_1)^{(7)} \quad *84$$

III. If $0 < (v_1)^{(7)} \leq (\bar{v}_1)^{(7)} \leq \boxed{(v_0)^{(7)} = \frac{G_{36}^0}{G_{37}^0}}$, we obtain

$$(v_1)^{(7)} \leq v^{(7)}(t) \leq \frac{(\bar{v}_1)^{(7)} + (\bar{C})^{(7)}(\bar{v}_2)^{(7)} e^{[-(a_{37})^{(7)}(\bar{v}_1)^{(7)} - (\bar{v}_2)^{(7)}]t}}{1 + (\bar{C})^{(7)} e^{[-(a_{37})^{(7)}(\bar{v}_1)^{(7)} - (\bar{v}_2)^{(7)}]t}} \leq (v_0)^{(7)}$$

And so with the notation of the first part of condition (c), we have

Definition of $v^{(7)}(t)$:-

$$(m_2)^{(7)} \leq v^{(7)}(t) \leq (m_1)^{(7)}, \quad \boxed{v^{(7)}(t) = \frac{G_{36}(t)}{G_{37}(t)}}$$

In a completely analogous way, we obtain

Definition of $u^{(7)}(t)$:-

$$(\mu_2)^{(7)} \leq u^{(7)}(t) \leq (\mu_1)^{(7)}, \quad \boxed{u^{(7)}(t) = \frac{T_{36}(t)}{T_{37}(t)}}$$

Now, using this result and replacing it in system equations for the system Quantum Information and Quantum Mechanical Behaviour we obtain:

Particular case :

If $(a_{36})^{(7)} = (a_{37})^{(7)}$, then $(\sigma_1)^{(7)} = (\sigma_2)^{(7)}$ and in this case $(v_1)^{(7)} = (\bar{v}_1)^{(7)}$ if in addition $(v_0)^{(7)} = (v_1)^{(7)}$ then $v^{(7)}(t) = (v_0)^{(7)}$ and as a consequence $G_{36}(t) = (v_0)^{(7)} G_{37}(t)$ **this also defines $(v_0)^{(7)}$ for the special case.**

Analogously if $(b_{36})^{(7)} = (b_{37})^{(7)}$, then $(\tau_1)^{(7)} = (\tau_2)^{(7)}$ and then

$(u_1)^{(7)} = (\bar{u}_1)^{(7)}$ if in addition $(u_0)^{(7)} = (u_1)^{(7)}$ then $T_{36}(t) = (u_0)^{(7)} T_{37}(t)$ This is an important consequence of the relation between $(v_1)^{(7)}$ and $(\bar{v}_1)^{(7)}$, **and definition of $(u_0)^{(7)}$.**

*85, 86, 87

IV. STATIONARY SOLUTIONS AND STABILITY

Stationary solutions and stability curve representative of the variation of the system Quantum Information and Quantum Mechanical Behaviour variation curve lies below the tangent at $(G_{39}) = G_0$ for $(G_{39}) < G_0$ and above the tangent for $(G_{39}) > G_0$. Wherever such a situation occurs the point G_0 is called the “**point of inflexion**”. In this case, the tangent has a positive slope that simply means the rate of change of Quantum Mechanical Behaviour vis a vis Quantum Information is

greater than zero. Above factor shows that it is possible, to draw a curve that has a point of inflexion at a point where the tangent (slope of the curve) is horizontal.

Stationary value :

In all the cases $(G_{39}) = G_0$, $(G_{39}) < G_0$, $(G_{39}) > G_0$ the condition that the rate of change of oxygen consumption is maximum or minimum holds. When this condition holds we have stationary value. We now infer that :

1. A necessary and sufficient condition for there to be stationary value of (G_{39}) is that the rate of change of oxygen consumption function at G_0 is zero.
2. A sufficient condition for the stationary value at G_0 , to be maximum is that the acceleration of the oxygen consumption is less than zero.
3. A sufficient condition for the stationary value at G_0 , to be minimum is that acceleration of oxygen consumption is greater than zero.
4. With the rate of change of (G_{39}) namely oxygen consumption defined as the accentuation term and the dissipation term, we are sure that the rate of change of Quantum Mechanical Behaviour-Quantum Information system is always positive.
5. Concept of stationary state is mere methodology although there might be closed system exhibiting symptoms of stationeries.

We can prove the following

Theorem 3: If $(a_i'')^{(7)}$ and $(b_i'')^{(7)}$ are independent on t , and the conditions :

$$(a'_{36})^{(7)}(a'_{37})^{(7)} - (a_{36})^{(7)}(a_{37})^{(7)} < 0$$

$$(a'_{36})^{(7)}(a'_{37})^{(7)} - (a_{36})^{(7)}(a_{37})^{(7)} + (a_{36})^{(7)}(p_{36})^{(7)} + (a'_{37})^{(7)}(p_{37})^{(7)} + (p_{36})^{(7)}(p_{37})^{(7)} > 0$$

$$(b'_{36})^{(7)}(b'_{37})^{(7)} - (b_{36})^{(7)}(b_{37})^{(7)} > 0,$$

$$(b'_{36})^{(7)}(b'_{37})^{(7)} - (b_{36})^{(7)}(b_{37})^{(7)} - (b'_{36})^{(7)}(r_{37})^{(7)} - (b'_{37})^{(7)}(r_{37})^{(7)} + (r_{36})^{(7)}(r_{37})^{(7)} < 0$$

with $(p_{36})^{(7)}, (r_{37})^{(7)}$ as defined by equation 37 are satisfied, then the system

*88

$$(a_{36})^{(7)}G_{37} - [(a'_{36})^{(7)} + (a''_{36})^{(7)}(T_{37})]G_{36} = 0 \quad *89$$

$$(a_{37})^{(7)}G_{36} - [(a'_{37})^{(7)} + (a''_{37})^{(7)}(T_{37})]G_{37} = 0 \quad *90$$

$$(a_{38})^{(7)}G_{37} - [(a'_{38})^{(7)} + (a''_{38})^{(7)}(T_{37})]G_{38} = 0 \quad *91$$

$$(b_{36})^{(7)}T_{37} - [(b'_{36})^{(7)} - (b''_{36})^{(7)}(G_{39})]T_{36} = 0 \quad *92$$

$$(b_{37})^{(7)}T_{36} - [(b'_{37})^{(7)} - (b''_{37})^{(7)}(G_{39})]T_{37} = 0 \quad *93$$

$$(b_{38})^{(7)}T_{37} - [(b'_{38})^{(7)} - (b''_{38})^{(7)}(G_{39})]T_{38} = 0$$

*94

has a unique positive solution, which is an equilibrium solution for the system Quantum Mechanical Behaviour(Quantum Entanglement, Coherence, Decoherence) and Quantum Information(Computer).

Proof:

(a) Indeed the first two equations have a nontrivial solution G_{36}, G_{37} if

$$F(T_{39}) =$$

$$(a'_{36})^{(7)}(a'_{37})^{(7)} - (a_{36})^{(7)}(a_{37})^{(7)} + (a'_{36})^{(7)}(a''_{37})^{(7)}(T_{37}) + (a'_{37})^{(7)}(a''_{36})^{(7)}(T_{37}) + (a''_{36})^{(7)}(T_{37})(a''_{37})^{(7)}(T_{37}) = 0$$

*95

Definition and uniqueness of T_{37}^* :-

After hypothesis $f(0) < 0, f(\infty) > 0$ and the functions $(a_i'')^{(7)}(T_{37})$ being increasing, it follows that there exists a unique T_{37}^* for which $f(T_{37}^*) = 0$. With this value, we obtain from the three first equations

$$G_{36} = \frac{(a_{36})^{(7)}G_{37}}{[(a'_{36})^{(7)} + (a''_{36})^{(7)}(T_{37}^*)]}, \quad G_{38} = \frac{(a_{38})^{(7)}G_{37}}{[(a'_{38})^{(7)} + (a''_{38})^{(7)}(T_{37}^*)]}$$

(b) By the same argument, the equations 92,93 admit solutions G_{36}, G_{37} if

$$\varphi(G_{39}) = (b'_{36})^{(7)}(b'_{37})^{(7)} - (b_{36})^{(7)}(b_{37})^{(7)} - [(b'_{36})^{(7)}(b''_{37})^{(7)}(G_{39}) + (b'_{37})^{(7)}(b''_{36})^{(7)}(G_{39})] + (b''_{36})^{(7)}(G_{39})(b''_{37})^{(7)}(G_{39}) = 0 \quad *96$$

97

Where in $(G_{39})(G_{36}, G_{37}, G_{38}), G_{36}, G_{38}$ must be replaced by their values from 96. It is easy to see that φ is a decreasing function in G_{37} taking into account the hypothesis $\varphi(0) > 0, \varphi(\infty) < 0$ it follows that there exists a unique G_{37}^* such that $\varphi(G^*) = 0$

Finally we obtain the unique solution of the defined system Quantum Mechanical Behaviour and Quantum Information: G_{37}^* given by $\varphi((G_{39})^*) = 0, T_{37}^*$ given by $f(T_{37}^*) = 0$ and

$$G_{36}^* = \frac{(a_{36})^{(7)} G_{37}^*}{[(a_{36})^{(7)} + (a_{36})^{(7)}(T_{37}^*)]} \quad , \quad G_{38}^* = \frac{(a_{38})^{(7)} G_{37}^*}{[(a_{38})^{(7)} + (a_{38})^{(7)}(T_{37}^*)]} \quad *98$$

$$T_{36}^* = \frac{(b_{36})^{(7)} T_{37}^*}{[(b_{36})^{(7)} - (b_{36})^{(7)}((G_{39})^*)]} \quad , \quad T_{38}^* = \frac{(b_{38})^{(7)} T_{37}^*}{[(b_{38})^{(7)} - (b_{38})^{(7)}((G_{39})^*)]} \quad *99$$

Obviously, these values represent an equilibrium solution of the system Quantum Mechanical Behaviour and Quantum mechanical System(Quantum Information)

ASYMPTOTIC STABILITY ANALYSIS

One of the studies that come to mind when one thinks of the Asymptotic Stability Analysis, is the study by Komech On asymptotic stability of solitary waves for Schrödinger equation coupled to nonlinear oscillator, The long-time asymptotics is analyzed for finite energy solutions of the 1D Schrödinger equation coupled to a nonlinear oscillator; mathematically the system under study is a Nonlinear Schrödinger equation, whose nonlinear term includes a Dirac delta. The coupled system is invariant with respect to the phase rotation group $U(1)$. The article, which extends the results of a previous one, provides a proof of asymptotic stability of solitary wave solutions in the case that the linearization contains a single discrete oscillatory mode satisfying a non-degeneracy assumption of the type known as the Fermi Golden Rule. In this article we continue the study of large time asymptotics for a model $U(1)$ -invariant nonlinear Schrödinger equation Main focus is on the role that certain solitary waves (also referred to as nonlinear bound states, or solitons) play in the description of the solution for large times.

Equilibrium: Stable or Unstable?

Equilibrium is a state of a system which does not change.

If the dynamics of a system is described by a differential equation (or a system of differential equations), then equilibria can be estimated by setting a derivative (all derivatives) to zero.

Example: Logistic model

$$\frac{dN}{dt} = r_0 N \left(1 - \frac{N}{K}\right)$$

To find equilibrium we have to solve the equation: $dN/dt = 0$:

$$r_0 N \left(1 - \frac{N}{K}\right) = 0$$

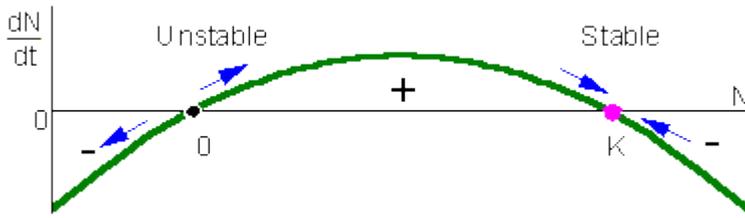

This equation has two roots: $N=0$ and $N=K$. An equilibrium may be stable or unstable. For example, the equilibrium of a pencil standing on its tip is unstable; The equilibrium of a picture on the wall is (usually) stable.

An equilibrium is considered **stable** (for simplicity we will consider asymptotic stability only) if the system always returns to it after small disturbances. If the system moves away from the equilibrium after small disturbances, then the equilibrium is **unstable**.

The notion of stability can be applied to other types of attractors (limit cycle, chaos), however, the general definition is more complex than for equilibria. Stability is probably the most important notion in science because it refers to what we call "reality". Everything should be stable to be observable. For example, in quantum mechanics, energy levels are those that are stable because unstable levels cannot be observed.

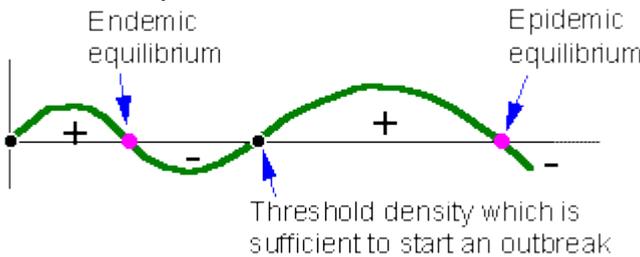

Now, let's examine stability of 2 equilibria points in the logistic model.

In this figure, population growth rate, dN/dt , is plotted versus population density, N . This is often called a **phase-plot** of population dynamics. If $0 < N < K$, then $dN/dt > 0$ and thus, population grows (the point in the graph moves to the right). If $N < 0$ or $N > K$ (of course, $N < 0$ has no biological sense), then population declines (the point in the graph moves to the left). The arrows show that the equilibrium $N=0$ is unstable, whereas the equilibrium $N=K$ is stable. From the biological point of view, this means that after small deviation of population numbers from $N=0$ (e.g., immigration of a small number of organisms), the population never returns back to this equilibrium. Instead, population numbers increase until they reach the stable equilibrium $N=K$. After any deviation from $N=K$ the population returns back to this stable equilibrium.

The difference between stable and unstable equilibria is in the slope of the line on the phase plot near the equilibrium point. Stable equilibria are characterized by a negative slope (negative feedback) whereas unstable equilibria are characterized by a positive slope (positive feedback).

The second example is the bark beetle model with two stable and two unstable equilibria. Stable equilibria correspond to endemic and epidemic populations. Endemic populations are regulated by the amount of susceptible trees in the forest. Epidemic populations are limited by the total number of trees because mass attack of beetle females may overcome the resistance of any tree.

Stability of models with several variables

Detection of stability in these models is not that simple as in one-variable models. Let's consider a predator-prey model with two variables: (1) density of prey and (2) density of predators. Dynamics of the model is described by the system of 2 differential equations:

$$\begin{cases} \frac{dH}{dt} = f(H, P) \\ \frac{dP}{dt} = g(H, P) \end{cases}$$

This is the 2-variable model in a general form. Here, H is the density of prey, and P is the density of predators. The first step is to find equilibrium densities of prey (H^*) and predator (P^*). We need to solve a system of equations:

$$\begin{cases} f(H^*, P^*) = 0 \\ g(H^*, P^*) = 0 \end{cases}$$

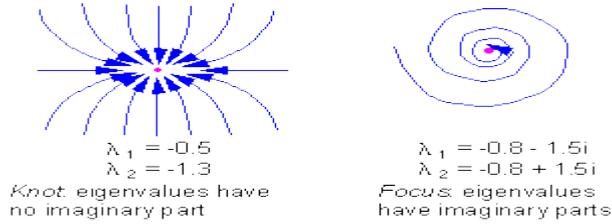

The second step is to linearize the model at the equilibrium point ($H = H^*, P = P^*$) by estimating the Jacobian matrix:

$$A = \begin{vmatrix} \frac{\partial f}{\partial H} & \frac{\partial f}{\partial P} \\ \frac{\partial g}{\partial H} & \frac{\partial g}{\partial P} \end{vmatrix}$$

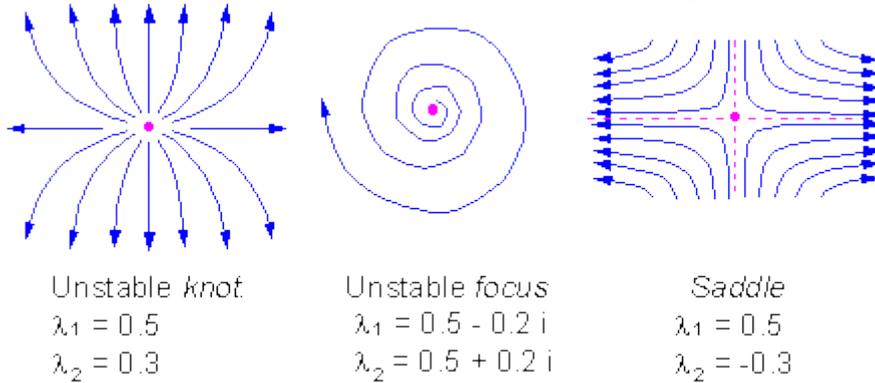

Third, eigenvalues of matrix A should be estimated. The number of eigenvalues is equal to the number of state variables. In our case there will be 2 eigenvalues. Eigenvalues are generally complex numbers. If real parts of all eigenvalues are negative, then the equilibrium is stable. If at least one eigenvalue has a positive real part, then the equilibrium is unstable.

Eigenvalues are used here to reduce a 2-dimensional problem to a couple of 1-dimensional problem problems. Eigenvalues have the same meaning as the slope of a line in phase plots. Negative real parts of eigenvalues indicate a negative feedback. It is important that ALL eigenvalues have negative real parts. If one eigenvalue has a positive real part then there is a direction in a 2-dimensional space in which the system will not tend to return back to the equilibrium point.

There are 2 types of stable equilibrium in a two-dimensional space: **knot** and **focus**

There are 3 types of unstable equilibrium in a two-dimensional space: **knot**, **focus**, and **saddle**

Stability in discrete-time models

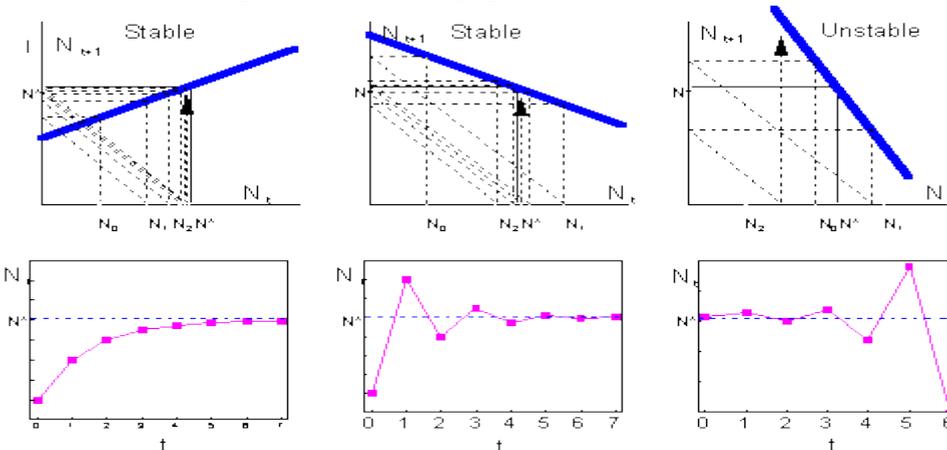

Consider a discrete-time model (a difference equation) with one state variable:

$$N_{t+1} = f(N_t)$$

This model is stable if and only if :

$$-1 < \frac{df}{dN_t} < 1$$

where $\frac{df}{dN_t}$ is the slope of a thick line in graphs below:

You can check this yourself using the following Excel spreadsheet:

Excel spreadsheet "ricker.xls"

If the slope is positive but less than 1, then the system approaches the equilibrium monotonically (left). If the slope is negative and greater than -1, then the system exhibits oscillations because of the "overcompensation" (center). Overcompensation means that the system jumps over the equilibrium point because the negative feedback is too strong. Then it returns back and again jumps over the equilibrium.

Continuous-time models with 1 variable never exhibit oscillations. In discrete-time models, oscillations are possible even with 1 variable. What causes oscillations is the delay between time steps. Overcompensation is a result of large time steps. If time steps were smaller, then the system would not jump over the equilibrium but will approach to it gradually.

Now we will analyze stability in the Ricker's model. This model is a discrete-time analog of the logistic model:

$$N_{t+1} = N_t \cdot \exp\left[r \left(1 - \frac{N_t}{K}\right)\right]$$

First, we need to find the equilibrium population density N^* by solving the equation:

$$N^* = N^* \cdot \exp\left[r \left(1 - \frac{N^*}{K}\right)\right]$$

This equation is obtained by substituting N_{t+1} and N_t with the equilibrium population density N^* in the initial equation. The roots are: $N^* = 0$ and $N^* = K$. We are not interested in the first equilibrium ($N^* = 0$) because there is no population. Let's estimate the slope df/dN at the second equilibrium point:

$$\frac{df}{dN_t} = \left(1 - \frac{r \cdot N_t}{K}\right) \cdot \exp\left[r \left(1 - \frac{N_t}{K}\right)\right] = 1 - r$$

$$N_t = N^* = K$$

Now we can apply the condition of stability:

$$-1 < 1 - r < 1$$

$$0 < r < 2$$

Thus, the Ricker's model has a stable equilibrium $N^* = K$ if $0 < r < 2$.

If a discrete time model has more than one state variable, then the analysis is similar to that in continuous-time models. The first step is to find equilibria. The second step is to linearize the model at the equilibrium state, i.e., to estimate the Jacobian matrix. The third step is to estimate eigenvalues of this matrix. The only difference from continuous models is the condition of stability. Discrete-time models are stable (asymptotically stable) if and only if all eigenvalues lie in the circle with the radius = 1 in the complex plain.

Theorem 7: If the conditions of the previous theorem are satisfied and if the functions $(a_i'')^{(7)}$ and $(b_i'')^{(7)}$ belong to $C^{(7)}(\mathbb{R}_+)$ then the above equilibrium point is asymptotically stable.

Proof: Denote

*

Definition of G_i, T_i :-

$$G_i = G_i^* + G_i \quad , \quad T_i = T_i^* + T_i$$

$$\frac{\partial (a_{37}'')^{(7)}}{\partial T_{37}}(T_{37}^*) = (q_{37})^{(7)} \quad , \quad \frac{\partial (b_i'')^{(7)}}{\partial G_j}((G_{39})^{**}) = s_{ij} \quad *100, 101$$

Then taking into account equations of the system Quantum Information and Quantum Mechanical Behaviour and neglecting the terms of power 2, we obtain*

$$\frac{dG_{36}}{dt} = -((a'_{36})^{(7)} + (p_{36})^{(7)})G_{36} + (a_{36})^{(7)}G_{37} - (q_{36})^{(7)}G_{36}^*T_{37} \quad *102$$

$$\frac{dG_{37}}{dt} = -((a'_{37})^{(7)} + (p_{37})^{(7)})G_{37} + (a_{37})^{(7)}G_{36} - (q_{37})^{(7)}G_{37}^*T_{37} \quad *103$$

$$\frac{dG_{38}}{dt} = -((a'_{38})^{(7)} + (p_{38})^{(7)})G_{38} + (a_{38})^{(7)}G_{37} - (q_{38})^{(7)}G_{38}^*T_{37} \quad *104$$

$$\frac{dT_{36}}{dt} = -((b'_{36})^{(7)} - (r_{36})^{(7)})T_{36} + (b_{36})^{(7)}T_{37} + \sum_{j=36}^{38} (s_{(36)(j)})T_{36}^*G_j \quad *105$$

$$\frac{dT_{37}}{dt} = -((b'_{37})^{(7)} - (r_{37})^{(7)})T_{37} + (b_{37})^{(7)}T_{36} + \sum_{j=36}^{38} (s_{(37)(j)})T_{37}^*G_j \quad *106$$

$$\frac{dT_{38}}{dt} = -((b'_{38})^{(7)} - (r_{38})^{(7)})T_{38} + (b_{38})^{(7)}T_{37} + \sum_{j=36}^{38} (s_{(38)(j)})T_{38}^*G_j \quad *107$$

The characteristic equation of this system is

$$\begin{aligned}
& ((\lambda)^{(7)} + (b'_{38})^{(7)} - (r_{38})^{(7)}) \{ ((\lambda)^{(7)} + (a'_{38})^{(7)} + (p_{38})^{(7)}) \\
& \left[((\lambda)^{(7)} + (a'_{36})^{(7)} + (p_{36})^{(7)}) (q_{37})^{(7)} G_{37}^* + (a_{37})^{(7)} (q_{36})^{(7)} G_{36}^* \right] \\
& \left(((\lambda)^{(7)} + (b'_{36})^{(7)} - (r_{36})^{(7)}) s_{(37),(37)} T_{37}^* + (b_{37})^{(7)} s_{(36),(37)} T_{37}^* \right) \\
& + \left(((\lambda)^{(7)} + (a'_{37})^{(7)} + (p_{37})^{(7)}) (q_{36})^{(7)} G_{36}^* + (a_{36})^{(7)} (q_{37})^{(7)} G_{37}^* \right) \\
& \left(((\lambda)^{(7)} + (b'_{36})^{(7)} - (r_{36})^{(7)}) s_{(37),(36)} T_{37}^* + (b_{37})^{(7)} s_{(36),(36)} T_{36}^* \right) \\
& \left(((\lambda)^{(7)})^2 + (a'_{36})^{(7)} + (a'_{37})^{(7)} + (p_{36})^{(7)} + (p_{37})^{(7)} \right) (\lambda)^{(7)} \\
& \left(((\lambda)^{(7)})^2 + (b'_{36})^{(7)} + (b'_{37})^{(7)} - (r_{36})^{(7)} + (r_{37})^{(7)} \right) (\lambda)^{(7)} \\
& + \left(((\lambda)^{(7)})^2 + (a'_{36})^{(7)} + (a'_{37})^{(7)} + (p_{36})^{(7)} + (p_{37})^{(7)} \right) (\lambda)^{(7)} (q_{38})^{(7)} G_{38} \\
& + ((\lambda)^{(7)} + (a'_{36})^{(7)} + (p_{36})^{(7)}) \left((a_{38})^{(7)} (q_{37})^{(7)} G_{37}^* + (a_{37})^{(7)} (a_{38})^{(7)} (q_{36})^{(7)} G_{36}^* \right) \\
& \left(((\lambda)^{(7)} + (b'_{36})^{(7)} - (r_{36})^{(7)}) s_{(37),(38)} T_{37}^* + (b_{37})^{(7)} s_{(36),(38)} T_{36}^* \right) \} = 0
\end{aligned}$$

And as one sees, all the coefficients are positive. It follows that all the roots have negative real part, and this proves the theorem.

DISSIPATION OF QUANTUM MECHANICAL EFFECTS:

The need for a quantum-mechanical formalism for systems with dissipation which is applicable to the radiation field of a cavity is discussed. Two methods that have been used in this connection are described. The first, which starts with the classical Newtonian equation of motion for a damped oscillator and applies the conventional formal quantization techniques, leads to an exact solution; but subsequent discussion shows that this method is invalid, the results being unacceptable from a quantum-mechanical viewpoint. The second method, which considers the interaction of two systems, the lossless oscillator and the loss mechanism, is adopted in the present article. No special model is used for the loss mechanism, but this mechanism is assumed to have a large number of densely-spaced energy states.

The approximations with respect to the loss mechanism that underlie the concept of dissipation are discussed. These approximations are then applied to the analysis, and a differential equation for a coordinate operator of the harmonic oscillator is obtained which has the formal appearance of the Newtonian equation of motion for a driven damped harmonic oscillator, the driving term being an operator referring to the loss mechanism. The presence of the driving term is responsible for the difference between the present theory and that of the first method mentioned above. A solution of the differential equation for the coordinate operator is given explicitly. An examination of the physical significance of the solution shows that the driving term is responsible not only for the thermal fluctuations which are due to the loss mechanism, but also for the proper commutation relationship of the conjugate coordinates of the oscillator and for its zero-point fluctuations.

A generalization of the solution to provide for a classical driving force and coupled atomic systems is given. The results are then restated in a form that refers to the loss mechanism only through the two parameters by which it is usually described—the dissipation constant and the temperature.

Some selected Examples:

A. O. Caldeira and A. J. Leggett studies the following system:

quantum system which can tunnel, at $T=0$, out of a metastable state and whose interaction with its environment is adequately described in the classically accessible region by a phenomenological friction coefficient η , is considered. By only assuming that the environment response is linear, it is found that dissipation multiplies the tunneling probability by the factor $\exp[-A\eta(\Delta q)^2/\hbar]$, where Δq is the "distance under the barrier" and A is a numerical factor which is generally of order unity

Measurements of the tunneling rate Γ out of the zero-voltage state for several Nb edge junctions with differing shunt capacitances are described. At zero temperature, increasing the shunt capacitance lowers Γ in agreement with dissipative calculations of the macroscopic-quantum-tunneling rate. As temperature increases, $\ln[\Gamma(T)/\Gamma(0)] \propto T^2$ as recently predicted.

Quantum dissipation

From Wikipedia, the free encyclopedia

Quantum Dissipation is the branch of physics that studies the quantum analogues of the process of irreversible loss of energy observed at the classical level. Its main purpose is to derive the laws of classical dissipation from the framework of quantum mechanics. It shares many features with the subjects of quantum decoherence and quantum theory of measurement.

Models of Quantum Dissipation

The main problem to address to study dissipation at the quantum level is the way to envisage the mechanism of irreversible loss of energy. Quantum mechanics usually deal with the Hamiltonian formalism, where the total energy of the system is a conserved quantity. So in principle it would not be possible to describe dissipation in this framework.

The idea to overcome this issue consists on splitting the total system in two parts: the quantum system where dissipation occurs, and a so-called environment or bath where the energy of the former will flow towards. The way both systems are coupled depends on the details of the microscopic model, and hence, the description of the bath. To include an irreversible flow of energy (i.e., to avoid Poincaré recurrences in which the energy eventually flows back to the system), requires that the

bath contain an infinite number of degrees of freedom. Notice that by virtue of the principle of universality, it is expected that the particular description of the bath will not affect the essential features of the dissipative process, as far as the model contains the minimal ingredients to provide the effect.

The simplest way to model the bath was proposed by Feynman and Vernon in a seminal paper from 1963^[1]. In this description the bath is a sum of an infinite number of harmonic oscillators, that in quantum mechanics represents a set of free bosonic particles.

[edit]The Caldeira-Leggett model

In 1981 Amir Caldeira and Anthony J. Leggett proposed a simple model to study in detail the way dissipation arises from a quantum point of view^[2]. It describes a quantum particle in one-dimension coupled to a bath. The Hamiltonian reads:

$$H = \frac{P^2}{2M} + V(X) + \sum_i \left(\frac{p_i^2}{2m_i} + \frac{1}{2} m_i \omega_i^2 q_i^2 \right) + X \sum_i C_i q_i + X^2 \sum_i \frac{C_i^2}{2m_i \omega_i^2},$$

The first two terms correspond to the Hamiltonian of a quantum particle of mass M and momentum P , in a potential V at position X . The third term describes the bath as a sum of infinite harmonic oscillators with masses m_i and momentum p_i , at positions q_i . ω_i are the frequencies of the harmonic oscillators. The next term describes the way system and bath are coupled. In the Caldeira - Leggett model the bath is coupled to the position of the particle. C_i are coefficients which depend on the details of the coupling. The last term is a counter-term which must be included to ensure that dissipation is homogeneous in all space. As the bath couples to the position, if this term is not included the model is not translationally invariant, in the sense that the coupling is different wherever the quantum particle is located. This gives rise to an unphysical renormalization of the potential, which can be shown to be suppressed by including the counter-term.

To provide a good description of the dissipation mechanism, a relevant quantity is the bath spectral function, defined as follows:

$$J(\omega) = \frac{\pi}{2} \sum_i \frac{C_i^2}{m_i \omega_i} \delta(\omega - \omega_i)$$

The bath spectral function provides a constraint in the choice of the coefficients C_i . When this function has the form $J(\omega) = \eta \omega$, the corresponding classical kind of dissipation can be shown to be Ohmic. A more generic form is $J(\omega) \propto \omega^s$. In this case, if $s > 1$ the dissipation is called "super-ohmic", while if $s < 1$ is sub-ohmic. An example of a super-ohmic bath is the electro-magnetic field under certain circumstances.

As mentioned, the main idea in the field of quantum dissipation is to explain the way classical dissipation can be described from a quantum mechanics point of view. To get the classical limit of the Caldeira - Leggett model, the bath must be integrated out (or traced out), which can be understood as taking the average over all the possible realizations of the bath and studying the effective dynamics of the quantum system. As a second step, the limit $\hbar \rightarrow 0$ must be taken to recover classical mechanics. To proceed with those technical steps mathematically, the path integral description of quantum mechanics is usually employed. The resulting classical equations of motion are:

$$M \frac{d^2}{dt^2} X(t) = -\frac{\partial V(X)}{\partial X} - \int_0^T dt' \alpha(t-t')(X(t) - X(t'))$$

where:

$$\alpha(t-t') = \frac{1}{2\pi} \int_0^\infty J(\omega) e^{-\omega|t-t'|} d\omega$$

is a kernel which characterizes the effective force that affects the motion of the particle in the presence of dissipation. For so-called Markovian baths, which do not keep memory of the interaction with the system, and for Ohmic dissipation, the equations of motion simplify to the classical equations of motion of a particle with friction:

$$M \frac{d^2}{dt^2} X(t) = -\frac{\partial V(X)}{\partial X} - \eta \frac{dX(t)}{dt}$$

Hence, one can see how Caldeira-Leggett model fulfills the goal of getting classical dissipation from the quantum mechanics framework. The Caldeira-Leggett model has been used to study **quantum dissipation** problems since its introduction in 1981, being extensively used as well in the field of quantum decoherence.

[edit]The dissipative two-level system

This particular realization of the Caldeira - Leggett model deserves special attention due to its interest in the field of Quantum Computation. The aim of the model is to study the effects of dissipation in the dynamics of a particle that can hop between two different positions. This reduced Hilbert space allows the problem to be described in terms of $1/2$ spin operators. The resulting Hamiltonian is also referred in the literature as the Spin-Boson model, reading:

$$H = \Delta S_x + \sum_i \left(\frac{p_i^2}{2m_i} + \frac{1}{2} m_i \omega_i^2 q_i^2 \right) + S_z \sum_i C_i q_i,$$

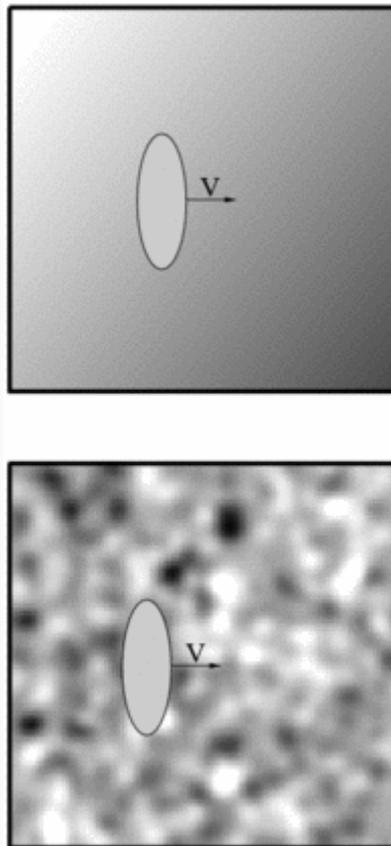

where $S_i = \frac{\sigma_i}{2}$, $i = x, y, z$ are proportional to the Pauli matrices σ_i , and Δ is the probability of hopping between the two possible positions. Notice that in this model the counter-term is no longer needed, as the coupling to S_z gives already homogeneous dissipation.

The model has many applications. In **quantum dissipation** it is used as a simple model to study the dynamics of a dissipative particle confined in a double-well potential. In the context of Quantum Computation it represents a qubit coupled to an environment, which can produce decoherence. In the study of amorphous solids it provides the basis of the standard theory to describe their thermodynamic properties.

The dissipative two-level systems represents also a paradigm in the study of quantum phase transitions. For a critical value of the coupling to the bath it shows a phase transition from a regime in which the particle is delocalized among the two positions to another in which it is localized in only one of them. The transition is of Kosterlitz-Thouless kind, as can be seen by deriving the Renormalization group flow equations for the hopping term.

Dissipation model for extended environment

From Wikipedia, the free encyclopedia

(a) The Brownian particle in the Caldeira-Leggett model experiences a fluctuating homogeneous field of force. (b) In case of the DLD model the fluctuating field is farther characterized by a finite correlation distance. The background image is a “snapshot” of the fluctuating environment. Namely, the gray levels correspond to the “height” of an instantaneous potential which is experienced by the Brownian particle.

A unified model for *Diffusion Localization and Dissipation* (DLD), optionally termed *Diffusion with Local Dissipation*, has been introduced for the study of *Quantal Brownian Motion* (QBM) in dynamical disorder^{[1], [2]}. It can be regarded as a generalization of the familiar Caldeira-Leggett model.

$$\mathcal{H} = \frac{p^2}{2m} + V(x) + \mathcal{H}_{int} + \mathcal{H}_{bath}$$

$$\mathcal{H}_{bath} = \sum_{\alpha} \left(\frac{P_{\alpha}^2}{2m_{\alpha}} + \frac{1}{2} m_{\alpha} \omega_{\alpha}^2 Q_{\alpha}^2 \right)$$

$$\mathcal{H}_{int} = - \sum_{\alpha} c_{\alpha} Q_{\alpha} u(x - x_{\alpha})$$

where Q_{α} denotes the dynamical coordinate of the α scatterer or bath mode. $u(x - x_{\alpha})$ is the interaction potential, and c_{α} are coupling constants. The spectral characterization of the bath is analogous to that of the Caldeira-Leggett model:

$$\frac{\pi}{2} \sum_{\alpha} \frac{c_{\alpha}^2}{m_{\alpha} \omega_{\alpha}} \delta(\omega - \omega_{\alpha}) \delta(x - x_{\alpha}) = J(\omega)$$

i.e. the oscillators that appear in the Hamiltonian are distributed uniformly over space, and in each location have the same spectral distribution $J(\omega)$. Optionally the environment is characterized by the power spectrum of the fluctuations $S(q, \omega)$, which is determined by $J(\omega)$ and by the assumed interaction $u(r)$. See examples.

The model can be used to describes the dynamics of a Brownian particle in an Ohmic environment whose fluctuations are uncorrelated in space This should be contrasted with the Zwanzig-Caldeira-Leggett model, where the induced fluctuating force is assumed to be uniform in space (see figure).

At high temperatures the propagator possesses a Markovian property and one can write down an equivalent Master equation. Unlike the case of the Zwanzig-Caldeira-Leggett model, genuine quantum mechanical effects manifest themselves due to the disordered nature of the environment.

Using Wigner picture of the dynamics one can distinguish between two different mechanisms for destruction of coherence: scattering mechanism and smearing mechanism. The analysis of dephasing can be extended to the low temperature regime by using a semiclassical strategy. In this context the dephasing rate SP formula can be derived. Various results can be derived for ballistic, chaotic, diffusive, both ergodic and non-ergodic motion.

In the following we give example of a recent study done in brief measure, not wholly or in full measure but very substantially as a review percussion:

Quantum Dissipation versus Classical Dissipation for Generalized Brownian motion (For details See Doron Cohen)

Authors' try to clarify what are the genuine quantal effects that **are associated with** generalized Brownian Motion (BM). All the quantal effects that are **associated with** the Zwanzig-Feynman-Vernon-Caldeira-Leggett model are (formally) a solution of the classical Langevin equation. Non-stochastic, genuine quantum mechanical effects are found for a model that takes into account either the disordered or the chaotic nature of some environment.

The role of **dissipation in** curve crossing phenomena in condensed phases is discussed. Adiabaticity criteria are found in two regimes via path integral arguments. In the high temperature regime a stochastic quantum Langevin approach is developed. In the low temperature region an instanton method is used. In both cases the curve crossing time scale competes with the time scale of molecular motion. Dissipation causes the process to be more likely to be adiabatic.

Quantum optics is one of the liveliest fields in physics at present. While it has been a dominant research field for at least two decades, with much graduated but incremental activity, in the past few years it has started **to impact the** study of Quantum Computation. There are plenty of good research monographs in this field, but it was felt that there was a genuine need for a straightforward account .This is a field which attracts the brightest students at present, in part because of the **extraordinary progress** in the field (e.g. **the implementation of teleportation, quantum cryptography, Schrödinger cat states, Bell violations of local realism and the like**).

The presentation is almost entirely concerned with the quantized electromagnetic field and its effects on atoms, and how nonclassical light behaves. One aim of presently is to connect **quantum optics** with the newly developing subject of **quantum information processing**.

Topics covered are: single-mode field quantization in a cavity, quantization of multimode fields, the issue of the quantum phase, coherent states, quasi-probability distributions in phase space, atom-field interactions, the Jaynes-Cummings model, quantum coherence theory, beam splitters and interferometers, nonclassical field states with squeezing, etc., test of local realism with entangled photons from down-conversion, experimental realizations of cavity quantum electrodynamics, trapped ions, etc., issues regarding decoherence, and some applications to quantum information processing, particularly quantum cryptography. Recent studies include involvement of computational work, some more extensively than others.

History

The ancient world already was wrestling with the nature of light as rays. By the seventeenth century the two rival concepts of waves and corpuscles were well established. Maxwell, in the second half of the nineteenth century, laid the foundations of

modern field theory, with a detailed account of light as electromagnetic waves and at that point classical physics seemed triumphant, with “minor” worries about the nature of black-body radiation and of the photoelectric effect. These of course were the seeds of the quantum revolution. Planck, an inherently conservative theorist, was led rather reluctantly, it seems, to propose that thermal radiation **was emitted and absorbed** in discrete quanta in order to explain the spectra of thermal bodies. It was Einstein who generalized this idea so that these new quanta represented the light itself rather than the processes of **absorption and emission**, and was able to describe how matter and radiation could come into **equilibrium** (introducing on the way the idea of stimulated emission), and how the photoelectric effect could be explained. By 1913, Bohr applied the basic idea of quantization to atomic dynamics and was able to predict the positions of atomic spectral lines. Gilbert Lewis, a chemist, coined the word photon well after the light quanta idea itself was introduced. In 1926 Lewis said:

It would seem appropriate to speak of one of these hypothetical entities as a particle of light, a corpuscle of light, a light quantum, or light quant, if we are to assume that it spends only a minute fraction of its existence as a carrier of radiant energy, while the rest of the time it remains as an important structural element within the atom . . . I therefore take the liberty of proposing for this hypothetical new atom, which is not light but plays an important part in every process of radiation, the name photon

Clearly Lewis’s idea and ours are rather distantly connected!

De Broglie in a remarkable leap of imagination generalized what we knew about light quanta, **exhibiting** wave and particle properties to matter itself. Heisenberg, Schrödinger and Dirac laid the foundations of quantum mechanics in an amazingly short period from 1925 to 1926. They gave us the whole machinery we still use: representations, quantum-state evolution, unitary transformations, perturbation theory and more. The intrinsic probabilistic nature of quantum mechanics was uncovered by Max Born, who proposed the idea of probability amplitudes which allowed a fully quantum treatment of interference.

Fermi and Dirac, pioneers of quantum mechanics, were also among the first to address the question of how quantized light interacts with atomic sources and propagates. Fermi’s *Reviews of Modern Physics* article in the 1930s, based on lectures he gave in Ann Arbor, summarize what was known at that time within the context of nonrelativistic quantum electrodynamics in the Coulomb gauge. His treatment of interference (especially Lipmann fringes) still repays reading today. It is useful to quote Willis Lamb in this context:

Begin by deciding how much of the universe needs to be brought into the discussion. Decide what normal modes are needed for an adequate treatment. Decide how to model the light sources and work out how they drive the system [4].

Weisskopf and Wigner applied the newly developed ideas of non-relativistic quantum mechanics to the dynamics of spontaneous emission and resonance fluorescence, predicting the exponential law for excited-state decay. This work already exhibited the self-energy problems, which were to plague quantum electrodynamics for the next 20 years until the development of the renormalization programme by Schwinger, Feynman, Tomonaga, and Dyson. The observation of the **anomalous magnetic moment** of the electron by Kusch, and of radiative level shifts of atoms by Lamb and Retherford, were the highlights of this era. The interested reader will find the history of this period very ably described by Schweber in his magisterial account of QED. This period of research demonstrated the importance of considering the vacuum as a field which had observable consequences. In a remarkable development in the late 1940s, triggered by the observation that colloids were more stable than expected from considerations of van der Waals interactions, Casimir showed that long-range intermolecular forces were intrinsically quantum electrodynamic. He **linked them to the idea** of zero-point motion of the field and showed that metal plates in vacuum attract as a consequence of such zero-point motion.

Einstein had continued his study of the basic nature of quantum mechanics and in 1935 in a remarkable paper with Podolsky and Rosen was able to show how peculiar quantum correlations were. The ideas in this paper were to explode into one of the most active parts of modern physics with the development by Bohm and Bell of concrete predictions of the nature of **these correlations**; this laid the foundations of what was to become the new subject of quantum information processing.

Optical coherence had been investigated for many years using amplitude interference: a first-order correlation. Hanbury Brown and Twiss in the 1950s worked on intensity correlations as a tool in stellar interferometry, and showed how thermal photon detection events were “bunched.” This **led to the** development of the theory of photon statistics and photon counting and to the beginnings of quantum optics as a separate subject. At the same time as ideas of photon statistics were being developed, researchers had begun to investigate coherence in **light-matter interactions**. Radio-frequency spectroscopy had already been initiated with atomic beams with the work of Rabi, Ramsey and others. Sensitive optical pumping probes of light interaction with atoms were developed in the 1950s and 1960s by Kastler, Brossel, Series, Dodd and others.

By the early 1950s, Townes and his group, and Basov and Prokhorov, had developed molecular microwave sources of radiation: the new masers, based on precise initial state preparation, population inversion and stimulated emission. Ed Jaynes in the 1950s played a major role in studies of whether quantization played a role in maser operation (and this set the stage for much later work on fully quantized atom–field coupling in what became known as the Jaynes–Cummings model). Extending the maser idea to the optical regime and the development of lasers of course revolutionized modern physics and technology.

Glauber, Wolf, Sudarshan, Mandel, Klauder and many others developed a quantum theory of coherence based on coherent states and photodetection. Coherent states allowed us to describe the behaviour of light in phase space, using the quasi-probabilities developed much earlier by Wigner and others.

For several years after the development of the laser there were no tuneable sources: researchers interested in the details of atom–light or molecule–light interactions had to rely on molecular chance resonances. Nevertheless, this led to the beginning of the study of coherent interactions and coherent transients such as photon echoes, self-induced transparency, optical notation and so on (well described in the standard monograph by Allen and Eberly). Tuneable lasers became available in the

early 1970s, and the dye laser in particular transformed precision studies in quantum optics and laser spectroscopy. Resonant interactions, coherent transients and the like became much more straightforward to study and led to the beginnings of quantum optics proper as we now understand it: for the first time we were able to study the dynamics of single atoms interacting with light in a non-perturbative manner. Stroud and his group initiated studies of resonance fluorescence with the observation of the splitting of resonance fluorescence spectral lines into component parts by the coherent driving predicted earlier by Mollow. Mandel, Kimble and others demonstrated how the resonance fluorescence light was antibunched, a feature studied by a number of theorists including Walls, Carmichael, Cohen-Tannoudji, Mandel and Kimble. The observation of antibunching and the associated (but in equivalent) sub-Poissonian photon statistics laid the foundation of the study of “non-classical light”. During the 1970s, several experiments explored the nature of photons: their indivisibility and the buildup of interference at the single photon level. Laser cooling rapidly developed in the 1980s and 1990s and allowed the preparation of states of matter under precise control. Indeed, this has become a major subject in its own right and we have taken the decision here to exclude laser cooling from this text.

Following the development of high-intensity pulses of light from lasers, a whole set of nonlinear optical phenomena were investigated, starting with the pioneering work in Ann Arbor by Franken and co-workers. Harmonic generation, parametric down-conversion and other phenomena were demonstrated. For the most part, none of this early work on nonlinear optics required field quantization and quantum optics proper for its description. But there were early signs that some could well do so: quantum nonlinear optics was really initiated by the study by Burnham and Weinberg of unusual nonclassical correlations in down-conversion. In the hands of Mandel and many others, these correlations in down-conversion became the fundamental tool used to uncover fundamental insights into quantum optics.

Until the 1980s, essentially all light fields investigated had phase-independent noise; this changed with the production of squeezed light sources with phase-sensitive noise. These squeezed light sources enabled us to investigate Heisenberg uncertainty relations for light fields. Again, parametric down-conversion proved to be the most effective tool to generate such unusual light fields.

Quantum opticians realized quite early that were atoms to be confined in resonators, then atomic radiative transition dynamics could be dramatically changed. Purcell, in a remarkable paper in 1946 within the context of magnetic resonance, had already predicted that spontaneous emission rates previously thought of as pretty immutable were in fact modified by enclosing the source atom within a cavity whose mode structure and densities are significantly different from those of free space. Putting atoms within resonators or close to mirrors became possible at the end of the 1960s. By the 1980s the theorists' dream of studying single atoms interacting with single modes of the electromagnetic field became possible. At this point the transition dynamics becomes wholly reversible, as the atom coherently exchanges excitation with the field, until coherence is eventually lost through a dissipative “decoherence” process. This dream is called the Jaynes–Cummings model after its proposers and forms a basic building block of quantum optics .

New fundamental concepts in information processing, leading to quantum cryptography and quantum computation, have been developed in recent years by Feynman, Benioff, Deutsch, Jozsa, Bennett, Ekert and others. Instead of using classical bits that can represent either the values 0 or 1, the basic unit of a quantum computer is a quantum mechanical two-level system (qubit) that can exist in coherent superpositions of the logical values 0 and 1. A set of n qubits can then be in a superposition of up to 2^n different states, each representing a binary number. Were we able to control and manipulate say 1500 qubits, we could access more states than there are particles in the visible universe. Computations are implemented by unitary transformations, which act on all states of a superposition simultaneously. Quantum gates form the basic units from which these unitary transformations are built up. In related developments, absolutely secure encryption can be guaranteed by using quantum sources of light.

The use of the quantum mechanical superpositions and entanglement results in a high degree of parallelism, which can increase the speed of computation exponentially. A number of problems which cannot feasibly be tackled on a classical computer can be solved efficiently on a quantum computer. In 1994 a quantum algorithm was discovered by Peter Shor that allows the solution of a practically important problem, namely factorization, with such an exponential increase of speed. Subsequently, possible experimental realizations of a quantum computer have been proposed, for example in linear ion traps and nuclear magnetic resonance schemes. Presently we are at a stage where quantum gates have been demonstrated in these two implementations. Quantum computation is closely related to quantum cryptography and quantum communication. Basic experiments demonstrating the in-principle possibility of these ideas have been carried out in various laboratories.

The linear ion trap is one of the most promising systems for quantum computation and is one we study in this book in detail. The quantum state preparation (laser cooling and optical pumping) in this system is a well-established technique, as is the state measurement by electron shelving and fluorescence. Singly charged ions of an atom such as calcium or beryllium are trapped and laser cooled to micro-Kelvin temperatures, where they form a string lying along the axis of a linear radio-frequency (r.f.) Paul trap. The internal state of any one ion can be exchanged with the quantum state of motion of the whole string. This can be achieved by illuminating the ion with a pulse of laser radiation at a frequency tuned below the ion's internal resonance by the vibrational frequency of one of the normal modes of oscillation of the string. This ouples single phonons into and out of the vibrational mode. The motional state can then be coupled to the internal state of another ion by directing the laser onto the second ion and applying a similar laser pulse. In this way general transformations of the quantum state of all the ions can be generated. The ion trap has several features to recommend it. It can achieve processing on quantum bits without the need for any new technological breakthroughs, such as micro-fabrication techniques or new cooling methods. The state of any ion can be measured and re-prepared many times without problem, which is an important feature for implementing quantum error correction protocols.

Trapped atoms or ions can be **strongly coupled to an** electromagnetic field mode in a cavity, which permits the powerful **combination of** quantum processing and long-distance quantum communication. This suggests ways in which we may construct quantum memories. These systems can in principle realize a quantum processor larger than any which could be thoroughly simulated by classical computing but the decoherence generated by dephasing and **spontaneous emission is a formidable obstacle.**

Entangled states are **the key ingredient** for certain forms of quantum cryptography and for quantum teleportation. Entanglement is also **responsible for** the power of quantum computing, which, under ideal conditions, **can accomplish** certain tasks exponentially faster than any classical computer. A deeper understanding of **the role of quantum** entanglement in quantum information theory **will allow us** to improve existing applications and to develop new methods of **quantum information manipulation.**

What then is the future of quantum optics? It underpins a great deal of laser science and novel atomic physics. It may even be the vehicle by which we can realize a whole new technology whereby quantum mechanics permits the processing and transmission of information in wholly novel ways. But of course, whatever we may predict now to emerge will be confounded by the unexpected: the field remains an adventure repeatedly throwing up the unexpected.

ESSENTIAL PREDICATIONS, PREDICATIONAL ANTERIORITIES, PRIMORDIAL EXACTITUDE, ONTOLOGICAL CONSONANCE OF VARIOUS VARIABLES OF QUANTUM COMPUTING SUCH AS ELECTROMAGNETIC FIELD, HARMONIC OSCILLATORS, PHASE INFORMATION, AND SPONTANEOUS DECAY; WITH SOME CONCOMITANT AND CORRESPONDING STUDIES DONE IN ABSTRACT AND SENTENTIOUS MANNER:

THE electromagnetic field can be quantized in terms of harmonic oscillators representing modes of the electromagnetic field, with states describing how many excitations (photons) are present in each normal mode.

1. Coherent states, superposition states carrying phase information are closely interrelated to each other
2. Light and matter interact.
3. Quantification of notions of coherence in terms of optical field correlation functions.
4. Optical elements such as beam splitters and interferometers, **manipulate the** states of light.
5. Nonclassical states have properties which are dictated by their fundamental quantum nature.
6. Spontaneous emission and decay in an open environment
7. How quantum optical sources of radiation can be used to provide tests of fundamental quantum mechanics, including tests of nonlocality and Bell inequalities.
8. Atoms confined in cavities and trapped laser-cooled ions **can be used to study** basic interaction phenomena.
9. Applications to the newly emerging problems of quantum information processing.

For a given 2-dimensional dissipative discrete **map generating** chaotic dynamics author presents the phenomenological construction of a quantum mechanical master equation **which reduces to the** given map in the classical limit. **Global dissipation**, caused by the non-invertibility of the map, and local dissipation, **caused by the** local contraction of the map, are both incorporated in the description. The behavior in the two opposite limits of vanishing **local dissipation and of strong local dissipation** is analyzed exactly. Using the representation of the statistical operator by the Wigner distribution, the classical and semi-classical limit has been studied. An estimate of the critical time is obtained, which determines the **crossover** between classical and quantum mechanical behavior in the chaotic state. This critical time diverges logarithmically for $\hbar \rightarrow 0$. In the main body of the text Emphasis is given to physical meaning **of dissipation** of background **fields due to** particle creation and statistical effects in **interacting** quantum field theories and in semiclassical gravitational theories. We indicate the possible existence of a **fluctuation-dissipation relation** for non-equilibrium quantum fields as occurring in cosmological particle **creation and back reaction processes**. Thus in the total, the sum and substance of the write is that it can be conjectured that all effective theories, including quantum gravity, **could manifest** dissipative behavior.

Effect of dissipation on the quantum-mechanical behavior of a macroscopic variable, in particular in situations **involving tunnelling** through a classically impenetrable barrier. Question of dissipation can be placed in the context of quantum measurement theory, and emphasize the importance of the distinction between the "adiabatic" and "dissipative" aspects **of the coupling of a macroscopic** variable to its environment. Next, there is a possible theoretical framework for the problem, with particular attention to how far the necessary input **parameters can be deduced** from the purely classical behavior of the system in question. Theoretical results obtained within this framework for the effects **of dissipation both on the decay of a metastable** state ("macroscopic quantum tunnelling") and on the coherent oscillations of a macroscopic two-state system ("macroscopic quantum coherence").

SOME RECENT DEVELOPMENTS:

The aim of recent research has been is the description of the electrical transport properties of Nanoscale systems. These properties **are influenced by** fundamental physical properties such as quantum mechanical coherence, dissipation, and **interaction among the charge carriers**. They are used to develop methods to describe the large variety of Nanoscale systems, but also work on the description of new measurable observables like current noise and **counting statistics** that provide a deeper understanding of the relevant transport processes. The following examples give an overview of the research:

Electron transport through quantum dot systems and molecules

In Nanoscale quantum dots electronic interactions play a **dominant role**, leading, e.g. to the Coulomb blockade. Electron transport and current noise using various methods like diagrammatic perturbation theory, full counting statistics, or path integral techniques are also taken in to consideration. Similar questions are relevant for charge transport through molecules. However, in long molecules (e.g. DNA) also inelastic transport processes and dissipation of energy to the molecular environment play an important role.

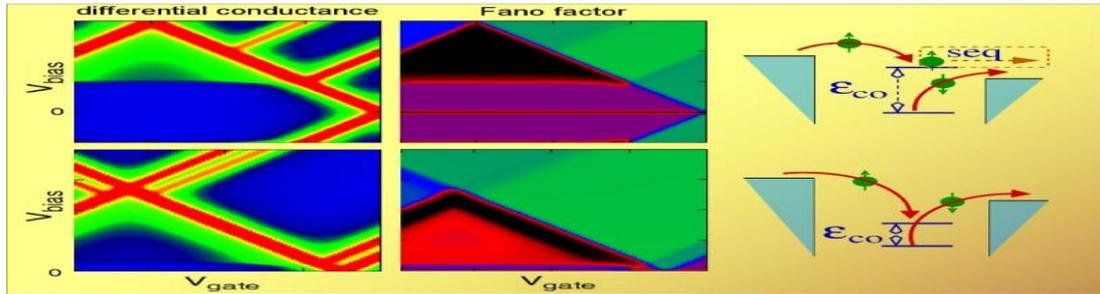

Figure 1: Differential conductance and shot **noise (Fano+ factor) of** a quantum dot with two energy levels. Within the so-called "Coulomb diamond" (area at low transport bias V_{bias} **limited by** the red lines of high differential conductance) second order processes ("**Co-tunneling**") are dominant. The sketches (right) show the dominant processes at small transport bias V_{bias} .

Electronic properties of carbon nanotubes and graphene

Carbon nanotubes and graphene are often considered as ideal examples of coherent quantum transport. In experiments, however, often effects due to disorder, in homogeneity of the environment, or phonon scattering are of importance. Some work studies observables like current noise in various experimental situations.

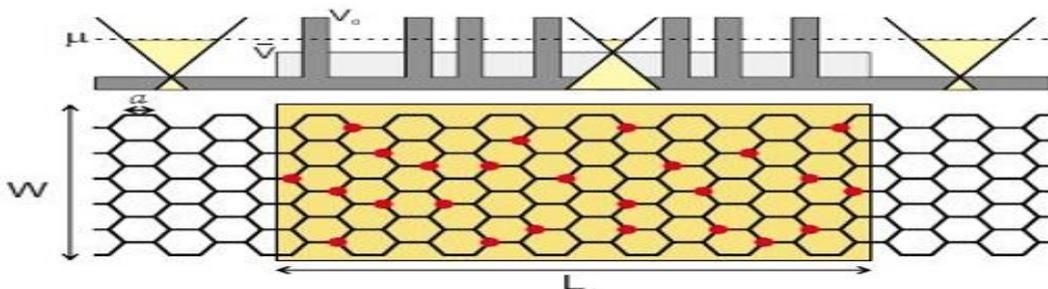

Figure 2: Sketch of the structure of a graphene ribbon with binary disorder. The disorder causes local scattering potentials V_s and a shift of the chemical potential μ away from the "Dirac points". The **conductivity depends on** the length of the graphene ribbon.

Transport through hybrid structures

In hybrid structures, materials of strongly differing (or even complementary) properties are brought together. An example is the combination of superconducting and ferromagnetic metals. Transport through such structures show phenomena that are so far poorly understood, e.g. Non-local Andreev reflections, that we describe by Green function methods. Hybrid structures are particularly interesting for applications, as their integration with established (semiconductor) technologies is feasible.

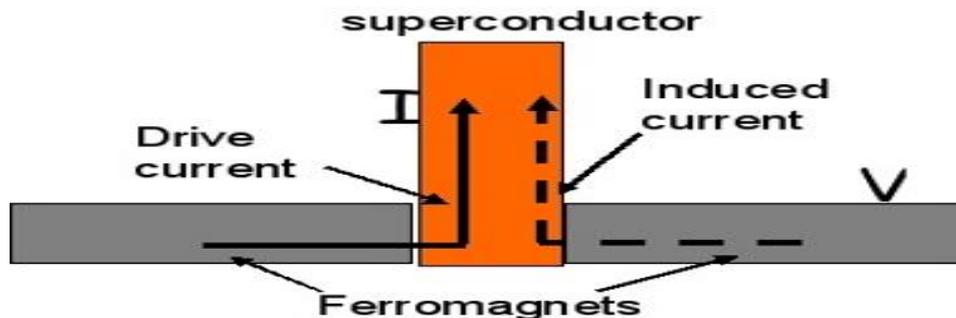

Figure 3: Sketch of a superconducting-ferromagnetic hybrid structure. The behavior of the non-local transport properties is under investigation.

Atomic contacts

The smallest possible transport system consists of single atoms. Here, the difficulty lies in the manufacturing of stable structure, with the possibility to control them via external "knobs". Our research applies a combination of Monte Carlo simulations and tight binding transport calculations, to make the bridge from a purely statistical description to possible applications of such systems with predictable transport properties.

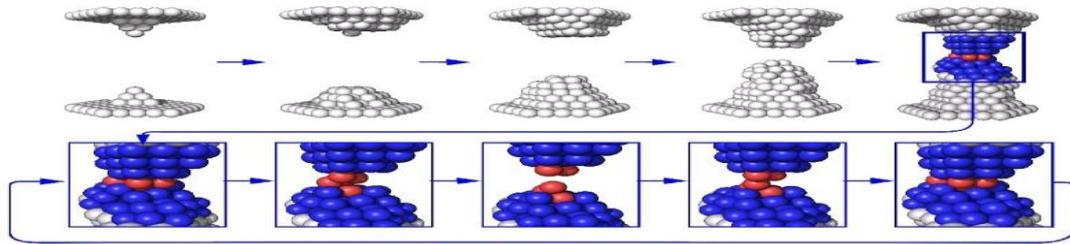

Figure 4: Monte Carlo simulation of the growth of an atomic contact of silver. In specific configurations the controlled opening and closing of the contact is possible.

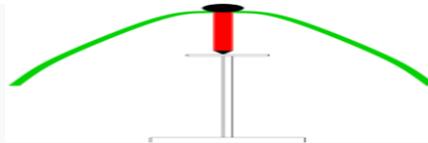

T Symmetry is the symmetry of physical laws under a **time reversal** transformation:

$$T : t \mapsto -t.$$

Although in restricted contexts one may find this symmetry, the observable universe itself does not show symmetry under time reversal, primarily due to the second law of thermodynamics. Time *asymmetries* are generally distinguished as between those intrinsic to the dynamic laws of nature, and those due to the initial conditions of our universe. The T-*asymmetry* of the weak force is of the first kind, while the T-*asymmetry* of the second law of thermodynamics is of the second kind.

Invariance

Physicists also discuss the time-reversal invariance of local and/or macroscopic descriptions of physical systems, independent of the invariance of the underlying microscopic physical laws. For example, Maxwell's equations with material absorption or Newtonian mechanics with friction are not time-reversal invariant at the macroscopic level where they are normally applied, even if they are invariant at the microscopic level when one includes the atomic motions the "lost" energy is translated into.

A toy called the teeter-totter illustrates the two aspects **of time reversal invariance**. When set into motion atop a pedestal, the figure oscillates for a very long time. The toy is engineered to minimize friction and illustrate the reversibility of Newton's laws of motion. However, the mechanically stable state of the toy is when the figure falls down from the pedestal into one of arbitrarily many positions. This is an illustration of the law of increase of entropy through Boltzmann's identification of the logarithm of the number of states with the entropy.

Macroscopic phenomena: the second law of thermodynamics

Our daily experience shows that T-symmetry does not hold for the behavior of bulk materials. Of these macroscopic laws, most notable is the second law of thermodynamics. Many other phenomena, such as the relative motion of bodies with friction, or viscous motion of fluids, **reduce to this, because the** underlying mechanism is the **dissipation of usable energy** (for example, kinetic energy) into heat.

Is this time-asymmetric **dissipation** really inevitable? This question has been considered by many physicists, often in the context of Maxwell's. The name comes from a thought experiment described by James Clerk Maxwell in which a microscopic demon guards a gate between two halves of a room. It only lets slow molecules into one half, only fast ones into the other. By eventually making one side of the room cooler than before and the other hotter, it seems **to reduce** the entropy of the room, **and reverse** the arrow of time. Many analysts have been made of this; all show that when the entropy of room and demon are taken together, this total entropy **does increase**. Modern analyses of this problem have taken into account Claude E. Shannon's relation between entropy and information. Many interesting results in modern computing are **closely related** to this problem — reversible computing, quantum computing and physical limits to computing, are examples. These seemingly metaphysical questions are today, in these ways, slowly being converted to the stuff of the physical sciences.

The current consensus hinges upon the Boltzmann-Shannon identification of the logarithm of phase space volume with the negative of Shannon, and hence to entropy. In this notion, a fixed initial state of a macroscopic system corresponds to relatively low entropy because the coordinates of the molecules of the body **are constrained**. As the system **evolves in** the presence of dissipation, the molecular coordinates can move into larger volumes of phase space, **becoming more** uncertain, and thus **leading to** increase in entropy.

One can, however equally well imagine a state of the universe in which the motions of all of the particles at one instant were the reverse (strictly, the CPT reverse). Such a state would then evolve in reverse, so presumably entropy would decrease (Loschmidt's paradox). Why is 'our' state preferred over the other?

One position is to say that the constant increase of entropy we observe **happens only because** of the initial state of our universe. Other possible states of the universe (for example, a universe at heat death equilibrium) would actually **result in** no increase of entropy. In this view, the apparent T-asymmetry of our universe is a problem in cosmology: why did the universe start with low entropy? This view, if it remains viable in the light of future cosmological observation, would connect this problem to one of the big open questions beyond the reach of today's physics — the question of initial conditions of the universe.

QUANTUM DISSIPATION AT MACROSCOPIC LEVEL- BLACK HOLES AND COSMOLOGY:

An object can cross through the event horizon of a black hole from the outside, and then fall rapidly to the central region where our understanding of physics breaks down. Since within a black hole the forward light-cone is directed towards the center and the backward light-cone is directed outward, it is not even possible to define time-reversal in the usual manner. The only way anything can escape from a black hole is as Hawking radiation.

The time reversal of a black hole would be a hypothetical object known as a white hole. From the outside they appear similar. While a black hole has a beginning and is inescapable, a white hole has an ending and cannot be entered. The forward light-cones of a white hole are directed outward; and its backward light-cones are directed towards the center.

The event horizon of a black hole may be thought of as a surface moving outward at the local speed of light and is just on the edge between escaping and falling back. The event horizon of a white hole is a surface moving inward at the local speed of light and is just on the edge between being swept outward and succeeding in reaching the center. They are two different kinds of horizons—the horizon of a white hole is like the horizon of a black hole turned inside-out.

The modern view of black hole irreversibility is to **relate it to** the second law of thermodynamics, since black holes are viewed as thermodynamic objects. Indeed, according to the Gauge-gravity duality conjecture, all microscopic processes in a black hole are **reversible**, and only the collective **behavior is irreversible**, as in any other macroscopic, thermal system.

Kinetic consequences: detailed balance and Onsager reciprocal relations

In physical and chemical kinetics, T-symmetry of the mechanical microscopic **equations implies two important** laws: the principle of detailed **balance and** the Onsager reciprocal relations. T-symmetry of the microscopic description together with its kinetic **consequences are** called microscopic reversibility.

Effect of time reversal on some variables of classical physics

Classical variables that do not change upon time reversal include:

\vec{x} , Position of a particle in three-space

\vec{a} , Acceleration of the particle

\vec{F} , Force on the particle

E , Energy of the particle

ϕ , Electric potential (voltage)

\vec{E} , Electric field

\vec{D} , Electric displacement

ρ , Density of electric charge

\vec{P} , Electric polarization

Energy density of the electromagnetic field

Maxwell stress tensor

All masses, charges, coupling constants, and other physical constants, except those associated with the weak force.

Odd

Classical variables that time reversal negates include:

t , The time when an event occurs

\vec{v} , Velocity of a particle

\vec{P} , Linear momentum of a particle

\vec{l} , Angular momentum of a particle (both orbital and spin)

\vec{A} , Electromagnetic vector potential

\vec{B} , Magnetic induction

\vec{H} , Magnetic field

\vec{j} , Density of electric current

\vec{M} , Magnetization

\vec{S} , Poynting vector

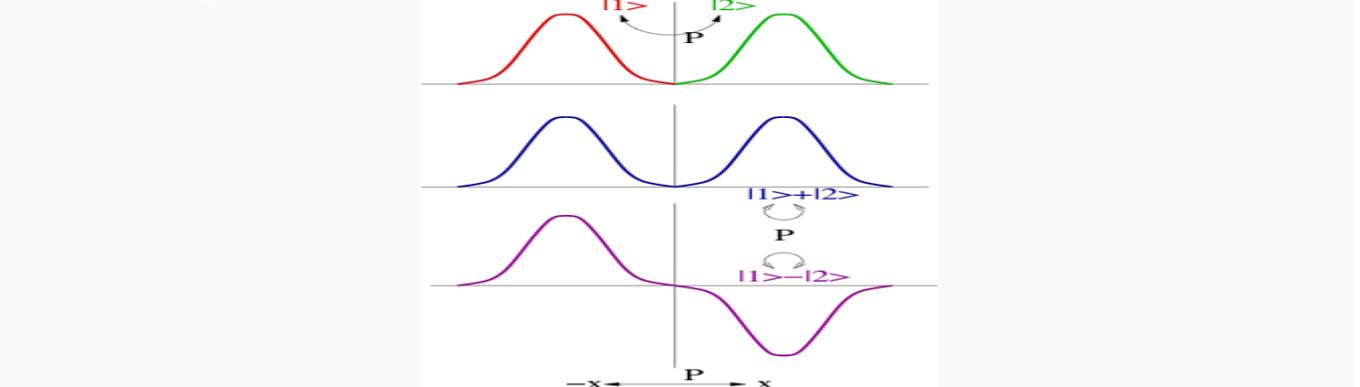

Power (rate of work done).

Microscopic phenomena: time reversal invariance

Since most systems are asymmetric under time reversal, it is interesting to ask whether there are phenomena **that do have** this symmetry. In classical mechanics, a **velocity reverses** under the operation of T , but **acceleration does not**. Therefore, one models dissipative phenomena through terms that are odd in v . However, delicate experiments in which **known sources of dissipation are removed** reveal that the laws of mechanics are time reversal invariant. **Dissipation itself is originated in the second law of thermodynamics.**

The motion of a charged body in a magnetic field, B **involves the** velocity through the Lorentz force term $v \times B$, and might seem at first to be asymmetric under T . A closer look assures us that B also changes sign under time reversal. This happens because a magnetic field **is produced** by an electric current, J , **which reverses sign** under T . Thus, the motion of classical charged particles in electromagnetic fields is also time reversal invariant. (Despite this, it is still useful to consider the time-reversal non-invariance in a *local* sense when the external field is held fixed, as when the magneto-optic effect is analyzed. This allows one to analyze the conditions under **which optical phenomena** that locally break time-reversal, such as Faraday isolators, can occur.) **The laws of gravity also** seem to be time reversal invariant in classical mechanics.

In physics one separates the laws of motion, called kinematics, from the laws of force, called dynamics. Following the classical kinematics of Newton's laws of motion, the kinematics of quantum mechanics is built in such a way that it presupposes nothing about the time reversal symmetry of the dynamics. In other words, if the **dynamics are invariant**, then the kinematics will allow it to remain invariant; if the dynamics is not, and then the kinematics will also show this. The structure of the quantum laws of motion is richer.

Time reversal in quantum mechanics

Two-dimensional representations of parity are given by a pair of quantum states that go into each other under parity. However, this representation can always be **reduced to** linear combinations of states, each of which is either even or odd under parity. One says that all irreducible representations of parity are one-dimensional. **Kramers' theorem** states that time reversal need not have this property **because it** is represented by an anti-unitary operator.

Fundamental properties of time reversal in quantum mechanics are:

1. that it must be **represented as** an anti-unitary operator,
2. that **it protects** non-degenerate quantum states from having an electric dipole moment,
3. that it has two-dimensional representations with the property $T^2 = -1$.

The strangeness of this result is clear if one compares it with parity. If parity **transforms a** pair of quantum states into each other, then the sum and difference of these two basis states are states of good parity. **Time reversal does not behave like this.** It seems **to violate the** theorem that all abelian groups be represented by one dimensional irreducible representation. **The reason it does this is that it is represented by an anti-unitary operator.** It thus opens the way to spinors in quantum mechanics.

Anti-unitary representation of time reversal

Eugene Wigner showed that a symmetry operation S of a Hamiltonian is represented, in quantum mechanics either by a **unitary operator, $S = U$, or an antiunitary one, $S = UK$ where** U is unitary, and K denotes complex conjugation. These are the only operations that act on Hilbert space so as to preserve the *length* of the projection of any one state-vector onto another state-vector.

Consider the **parity operator**. Acting on the position, it **reverses the** directions of space, so that $P^{-1}xP = -x$. Similarly, it **reverses the** direction of *momentum*, so that $PpP^{-1} = -p$, where x and p are the position and momentum operators. This preserves the canonical $[x, p] = i\hbar$, where \hbar is the reduced Planck constant, only if P is chosen to be unitary, $PiP^{-1} = i$.

On the other hand, for time reversal, the time-component of the momentum is the energy. If time reversal were implemented as a unitary operator, it **would reverse the sign of the energy** just as space-reversal **reverses the sign of the momentum**. This is not possible, because, unlike momentum, energy is always positive. Since energy in quantum mechanics is defined as **the phase factor** $\exp(-iEt)$ that one gets when one moves forward in time, the way to reverse time while preserving the sign of the energy is to reverse the sense of "i", so that the sense of phases is reversed.

Similarly, any operation that reverses the sense of phase, which changes the sign of i , will turn positive energies into negative energies unless it also changes the direction of time. So every antiunitary symmetry in a theory with positive energy must reverse the direction of time. The only antiunitary symmetry is time reversal, together with a unitary symmetry that does not reverse time.

Given the *time reversal* operator T , it does nothing to the x -operator, $TxT^{-1} = x$, but it reverses the direction of p , so that $TpT^{-1} = -p$. The canonical commutator is invariant only if T is chosen to be anti-unitary, i.e., $TiT^{-1} = -i$. For a particle with spin J , one can use the representation

$$T = e^{-i\pi J_y/\hbar} K,$$

where J_y is the y -component of the spin, and use of $TJT^{-1} = -J$ has been made.

Electric dipole moments

This has an interesting consequence on the electric dipole moment (EDM) of any particle. The EDM is defined through the shift in the energy of a state when it is put in an external electric field: $\Delta e = d \cdot E + E \cdot \delta \cdot E$, where d is called the EDM and δ , the induced dipole moment. One important property of an EDM is that the energy shift due to it changes sign under a parity transformation. However, since \mathbf{d} is a vector, its expectation value in a state $|\psi\rangle$ must be proportional to $\langle\psi|J|\psi\rangle$. Thus, under time reversal, an invariant state must have vanishing EDM. In other words, a non-vanishing EDM signals both P and T symmetry-breaking.

It is interesting to examine this argument further, since one feels that some molecules, such as water, must have EDM irrespective of whether \mathbf{T} is symmetry. This is correct: if a quantum system has degenerate ground states that transform into each other under parity, then time reversal need not be broken to give EDM.

Experimentally observed bounds on the electric dipole moment of the nucleon currently set stringent limits on the violation of time reversal symmetry in the strong interactions, and their modern theory: quantum chromodynamics. Then, using the CPT invariance of a relativistic quantum field theory, this puts strong bounds on strong CP violation. Experimental bounds on the electron electric dipole moment also place limits on theories of particle physics and their parameters.

Kramers' theorem

For T , which is an anti-unitary Z_2 symmetry generator

$$T^2 = UKUK = U U^* = U (U^T)^{-1} = \Phi,$$

where Φ is a diagonal matrix of phases. As a result, $U = \Phi U^T$ and $U^T = U\Phi$, showing that

$$U = \Phi U \Phi.$$

This means that the entries in Φ are ± 1 , as a result of which one may have either $T^2 = \pm 1$. This is specific to the anti-unitarity of T . For a unitary operator, such as the parity, any phase is allowed. Next, take a Hamiltonian invariant under T . Let $|a\rangle$ and $T|a\rangle$ be two quantum states of the same energy. Now, if $T^2 = -1$, then one finds that the states are orthogonal: a result called **Kramers' theorem**. This implies that if $T^2 = -1$, then there is a twofold degeneracy in the state. This result in non-relativistic quantum mechanics presages the spin statistics theorem of quantum field theory.

Quantum states that give unitary representations of time reversal, i.e., have $\mathbf{T}^2=1$, are characterized by a multiplicative quantum number, sometimes called the **T-parity**.

Time reversal transformation for fermions in quantum field theories can be represented by an 8-component spinor in which the above mentioned **T-parity** can be a complex number with unit radius. The CPT invariance is not a theorem but a **better to have** property in these classes of theories.

Time reversal of the known dynamical laws

Particle physics codified the basic laws of dynamics into the standard model. This is formulated as a quantum field theory that has CPT symmetry, i.e., the laws are invariant under simultaneous operation of time reversal, parity and charge conjugation. However, time reversal itself is seen not to be symmetry (this is usually called CP violation). There are two possible origins of this asymmetry, one through the mixing of different flavours of quarks in their weak decays, the second through a direct CP violation in strong interactions. The first is seen in experiments, the second is strongly constrained by the non-observation of the EDM of a neutron.

It is important to stress that this time reversal violation is unrelated to the second law of thermodynamics, because due to the conservation of the CPT symmetry, the effect of time reversal is to rename particles as antiparticles and *vice versa*. Thus the second law of thermodynamics is thought to originate in the initial conditions in the universe.

SOME RECENT DEVELOPMENTS IN THE CONTEXT OF QUANTUM INFORMATION OR QUANTUM MECHANICAL BEHAVIOUR DISSIPATION: A REVIEW STUDY THAT SUBSTANTIATES THE DISSIPATION COEFFICIENT USAGE IN THE MODEL:

Influence of dissipation on phase tunneling in Josephson-junctions (For details see. Zwerger)

The coupling between the phase and the electromagnetic field in the case of a tunnel junction is treated by Feynman's path integral method. It is shown that the elimination of the field leads to a frequency dependent mass for the motion of the

phase ψ , which is simply related to the effective dielectric constant of the junction. Considering tunneling as a motion in

imaginary time **one obtains** a polaron like mass enhancement **connected** to the dielectric function at positive imaginary frequencies, which **essentially leads to** the Caldeira-Leggett **reduction** of the elastic tunneling probability. In the weak damping limit it is shown that the emission of real excitations during tunneling is a higher order effect. At low temperatures the damping finally **is determined** by the line width of electromagnetic radiation at the Josephson plasma frequency

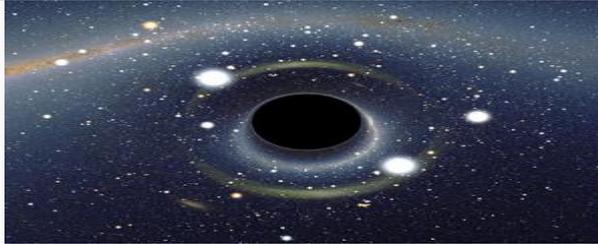

The quantum-mechanical two-level system with dissipation and feedback: multimode applied electric-field case

A two-level dissipative quantum-mechanical system subjected to a small applied multimode electric field plus a feedback term proportional to the induced dipole moment is discussed. The long-term behaviour of the induced dipole moment and of the upper level occupation probability is represented by a series expansion in terms of the applied electric-field amplitudes. First-order and third-order internal, external, and intrinsic polarizabilities **are introduced** and calculated for the model. Certain ratios of third-order to first-order polarizabilities are shown to have a common value for the internal, external, and intrinsic cases. Clausius-Mossotti relations for the linear and third-order susceptibilities **are derived**.

The quantum mechanical fluctuation-dissipation theorem:

In this paper, Kubo's spectral theorem is re-derived and developed into a fluctuation-dissipation theorem for systems which fluctuate about their equilibrium positions. This is accomplished by introducing a general link between the operator corresponding to the observable and the operator which joins the external force to the Hamiltonian. For certain systems this link takes on simple forms and the theorem then reduces to previously derived results. It is also shown how different forms of the link are related to different Langevin equations which are the basis of the corresponding classical theory.

Black hole: Quantum Information Loss:

Simulated view of a black hole (center) in front of the Large. Note the gravitational lensing effect, which **produces** two enlarged but highly distorted views of the Cloud. Across the top, the Milky Way disk appears distorted into an arc.

A **black hole** is a region of spacetime whose gravitational field is so strong that nothing which enters it, not even light, can escape. The theory of general relativity predicts that a sufficiently compact mass **will deform** spacetime to form a black hole. Around a black hole there is a mathematically defined surface called an **event horizon** that marks the point of no return. It is called "black" because it absorbs all the light that hits the horizon, reflecting nothing, just like a perfect **black body in thermodynamics**. Quantum mechanics predicts that black holes emit radiation like a black body with a finite temperature. This temperature is **inversely proportional** to the mass of the black hole, making it difficult to observe this radiation for **black holes of stellar mass** or greater.

Objects whose **gravity field** is too strong for light to escape were first considered in the 18th century by John Michell and Pierre-Simon Laplace. The first modern solution of general relativity that would characterize a black hole was found by Karl Schwarzschild in 1916, although its interpretation as a region of space from which nothing can escape was not fully appreciated for another four decades. Long considered a mathematical curiosity, it was during the 1960s that theoretical work showed black holes were a generic prediction of general relativity. The discovery of **neutron stars** sparked interest in **gravitationally compact** objects as a possible astrophysical reality.

Black holes of stellar mass are expected to form when a star of more than 5 solar masses runs out of energy fuel. **This results** in the outer layers of gas being thrown out in a supernova explosion. The core of the star **collapses** and **becomes** super dense where even the atomic nuclei are squeezed together. The energy density at the core goes to infinity. After a black hole has **formed it** can continue to grow **by absorbing mass** from its surroundings. By absorbing other stars and **merging with** other black holes, supermassive black holes of millions of solar masses may form. There is general consensus that supermassive black holes exist in the centers of most galaxies. In particular, there is strong evidence of a black hole of more than 4 million solar masses at the center of our galaxy, the Milky Way.

Despite its invisible interior, the presence of a black hole can be inferred through **its interaction** with other **matter and with light** and other electromagnetic radiation. From stellar movement, the mass and location of an invisible companion object can be calculated. A half-dozen or so binary star systems have been discovered by Astronomers where one of the stars is invisible, yet must surely exist since it pulls with enough gravitational force on the other visible star to make it orbit around their common center of gravity. Therefore these invisible stars are thought to be good **candidate black holes**. **Astronomers have identified numerous stellar black hole candidates in binary systems by studying the movement of their companion stars in this way.**

GRAVITATIONAL LENSING-PRODUCTION OF DISTORTED PICTURE:

Simulation of gravitational lensing by a black hole, **which distorts** the image of a galaxy in the background (larger animation)

The idea of a body so massive that even light could not escape was first put forward by geologist John Michell in a letter written to Henry Cavendish in 1783 of the Royal Society:

If the semi-diameter of a sphere of the same density as the Sun were to exceed that of the Sun in the proportion of 500 to 1, a body falling from an infinite height towards it would have acquired at its surface greater velocity than that of light, and consequently supposing light to be attracted by the same force in proportion to its vis inertiae, with other bodies, all light emitted from such a body would be made to return towards it by its own proper gravity.

—John Michell

In 1796, mathematician Pierre-Simon Laplace promoted the same idea in the first and second editions of his book *Exposition du système du Monde* (it was removed from later editions). Such "dark stars" were largely ignored in the nineteenth century, since it was not understood how a massless wave such as light could be influenced by gravity.

STABILITY ANALYSIS OR UNSTABILITY AT MACROSCOPIC LEVEL: A POINTER TO IMPORTANCE TO STABILITY ANALYSIS CARRIED OUT IN THE MIODEL:

In 1915, Albert Einstein developed his theory of general relativity, having earlier shown that gravity does influence light's motion. Only a few months later, Karl Schwarzschild found a solution to Einstein field equations, which describes the gravitational field of a point mass and a spherical mass. A few months after Schwarzschild, Johannes Droste, a student of Hendrik Lorentz, independently gave the same solution for the point mass and wrote more extensively about its properties. This solution had a peculiar behaviour at what is now called the Schwarzschild radius, where it became singular, meaning that some of the terms in the Einstein equations became infinite. The nature of this surface was not quite understood at the time. In 1924, Arthur Eddington showed that the singularity disappeared after a change of coordinates (see Eddington–Finkelstein coordinates), although it took until 1933 for Georges Lemaître to realize that this meant the singularity at the Schwarzschild radius was an unphysical coordinate singularity.³

In 1931, Subrahmanyan Chandrasekhar calculated, using special relativity, that a non-rotating body of electron-degenerate matter above a certain limiting mass (now called the Chandrasekhar at 1.4 solar masses) has no stable solutions. His arguments were opposed by many of his contemporaries like Eddington and Lev Landau, who argued that some yet unknown mechanism would stop the collapse. They were partly correct: a white dwarf slightly more massive than the Chandrasekhar limit will collapse into a neutron star, which is itself stable because of the Pauli exclusion principle. But in 1939, Robert Oppenheimer and others predicted that neutron stars above approximately three solar masses (the Tolman–Oppenheimer–Volkoff limit) would collapse into black holes for the reasons presented by Chandrasekhar, and concluded that no law of physics was likely to intervene and stop at least some stars from collapsing to black holes.

Oppenheimer and his co-authors interpreted the singularity at the boundary of the Schwarzschild radius as indicating that this was the boundary of a bubble in which time stopped. This is a valid point of view for external observers, but not for infalling observers. Because of this property, the collapsed stars were called "frozen stars, because an outside observer would see the surface of the star frozen in time at the instant where its collapse takes it inside the Schwarzschild radius.

BLACK HOLES: THE MACROSCOPIC LEVEL IMPECCABLE TESTIMONY FOR THE QUNTUM DISSIPATION EFFECTS (HAWKING RADIATION):

In 1958, David Finkelstein identified the Schwarzschild surface as an event horizon, "a perfect unidirectional membrane: causal influences can cross it in only one direction". This did not strictly contradict Oppenheimer's results, but extended them to include the point of view of infalling observers. Finkelstein's solution extended the Schwarzschild solution for the future of observers falling into a black hole. A complete extension had already been found by Martin Kruskal,

These results came at the beginning of the golden age of general relativity, which was marked by general relativity and black holes becoming mainstream subjects of research. This process was helped by the discovery of pulsars in 1967, which, by 1969, were shown to be rapidly rotating neutron stars. Until that time, neutron stars, like black holes, were regarded as just theoretical curiosities; but the discovery of pulsars showed their physical relevance and spurred a further interest in all types of compact objects that might be formed by gravitational collapse.

In this period more general black hole solutions were found. In 1963, Roy Kerr found the exact solution for a rotating black hole. Two years later, Ezra Newman found the axisymmetric solution for a black hole that is both rotating and electrically charged. Through the work of Werner Israel, Brandon Carter, and David Robinson, the no-hair theorem emerged, stating that a stationary black hole solution is completely described by the three parameters of the Kerr–Newman metric; mass, angular momentum, and electric charge.

For a long time, it was suspected that the strange features of the black hole solutions were pathological artifacts from the symmetry conditions imposed, and that the singularities would not appear in generic situations. This view was held in particular by Vladimir Belinsky, Isaak Khalatnikov, and Evgeny Lifshitz, who tried to prove that no singularities appear in generic solutions. However, in the late sixties Roger Penrose and Stephen Hawking used global techniques to prove those singularities are generic.

Work by James Bardeen, Jacob Bekenstein, Carter, and Hawking in the early 1970s led to the formulation of black hole thermodynamics. These laws describe the behaviour of a black hole in close analogy to the laws of thermodynamics by relating mass to energy, area to entropy, and surface gravity to temperature. The analogy was completed when Hawking, in 1974, showed that quantum field theory predicts that black holes should radiate like a black body with a temperature proportional to the surface gravity of the black hole.

The term "black hole" was first publicly used by John Wheeler during a lecture in 1967. Although he is usually credited with coining the phrase, he always insisted that it was suggested to him by somebody else..

Properties and structure

The no-hair theorem states that, once it achieves a stable condition after formation, a black hole has only three independent physical properties: mass, charge, and angular momentum. Any two black holes that share the same values for these properties, or parameters, are indistinguishable according to classical (i.e. non-quantum) mechanics. These properties are special because they are visible from outside a black hole. For example, a charged black hole repels other like charges just like any other charged object. Similarly, the total mass inside a sphere containing a black hole can be found by using the gravitational analog of Gauss's law, the ADM mass, far away from the black hole. Likewise, the angular momentum can be measured from far away using frame dragging by the gravitomagnetic field.

QUANTUM INFORMATION LOSS PARADOX IN BLACK HOLE:

When an object falls into a black hole, any information about the shape of the object or distribution of charge on it is evenly distributed along the horizon of the black hole, and is lost to outside observers. The behavior of the horizon in this situation is a dissipative system that is closely analogous to that of a conductive stretchy membrane with friction and electrical—the membrane paradigm. This is different from other field theories like electromagnetism, which do not have any friction or resistivity at the microscopic level, because they are time-reversible. Because a black hole eventually achieves a stable state with only three parameters, there is no way to avoid losing information about the initial conditions: the gravitational and electric fields of a black hole give very little information about what went in. The information that is lost includes every quantity that cannot be measured far away from the black hole horizon, including the total baryon number, lepton number, and all the other nearly conserved pseudo-charges of particle physics. This behavior is so puzzling that it has been called the black hole information loss paradox.

Physical properties

The simplest black holes have mass but neither electric charge nor angular momentum. These black holes are often referred to as Schwarzschild black holes after Karl Schwarzschild who discovered this solution in 1916.¹ According to Birkhoff's theorem, it is the only vacuum solution that is spherically symmetric. This means that there is no observable difference between the gravitational field of such a black hole and that of any other spherical object of the same mass. The popular notion of a black hole "sucking in everything" in its surroundings is therefore only correct near a black hole's horizon; far away, the external gravitational field is identical to that of any other body of the same mass.

Solutions describing more general black holes also exist. Charged black holes are described by the Reissner–Nordström metric, while the Kerr metric describes a rotating black hole. The most general stationary black hole solution known is the Kerr–Newman metric, which describes a black hole with both charge and angular momentum.

While the mass of a black hole can take any positive value, the charge and angular momentum are constrained by the mass. In Planck units, the total electric charge Q and the total angular momentum J are expected to satisfy

$$Q^2 + \left(\frac{J}{M}\right)^2 \leq M^2$$

for a black hole of mass M . Black holes saturating this inequality are called extremal. Solutions of Einstein's equations that violate this inequality exist, but they do not possess an event horizon. These solutions have so-called naked singularities that can be observed from the outside, and hence are deemed unphysical. The hypothesis rules out the formation of such singularities, when they are created through the gravitational collapse of realistic matter. This is supported by numerical simulations.

Due to the relatively large strength of the electromagnetic force, black holes forming from the collapse of stars are expected to retain the nearly neutral charge of the star. Rotation, however, is expected to be a common feature of compact

objects. The black-hole candidate binary X-ray source **GRS 1915+105^[41]** appears to have an angular momentum near the maximum allowed value.

Black hole classifications

Class*Mass*Size

Supermassive black hole* $\sim 10^5$ – $10^9 M_{\text{Sun}}$ * ~ 0.001 – 10 AU

Intermediate-mass black hole* $\sim 10^3 M_{\text{Sun}}$ * $\sim 10^3$ km = R_{Earth}

Stellar black hole* $\sim 10 M_{\text{Sun}}$ * ~ 30 km

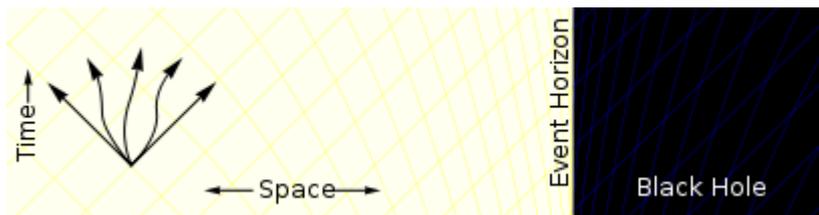

Micro black hole*up to $\sim M_{\text{Moon}}$ *up to ~ 0.1 mm

Black holes are commonly classified according to their mass, independent of angular momentum J or electric charge Q . The size of a black hole, as determined by the radius of the event horizon, or **Schwarzschild radius**, is roughly proportional to the mass M through

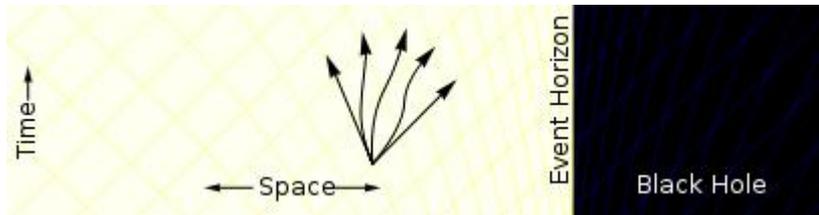

$$r_{\text{sh}} = \frac{2GM}{c^2} \approx 2.95 \frac{M}{M_{\text{Sun}}} \text{ km},$$

where r_{sh} is the Schwarzschild radius and M_{Sun} is the **mass of the Sun**. This relation is exact only for black holes with zero charge and angular momentum; for more general black holes it can differ up to a factor of 2.

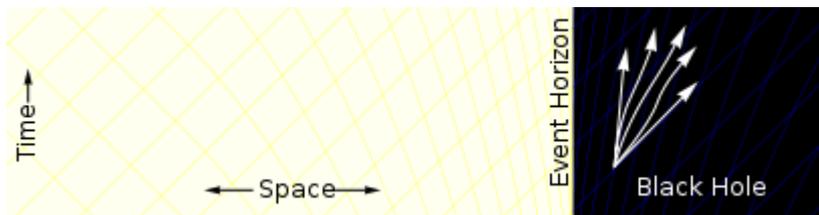

Event horizon

Far away from the black hole a particle can move in any direction, as illustrated by the set of arrows. It is only restricted by the speed of light.

Closer to the black hole spacetime *starts to deform*. There are more *paths going towards* the black hole than paths moving away

Inside of the event horizon all paths bring the particle *closer* to the center of the black hole. It is no longer possible for the particle to escape. Particle is captured

The defining feature of a black hole is the appearance of an event horizon—a boundary in spacetime through which matter and light can only pass **inward towards** the mass of the black hole. Nothing, not even light, can escape from inside the event horizon. The event horizon is referred to as such because if an event **occurs within** the boundary, **information from that event cannot reach an outside observer, making it impossible to determine if such an event occurred**

As predicted by general relativity, the presence of a mass **deforms spacetime** in such a way that the paths taken by particles bend towards the mass. At the event horizon of a black hole, this deformation becomes so strong that there are no paths that lead away from the black hole.

To a distant observer, clocks near a black hole appear to tick more slowly than those further away from the black hole. **Due to this effect**, known as **gravitational time dilation**, an object falling into a black hole appears **to slow down** as it approaches the event horizon, taking an infinite time to reach it. At the same time, all processes on this **object slow down** **causing** emitted light to appear redder and dimmer, an effect known as **gravitational redshift**. Eventually, at a point just before it reaches the event horizon, the falling object becomes so dim that it can no longer be seen.

On the other hand, an observer falling into a black hole does not notice any of these effects as he crosses the event horizon. According to his own clock, he crosses the event horizon after a finite time, although he is **unable to determine** exactly when he crosses it, as it is impossible to determine the location of the event horizon from local observations

The shape of the event horizon of a black hole is always approximately spherical. For non-rotating (static) black holes the geometry is precisely spherical, while for rotating black holes the sphere is somewhat oblate.

GRAVITATIONAL SINGULARITY-ANOTHER CARDINAL WAY OF DISSIPATION AND ENTANGLEMENT WITH QUANTUM INFORMATION:

At the center of a black hole as described by general relativity lies a **gravitational singularity**, a region where the spacetime curvature becomes infinite. For a non-rotating black hole, this region takes the shape of a single point and for a **rotating black hole**, it is **smeared out to** form a **ring singularity** lying in the plane of rotation. In both cases, the singular region has zero volume. It can also be shown that the singular region contains all the mass of the black hole solution. The singular region can thus be thought of as having **infinite density**.

Observers falling into a Schwarzschild black hole (i.e. non-rotating and no charges) cannot avoid being carried into the singularity, once they cross the event horizon. They can prolong the experience by accelerating away to slow their descent, but only up to a point; after attaining a certain ideal velocity, it is best **to free fall** the rest of the way. When they reach the singularity, they are **crushed to** infinite density and their mass is added to the **total of the** black hole. Before that happens, they will have been torn apart by the growing **tidal forces** in a process sometimes referred to as **spaghettification** or the "noodle effect".

THE ULTIMATE ELDORADO OF DESTRUCTION/OBLITERATION OF INFORMATION QUANTUM INFORMATION LOSS SYNDROME AND ARMAGEDDON OR APOCHRYPHAL ANEURISM-THE BLACK HOLE SPAGATEFICATION

In the case of a charged (Reissner–Nordström) or rotating (Kerr) black hole, it is possible to avoid the singularity. Extending these solutions as far as possible reveals the hypothetical possibility of exiting the black hole into a different spacetime with the **black hole acting as a wormhole**. The possibility of traveling to another universe is however only theoretical, since any perturbation will destroy this possibility. It also appears to be possible to follow **closed timelike curves** (going back to one's own past) around **the Kerr singularity**, which lead to problems with **causality** like the **grandfather paradox**. It is expected that none of these peculiar effects would survive in a proper quantum mechanical treatment of rotating and charged black holes

The appearance of singularities in general relativity is commonly perceived as signaling the breakdown of the theory.^[62] This breakdown, however, is expected; it occurs in a situation where **quantum mechanical effects** should describe these actions due to the extremely high density and therefore particle interactions. To date, it has not been possible to combine quantum and gravitational effects into a single theory. It is generally expected that a theory of **quantum gravity** will feature black holes without singularities.

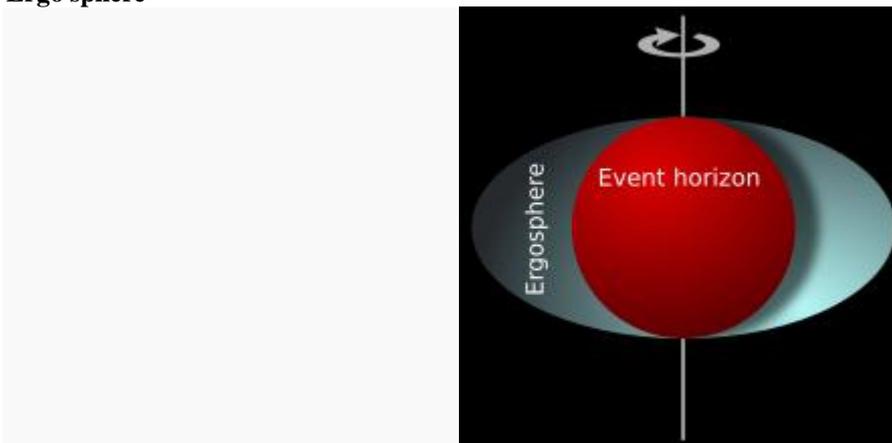

Photon sphere

The photon sphere is a spherical boundary of zero thickness such **that photons** moving **along tangents to** the sphere will be trapped in a circular orbit. For non-rotating black holes, the photon sphere has a radius 1.5 times the Schwarzschild radius. The orbits are **dynamically unstable**, hence any small perturbation (such as a particle of infalling matter) **will grow over time**, either setting it on an outward trajectory escaping the black hole or on an inward spiral eventually crossing the event horizon.

While light can still escape from inside the photon sphere, any light that crosses the photon sphere on an inbound trajectory will be captured by the black hole. Hence any light reaching an outside observer from inside the photon sphere must have been emitted by objects inside the photon sphere but still outside of the event horizon.

Other compact objects, such as **neutron stars**, can also have photon spheres. This follows from the fact that the gravitational field of an object **does not depend** on its actual size; hence any object that is smaller than 1.5 times the Schwarzschild radius corresponding to its mass will indeed have a photon sphere.

Ergo sphere

The ergo sphere is an oblate spheroid region outside of the event horizon, where objects **cannot remain** stationary.

Rotating black holes are surrounded by a region of spacetime in which it is impossible to stand still, called the ergo sphere. This is **the result of** a process known as **frame-dragging**; general relativity predicts that any rotating mass will tend to slightly "drag" along the spacetime immediately surrounding it. Any object near the rotating mass will tend to start moving in the direction of rotation. For a rotating black hole, this effect becomes so strong near the event horizon that an object would have to move faster than the speed of light in the opposite direction to just stand still.

The ergo sphere of a black hole is bounded by the (outer) event horizon on the inside and an **oblate spheroid**, which coincides with the event horizon at the poles and is noticeably wider around the equator. The outer boundary is sometimes called the **ergo surface**. Objects and radiation can escape normally from the ergo sphere. Through the **Penrose process**, objects can emerge from the ergo sphere with more energy than they entered. This energy is taken from the rotational energy of the black hole causing it to slow down.

Formation and evolution

Considering the exotic nature of black holes, it may be natural to question if such bizarre objects could exist in nature or to suggest that they are merely pathological solutions to Einstein's equations. Einstein himself wrongly thought that **black holes would not form**, because he held that the angular momentum of collapsing particles would stabilize their motion at some radius. This led the general relativity community to dismiss all results to the contrary for many years. However, a minority of relativists continued to contend that black holes were physical objects, and by the end of the 1960s, they had persuaded the majority of researchers in the field that there is no obstacle to forming an event horizon.

Once an event horizon forms, Penrose proved that a singularity will form somewhere inside it. Shortly afterwards, Hawking showed that many cosmological solutions describing **the Big Bang** have singularities without scalar fields or other exotic matter (see **Penrose-Hawking singularity theorems**). The **Kerr solution, the no-hair theorem** and the laws of **black hole thermodynamics** showed that the physical properties of black holes were simple and comprehensible, making them respectable subjects for research. The primary formation process for black holes is expected to be **the gravitational collapse** of heavy objects such as stars, but there are also more exotic processes that can lead to the production of black holes.

Gravitational collapse

Gravitational collapse **occurs when** an object's internal **pressure** is insufficient **to resist(E) the** object's own gravity. For stars this **usually occurs** either because a star has too little "fuel" left to maintain its temperature through **stellar nucleosynthesis**, or because a star that would have been stable **receives extra** matter in a way that does not raise its core temperature. In either case the star's temperature is no longer high enough to **prevent it from collapsing** under its own weight. The ideal gas law explains the **connection** between pressure, temperature, and volume.

The collapse may be stopped by the **degeneracy pressure** of the star's constituents, condensing the matter in an **exotic denser state**. The **result is** one of the various types of compact STARS. The type of compact star formed **depends on the** mass of the remnant—the matter left over after the outer layers have been blown away, such from a supernova explosion or by pulsations leading to **a planetary nebula**. Note that this mass can be substantially less than the original star—remnants exceeding 5 solar masses **are produced** by stars that were over 20 solar masses before the collapse.

If the mass of the remnant exceeds about 3–4 solar masses (the **Tolman–Oppenheimer–Volkoff limit**¹)—either because the original star was very heavy or because the remnant collected additional mass through **accretion** of matter—even the degeneracy pressure **of neutrons** is insufficient to stop the collapse. No known mechanism (except possibly quark degeneracy pressure, see **quark star**) is powerful enough to stop the implosion and the object will inevitably **collapse to form a black hole**.

The gravitational collapse of heavy stars is assumed to be responsible for the formation of **stellar mass black holes**. **Star formation** in the early universe may have resulted in very massive stars, which upon their collapse would **have produced** black holes of up to 10^3 solar masses. These black holes could be the seeds of the supermassive black holes found in the centers of most galaxies.

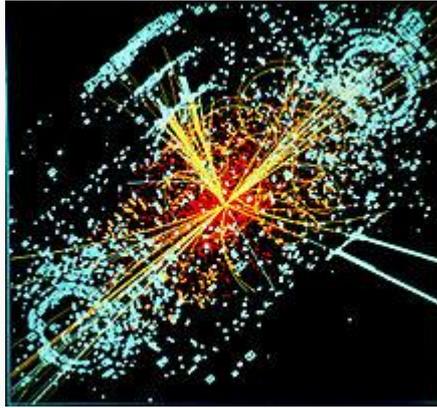

While most of the energy released during gravitational collapse is emitted very quickly, an outside observer does not actually see the end of this process. Even though the collapse takes a finite amount of time from the **reference frame** of infalling matter, a distant observer sees the infalling material slow and halts just above the event horizon, due to **gravitational time dilation**. Light from the collapsing material takes longer and longer to reach the observer, with the light emitted just before the event horizon forms is delayed an infinite amount of time. Thus the external observer never sees the formation of the event horizon; instead, the collapsing material seems to become dimmer and increasingly red-shifted, eventually fading away.

Primordial black holes in the Big Bang

Gravitational collapse requires great density. In the current epoch of the universe these high densities are only found in stars, but in the early universe shortly after the bang densities were much greater, possibly allowing for the creation of black holes. The high density alone is not enough to allow the formation of black holes since a uniform mass distribution will not allow the mass to bunch up. In order for **primordial black holes** to form in such a dense medium, there must be initial density perturbations that can then grow under their own gravity. Different models for the early universe vary widely in their predictions of the size of these perturbations. Various models predict the creation of black holes, ranging from a **Planck**

mass to hundreds of thousands of solar masses.^[25] Primordial black holes could thus account for the creation of any type of black hole.

High-energy collisions

A simulated event in the CMS detector, a collision in which a micro black hole may be created.

Gravitational collapse is not the only process that could create black holes. In principle, black holes could be formed in **high-energy collisions** that achieve sufficient density. As of 2002, no such events have been detected, either directly or indirectly as a deficiency of the mass balance in **particle accelerator** experiments. This suggests that there must be a lower limit for the mass of black holes. Theoretically, this boundary is expected to lie around the **Planck mass** ($m_P = \sqrt{\hbar c/G} \approx 1.2 \times 10^{19} \text{ GeV}/c^2 \approx 2.2 \times 10^{-8} \text{ kg}$), where quantum effects are expected to invalidate the predictions of general relativity. This would put the creation of black holes firmly out of reach of any high energy process occurring on or near the Earth. However, certain developments in quantum gravity suggest that the Planck mass could be much lower: some **braneworld** scenarios for example put the boundary as low as **1 TeV/c²**. This would make it conceivable for **micro black holes** to be created in the high energy collisions occurring when **cosmic rays** hit the Earth's atmosphere, or possibly in the new **Large Hadron Collider at CERN**. Yet these theories are very speculative, and the creation of black holes in these processes is deemed unlikely by many specialists. Even if micro black holes should be formed in these collisions, it is expected that they would **evaporate** in about 10^{-25} seconds, posing no threat to the Earth.

Growth

Once a black hole has formed, it can continue to grow by absorbing additional matter. Any black hole will continually absorb gas and interstellar from its direct surroundings and omnipresent **cosmic background radiation**. This is the primary process through which supermassive black holes seem to have grown. A similar process has been suggested for the formation of **intermediate-mass black holes in globular clusters**.

Another possibility is for a black hole to merge with other objects such as stars or even other black holes. This is thought to have been important especially for the early development of supermassive black holes, which could have formed from the coagulation of many smaller objects. The process has also been proposed as the origin of **some intermediate-mass black holes**.

Evaporation-Another Dissipatory Mode:

In 1974, Hawking showed that black holes are not entirely black but emit small amounts of thermal radiation;^[30] an effect that has become known as **Hawking radiation**. By **applying quantum** to a static black hole background, he determined that a black hole should emit particles in a perfect **black body spectrum**. Since **Hawking's publication**, many others have verified the result through various approaches.^[84] If **Hawking's theory of black hole radiation** is correct, then black holes are expected to shrink and evaporate over time because they lose mass by the emission of photons and other particles. The temperature of this thermal spectrum (**Hawking temperature**) is proportional to the **surface gravity** of the black hole, which, for a Schwarzschild black hole, is inversely proportional to the mass. Hence, large black holes emit less radiation than small black holes.

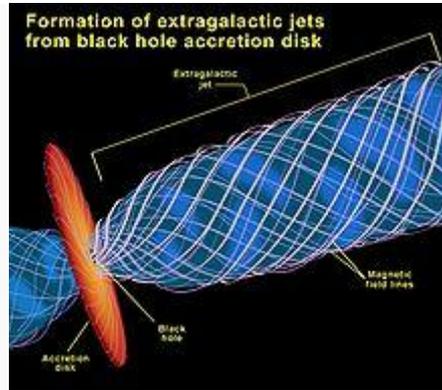

A stellar black hole of one solar mass has a Hawking temperature of about **100 nanokelvins**. This is far less than the 2.7 K temperature of the **cosmic microwave background radiation**. Stellar mass or larger black holes receive more mass from the cosmic microwave background than they emit through Hawking radiation and thus will grow instead of shrink. To have a Hawking temperature larger than 2.7 K (and be able to evaporate), a black hole needs to have less mass than **the Moon**. Such a black hole would have a diameter of less than a tenth of a millimeter.

If a black hole is very small the radiation effects are expected to become very strong. Even a black hole that is heavy compared to a human would evaporate in an instant. A black hole the weight of a car would have a diameter of about 10^{-24} m and take a nanosecond to evaporate, during which time it would briefly have luminosity more than 200 times that of the sun. Lower mass black holes are expected to evaporate even faster; for example, a black hole of mass $1 \text{ TeV}/c^2$ would take less than 10^{-88} seconds to evaporate completely. For such a small black hole, **quantum gravitation** effects are expected to play an important role and could even—although current developments in quantum gravity do not indicate so^[87]—hypothetically make such a small black hole stable.

By their very nature, black holes do not directly emit any signals other than the hypothetical Hawking radiation; since the Hawking radiation for an astrophysical black hole is predicted to be very weak, this makes it impossible to directly detect astrophysical black holes from the Earth. A possible exception to the Hawking radiation being weak is the last stage of the evaporation of light (primordial) black holes; searches for such flashes in the past has proven unsuccessful and provides stringent limits on the possibility of existence of light primordial black holes NASA's **Fermi Gamma-ray Space Telescope** launched in 2008 will continue the search for these flashes

Astrophysicists searching for black holes thus have to rely on indirect observations. A black hole's existence can sometimes be inferred by observing its gravitational interactions with its surroundings. A project run by **MIT's Haystack Observatory** is attempting to observe the event horizon of a black hole directly. Initial results are encouraging

Accretion of matter-The Accentuation Coefficient in the Model:

Formation of extragalactic jets from a black hole's accretion disk

Due to conservation of angular momentum, gas falling into the gravitational well created by a massive object will typically form a disc-like structure around the object. Friction within the disc causes angular momentum to be transported outward, allowing matter to fall further inward, releasing potential energy and increasing the temperature of the gas. In the case of compact objects such as white dwarfs, neutron, and black holes, the gas in the inner regions becomes so hot that it will emit vast amounts of radiation (mainly X-rays), which may be detected by telescopes. This process of accretion is one of the most efficient energy-producing processes known; up to 40% of the rest mass of the accreted material can be emitted in radiation (In nuclear fusion only about 0.7% of the rest mass will be emitted as energy.) In many cases, accretion discs are accompanied by relativistic jets emitted along the poles, which carry away much of the energy. The mechanism for the creation of these jets is currently not well understood.

As such many of the universe's more energetic phenomena have been attributed to the accretion of matter on black holes. In particular, active and quasars are believed to be the accretion discs of supermassive black holes.^[93] Similarly, X-ray binaries are generally accepted to be binary star systems in which one of the two stars is a compact object accreting matter from its companion.^[93] It has also been suggested that some ultra luminous X-ray sources may be the accretion discs of intermediate-mass black holes.^[94]

X-ray binaries

X-ray binaries are binary star systems that are luminous in the X-ray part of the spectrum. These X-ray emissions are generally thought to be caused by one of the component stars being a compact object accreting matter from the other (regular) star. The presence of an ordinary star in such a system provides a unique opportunity for studying the central object and determining if it might be a black hole.

Artist impression of a binary system with an accretion disk around a black hole being fed by material from the companion star.

If such a system emits signals that can be directly traced back to the compact object, it cannot be a black hole. The absence of such a signal does, however, not exclude the possibility that the compact object is a neutron star. By studying the

companion star it is often possible to obtain the orbital parameters of the system and obtain an estimate for the mass of the compact object. If this is much larger than the Tolman–Oppenheimer–Volkoff limit (that is, the maximum mass a neutron star can have before collapsing) then the object cannot be a neutron star and is generally expected to be a black hole.

The first strong candidate for a black hole, **Cygnus X-1, was discovered in this way by Charles Thomas Bolton**, Louise Webster and Paul Murdin in 1972. Some doubt, however, remained due to the uncertainties resultant from the companion star being much heavier than the candidate black hole. Currently, better candidates for black holes are found in a class of X-ray binaries called soft X-ray transients.^[93] In this class of system the companion star is relatively low mass allowing for more accurate estimates in the black hole mass. Moreover, these systems are only active in X-ray for several months once every 10–50 years. During the period of low X-ray emission (called quiescence), the accretion disc is extremely faint allowing for detailed observation of the companion star during this period. One of the best such candidates is **V404 Cyg**.

Quiescence and advection-dominated accretion flow

The faintness of the accretion disc during quiescence is suspected to be caused by the flow entering a mode called **an advection-dominated accretion flow** (ADAF). In this mode, almost all the energy generated by friction in the disc is swept along with the flow instead of radiated away. If this model is correct, then it forms strong qualitative evidence for the presence of an event horizon. Because, if the object at the center of the disc had a solid surface, it would emit large amounts of radiation as the highly energetic gas hits the surface, an effect that is observed for neutron stars in a similar state

Quasi-periodic oscillations

The X-ray emission from accretion disks sometimes flickers at certain frequencies. These signals are called quasi-periodic oscillations and are thought to be caused by material moving along the inner edge of the accretion disk (the innermost stable circular orbit). As such their frequency is linked to the mass of the compact object. They can thus be used as an alternative way to determine the mass of potential black holes.^[100]

Galactic nuclei

" to describe galaxies with unusual characteristics, such as **unusual spectral line emission** and very strong radio emission. Theoretical and observational studies have shown that the activity in these active galactic nuclei (AGN) may be explained by the presence of supermassive black holes. The models of these AGN consist of a central black hole that may be millions or billions of times more massive than the Sun; a disk of **gas and dust called an accretion disk**; and **two jets** that are perpendicular to the accretion disk.¹

Although supermassive black holes are expected to be found in most AGN, only some galaxies' nuclei have been more carefully studied in attempts to both identify and measure the actual masses of the central supermassive black hole candidates. Some of the most notable galaxies with supermassive black hole candidates include **the Andromeda Galaxy, M32, M87, NGC 3115, NGC 3377, NGC 4258, and the Sombrero Galaxy.**

It is now widely accepted that the center of (nearly) every galaxy (not just active ones) contains a supermassive black hole. The close observational correlation between the mass of this hole and the velocity dispersion of the host **galaxy's bulge, known as the M-sigma relation**, strongly suggests a connection between the formation of the black hole and the galaxy itself.

Currently, the best evidence for a supermassive black hole comes from studying **the proper motion of stars near the center of our own Milky Way. Since 1995 astronomers have tracked the motion of 90 stars in a region called Sagittarius A*. By fitting their motion to Keplerian orbits they were able to infer in 1998 that 2.6 million solar masses must be contained in a volume with a radius of 0.02 lightyears** Since then one of the stars—called S2—has completed a full orbit. From the orbital data they were able to place better constraints on the mass and size of the object causing the orbital motion of stars in the Sagittarius A* region, finding that there is a spherical mass of 4.3 million solar masses contained within a radius of less than 0.002 lightyears. While this is more than 3000 times the Schwarzschild radius corresponding to that mass, it is at least consistent with the central object being a supermassive black hole, and no "realistic cluster [of stars] is physically tenable.

Gravitational lensing

The deformation of spacetime around a massive object causes light rays to be deflected much like light passing through an **optic lens. This phenomenon is known as gravitational lensing. Observations have been made of weak gravitational lensing, in which photons are deflected by only a few arcseconds. However, it has never been directly observed for a black hole. One possibility for observing gravitational lensing by a black hole would be to observe stars in orbit around the black hole. There are several candidates for such an observation in orbit around Sagittarius A***

Alternatives

The evidence for stellar black holes strongly relies on the existence of an upper limit for the mass of a neutron star. The size of this limit heavily depends on the assumptions made about the properties of dense matter. New **exotic phases of matter could push up this bound. A phase of free quarks at high density might allow the existence of dense quark stars, and some supersymmetric models predict the existence of Q stars** Some extensions of the standard model posit **the existence of preons as fundamental building blocks of quarks and leptons, which could hypothetically form preon stars. These hypothetical models could potentially explain a number of observations** of stellar black hole candidates. However, it can be shown from general arguments in general relativity that any such object will have a maximum mass.

Since the average density of a black hole inside its Schwarzschild radius is inversely proportional to the square of its mass, supermassive black holes are much less dense than stellar black holes (the average density of a 10^8 solar mass black hole is comparable to that of water) Consequently, the physics of matter forming a supermassive black hole is much better understood and the possible alternative explanations for supermassive black hole observations are much more mundane. For example, a supermassive black hole could be modeled by a large cluster of very dark objects. However, typically such alternatives are not stable enough to explain the supermassive black hole candidates.

The evidence for stellar and supermassive black holes implies that in order for black holes not to form, general relativity must fail as a theory of gravity, perhaps due to the **onset of quantum corrections**. A much anticipated feature of a theory of quantum gravity is that it will not feature singularities or event horizons (and thus no black holes) In recent years, much attention has been drawn by the fuzz ball model in string theory. Based on calculations in specific situations in string theory, the proposal suggest that generically the individual states of a black hole solution do not have an event horizon or singularity, but that for a classical/semi-classical observer the statistical average of such states does appear just like an ordinary black hole in general relativity.

Open questions

Entropy and thermodynamics

The formula for the Bekenstein–Hawking entropy (S) of a black hole, which depends on the area of the black hole (A). The constants are the speed of light (c), the Boltzmann (k), Newton's constant (G), and the reduced Planck constant (ħ).

In 1971, Hawking showed under general conditions that the total area of the event horizons of any collection of classical black holes can never decrease, even if they collide and merge This result, now known as the second law of black hole mechanics, is remarkably similar to the second law of thermodynamics, which states that the total entropy of a system can never decrease. As with classical objects at absolute zero temperature, it was assumed that black holes had zero entropy. If this were the case, the second law of thermodynamics would be violated by entropy-laden matter entering a black hole, resulting in a decrease of the total entropy of the universe. Therefore, Bekenstein proposed that a black hole should have an entropy, and that it should be proportional to its horizon area

The link with the laws of thermodynamics was further strengthened by Hawking's discovery that quantum field theory predicts that a black hole radiates blackbody radiation at a constant temperature. This seemingly causes a violation of the second law of black hole mechanics, since the radiation will carry away energy from the black hole causing it to shrink. The radiation, however also carries away entropy, and it can be proven under general assumptions that the sum of the entropy of the matter surrounding a black hole and one quarter of the area of the horizon as measured in Planck units is in fact always increasing. This allows the formulation of the first law of black hole mechanics as an analogue of the first law of thermodynamics, with the mass acting as energy, the surface gravity as temperature and the area as entropy

One puzzling feature is that the entropy of a black hole scales with its area rather than with its volume, since entropy is normally an extensive quantity that scales linearly with the volume of the system. This odd property led Gerard 't Hooft and Leonard Susskind to propose the holographic principle, which suggests that anything that happens in a volume of spacetime can be described by data on the boundary of that volume.

Although general relativity can be used to perform a semi-classical calculation of black hole entropy, this situation is theoretically unsatisfying. In statistical mechanics, entropy is understood as counting the number of microscopic configurations of a system that have the same macroscopic qualities (such as mass, charge, pressure, etc.). Without a satisfactory theory of quantum gravity, one cannot perform such a computation for black holes. Some progress has been made in various approaches to quantum gravity. In 1995, Andrew Strominger and Cumrun Vafa showed that counting the microstates of a specific supersymmetric black hole in string theory reproduced the Bekenstein–Hawking entropy Since then, similar results have been reported for different black holes both in string theory and in other approaches to quantum gravity like loop quantum gravity

Black hole unitarity<.>

An open question in fundamental physics is the so-called information loss paradox, or black hole unitarity paradox. Classically, the laws of physics are the same run forward or in reverse (T-symmetry). Liouville's theorem dictates conservation of phase space volume, which can be thought of as "conservation of information", so there is some problem even in classical physics. In quantum mechanics, this corresponds to a vital property called unitarity, which has to do with the conservation of probability (it can also be thought of as a conservation of quantum phase space volume as expressed by the density matrix).

Open questions

Entropy and thermodynamics

, Hawking showed under general conditions that the total area of the event horizons of any collection of classical black holes can never decrease, even if they **collide and merge**. This result, now known as the second law of black hole mechanics, is remarkably similar to the second law of thermodynamics, which states that the total entropy of a system can never decrease. As with classical objects at absolute zero temperature, it was assumed that black holes had zero entropy. If this were the case, the second law of thermodynamics would be violated by entropy-laden matter entering a black hole, resulting in a decrease of the total entropy of the universe. Therefore, Bekenstein proposed that a black hole should have entropy, and that it should be proportional to its horizon area.

The link with the laws of thermodynamics was further strengthened by Hawking's discovery that quantum field theory predicts that a black hole radiates blackbody radiation at a constant temperature. This seemingly causes a violation of the second law of black hole mechanics, since the radiation will carry away energy from the black hole(-) causing it to shrink. The radiation, however also carries away (E)entropy, and it can be proven under general assumptions that the sum of the entropy of the matter surrounding a black hole and one quarter of the area of the horizon as measured in Planck units is in fact always increasing. This allows the formulation of the first law of black hole mechanics as an analogue of the first law of thermodynamics, with the mass acting as energy, the surface gravity as temperature and the area as entropy

One puzzling feature is that the entropy of a black hole scales with its area rather than with its volume, since entropy is normally an extensive quantity that scales linearly with the volume of the system. This odd property led Gerard 't Hooft and Leonard Susskind to propose the holographic principle, which suggests that anything that happens in a volume of spacetime can be described by data on the boundary of that volume.

Although general relativity can be used to perform a semi-classical calculation of black hole entropy, this situation is theoretically unsatisfying. In statistical mechanics, entropy is understood as counting the number of microscopic configurations of a system that have the same macroscopic qualities (such as mass, charge, pressure, etc.). Without a satisfactory theory of quantum gravity, one cannot perform such a computation for black holes. Some progress has been made in various approaches to quantum gravity. Black hole unitarity Black hole information paradox

An open question in fundamental physics is the so-called information loss paradox, or black hole unitarity paradox. Classically, the laws of physics are the same run forward or in reverse (T-symmetry). Liouville's theorem dictates conservation of phase space volume, which can be thought of as "conservation of information", so there is some problem even in classical physics. In quantum mechanics, this corresponds to a vital property called unitarity, which has to do with the conservation of probability (it can also be thought of as a conservation of quantum phase space volume as expressed by the density matrix)

Some Salient Notes Relating to the relation between the Quantum Information and Quantum Mechanical Behaviour

^ The set of possible paths, or more accurately the future light cone containing all possible world line is tilted in this way in Eddington–Finkelstein coordinates, but in other coordinates the light cones are not tilted in this way, for example in Schwarzschild coordinates they simply narrow without tilting as one approaches the event horizon, and in Kruskal–Szekeres coordinates the light cones don't change shape or orientation at all.^ This is true only for 4-dimensional spacetimes. In higher dimensions more complicated horizon topologies like a black ring are possible^ In particular, he assumed that all matter satisfies the weak energy condition.

Effective routing protocols for delay tolerant network

Sukhbir¹, Dr. Rishipal Singh²

¹M.Tech Student, ²Assistant Prof. CSE Deptt.

Guru jambheshwar university science & technology, hisar

Abstract: Delay-tolerant Networking (DTN) enables communication in sparse mobile ad-hoc networks and other challenged environments where traditional networking fails and new routing and application protocols are required. Past experience with DTN routing and application protocols has shown that their performance is highly dependent on the underlying mobility and node characteristics. Evaluating DTN protocols across many scenarios requires suitable simulation tools. This paper presents the existing routing protocols techniques and Comparative study of existing routing protocols of Delay-Tolerant Networks based upon the metrics like Overhead Ratio, Hop Count and Buffer Size.

I. INTRODUCTION

Delay tolerant networks are an emerging field of networks that show some different characteristics from today's internet such as intermittent connectivity, long delays etc. Delay tolerant networks arise in a variety of situation like disaster relief, military rescue operations, rural internet access etc. There are some critical situations where the ability to communicate make a significant difference for human lives. In DTN decision to drop a message is taken on several constraints like size of message, no of copies, time to live and buffer size etc.

In DTN, end to end path is very rare and unstable in nature and opportunity to establish complete route is negligible. DTN support those applications, whose time requirement is hours or even day or longer. It is necessary to deliver high priority message during "contact" phase [1]. DTN enable communication by taking advantage of Temporary connections to relay data in a fashion similar to Postal network instead of requiring an end to end network path to be available.

However communication in DTN is a very challenging task. Traditional network simply assume a complete connected graph should be there and a period of time that is long enough to allow communication. In DTN there might not even be end to end path between a pair of nodes at any moment of time as shown in the figure 1 [2]. Due to this unique feature of DTN, existing routing algorithm that are developed for Internet and MANETS do not performing well. Reason for this is that all these algorithm assume that the network is connected and end to end path exist between each pair of nodes. DTN are often resource limited and not able to deliver required performance in case of intermittent connectivity. Due to given resource limitation and uncertainty in DTN it is very difficult to deliver data.

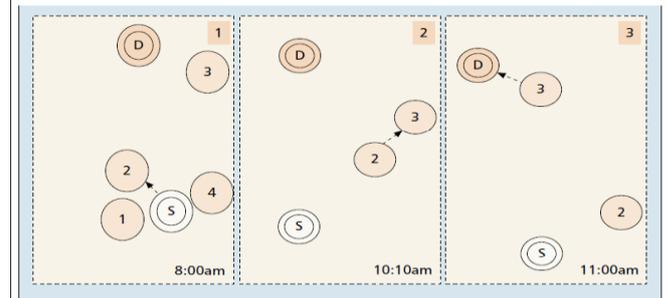

Figure 1: Time Evolving Behavior of the Network efficiently.

DTN follow store carry and forward approach. Node should carry the message until proper custodian is not found. Because of resource limitation each node in DTN has some fix size of buffer. Node store the message in its own buffer until the next custodian is found in the path towards the destination. As the buffer size is limited node should follow some policy to decide which message is dropped when the buffer size is full. Develop an algorithm and a weight function to make this decision that effectively choose message to be dropped. As a result proposed algorithm has been compare with already existing DROP FRONT policy. The approach better results in terms of delivery probability, buffer time avg and Hop count avg..

II. RELATED WORK

The major objective of routing in DTNs is to deliver packets from the source to the destination by means of the mobility of nodes. Since the end-to-end path may not be available, routing schemes have to optimize data dissemination by utilizing the connectivity information and network conditions maintained by each node. For example, in [3], the routing scheme based on the estimates of the average inter contact time between the mobile nodes in the network was proposed. This routing scheme was designed to minimize the packet delivery time. The routing properties in terms of loop-free forwarding and polynomial convergence were studied, which ensure the performance of the packet delivery in DTNs. In [4], the packet-delivery scheme based on the super node architecture and epidemic routing was introduced. With epidemic routing, the packets are forwarded to other contacted nodes (i.e., nodes with a direct connection). Unlike traditional epidemic routing, the packets are forwarded to the super nodes to improve the performance and reduce overhead. The super nodes are then responsible in carrying the packets to the destination.

III. ROUTING PROTOCOLS

(a) **First contact:** – This is simplest strategy to transmit the data from source to destination in DTN. This transmit message immediately as soon as the source and destination come in contact with each other directly. This is possible when the source and destination are one hop apart or immediately neighbor of each other.

(b) **Direct delivery:-** Scheme lets the source hold the data until it comes in contact with the destination. This simple strategy uses one message transmission. It is a degenerate case of flooding family, requiring no info about network but requires a direct path between source and destination. Hence if no contact occurs, message is not delivered.

(c) **ProPHET:-**Improve the routing performance by adopting the probabilistic scheme that reflects the contact observation of nodes. However, the single copy forwarding based on the probability may affect to the performance with limitation of the initial probability distribution and a message drop. The limited buffer space and use of an ACK message should be investigated to enhance the performance further.

Finally, although Spray and Wait can overcome the shortcomings of Epidemic routing protocol, the usability of the wait phase with an efficient single copy forwarding scheme and the optimal decision of an initial spray number are open issues.

(d) **Spray and Wait:-** The operation of Spray and Wait consists of two phases:

the spray phase and the wait phase. In the spray phase, when a node generates a message, the node makes N copies of the message to spread it to relay nodes. When the node meets the other node, the node checks N (i.e., $N > 1$). If the node has the spray message, the node hands over the message and revised N (i.e., $N/2$) to the other node. After the spray phase is finished, each of N nodes carrying a message copy performs the direct message transmission until it successfully delivered the message to the destination.

(e) **Epidemic Routing:** - Epidemic routing is an early sparse network routing protocol proposed for DTN. It assumes that each node has unlimited storage space and bandwidth. Therefore every node can store all the messages transmitted during "contact" phase. This use the concept of database replication also a relay node can exchange the entire message during "contact" phase. Each node maintains list of messages in the database called summary vector.

IV. Dynamic Spray and Wait with Quality of Node (QoN)

4.1. Delivery utility

When delivery rate stay the same, consider the relationship between network overhead and delivery utility. Delivery utility is defined as the ratio of the number of messages received by destination nodes to the number of messages forwarded by relay nodes, as shown in Equation (1).

$$delivery_utility = \frac{Messages\ of\ received}{Messages\ of\ forwarded}$$

4.2. The definition of Quality of Node (QoN)

The Epidemic and The Spray and Wait routing protocols forward messages without taking node mobile patterns into consideration, therefore the delivery utility is too low.

Now present the notion of QoN. QoN indicates the activity of a node, or the number one node meets other different nodes within a given interval. In the same period of time, the more nodes that one node meets, the greater the QoN. The variation of QoN can dynamically represents the node activity in a given period of time.

V. Drop policy algorithm

Let us assume

n = number of nodes in the network

t = number of digits in n

Bavail=buffer available at particular node

Mnew=new message

Snew=size of new incoming message

$N_i(t)$ =no copies of message i at time t

Ttl= time to live /*time duration in which message is live means message is useful only this time duration */

Rtli=remaining time to live of message for message i

5.1 Proposed Algorithm

When two nodes communicate with each other they share message to each other. It might be possible when they communicate the buffer available is not enough to accommodate a new message. At that time scheduling take place. Each node have two options at that moment of time: first it will discard a new message and second one is that it will drop some message from its buffer and make some room for the new message.

Until now all DTN routing protocol follow the DROP FRONT message approach in which they drop message from the front of nodes buffer queue.

5.2 Weight function

This function value makes the decision to drop a message from the node buffer. This weight function consider various properties of the message and node. As a result it gives a value on basis of that a node drop a particular message whose value is minimum.

Let N = no of nodes in the network

MaxTTL= maximum value of time to live of any node in the network

While($S_{new} > B_{avail}$)

```
{
Mid=call message equal (Snew); /* Search those message
in the buffer of node whose size is equal to or greater then
the size of incoming new message. This function will
return the message id of those messages who will be drop
according to SRT algo */
Bavail=Bavail+ MessageCollection.get(MID).Size();
Delete MessageCollection.get(MID);
}
```

/* Body of the function call messageEqual(Snew) */

```
Int callmessageEqual(Snew)
{
For (each message M in node buffer)
{
If (Mni>=Snew)
Add MessageCollection m; /* message id */
}
```

```
}
```

```

/* Then apply a weight function on MessageCollection m.
*/
float F,F1, $\alpha$ ;
/* initially F1 contain the function value (F) of m0
message */
int MessageId;
While (MessageCollection m)
{
F=a*(size of message)+ b/N *(no of copies) + c/MaxTTL
a=b+ $\alpha$ +1;
 $\alpha$  = 1/n
b=10n;
c =RTLi /* remaining time to live */
If (F<F1)
{
F1=F;
Messageid=MessageCollection.get(F);
}
Return MessageId;
}
    
```

VI. SIMULATION

One is an agent based discrete event simulator engine. The main functions of one simulator are the modeling of node movement, inter node contact, routing and message handling. Analysis of the result are done through visualization or reports. Movement models are used to implement the node movement. Connectivity between the nodes depends on their location and communication range. Routing modules are used to implement the routing function that decide which message to forward. Finally the message are generated through event generator. The graphical user interface(GUI) displays a visualization of the simulation.

VII. RESULTS

The results given below indicate the comparative study between DROP FRONT and SRT. The results show the comparison between DROP FRONT and SRT drop policy. These results prove that it is beneficial to use SRT drop policy as it improves the performance of any DTN.

7.1 Comparison Based on Delivery Probability

The comparative study of DROP FRONT and SRT DROP policy with respect to delivery probability has been plotted in the figure 2. The DROP FRONT policy drops the front messages from the buffer; however the SRT drops the bigger size message. But in case of FIRST CONTACT and DIRECT DELIVERY router the probability of encounter is less as a result the delivery probability is not increasing significant as compared to previous results.

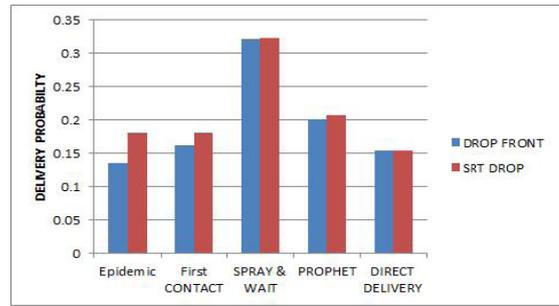

Figure 2: Drop Front, SRT Drop Delivery Probability W.R.T to Routers

7.2 Comparison Based on Buffer Time Average

Figure 3 indicates that the buffer time average for SRT DROP and DROP FRONT policy for various routers. The value of buffer time average is large in SRT drop as compared to DROP FRONT. High value of buffer time average increase the probability of message delivery in the DTN paradigm. High value of buffer time average also decreases the drop ratio. Figure 3 shows that SRT DROP increases the buffer time average as compared to DROP FRONT.

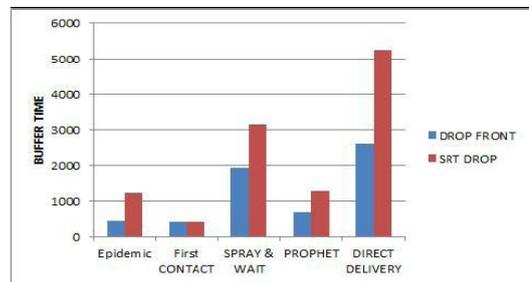

Figure 3: Drop Front, SRT Drop Buffer Time Avg. W.R.T to Routers

7.3 Comparison Based on Overhead Ratio

The overhead ratio with respect to various routers has been plotted in figure 4 for SRT DROP and DROP FRONT. The results show that the SRT DROP is less in terms of overhead ratio in all routers. Overhead ratio in DIRECT DELIVERY router is zero due to direct transmission while the overhead ratio is decreases in epidemic, prophet, fc, spray and waits up to a significant level. SRT DROP less no of messages as compare to DROP FRONT because it drop the message of nearly greater or equal size of messages.

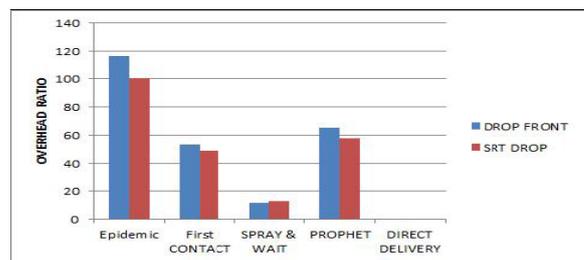

Figure 4: Drop Front, SRT Drop Overhead Ratio W.R.T to Routers

7.4 Comparison Based on Packet Dropped

The results in the figure 5 show that the SRT DROP drops less no. of messages as compared to DROP FRONT because it drops the message of nearly greater or equal size of messages. Therefore, the network overhead also decreases.

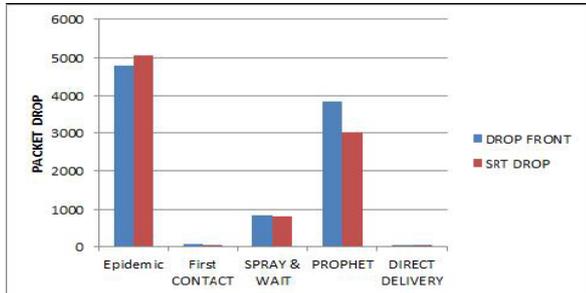

Figure 5: Drop Front,SRT Drop Packet Drop W.R.T to Routers

7.5 Comparison Based on Hop Count Avg.

Figure 6 shows the hop count for various routers for SRT DROP and DROP FRONT policy. The lower value of hop count means that message has consumed less resource to reach its destination. SRT DROP drops the messages whose size is nearly equal to the incoming message. Due to this logic it will drop less no of messages and decreases the value of hop count average.

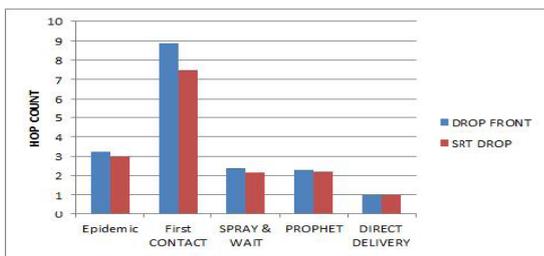

Figure 6: Drop Front,SRT Drop Hop Count W.R.T to Routers

VIII. CONCLUSION

In this paper investigated SRT DROP policy with DROP FRONT policy with respect to DTN routing protocols. Results shows that our SRT DROP policy perform well with respect to delivery probability, buffer time, overhead ratio, hop count average and packet dropped. It should motivate to examine SRT DROP policy to other existing drop policy.

Compare the SRT DROP POLICY with DROP FRONT policy. This comparison motivate to compare SRT DROP policy with DROP LARGEST POLICY because both policy gives importance to size of messages. The routing protocol other then the EPIDEMIC, FC, DIRECT DELIVERY, SPRAY ANDWAIT and PROPHET routing protocols are also an interesting direction of work.
