has a unique positive solution , which is an equilibrium solution for the system

(a) Indeed the first two equations have a nontrivial solution G_{13}, G_{14} if

$$F(T) = (a'_{13})^{(1)}(a'_{14})^{(1)} - (a_{13})^{(1)}(a_{14})^{(1)} + (a'_{13})^{(1)}(a''_{14})^{(1)}(T_{14}) + (a'_{14})^{(1)}(a''_{13})^{(1)}(T_{14}) + (a''_{13})^{(1)}(T_{14})(a''_{14})^{(1)}(T_{14}) = 0 .$$

(a) Indeed the first two equations have a nontrivial solution G_{16}, G_{17} if

$$F(T_{19}) = (a'_{16})^{(2)}(a'_{17})^{(2)} - (a_{16})^{(2)}(a_{17})^{(2)} + (a'_{16})^{(2)}(a''_{17})^{(2)}(T_{17}) + (a'_{17})^{(2)}(a''_{16})^{(2)}(T_{17}) + (a''_{16})^{(2)}(T_{17})(a''_{17})^{(2)}(T_{17}) = 0 .$$

(a) Indeed the first two equations have a nontrivial solution G_{20}, G_{21} if

$$F(T_{23}) = (a'_{20})^{(3)}(a'_{21})^{(3)} - (a_{20})^{(3)}(a_{21})^{(3)} + (a'_{20})^{(3)}(a''_{21})^{(3)}(T_{21}) + (a'_{21})^{(3)}(a''_{20})^{(3)}(T_{21}) + (a''_{20})^{(3)}(T_{21})(a''_{21})^{(3)}(T_{21}) = 0 .$$

(a) Indeed the first two equations have a nontrivial solution G_{24}, G_{25} if

$$F(T_{27}) = (a'_{24})^{(4)}(a'_{25})^{(4)} - (a_{24})^{(4)}(a_{25})^{(4)} + (a'_{24})^{(4)}(a''_{25})^{(4)}(T_{25}) + (a'_{25})^{(4)}(a''_{24})^{(4)}(T_{25}) + (a''_{24})^{(4)}(T_{25})(a''_{25})^{(4)}(T_{25}) = 0 .$$

(a) Indeed the first two equations have a nontrivial solution G_{28}, G_{29} if

$$F(T_{31}) = (a'_{28})^{(5)}(a'_{29})^{(5)} - (a_{28})^{(5)}(a_{29})^{(5)} + (a'_{28})^{(5)}(a''_{29})^{(5)}(T_{29}) + (a'_{29})^{(5)}(a''_{28})^{(5)}(T_{29}) + (a''_{28})^{(5)}(T_{29})(a''_{29})^{(5)}(T_{29}) = 0 .$$

(a) Indeed the first two equations have a nontrivial solution G_{32}, G_{33} if

$$F(T_{35}) = (a'_{32})^{(6)}(a'_{33})^{(6)} - (a_{32})^{(6)}(a_{33})^{(6)} + (a'_{32})^{(6)}(a''_{33})^{(6)}(T_{33}) + (a'_{33})^{(6)}(a''_{32})^{(6)}(T_{33}) + (a''_{32})^{(6)}(T_{33})(a''_{33})^{(6)}(T_{33}) = 0 .$$

Definition and uniqueness of T_{14}^* :-

After hypothesis $f(0) < 0, f(\infty) > 0$ and the functions $(a_i'')^{(1)}(T_{14})$ being increasing, it follows that there exists a unique T_{14}^* for which $f(T_{14}^*) = 0$. With this value, we obtain from the three first equations

$$G_{13} = \frac{(a_{13})^{(1)}G_{14}}{[(a'_{13})^{(1)}+(a''_{13})^{(1)}(T_{14}^*)]} \quad , \quad G_{15} = \frac{(a_{15})^{(1)}G_{14}}{[(a'_{15})^{(1)}+(a''_{15})^{(1)}(T_{14}^*)]}$$

Definition and uniqueness of T_{17}^* :-

After hypothesis $f(0) < 0, f(\infty) > 0$ and the functions $(a_i'')^{(2)}(T_{17})$ being increasing, it follows that there exists a unique T_{17}^* for which $f(T_{17}^*) = 0$. With this value, we obtain from the three first equations .

$$G_{16} = \frac{(a_{16})^{(2)}G_{17}}{[(a'_{16})^{(2)}+(a''_{16})^{(2)}(T_{17}^*)]} \quad , \quad G_{18} = \frac{(a_{18})^{(2)}G_{17}}{[(a'_{18})^{(2)}+(a''_{18})^{(2)}(T_{17}^*)]}$$

Definition and uniqueness of T_{21}^* :-

After hypothesis $f(0) < 0, f(\infty) > 0$ and the functions $(a_i'')^{(3)}(T_{21})$ being increasing, it follows that there exists a unique T_{21}^* for which $f(T_{21}^*) = 0$. With this value, we obtain from the three first equations

$$G_{20} = \frac{(a_{20})^{(3)}G_{21}}{[(a'_{20})^{(3)}+(a''_{20})^{(3)}(T_{21}^*)]} \quad , \quad G_{22} = \frac{(a_{22})^{(3)}G_{21}}{[(a'_{22})^{(3)}+(a''_{22})^{(3)}(T_{21}^*)]}$$

Definition and uniqueness of T_{25}^* :-

After hypothesis $f(0) < 0, f(\infty) > 0$ and the functions $(a_i'')^{(4)}(T_{25})$ being increasing, it follows that there exists a unique T_{25}^* for which $f(T_{25}^*) = 0$. With this value, we obtain from the three first equations

$$G_{24} = \frac{(a_{24})^{(4)}G_{25}}{[(a'_{24})^{(4)}+(a''_{24})^{(4)}(T_{25}^*)]} \quad , \quad G_{26} = \frac{(a_{26})^{(4)}G_{25}}{[(a'_{26})^{(4)}+(a''_{26})^{(4)}(T_{25}^*)]}$$

Definition and uniqueness of T_{29}^* :-

After hypothesis $f(0) < 0, f(\infty) > 0$ and the functions $(a_i'')^{(5)}(T_{29})$ being increasing, it follows that there exists a unique T_{29}^* for which $f(T_{29}^*) = 0$. With this value, we obtain from the three first equations

$$G_{28} = \frac{(a_{28})^{(5)}G_{29}}{[(a'_{28})^{(5)}+(a''_{28})^{(5)}(T_{29}^*)]} \quad , \quad G_{30} = \frac{(a_{30})^{(5)}G_{29}}{[(a'_{30})^{(5)}+(a''_{30})^{(5)}(T_{29}^*)]}$$

Definition and uniqueness of T_{33}^* :-

After hypothesis $f(0) < 0, f(\infty) > 0$ and the functions $(a_i'')^{(6)}(T_{33})$ being increasing, it follows that there exists a unique T_{33}^* for which $f(T_{33}^*) = 0$. With this value, we obtain from the three first equations

$$G_{32} = \frac{(a_{32})^{(6)}G_{33}}{[(a'_{32})^{(6)}+(a''_{32})^{(6)}(T_{33}^*)]} \quad , \quad G_{34} = \frac{(a_{34})^{(6)}G_{33}}{[(a'_{34})^{(6)}+(a''_{34})^{(6)}(T_{33}^*)]}$$

(e) By the same argument, the equations 92,93 admit solutions G_{13}, G_{14} if

$$\varphi(G) = (b'_{13})^{(1)}(b'_{14})^{(1)} - (b_{13})^{(1)}(b_{14})^{(1)} - [(b'_{13})^{(1)}(b''_{14})^{(1)}(G) + (b'_{14})^{(1)}(b''_{13})^{(1)}(G)] + (b''_{13})^{(1)}(G)(b''_{14})^{(1)}(G) = 0$$

Where in $G(G_{13}, G_{14}, G_{15}), G_{13}, G_{15}$ must be replaced by their values from 96. It is easy to see that φ is a decreasing function in G_{14} taking into account the hypothesis $\varphi(0) > 0, \varphi(\infty) < 0$ it follows that there exists a unique G_{14}^* such that $\varphi(G^*) = 0$.

(f) By the same argument, the equations 92,93 admit solutions G_{16}, G_{17} if

$$\varphi(G_{19}) = (b'_{16})^{(2)}(b'_{17})^{(2)} - (b_{16})^{(2)}(b_{17})^{(2)} - [(b'_{16})^{(2)}(b''_{17})^{(2)}(G_{19}) + (b'_{17})^{(2)}(b''_{16})^{(2)}(G_{19})] + (b''_{16})^{(2)}(G_{19})(b''_{17})^{(2)}(G_{19}) = 0 .$$

Where in $(G_{19})(G_{16}, G_{17}, G_{18}), G_{16}, G_{18}$ must be replaced by their values from 96. It is easy to see that φ is a decreasing function in G_{17} taking into account the hypothesis $\varphi(0) > 0, \varphi(\infty) < 0$ it follows that there exists a unique G_{14}^* such that $\varphi((G_{19})^*) = 0$.

(g) By the same argument, the concatenated equations admit solutions G_{20}, G_{21} if

$$\varphi(G_{23}) = (b'_{20})^{(3)}(b'_{21})^{(3)} - (b_{20})^{(3)}(b_{21})^{(3)} -$$

$$[(b'_{20})^{(3)}(b''_{21})^{(3)}(G_{23}) + (b'_{21})^{(3)}(b''_{20})^{(3)}(G_{23})] + (b''_{20})^{(3)}(G_{23})(b''_{21})^{(3)}(G_{23}) = 0$$

Where in $G_{23}(G_{20}, G_{21}, G_{22}), G_{20}, G_{22}$ must be replaced by their values from 96. It is easy to see that φ is a decreasing function in G_{21} taking into account the hypothesis $\varphi(0) > 0, \varphi(\infty) < 0$ it follows that there exists a unique G_{21}^* such that $\varphi((G_{23})^*) = 0$.

(h) By the same argument, the equations of modules admit solutions G_{24}, G_{25} if

$$\varphi(G_{27}) = (b'_{24})^{(4)}(b'_{25})^{(4)} - (b_{24})^{(4)}(b_{25})^{(4)} -$$

$$[(b'_{24})^{(4)}(b''_{25})^{(4)}(G_{27}) + (b'_{25})^{(4)}(b''_{24})^{(4)}(G_{27})] + (b''_{24})^{(4)}(G_{27})(b''_{25})^{(4)}(G_{27}) = 0$$

Where in $(G_{27})(G_{24}, G_{25}, G_{26}), G_{24}, G_{26}$ must be replaced by their values from 96. It is easy to see that φ is a decreasing function in G_{25} taking into account the hypothesis $\varphi(0) > 0, \varphi(\infty) < 0$ it follows that there exists a unique G_{25}^* such that $\varphi((G_{27})^*) = 0$.

(i) By the same argument, the equations (modules) admit solutions G_{28}, G_{29} if

$$\varphi(G_{31}) = (b'_{28})^{(5)}(b'_{29})^{(5)} - (b_{28})^{(5)}(b_{29})^{(5)} -$$

$$[(b'_{28})^{(5)}(b''_{29})^{(5)}(G_{31}) + (b'_{29})^{(5)}(b''_{28})^{(5)}(G_{31})] + (b''_{28})^{(5)}(G_{31})(b''_{29})^{(5)}(G_{31}) = 0$$

Where in $(G_{31})(G_{28}, G_{29}, G_{30}), G_{28}, G_{30}$ must be replaced by their values from 96. It is easy to see that φ is a decreasing function in G_{29} taking into account the hypothesis $\varphi(0) > 0, \varphi(\infty) < 0$ it follows that there exists a unique G_{29}^* such that $\varphi((G_{31})^*) = 0$.

(j) By the same argument, the equations (modules) admit solutions G_{32}, G_{33} if

$$\varphi(G_{35}) = (b'_{32})^{(6)}(b'_{33})^{(6)} - (b_{32})^{(6)}(b_{33})^{(6)} -$$

$$[(b'_{32})^{(6)}(b''_{33})^{(6)}(G_{35}) + (b'_{33})^{(6)}(b''_{32})^{(6)}(G_{35})] + (b''_{32})^{(6)}(G_{35})(b''_{33})^{(6)}(G_{35}) = 0$$

Where in $(G_{35})(G_{32}, G_{33}, G_{34}), G_{32}, G_{34}$ must be replaced by their values It is easy to see that φ is a decreasing function in G_{33} taking into account the hypothesis $\varphi(0) > 0, \varphi(\infty) < 0$ it follows that there exists a unique G_{33}^* such that $\varphi(G^*) = 0$.

Finally we obtain the unique solution of 89 to 94

G_{14}^* given by $\varphi(G^*) = 0, T_{14}^*$ given by $f(T_{14}^*) = 0$ and

$$G_{13}^* = \frac{(a_{13})^{(1)}G_{14}^*}{[(a'_{13})^{(1)} + (a''_{13})^{(1)}(T_{14}^*)]} \quad , \quad G_{15}^* = \frac{(a_{15})^{(1)}G_{14}^*}{[(a'_{15})^{(1)} + (a''_{15})^{(1)}(T_{14}^*)]}$$

$$T_{13}^* = \frac{(b_{13})^{(1)}T_{14}^*}{[(b'_{13})^{(1)} - (b''_{13})^{(1)}(G^*)]} \quad , \quad T_{15}^* = \frac{(b_{15})^{(1)}T_{14}^*}{[(b'_{15})^{(1)} - (b''_{15})^{(1)}(G^*)]}$$

Obviously, these values represent an equilibrium solution .

Finally we obtain the unique solution .

G_{17}^* given by $\varphi((G_{19})^*) = 0$, T_{17}^* given by $f(T_{17}^*) = 0$ and.

$$G_{16}^* = \frac{(a_{16})^{(2)}G_{17}^*}{[(a'_{16})^{(2)}+(a''_{16})^{(2)}(T_{17}^*)]} , G_{18}^* = \frac{(a_{18})^{(2)}G_{17}^*}{[(a'_{18})^{(2)}+(a''_{18})^{(2)}(T_{17}^*)]} .$$

$$T_{16}^* = \frac{(b_{16})^{(2)}T_{17}^*}{[(b'_{16})^{(2)}-(b''_{16})^{(2)}((G_{19})^*)]} , T_{18}^* = \frac{(b_{18})^{(2)}T_{17}^*}{[(b'_{18})^{(2)}-(b''_{18})^{(2)}((G_{19})^*)]} .$$

Obviously, these values represent an equilibrium solution.

Finally we obtain the unique solution

G_{21}^* given by $\varphi((G_{23})^*) = 0$, T_{21}^* given by $f(T_{21}^*) = 0$ and

$$G_{20}^* = \frac{(a_{20})^{(3)}G_{21}^*}{[(a'_{20})^{(3)}+(a''_{20})^{(3)}(T_{21}^*)]} , G_{22}^* = \frac{(a_{22})^{(3)}G_{21}^*}{[(a'_{22})^{(3)}+(a''_{22})^{(3)}(T_{21}^*)]}$$

$$T_{20}^* = \frac{(b_{20})^{(3)}T_{21}^*}{[(b'_{20})^{(3)}-(b''_{20})^{(3)}(G_{23}^*)]} , T_{22}^* = \frac{(b_{22})^{(3)}T_{21}^*}{[(b'_{22})^{(3)}-(b''_{22})^{(3)}(G_{23}^*)]}$$

Obviously, these values represent an equilibrium solution .

Finally we obtain the unique solution

G_{25}^* given by $\varphi(G_{27}) = 0$, T_{25}^* given by $f(T_{25}^*) = 0$ and

$$G_{24}^* = \frac{(a_{24})^{(4)}G_{25}^*}{[(a'_{24})^{(4)}+(a''_{24})^{(4)}(T_{25}^*)]} , G_{26}^* = \frac{(a_{26})^{(4)}G_{25}^*}{[(a'_{26})^{(4)}+(a''_{26})^{(4)}(T_{25}^*)]} .$$

$$T_{24}^* = \frac{(b_{24})^{(4)}T_{25}^*}{[(b'_{24})^{(4)}-(b''_{24})^{(4)}((G_{27})^*)]} , T_{26}^* = \frac{(b_{26})^{(4)}T_{25}^*}{[(b'_{26})^{(4)}-(b''_{26})^{(4)}((G_{27})^*)]}$$

Obviously, these values represent an equilibrium solution .

Finally we obtain the unique solution

G_{29}^* given by $\varphi((G_{31})^*) = 0$, T_{29}^* given by $f(T_{29}^*) = 0$ and

$$G_{28}^* = \frac{(a_{28})^{(5)}G_{29}^*}{[(a'_{28})^{(5)}+(a''_{28})^{(5)}(T_{29}^*)]} , G_{30}^* = \frac{(a_{30})^{(5)}G_{29}^*}{[(a'_{30})^{(5)}+(a''_{30})^{(5)}(T_{29}^*)]}$$

$$T_{28}^* = \frac{(b_{28})^{(5)}T_{29}^*}{[(b'_{28})^{(5)}-(b''_{28})^{(5)}((G_{31})^*)]} , T_{30}^* = \frac{(b_{30})^{(5)}T_{29}^*}{[(b'_{30})^{(5)}-(b''_{30})^{(5)}((G_{31})^*)]}$$

Obviously, these values represent an equilibrium solution.

Finally we obtain the unique solution

G_{33}^* given by $\varphi((G_{35})^*) = 0$, T_{33}^* given by $f(T_{33}^*) = 0$ and

$$G_{32}^* = \frac{(a_{32})^{(6)}G_{33}^*}{[(a'_{32})^{(6)}+(a''_{32})^{(6)}(T_{33}^*)]} , G_{34}^* = \frac{(a_{34})^{(6)}G_{33}^*}{[(a'_{34})^{(6)}+(a''_{34})^{(6)}(T_{33}^*)]} .$$

$$T_{32}^* = \frac{(b_{32})^{(6)}T_{33}^*}{[(b'_{32})^{(6)}-(b''_{32})^{(6)}((G_{35})^*)]} , T_{34}^* = \frac{(b_{34})^{(6)}T_{33}^*}{[(b'_{34})^{(6)}-(b''_{34})^{(6)}((G_{35})^*)]}$$

Obviously, these values represent an equilibrium solution .

ASYMPTOTIC STABILITY ANALYSIS

Theorem 4: If the conditions of the previous theorem are satisfied and if the functions $(a_i'')^{(1)}$ and $(b_i'')^{(1)}$ Belong to $C^{(1)}(\mathbb{R}_+)$ then the above equilibrium point is asymptotically stable.

Proof: Denote

Definition of $\mathbb{G}_i, \mathbb{T}_i$:-

$$G_i = G_i^* + \mathbb{G}_i \quad , \quad T_i = T_i^* + \mathbb{T}_i$$

$$\frac{\partial (a_{14}'')^{(1)}}{\partial T_{14}} (T_{14}^*) = (q_{14})^{(1)} \quad , \quad \frac{\partial (b_i'')^{(1)}}{\partial G_j} (G^*) = s_{ij} .$$

Then taking into account equations (global) and neglecting the terms of power 2, we obtain .

$$\frac{d\mathbb{G}_{13}}{dt} = -((a'_{13})^{(1)} + (p_{13})^{(1)})\mathbb{G}_{13} + (a_{13})^{(1)}\mathbb{G}_{14} - (q_{13})^{(1)}G_{13}^*\mathbb{T}_{14} .$$

$$\frac{d\mathbb{G}_{14}}{dt} = -((a'_{14})^{(1)} + (p_{14})^{(1)})\mathbb{G}_{14} + (a_{14})^{(1)}\mathbb{G}_{13} - (q_{14})^{(1)}G_{14}^*\mathbb{T}_{14} .$$

$$\frac{d\mathbb{G}_{15}}{dt} = -((a'_{15})^{(1)} + (p_{15})^{(1)})\mathbb{G}_{15} + (a_{15})^{(1)}\mathbb{G}_{14} - (q_{15})^{(1)}G_{15}^*\mathbb{T}_{14} .$$

$$\frac{d\mathbb{T}_{13}}{dt} = -((b'_{13})^{(1)} - (r_{13})^{(1)})\mathbb{T}_{13} + (b_{13})^{(1)}\mathbb{T}_{14} + \sum_{j=13}^{15} (s_{(13)(j)})T_{13}^*\mathbb{G}_j .$$

$$\frac{d\mathbb{T}_{14}}{dt} = -((b'_{14})^{(1)} - (r_{14})^{(1)})\mathbb{T}_{14} + (b_{14})^{(1)}\mathbb{T}_{13} + \sum_{j=13}^{15} (s_{(14)(j)})T_{14}^*\mathbb{G}_j .$$

$$\frac{d\mathbb{T}_{15}}{dt} = -((b'_{15})^{(1)} - (r_{15})^{(1)})\mathbb{T}_{15} + (b_{15})^{(1)}\mathbb{T}_{14} + \sum_{j=13}^{15} (s_{(15)(j)})T_{15}^*\mathbb{G}_j .$$

If the conditions of the previous theorem are satisfied and if the functions $(a_i'')^{(2)}$ and $(b_i'')^{(2)}$ Belong to $C^{(2)}(\mathbb{R}_+)$ then the above equilibrium point is asymptotically stable.

Denote

Definition of $\mathbb{G}_i, \mathbb{T}_i$:-

$$G_i = G_i^* + \mathbb{G}_i \quad , \quad T_i = T_i^* + \mathbb{T}_i .$$

And as one sees, all the coefficients are positive. It follows that all the roots have negative real part, and this proves the theorem.

Acknowledgments:

The introduction is a collection of information from various articles, Books, News Paper reports, Home Pages Of authors, Journal Reviews, Nature 's L:etters,Article Abstracts, Research papers, Abstracts Of Research Papers, Stanford Encyclopedia, Web Pages, Ask a Physicist Column, Deliberations with Professors, the internet including Wikipedia. We acknowledge all authors who have contributed to the same. In the eventuality of the fact that there has been any act of omission on the part of the authors, we regret with great deal of compunction, contrition, regret, trepidiation and remorse. As Newton said, it is only because erudite and eminent people allowed one to piggy ride on their backs; probably an attempt has been made to look slightly further. Once again, it is stated that the references are only illustrative and not comprehensive

- [26] There is usually more than one possible way to define a field energy, because any field can be made to couple to gravity in many different ways. By general scaling arguments, the correct answer at everyday distances, which are long compared to the quantum gravity scale, should be minimal coupling, which means that no powers of the curvature tensor appear. Any non-minimal couplings, along with other higher order terms, are presumably only determined by a theory of quantum gravity, and within string theory, they only start to contribute to experiments at the string scale.

Abstract: A mobile ad-hoc network (MANET) consists of mobile computing entities such as laptop and palmtop computers which communicate with each other through wireless links and without relying on a static infrastructure such as a base station or access point. Without centralized administration, a MANET is highly unpredictable due to its unstable links and resource-poor as most of the nodes have limited battery power. Due to these physical limitations, we propose a geo graphically location aided routing; in this proposed method nodes are require the cooperation of other nodes to successfully send a message to a destination. Figure 1.1 shows the mobile Ad hoc network. We follow with a simulation study to evaluate the performance in large networks. In this paper, we specifically address the issues and comparison of AODV and with the proposed geographically location aided routing (Terminode Routing) using ns2 to illustrate that routing overhead is low and packet delivery ratio is high compared to AODV.

I. Introduction

1.1 MANET

A mobile ad hoc network is one where in all nodes work independent of any common centralized admin. Each one of them performs the tasks of a router. They should be self-adapting in that if their connection topology changes, their routing tables should reflect the change. There are numerous scenarios that do not have an available network infrastructure and could benefit from the creation of an ad hoc network:

- o Rescue/Emergency operations: Rapid installation of a communication infrastructure during a natural/environmental disaster (or a disaster due to terrorism) that demolished the previous communication infrastructure.
- o Law enforcement activities: Rapid installation of a communication infrastructure during special operations.
- o Tactical missions: Rapid installation of a communication infrastructure in a hostile and/or unknown territory.
- o Commercial projects: Simple installation of a communication infrastructure for commercial gatherings such as conferences, exhibitions, workshops and meetings.
- o Educational classrooms: Simple installation of a communication infrastructure to create an interactive classroom on demand.

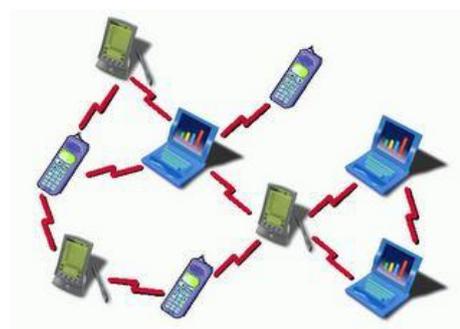

Fig:1.1 Mobile Ad Hoc Network

1.2 Main Characteristics of Ad-Hoc Networks

Dynamic topology: Hosts are mobile and can be connected dynamically in any arbitrary manner. Links of the network vary and are based on the proximity of one host to another one.

Variable capacity links: Wireless links have significantly lower capacity than their hardwired counterparts. Moreover, the realized throughput of wireless communications is often much less than a radio's maximum transmission rate.

Autonomous: No centralized administration entity is required to manage the operation of the different mobile hosts.

Bandwidth constrained: Wireless links have a significantly lower capacity than the wired ones; they are affected by several error sources that result in degradation of the received signal.

Energy constrained: Mobile hosts rely on battery power, which is a scarce resource the most important system design criterion for optimization may be energy conservation.

Limited security: Mobility implies higher security risks than static operations because portable devices may be stolen or their traffic may cross insecure wireless links.

1.3 Classification of Ad-hoc Protocols

Routing protocols can be classified into different categories depending on their properties:

- ▶ Centralized vs. Distributed
- ▶ Static vs. Adaptive
- ▶ Reactive vs. Proactive

In centralized algorithms, all route choices are made at central node, while in distributed algorithms, the computation of routers is shared among the network nodes.

1.4 Routing And Types Of Routing Protocols In Manet

In order to enable communication within a MANET, a routing protocol is required to establish routes between participating nodes. Because of limited transmission range, multiple network hops may be needed to enable data communication between two nodes in the network. Since MANET is an infrastructure less network, each mobile node operates not only as a host but also as a router, forwarding packets for other mobile nodes in the network. Mobile Ad hoc ETworks (MANET), are characterized by wireless nodes, which are free to move arbitrarily, but cooperate to forward packets for each other in a totally wireless environment.

The routing requirement of a mobile ad hoc network is achieved in distributed fashion among the nodes. Conventional routing protocols based on distance vector or link state algorithms cannot be applied here, since the amount of routing related traffic would waste a large portion of the wireless bandwidth, and such discovered routes would soon become obsolete due to mobility of Nodes. In MANETs mobile nodes share the same frequency channel thereby limiting the network capacity. Thus one of the highly desirable properties of a routing protocol for MANETs is that it should be bandwidth efficient. The routing protocols are categorized into two broad categories: namely, on-demand protocols and table driven protocols. They are also known as reactive and proactive protocols respectively.

1.4.1 Proactive or Table-driven protocols

It maintains one or more routing tables in every node in order to store routing information about other nodes in the MANET. These routing protocols attempt to update the routing table information either periodically or in response to change in network topology in order to maintain consistent and up-to-date routing information. The advantage of these protocols is that a source node does not need route-discovery procedures to find a route to a destination node. The drawback of these protocols is that maintaining a consistent and up-to-date routing table requires substantial messaging overhead, which consumes bandwidth and power usage, and decreases throughput, especially in the case of a large number of high-mobility mobile nodes. The different types of Table driven protocols are: Destination Sequenced Distance Vector routing (DSDV), Wireless routing protocol (WRP), Fish eye State Routing protocol (FSR), Optimized Link State Routing protocol (OLSR), Cluster Gateway switch routing protocol (CGSR), Topology Dissemination Based on Reverse path forwarding (TBRPF).

1.4.2 Reactive or On-demand routing protocols

Another in the family of routing protocols for mobile ad-hoc network is on-demand routing protocols. It initiates a route discovery mechanism by the source node to discover the route to the destination node when the source node has data packets to send to the destination node. After discovering the route, the route maintenance is initiated to main this route until the routes no longer required or the destination is not reachable. The main advantage of these protocols is that overhead messaging is less. One of the drawbacks of these protocols is the delay of discovering a new route. The different types of Reactive routing protocols are: Dynamic Source Routing (DSR), Ad hoc On-Demand Distance Vector routing (AODV), Location-Aided Routing (LAR), Temporally Ordered Routing Algorithm (TORA) and Dynamic MANET On-demand (DYMO).

1.5 Major MANET Issue Categories

In this section the MANET research issues are presented and classified. Hundreds of research aspects have been developed and discussed in this field. To analyze various research issues, this article covers most of the major investigation problems. Various fundamental and frequently discussed aspects of MANETs are identified and grouped into fifteen categories. These issues have the potential to significantly increase MANET survivability:

Routing: Routing is an essential one, because change in network topology occurs frequently. An efficient routing protocol is required to cope with highly fluid network conditions.

Multicasting/ Broadcasting: Multicast service supports users communicating with other members in a multicast group. Broadcast service supports users communicating with all members on a network.

Location Service: Location information uses the Global Positioning System (GPS) or the network-based geo-location technique to obtain the physical position of a destination.

Mobility Management: In the ad-hoc network environment, mobile hosts can move unrestricted from place to place. Mobility management handles the storage, maintenance and retrieval of the mobile node position information.

Multiple Accesses: A major issue is to develop efficient medium access protocols that optimize spectral reuse, and hence, maximize aggregate channel utilization in MANETs.

Bandwidth Management: Bandwidth management in MANETs is a typical characterization. Because the bandwidth is usually limited, effectively managing and using it is a very important issue.

Power Management: A power management approach would help reducing power consumption and hence prolonging the battery life of mobile nodes. Because most devices operate on batteries, power management becomes an important issue.

Security: The mobile nodes in MANETs are highly susceptible to malicious damage. Security issues are important in MANETs to prevent potential attacks, threats and system vulnerabilities.

Fault Tolerance: This issue involves detecting and correcting faults when network failures occur. Fault-tolerance techniques are brought in for maintenance when a failure occurs during node movement, joining, or leaving the network.

QoS/ Multimedia: Quality of Service (QoS) and Multimedia require high bandwidth, low delay, and high reliability.

Standards/ Products: The standards and products issues that allow the development of small scale is emerging for this field. For instance, Bluetooth is a low-cost technology for short-range communications techniques.

II. Geographical Map Path Discovery (GMPD)

The basic idea behind GMPD is that, mapping information of the network density is known to all nodes in the network. Areas with high node density are called “towns”. The Source node determines the town area in which it is actually situated; also determines the town area of the destination node. The Source node refers the network map in order to find anchor path from source to destination. The shortest path between source and destination is chosen for routing the packets. For GMPD each town, a map gives the location of its center and the size of the square area. A map of the network can be presented as a graph with nodes corresponding to towns and edges corresponding to highways. Macroscopically, the graph of towns does not change frequently.

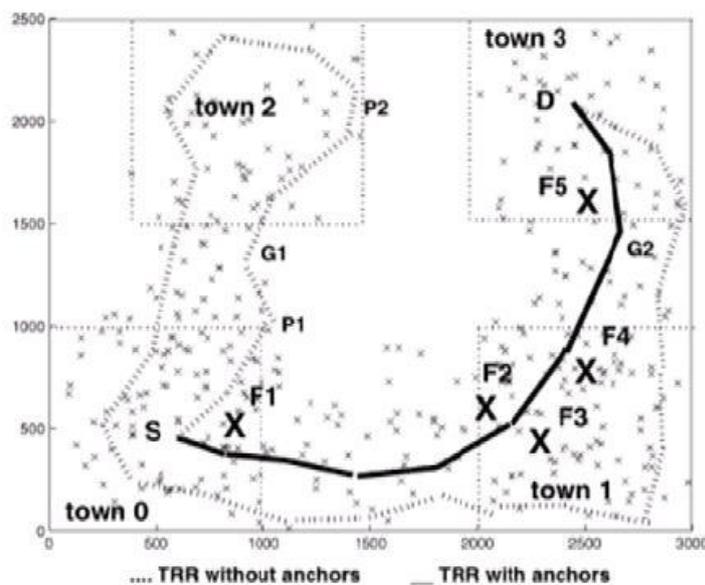

Fig: 2.1 GMPD with a given map of towns works as follows

For Figure 2.1 Source S determines from its own location LDAS the town area ST (Source town) in which S is situated (or, the nearest town to LDAS if it is not in the town area). In addition, since S knows the location of destination D (LDAD), it can determine from the LDAD the town area DT (Destination town), where D is situated (or, the nearest town to LDAD if it is not in the town area). Then, S accesses the network map in order to find the anchored path from S to D. An anchored path is the list of the geographical points: The points correspond to centers of the towns that the packet has to visit from ST in order to reach DT.

III. Location Based Routing

In ad hoc network location information to help routing is often routing (Terminode remote Routing, TRR), used when the destination is far, and link state routing (Terminode Local Routing (TLR), proposed as a means to achieve scalability in large mobile ad hoc networks. In order to enhance the life time of the network a location based routing protocol which uses anchored paths a list of geographic points is used as loose source routing information. It is a high probability that there are nodes to ensure connectivity from one town to another source and destination of the location have sufficient of its centre and size of the square area.

3.1 Terminode Routing

First, it combines a location-based routing method with a link state-based mechanism. Second, it uses a special form of restricted search mode (Restricted Local Flooding, RLF). These first two ingredients solve problems due to the inaccuracy of location information, in particular for control packets. Third, it introduces the concept of anchors, which are geographical points imagined by sources for routing to specific destinations. This helps efficiently route around connectivity holes. In order for the comparison to be fair to MANET protocols, we implemented an ad hoc location management scheme. In smaller ad hoc networks we compared Terminode routing to some existing MANET like routing protocols (AODV and LAR1) and found similar performance.

In larger mobile ad hoc networks of 500 nodes, MANET-like routing protocols do not perform well (except when mobility is small), while our routing protocol still performs well. In networks that are regularly populated with nodes, Terminode routing performs comparable to GPSR when the location management accuracy is high; however, terminode routing performs better when the location information accuracy is low. We also consider irregular networks with holes in node distribution. Here, too, we find that terminode routing outperforms GPSR. An existing MANET and location-based routing protocols we compared it to. Non uniform topologies are likely to appear in metropolitan .

IV. Performance Evaluation OF Terminode Routing

4.1. Performance Evaluation

In the NS 2 settings, The IEEE 802.11 Medium Access Control (MAC) protocol is used. And the radio range is 250 meters. The channel capacity is 2Mb/s. The propagation model is two-ray. It uses free space path loss for near sight and plane earth path loss for far sight.

4.2 Protocol Constants

We used the following configuration for the Helloing protocol. The HELLO timer is 1 second. Each entry in the routing table expires after two seconds, if it is not updated. All nodes promiscuously listen to all HELLO messages within their radio range. Nodes that have data or control packets to send should defer sending HELLO messages (up to the timer value) and piggyback the HELLO message to the data or control packet.

V. Network Simulator 2

The simulator used and the experimental results are explained in this chapter.

5.1 NS-2

The NS network simulator(www.isi.edu/nsnam/ns), from U.C. Berkeley/LBNL, is a object oriented discrete event simulator targeted at networking research and available as public domain. Its first version (NS-1) began in 1989 as a variant of the REAL network simulator and was developed by the Network Research Group at the Lawrence Berkeley National Laboratory (LBNL), USA. Its development was then part of the VINT project (www.isi.edu/nsnam/vint/index.html), supported by DARPA, at LBNL, Xerox PARC, and UCB, under which NS version 2.0 (NS-2) was released, evolving substantially from the first version. NS-2 is widely used in the networking research community and has found large acceptance as a tool to experiment new ideas, protocols and distributed algorithms.

Currently NS-2 development is still supported through DARPA. NS has always included substantial contributions from other researchers, including wireless code for both mobile ad hoc networks and wireless LANs from the UCB Daedalus and CMU Monarch projects and Sun Microsystems. At the time being, NS-2 is well suited for packets switched networks and wireless networks (ad hoc, local and satellite), and is used mostly for small scale simulations of queuing and routing algorithms, transport protocols, congestion control, and some multicast related work. It provides substantial support for simulation of TCP, routing, and multicast protocols over wired and wireless networks. NS-2 is suitable not only for simulation but also for emulation, that is, it is possible to introduce the simulator into a live network. Special objects within the simulator are capable of introducing live traffic into the simulator and injecting traffic from the simulator into the live network.

NS-2 plays an important role in the research community of mobile ad hoc networks, being a sort of reference simulator. NS-2 is the most used simulator for studies on mobile ad hoc networks, and it comes with a rich suite of algorithms and models. Unfortunately, its software architecture is such that adding new components and/or modifying existing ones is not a straightforward process. That is, in terms of ease to implement/test new algorithms or scenarios, NS-2 scores poorly with respect to other candidates. Moreover, NS-2 does not scale well in terms of number of nodes and it is

reported to be in general quite slow from a computational point of view. Implementation and simulation under NS-2 consists of 4 steps.

1. Implementing the protocol by adding a combination of c++ and Otcl code to NS-2 source base.
2. Describing the simulation in an Otcl script
3. Running the simulation
4. Analyzing the generated trace files.

VI. Simulation Results

6.1 Simulation Environment

An event driven simulator ns-2 was used for simulations. The simulation setup 10 nodes and Radio range of each node is assumed to be 250m. Reliable connections are established at random in the network and the connections with constant bit rate. Two ray ground propagation models were used. The size of the data payload was 512 bytes

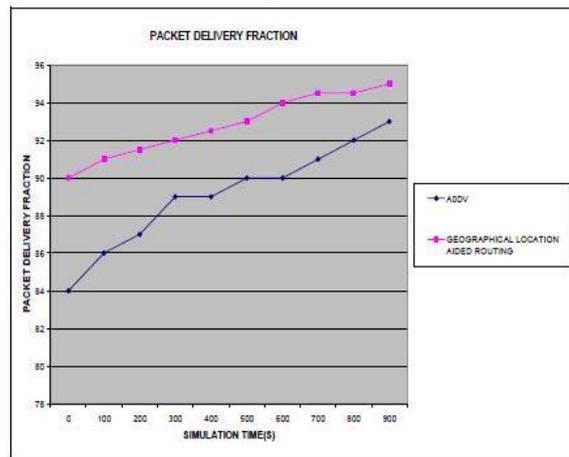

Fig:6.1 Cumulative sum of Numbers of Received Packets vs receive event time(s)

6.1.1 Cumulative sum of Numbers of Received Packets

In Figure 6.1 shows the Cumulative sum of Numbers of Received Packets vs received event time (s) of Geographical location aided routing

6.1.2 Packet Delivery Ratio

It is the ratio between the numbers of data packets delivered to that of the number of packets supposed to be received by it. This metric gives a measure about the packet loss. A high packet delivery ratio implies an efficient protocol. The figure 6a shows the packet delivery fraction vs simulation time of AODV and Geographical location aided routing. Packet Delivery Ratio (in%) = Actual packets received divided by Packets supposed to be received x 100. On an average, the packet delivery ratio improved by 5.08% than AODV.

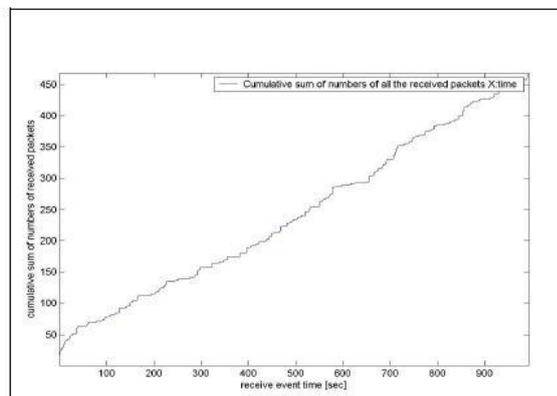

Fig:6.2 Packet Delivery fraction vs Simulation time(s)

6.1.3 Throughput

Throughput are mainly of network parameters in figure 6.5 and 6.6 shows the throughput receiving packets vs simulation time in that manner slightly increase in simulation of throughput receiving packets in simulation time of 300 sec. It is observed that throughput is better than AODV by 37.5%

VII. Conclusion

Terminode routing aims to support Geographical map path discovery (GMPD) location-based routing on irregular topologies with mobile nodes. It achieves its goal by combining a location-based routing method with a link state-based mechanism. Further, it introduces the concept of anchors, which are geographical points imagined by sources for routing to specific destinations, and proposes low overhead methods for computing anchors. Last, a special form of restricted search mode (Restricted Local Flooding, RLF), solves problems due to the inaccuracy of location information, in particular for control packets. The performance analysis shows that, in large mobile ad hoc networks, terminode routing performs better than existing location-based routing protocols. It does so by maintaining its routing overhead low and by efficiently solving location inaccuracies GMPD(Geographical Map Path Discovery) It is a high probability and packet received information's are good that there are nodes to ensure connectivity from one town to another source and destination of the location have sufficient of its centre and size of the square area.

VIII. Future Work

In this implementation, the communication is established between single sender and receiver in future versions, this can be extended to multiple senders and receivers and the performance levels and using Global positioning system still can be improved.

IX. Acknowledgement

The authors would like to thank the Director cum Secretary, Correspondent, Principal, SNS College of Technology, and Coimbatore for their motivation and constant encouragement. The authors would like to thank the Faculty Members of Department of Computer Science and Engineering for critical review of this manuscript and for his valuable input and fruitful discussions. Also, he takes privilege in extending gratitude to his family members and friends who rendered their support throughout this research work.

Some Contributions to Yang Mills Theory Fortification – Dissipation Models

¹Dr. K. N. Prasanna Kumar, ²Prof. B. S. Kiranagi, ³Prof. C. S. Bagewadi

ABSTRACT: We provide a series of Models for the problems that arise in Yang Mills Theory. No claim is made that the problem is solved. We do factorize the Yang Mills Theory and give a Model for the values of LHS and RHS of the yang Mills theory. We hope these forms the stepping stone for further factorizations and solutions to the subatomic denominations at Planck’s scale. Work also throws light on some important factors like mass acquisition by symmetry breaking, relation between strong interaction and weak interaction, Lagrangian Invariance despite transformations, Gauge field, Noncommutative symmetry group of Gauge Theory and Yang Mills Theory itself..

We take in to consideration the following parameters, processes and concepts:

- (1) Acquisition of mass
- (2) Symmetry Breaking
- (3) Strong interaction
- (4) Unified Electroweak interaction
- (5) Continuous group of local transformations
- (6) Lagrangian Variance
- (7) Group generator in Gauge Theory
- (8) Vector field or Gauge field
- (9) Non commutative symmetry group in Gauge Theory
- (10) Yang Mills Theory (We repeat the same Bank’s example. Individual debits and Credits are conservative so also the holistic one. Generalized theories are applied to various systems which are parameterized. And we live in ‘measurement world’. Classification is done on the parameters of various systems to which the Theory is applied.).
- (11) First Term of the Lagrangian of the Yang Mills Theory(LHS)

$$\mathcal{L}_{gf} = -\frac{1}{4} \text{Tr}(F^2) = -\frac{1}{4} F^{\mu\nu a} F_{\mu\nu}^a$$

(12) RHS of the Yang Mills Theory

$$\mathcal{L}_{gf} = -\frac{1}{4} \text{Tr}(F^2) = -\frac{1}{4} F^{\mu\nu a} F_{\mu\nu}^a$$

Where $s_{(32)}$ is the integrand that is integrated over an interval $(0, t)$.261

262

(a) The operator $\mathcal{A}^{(1)}$ maps the space of functions satisfying GLOBAL EQUATIONS into itself .Indeed it is obvious that

$$G_{13}(t) \leq G_{13}^0 + \int_0^t \left[(a_{13})^{(1)} \left(G_{14}^0 + (\hat{P}_{13})^{(1)} e^{(\hat{M}_{13})^{(1)} s_{(13)}} \right) \right] ds_{(13)} =$$

$$\left(1 + (a_{13})^{(1)} t \right) G_{14}^0 + \frac{(a_{13})^{(1)} (\hat{P}_{13})^{(1)}}{(\hat{M}_{13})^{(1)}} \left(e^{(\hat{M}_{13})^{(1)} t} - 1 \right) \quad .263$$

From which it follows that

$$(G_{13}(t) - G_{13}^0) e^{-(\hat{M}_{13})^{(1)} t} \leq \frac{(a_{13})^{(1)}}{(\hat{M}_{13})^{(1)}} \left[\left((\hat{P}_{13})^{(1)} + G_{14}^0 \right) e^{-\frac{(\hat{P}_{13})^{(1)} + G_{14}^0}{G_{14}^0}} + (\hat{P}_{13})^{(1)} \right]$$

(G_i^0) is as defined in the statement of theorem 1.264

Analogous inequalities hold also for $G_{14}, G_{15}, T_{13}, T_{14}, T_{15}$.265

The operator $\mathcal{A}^{(2)}$ maps the space of functions satisfying GLOBAL EQUATIONS into itself .Indeed it is obvious that.266

$$G_{16}(t) \leq G_{16}^0 + \int_0^t \left[(a_{16})^{(2)} \left(G_{17}^0 + (\hat{P}_{16})^{(2)} e^{(\hat{M}_{16})^{(2)} s_{(16)}} \right) \right] ds_{(16)} = \left(1 + (a_{16})^{(2)} t \right) G_{17}^0 + \frac{(a_{16})^{(2)} (\hat{P}_{16})^{(2)}}{(\hat{M}_{16})^{(2)}} \left(e^{(\hat{M}_{16})^{(2)} t} - 1 \right)$$

.267

From which it follows that

$$(G_{16}(t) - G_{16}^0) e^{-(\hat{M}_{16})^{(2)} t} \leq \frac{(a_{16})^{(2)}}{(\hat{M}_{16})^{(2)}} \left[\left((\hat{P}_{16})^{(2)} + G_{17}^0 \right) e^{-\frac{(\hat{P}_{16})^{(2)} + G_{17}^0}{G_{17}^0}} + (\hat{P}_{16})^{(2)} \right] \quad .268$$

Analogous inequalities hold also for $G_{17}, G_{18}, T_{16}, T_{17}, T_{18}$.269

(a) The operator $\mathcal{A}^{(3)}$ maps the space of functions satisfying GLOBAL EQUATIONS into itself .Indeed it is obvious that

$$G_{20}(t) \leq G_{20}^0 + \int_0^t \left[(a_{20})^{(3)} \left(G_{21}^0 + (\hat{P}_{20})^{(3)} e^{(\hat{M}_{20})^{(3)} s_{(20)}} \right) \right] ds_{(20)} =$$

$$\left(1 + (a_{20})^{(3)} t \right) G_{21}^0 + \frac{(a_{20})^{(3)} (\hat{P}_{20})^{(3)}}{(\hat{M}_{20})^{(3)}} \left(e^{(\hat{M}_{20})^{(3)} t} - 1 \right) \quad .270$$

From which it follows that

$$(G_{20}(t) - G_{20}^0) e^{-(\hat{M}_{20})^{(3)} t} \leq \frac{(a_{20})^{(3)}}{(\hat{M}_{20})^{(3)}} \left[\left((\hat{P}_{20})^{(3)} + G_{21}^0 \right) e^{-\frac{(\hat{P}_{20})^{(3)} + G_{21}^0}{G_{21}^0}} + (\hat{P}_{20})^{(3)} \right] \quad .271$$

Analogous inequalities hold also for $G_{21}, G_{22}, T_{20}, T_{21}, T_{22}$.272

(b) The operator $\mathcal{A}^{(4)}$ maps the space of functions satisfying GLOBAL EQUATIONS into itself .Indeed it is obvious that

$$G_{24}(t) \leq G_{24}^0 + \int_0^t \left[(a_{24})^{(4)} \left(G_{25}^0 + (\hat{P}_{24})^{(4)} e^{(\hat{M}_{24})^{(4)} s_{(24)}} \right) \right] ds_{(24)} =$$

$$\left(1 + (a_{24})^{(4)} t \right) G_{25}^0 + \frac{(a_{24})^{(4)} (\hat{P}_{24})^{(4)}}{(\hat{M}_{24})^{(4)}} \left(e^{(\hat{M}_{24})^{(4)} t} - 1 \right) \quad .273$$

From which it follows that

$$(G_{24}(t) - G_{24}^0) e^{-(\hat{M}_{24})^{(4)} t} \leq \frac{(a_{24})^{(4)}}{(\hat{M}_{24})^{(4)}} \left[\left((\hat{P}_{24})^{(4)} + G_{25}^0 \right) e^{-\frac{(\hat{P}_{24})^{(4)} + G_{25}^0}{G_{25}^0}} + (\hat{P}_{24})^{(4)} \right]$$

(G_i^0) is as defined in the statement of theorem 1.274

(c) The operator $\mathcal{A}^{(5)}$ maps the space of functions satisfying GLOBAL EQUATIONS into itself .Indeed it is obvious that

$$G_{28}(t) \leq G_{28}^0 + \int_0^t \left[(a_{28})^{(5)} \left(G_{29}^0 + (\hat{P}_{28})^{(5)} e^{(\hat{M}_{28})^{(5)} s_{(28)}} \right) \right] ds_{(28)} =$$

$$\left(1 + (a_{28})^{(5)} t \right) G_{29}^0 + \frac{(a_{28})^{(5)} (\hat{P}_{28})^{(5)}}{(\hat{M}_{28})^{(5)}} \left(e^{(\hat{M}_{28})^{(5)} t} - 1 \right) \quad .275$$

From which it follows that

$$(G_{28}(t) - G_{28}^0) e^{-(\hat{M}_{28})^{(5)} t} \leq \frac{(a_{28})^{(5)}}{(\hat{M}_{28})^{(5)}} \left[\left((\hat{P}_{28})^{(5)} + G_{29}^0 \right) e^{-\frac{(\hat{P}_{28})^{(5)} + G_{29}^0}{G_{29}^0}} + (\hat{P}_{28})^{(5)} \right]$$

(G_i^0) is as defined in the statement of theorem 1.276

(d) The operator $\mathcal{A}^{(6)}$ maps the space of functions satisfying GLOBAL EQUATIONS into itself .Indeed it is obvious that

$$G_{32}(t) \leq G_{32}^0 + \int_0^t \left[(a_{32})^{(6)} \left(G_{33}^0 + (\hat{P}_{32})^{(6)} e^{(\bar{M}_{32})^{(6)} s_{(32)}} \right) \right] ds_{(32)} =$$

$$(1 + (a_{32})^{(6)} t) G_{33}^0 + \frac{(a_{32})^{(6)} (\hat{P}_{32})^{(6)}}{(\bar{M}_{32})^{(6)}} \left(e^{(\bar{M}_{32})^{(6)} t} - 1 \right) .277$$

From which it follows that

$$(G_{32}(t) - G_{32}^0) e^{-(\bar{M}_{32})^{(6)} t} \leq \frac{(a_{32})^{(6)}}{(\bar{M}_{32})^{(6)}} \left[\left((\hat{P}_{32})^{(6)} + G_{33}^0 \right) e^{-\left(\frac{(\hat{P}_{32})^{(6)} + G_{33}^0}{G_{33}^0} \right)} + (\hat{P}_{32})^{(6)} \right]$$

(G_i^0) is as defined in the statement of theorem 6

Analogous inequalities hold also for $G_{25}, G_{26}, T_{24}, T_{25}, T_{26}$.278

279

.280

It is now sufficient to take $\frac{(a_i)^{(1)}}{(\bar{M}_{13})^{(1)}}, \frac{(b_i)^{(1)}}{(\bar{M}_{13})^{(1)}} < 1$ and to choose $(\hat{P}_{13})^{(1)}$ and $(\hat{Q}_{13})^{(1)}$ large to have.281

282

$$\frac{(a_i)^{(1)}}{(\bar{M}_{13})^{(1)}} \left[(\hat{P}_{13})^{(1)} + \left((\hat{P}_{13})^{(1)} + G_j^0 \right) e^{-\left(\frac{(\hat{P}_{13})^{(1)} + G_j^0}{G_j^0} \right)} \right] \leq (\hat{P}_{13})^{(1)} .283$$

$$\frac{(b_i)^{(1)}}{(\bar{M}_{13})^{(1)}} \left[\left((\hat{Q}_{13})^{(1)} + T_j^0 \right) e^{-\left(\frac{(\hat{Q}_{13})^{(1)} + T_j^0}{T_j^0} \right)} + (\hat{Q}_{13})^{(1)} \right] \leq (\hat{Q}_{13})^{(1)} .284$$

In order that the operator $\mathcal{A}^{(1)}$ transforms the space of sextuples of functions G_i, T_i satisfying GLOBAL EQUATIONS into itself.285

The operator $\mathcal{A}^{(1)}$ is a contraction with respect to the metric

$$d \left((G^{(1)}, T^{(1)}), (G^{(2)}, T^{(2)}) \right) =$$

$$\sup_i \left\{ \max_{t \in \mathbb{R}_+} |G_i^{(1)}(t) - G_i^{(2)}(t)| e^{-(\bar{M}_{13})^{(1)} t}, \max_{t \in \mathbb{R}_+} |T_i^{(1)}(t) - T_i^{(2)}(t)| e^{-(\bar{M}_{13})^{(1)} t} \right\} .286$$

Indeed if we denote

Definition of \tilde{G}, \tilde{T} :

$$(\tilde{G}, \tilde{T}) = \mathcal{A}^{(1)}(G, T)$$

It results

$$|\tilde{G}_{13}^{(1)} - \tilde{G}_{13}^{(2)}| \leq \int_0^t (a_{13})^{(1)} |G_{14}^{(1)} - G_{14}^{(2)}| e^{-(\bar{M}_{13})^{(1)} s_{(13)}} e^{(\bar{M}_{13})^{(1)} s_{(13)}} ds_{(13)} +$$

$$\int_0^t \{ (a'_{13})^{(1)} |G_{13}^{(1)} - G_{13}^{(2)}| e^{-(\bar{M}_{13})^{(1)} s_{(13)}} e^{-(\bar{M}_{13})^{(1)} s_{(13)}} +$$

$$(a''_{13})^{(1)} (T_{14}^{(1)}, s_{(13)}) |G_{13}^{(1)} - G_{13}^{(2)}| e^{-(\bar{M}_{13})^{(1)} s_{(13)}} e^{(\bar{M}_{13})^{(1)} s_{(13)}} +$$

$$G_{13}^{(2)} | (a'_{13})^{(1)} (T_{14}^{(1)}, s_{(13)}) - (a'_{13})^{(1)} (T_{14}^{(2)}, s_{(13)}) | e^{-(\bar{M}_{13})^{(1)} s_{(13)}} e^{(\bar{M}_{13})^{(1)} s_{(13)}} \} ds_{(13)}$$

Where $s_{(13)}$ represents integrand that is integrated over the interval $[0, t]$

From the hypotheses it follows.287

$$|G^{(1)} - G^{(2)}| e^{-(\bar{M}_{13})^{(1)} t} \leq \frac{1}{(\bar{M}_{13})^{(1)}} \left((a_{13})^{(1)} + (a'_{13})^{(1)} + (\bar{A}_{13})^{(1)} + (\hat{P}_{13})^{(1)} (\hat{k}_{13})^{(1)} \right) d \left((G^{(1)}, T^{(1)}); (G^{(2)}, T^{(2)}) \right)$$

And analogous inequalities for G_i and T_i . Taking into account the hypothesis the result follows.288

Remark 1: The fact that we supposed $(a'_{13})^{(1)}$ and $(b'_{13})^{(1)}$ depending also on t can be considered as not conformal with the reality, however we have put this hypothesis ,in order that we can postulate condition necessary to prove the uniqueness of the solution bounded by $(\hat{P}_{13})^{(1)} e^{(\bar{M}_{13})^{(1)} t}$ and $(\hat{Q}_{13})^{(1)} e^{(\bar{M}_{13})^{(1)} t}$ respectively of \mathbb{R}_+ .

If instead of proving the existence of the solution on \mathbb{R}_+ , we have to prove it only on a compact then it suffices to consider that $(a_i)^{(1)}$ and $(b_i)^{(1)}, i = 13,14,15$ depend only on T_{14} and respectively on G (and not on t) and hypothesis can be replaced by a usual Lipschitz condition..289

Remark 2: There does not exist any t where $G_i(t) = 0$ and $T_i(t) = 0$

From 19 to 24 it results

$$G_i(t) \geq G_i^0 e^{-\int_0^t \{ (a'_i)^{(1)} - (a''_i)^{(1)} (T_{14}(s_{(13)}), s_{(13)}) \} ds_{(13)}} \geq 0$$

$$T_i(t) \geq T_i^0 e^{-(b'_i)^{(1)} t} > 0 \text{ for } t > 0.290$$

291

Definition of $(\bar{M}_{13})^{(1)}_1$, and $(\bar{M}_{13})^{(1)}_3$:

Remark 3: if G_{13} is bounded, the same property have also G_{14} and G_{15} . indeed if $G_{13} < (\bar{M}_{13})^{(1)}$ it follows $\frac{dG_{14}}{dt} \leq ((\bar{M}_{13})^{(1)})_1 - (a'_{14})^{(1)} G_{14}$ and by integrating

$$G_{14} \leq ((\widehat{M}_{13})^{(1)})_2 = G_{14}^0 + 2(a_{14})^{(1)}((\widehat{M}_{13})^{(1)})_1 / (a'_{14})^{(1)}$$

In the same way, one can obtain

$$G_{15} \leq ((\widehat{M}_{13})^{(1)})_3 = G_{15}^0 + 2(a_{15})^{(1)}((\widehat{M}_{13})^{(1)})_2 / (a'_{15})^{(1)}$$

If G_{14} or G_{15} is bounded, the same property follows for G_{13} , G_{15} and G_{13} , G_{14} respectively..292

Remark 4: If G_{13} is bounded, from below, the same property holds for G_{14} and G_{15} . The proof is analogous with the preceding one. An analogous property is true if G_{14} is bounded from below..293

Remark 5: If T_{13} is bounded from below and $\lim_{t \rightarrow \infty} ((b''_i)^{(1)}(G(t), t)) = (b'_{14})^{(1)}$ then $T_{14} \rightarrow \infty$.

Definition of $(m)^{(1)}$ and ε_1 :

Indeed let t_1 be so that for $t > t_1$

$$(b_{14})^{(1)} - (b''_i)^{(1)}(G(t), t) < \varepsilon_1, T_{13}(t) > (m)^{(1)} .294$$

Then $\frac{dT_{14}}{dt} \geq (a_{14})^{(1)}(m)^{(1)} - \varepsilon_1 T_{14}$ which leads to

$$T_{14} \geq \left(\frac{(a_{14})^{(1)}(m)^{(1)}}{\varepsilon_1} \right) (1 - e^{-\varepsilon_1 t}) + T_{14}^0 e^{-\varepsilon_1 t} \text{ If we take } t \text{ such that } e^{-\varepsilon_1 t} = \frac{1}{2} \text{ it results}$$

$T_{14} \geq \left(\frac{(a_{14})^{(1)}(m)^{(1)}}{2} \right), t = \log \frac{2}{\varepsilon_1}$ By taking now ε_1 sufficiently small one sees that T_{14} is unbounded. The same property holds for T_{15} if $\lim_{t \rightarrow \infty} ((b''_i)^{(1)}(G(t), t)) = (b'_{15})^{(1)}$

We now state a more precise theorem about the behaviors at infinity of the solutions .295
 .296

It is now sufficient to take $\frac{(a_i)^{(2)}}{(\widehat{M}_{16})^{(2)}}, \frac{(b_i)^{(2)}}{(\widehat{M}_{16})^{(2)}} < 1$ and to choose

$(\widehat{P}_{16})^{(2)}$ and $(\widehat{Q}_{16})^{(2)}$ large to have.297

$$\frac{(a_i)^{(2)}}{(\widehat{M}_{16})^{(2)}} \left[(\widehat{P}_{16})^{(2)} + ((\widehat{P}_{16})^{(2)} + G_j^0) e^{-\left(\frac{(\widehat{P}_{16})^{(2)} + G_j^0}{G_j^0} \right)} \right] \leq (\widehat{P}_{16})^{(2)} .298$$

$$\frac{(b_i)^{(2)}}{(\widehat{M}_{16})^{(2)}} \left[((\widehat{Q}_{16})^{(2)} + T_j^0) e^{-\left(\frac{(\widehat{Q}_{16})^{(2)} + T_j^0}{T_j^0} \right)} + (\widehat{Q}_{16})^{(2)} \right] \leq (\widehat{Q}_{16})^{(2)} .299$$

In order that the operator $\mathcal{A}^{(2)}$ transforms the space of sextuples of functions G_i, T_i satisfying .300

The operator $\mathcal{A}^{(2)}$ is a contraction with respect to the metric

$$d \left(((G_{19})^{(1)}, (T_{19})^{(1)}), ((G_{19})^{(2)}, (T_{19})^{(2)}) \right) =$$

$$\sup_i \left\{ \max_{t \in \mathbb{R}_+} |G_i^{(1)}(t) - G_i^{(2)}(t)| e^{-(\widehat{M}_{16})^{(2)}t}, \max_{t \in \mathbb{R}_+} |T_i^{(1)}(t) - T_i^{(2)}(t)| e^{-(\widehat{M}_{16})^{(2)}t} \right\} .301$$

Indeed if we denote

$$\underline{\text{Definition of}} \widehat{G}_{19}, \widehat{T}_{19} : (\widehat{G}_{19}, \widehat{T}_{19}) = \mathcal{A}^{(2)}(G_{19}, T_{19}).302$$

It results

$$\begin{aligned} & |\widehat{G}_{16}^{(1)} - \widehat{G}_{16}^{(2)}| \leq \int_0^t (a_{16})^{(2)} |G_{17}^{(1)} - G_{17}^{(2)}| e^{-(\widehat{M}_{16})^{(2)}s_{(16)}} e^{(\widehat{M}_{16})^{(2)}s_{(16)}} ds_{(16)} + \\ & \int_0^t \{ (a_{16}')^{(2)} |G_{16}^{(1)} - G_{16}^{(2)}| e^{-(\widehat{M}_{16})^{(2)}s_{(16)}} e^{-(\widehat{M}_{16})^{(2)}s_{(16)}} + \\ & (a_{16}'')^{(2)}(T_{17}^{(1)}, s_{(16)}) |G_{16}^{(1)} - G_{16}^{(2)}| e^{-(\widehat{M}_{16})^{(2)}s_{(16)}} e^{(\widehat{M}_{16})^{(2)}s_{(16)}} + \\ & G_{16}^{(2)} | (a_{16}'')^{(2)}(T_{17}^{(1)}, s_{(16)}) - (a_{16}'')^{(2)}(T_{17}^{(2)}, s_{(16)}) | e^{-(\widehat{M}_{16})^{(2)}s_{(16)}} e^{(\widehat{M}_{16})^{(2)}s_{(16)}} \} ds_{(16)} .303 \end{aligned}$$

Where $s_{(16)}$ represents integrand that is integrated over the interval $[0, t]$

From the hypotheses it follows.304

$$\begin{aligned} & |(G_{19})^{(1)} - (G_{19})^{(2)}| e^{-(\widehat{M}_{16})^{(2)}t} \leq \\ & \frac{1}{(\widehat{M}_{16})^{(2)}} \left((a_{16})^{(2)} + (a'_{16})^{(2)} + (\widehat{A}_{16})^{(2)} + (\widehat{P}_{16})^{(2)} (\widehat{k}_{16})^{(2)} \right) d \left(((G_{19})^{(1)}, (T_{19})^{(1)}); (G_{19})^{(2)}, (T_{19})^{(2)} \right) .305 \end{aligned}$$

And analogous inequalities for G_i and T_i . Taking into account the hypothesis the result follows.306

Remark 1: The fact that we supposed $(a''_{16})^{(2)}$ and $(b''_{16})^{(2)}$ depending also on t can be considered as not conformal with the reality, however we have put this hypothesis, in order that we can postulate condition necessary to prove the uniqueness of the solution bounded by $(\widehat{P}_{16})^{(2)} e^{(\widehat{M}_{16})^{(2)}t}$ and $(\widehat{Q}_{16})^{(2)} e^{(\widehat{M}_{16})^{(2)}t}$ respectively of \mathbb{R}_+ .

If instead of proving the existence of the solution on \mathbb{R}_+ , we have to prove it only on a compact then it suffices to consider that $(a''_i)^{(2)}$ and $(b''_i)^{(2)}$, $i = 16, 17, 18$ depend only on T_{17} and respectively on (G_{19}) (and not on t) and hypothesis can be replaced by a usual Lipschitz condition..307

Remark 2: There does not exist any t where $G_i(t) = 0$ and $T_i(t) = 0$

From 19 to 24 it results

$$G_i(t) \geq G_i^0 e^{-\int_0^t \{ (a'_i)^{(2)} - (a''_i)^{(2)}(T_{17}(s_{(16)}), s_{(16)}) \} ds_{(16)}} \geq 0$$

$$T_i(t) \geq T_i^0 e^{-(b'_i)^{(2)}t} > 0 \text{ for } t > 0.308$$

Definition of $((\widehat{M}_{16})^{(2)})_1, ((\widehat{M}_{16})^{(2)})_2$ and $((\widehat{M}_{16})^{(2)})_3$:

Remark 3: if G_{16} is bounded, the same property have also G_{17} and G_{18} . indeed if

$G_{16} < ((\widehat{M}_{16})^{(2)})$ it follows $\frac{dG_{17}}{dt} \leq ((\widehat{M}_{16})^{(2)})_1 - (a'_{17})^{(2)}G_{17}$ and by integrating

$$G_{17} \leq ((\widehat{M}_{16})^{(2)})_2 = G_{17}^0 + 2(a_{17})^{(2)}((\widehat{M}_{16})^{(2)})_1 / (a'_{17})^{(2)}$$

In the same way , one can obtain

$$G_{18} \leq ((\widehat{M}_{16})^{(2)})_3 = G_{18}^0 + 2(a_{18})^{(2)}((\widehat{M}_{16})^{(2)})_2 / (a'_{18})^{(2)}$$

If G_{17} or G_{18} is bounded, the same property follows for G_{16} , G_{18} and G_{16} , G_{17} respectively..309

310

Remark 4: If G_{16} is bounded, from below, the same property holds for G_{17} and G_{18} . The proof is analogous with the preceding one. An analogous property is true if G_{17} is bounded from below..311

Remark 5: If T_{16} is bounded from below and $\lim_{t \rightarrow \infty} ((b''_i)^{(2)}((G_{19})(t), t)) = (b'_{17})^{(2)}$ then $T_{17} \rightarrow \infty$.

Definition of $(m)^{(2)}$ and ε_2 :

Indeed let t_2 be so that for $t > t_2$

$$(b_{17})^{(2)} - (b''_i)^{(2)}((G_{19})(t), t) < \varepsilon_2, T_{16}(t) > (m)^{(2)} .312$$

Then $\frac{dT_{17}}{dt} \geq (a_{17})^{(2)}(m)^{(2)} - \varepsilon_2 T_{17}$ which leads to

$$T_{17} \geq \left(\frac{(a_{17})^{(2)}(m)^{(2)}}{\varepsilon_2} \right) (1 - e^{-\varepsilon_2 t}) + T_{17}^0 e^{-\varepsilon_2 t} \text{ If we take } t \text{ such that } e^{-\varepsilon_2 t} = \frac{1}{2} \text{ it results .313}$$

$T_{17} \geq \left(\frac{(a_{17})^{(2)}(m)^{(2)}}{2} \right), t = \log \frac{2}{\varepsilon_2}$ By taking now ε_2 sufficiently small one sees that T_{17} is unbounded. The same property

holds for T_{18} if $\lim_{t \rightarrow \infty} (b''_{18})^{(2)}((G_{19})(t), t) = (b'_{18})^{(2)}$

We now state a more precise theorem about the behaviors at infinity of the solutions .314

.315

It is now sufficient to take $\frac{(a_i)^{(3)}}{(M_{20})^{(3)}}, \frac{(b_i)^{(3)}}{(M_{20})^{(3)}} < 1$ and to choose

$(\widehat{P}_{20})^{(3)}$ and $(\widehat{Q}_{20})^{(3)}$ large to have.316

$$\frac{(a_i)^{(3)}}{(M_{20})^{(3)}} \left[(\widehat{P}_{20})^{(3)} + ((\widehat{P}_{20})^{(3)} + G_j^0) e^{-\left(\frac{(\widehat{P}_{20})^{(3)} + G_j^0}{G_j^0} \right)} \right] \leq (\widehat{P}_{20})^{(3)} .317$$

$$\frac{(b_i)^{(3)}}{(M_{20})^{(3)}} \left[((\widehat{Q}_{20})^{(3)} + T_j^0) e^{-\left(\frac{(\widehat{Q}_{20})^{(3)} + T_j^0}{T_j^0} \right)} + (\widehat{Q}_{20})^{(3)} \right] \leq (\widehat{Q}_{20})^{(3)} .318$$

In order that the operator $\mathcal{A}^{(3)}$ transforms the space of sextuples of functions G_i, T_i into itself.319

The operator $\mathcal{A}^{(3)}$ is a contraction with respect to the metric

$$d \left(((G_{23})^{(1)}, (T_{23})^{(1)}), ((G_{23})^{(2)}, (T_{23})^{(2)}) \right) =$$

$$\sup_i \left\{ \max_{t \in \mathbb{R}_+} |G_i^{(1)}(t) - G_i^{(2)}(t)| e^{-(M_{20})^{(3)}t}, \max_{t \in \mathbb{R}_+} |T_i^{(1)}(t) - T_i^{(2)}(t)| e^{-(M_{20})^{(3)}t} \right\} .320$$

Indeed if we denote

$$\widetilde{G}_{23}, \widetilde{T}_{23} : ((\widetilde{G}_{23}), (\widetilde{T}_{23})) = \mathcal{A}^{(3)}((G_{23}), (T_{23})) .321$$

It results

$$\begin{aligned} |\widetilde{G}_{20}^{(1)} - \widetilde{G}_{20}^{(2)}| &\leq \int_0^t (a_{20})^{(3)} |G_{21}^{(1)} - G_{21}^{(2)}| e^{-(M_{20})^{(3)}s_{(20)}} e^{(M_{20})^{(3)}s_{(20)}} ds_{(20)} + \\ &\int_0^t \{ (a'_{20})^{(3)} |G_{20}^{(1)} - G_{20}^{(2)}| e^{-(M_{20})^{(3)}s_{(20)}} e^{-(M_{20})^{(3)}s_{(20)}} + \\ &(a''_{20})^{(3)} (T_{21}^{(1)}, s_{(20)}) |G_{20}^{(1)} - G_{20}^{(2)}| e^{-(M_{20})^{(3)}s_{(20)}} e^{(M_{20})^{(3)}s_{(20)}} + \\ &G_{20}^{(2)} | (a''_{20})^{(3)} (T_{21}^{(1)}, s_{(20)}) - (a''_{20})^{(3)} (T_{21}^{(2)}, s_{(20)}) | e^{-(M_{20})^{(3)}s_{(20)}} e^{(M_{20})^{(3)}s_{(20)}} \} ds_{(20)} \end{aligned}$$

Where $s_{(20)}$ represents integrand that is integrated over the interval $[0, t]$

From the hypotheses it follows.322

323

$$|G^{(1)} - G^{(2)}| e^{-(M_{20})^{(3)}t} \leq$$

$$\frac{1}{(M_{20})^{(3)}} ((a_{20})^{(3)} + (a'_{20})^{(3)} + (\widehat{A}_{20})^{(3)} + (\widehat{P}_{20})^{(3)} (\widehat{k}_{20})^{(3)}) d \left(((G_{23})^{(1)}, (T_{23})^{(1)}); (G_{23})^{(2)}, (T_{23})^{(2)} \right)$$

And analogous inequalities for G_i and T_i . Taking into account the hypothesis the result follows.324

Remark 1: The fact that we supposed $(a''_{20})^{(3)}$ and $(b''_{20})^{(3)}$ depending also on t can be considered as not conformal with the reality, however we have put this hypothesis ,in order that we can postulate condition necessary to prove the uniqueness of the solution bounded by $(\widehat{P}_{20})^{(3)} e^{(M_{20})^{(3)}t}$ and $(\widehat{Q}_{20})^{(3)} e^{(M_{20})^{(3)}t}$ respectively of \mathbb{R}_+ .

If instead of proving the existence of the solution on \mathbb{R}_+ , we have to prove it only on a compact then it suffices to consider that $(a_i'')^{(3)}$ and $(b_i'')^{(3)}$, $i = 20, 21, 22$ depend only on T_{21} and respectively on (G_{23}) (and not on t) and hypothesis can be replaced by a usual Lipschitz condition..325

Remark 2: There does not exist any t where $G_i(t) = 0$ and $T_i(t) = 0$

From 19 to 24 it results

$$G_i(t) \geq G_i^0 e^{-\int_0^t \{(a_i')^{(3)} - (a_i'')^{(3)}\} (T_{21}(s_{(20)}), s_{(20)}) ds_{(20)}} \geq 0$$

$$T_i(t) \geq T_i^0 e^{-(b_i')^{(3)}t} > 0 \text{ for } t > 0.326$$

Definition of $((\widehat{M}_{20})^{(3)})_1, ((\widehat{M}_{20})^{(3)})_2$ and $((\widehat{M}_{20})^{(3)})_3$:

Remark 3: if G_{20} is bounded, the same property have also G_{21} and G_{22} . indeed if

$G_{20} < ((\widehat{M}_{20})^{(3)})$ it follows $\frac{dG_{21}}{dt} \leq ((\widehat{M}_{20})^{(3)})_1 - (a_{21}')^{(3)}G_{21}$ and by integrating

$$G_{21} \leq ((\widehat{M}_{20})^{(3)})_2 = G_{21}^0 + 2(a_{21}')^{(3)}((\widehat{M}_{20})^{(3)})_1 / (a_{21}')^{(3)}$$

In the same way , one can obtain

$$G_{22} \leq ((\widehat{M}_{20})^{(3)})_3 = G_{22}^0 + 2(a_{22}')^{(3)}((\widehat{M}_{20})^{(3)})_2 / (a_{22}')^{(3)}$$

If G_{21} or G_{22} is bounded, the same property follows for G_{20} , G_{22} and G_{20} , G_{21} respectively..327

Remark 4: If G_{20} is bounded, from below, the same property holds for G_{21} and G_{22} . The proof is analogous with the preceding one. An analogous property is true if G_{21} is bounded from below..328

Remark 5: If T_{20} is bounded from below and $\lim_{t \rightarrow \infty} ((b_i'')^{(3)})((G_{23})(t), t) = (b_{21}')^{(3)}$ then $T_{21} \rightarrow \infty$.

Definition of $(m)^{(3)}$ and ε_3 :

Indeed let t_3 be so that for $t > t_3$

$$(b_{21}')^{(3)} - (b_i'')^{(3)}((G_{23})(t), t) < \varepsilon_3, T_{20}(t) > (m)^{(3)} .329$$

330

Then $\frac{dT_{21}}{dt} \geq (a_{21}')^{(3)}(m)^{(3)} - \varepsilon_3 T_{21}$ which leads to

$$T_{21} \geq \left(\frac{(a_{21}')^{(3)}(m)^{(3)}}{\varepsilon_3} \right) (1 - e^{-\varepsilon_3 t}) + T_{21}^0 e^{-\varepsilon_3 t} \text{ If we take } t \text{ such that } e^{-\varepsilon_3 t} = \frac{1}{2} \text{ it results}$$

$$T_{21} \geq \left(\frac{(a_{21}')^{(3)}(m)^{(3)}}{2} \right), t = \log \frac{2}{\varepsilon_3} \text{ By taking now } \varepsilon_3 \text{ sufficiently small one sees that } T_{21} \text{ is unbounded. The same property}$$

holds for T_{22} if $\lim_{t \rightarrow \infty} ((b_{22}')^{(3)})((G_{23})(t), t) = (b_{22}')^{(3)}$

We now state a more precise theorem about the behaviors at infinity of the solutions .331

.332

It is now sufficient to take $\frac{(a_i)^{(4)}}{(\widehat{M}_{24})^{(4)}}, \frac{(b_i)^{(4)}}{(\widehat{M}_{24})^{(4)}} < 1$ and to choose

$(\widehat{P}_{24})^{(4)}$ and $(\widehat{Q}_{24})^{(4)}$ large to have.333

$$\frac{(a_i)^{(4)}}{(\widehat{M}_{24})^{(4)}} \left[(\widehat{P}_{24})^{(4)} + ((\widehat{P}_{24})^{(4)} + G_j^0) e^{-\left(\frac{(\widehat{P}_{24})^{(4)} + G_j^0}{G_j^0} \right)} \right] \leq (\widehat{P}_{24})^{(4)} .334$$

$$\frac{(b_i)^{(4)}}{(\widehat{M}_{24})^{(4)}} \left[((\widehat{Q}_{24})^{(4)} + T_j^0) e^{-\left(\frac{(\widehat{Q}_{24})^{(4)} + T_j^0}{T_j^0} \right)} + (\widehat{Q}_{24})^{(4)} \right] \leq (\widehat{Q}_{24})^{(4)} .335$$

In order that the operator $\mathcal{A}^{(4)}$ transforms the space of sextuples of functions G_i, T_i satisfying IN to itself.336

The operator $\mathcal{A}^{(4)}$ is a contraction with respect to the metric

$$d \left(((G_{27})^{(1)}, (T_{27})^{(1)}), ((G_{27})^{(2)}, (T_{27})^{(2)}) \right) =$$

$$\sup_i \left\{ \max_{t \in \mathbb{R}_+} |G_i^{(1)}(t) - G_i^{(2)}(t)| e^{-(\widehat{M}_{24})^{(4)}t}, \max_{t \in \mathbb{R}_+} |T_i^{(1)}(t) - T_i^{(2)}(t)| e^{-(\widehat{M}_{24})^{(4)}t} \right\}$$

Indeed if we denote

Definition of $(\widetilde{G}_{27}), (\widetilde{T}_{27})$: $((\widetilde{G}_{27}), (\widetilde{T}_{27})) = \mathcal{A}^{(4)}((G_{27}), (T_{27}))$

It results

$$\begin{aligned} |\widetilde{G}_{24}^{(1)} - \widetilde{G}_{24}^{(2)}| &\leq \int_0^t (a_{24})^{(4)} |G_{25}^{(1)} - G_{25}^{(2)}| e^{-(\widehat{M}_{24})^{(4)}s_{(24)}} e^{(\widehat{M}_{24})^{(4)}s_{(24)}} ds_{(24)} + \\ &\int_0^t \{(a_{24}')^{(4)} |G_{24}^{(1)} - G_{24}^{(2)}| e^{-(\widehat{M}_{24})^{(4)}s_{(24)}} e^{-(\widehat{M}_{24})^{(4)}s_{(24)}} + \\ &(a_{24}'')^{(4)}(T_{25}^{(1)}, s_{(24)}) |G_{24}^{(1)} - G_{24}^{(2)}| e^{-(\widehat{M}_{24})^{(4)}s_{(24)}} e^{(\widehat{M}_{24})^{(4)}s_{(24)}} + \\ &G_{24}^{(2)} |(a_{24}')^{(4)}(T_{25}^{(1)}, s_{(24)}) - (a_{24}')^{(4)}(T_{25}^{(2)}, s_{(24)})| e^{-(\widehat{M}_{24})^{(4)}s_{(24)}} e^{(\widehat{M}_{24})^{(4)}s_{(24)}}\} ds_{(24)} \end{aligned}$$

Where $s_{(24)}$ represents integrand that is integrated over the interval $[0, t]$

From the hypotheses it follows.337

338

$$\left| (G_{27})^{(1)} - (G_{27})^{(2)} \right| e^{-(\widehat{M}_{24})^{(4)}t} \leq \frac{1}{(\widehat{M}_{24})^{(4)}} \left((a_{24})^{(4)} + (a'_{24})^{(4)} + (\widehat{A}_{24})^{(4)} + (\widehat{P}_{24})^{(4)} (\widehat{k}_{24})^{(4)} \right) d \left(((G_{27})^{(1)}, (T_{27})^{(1)}; (G_{27})^{(2)}, (T_{27})^{(2)}) \right)$$

And analogous inequalities for G_i and T_i . Taking into account the hypothesis the result follows.339

Remark 1: The fact that we supposed $(a''_{24})^{(4)}$ and $(b''_{24})^{(4)}$ depending also on t can be considered as not conformal with the reality, however we have put this hypothesis, in order that we can postulate condition necessary to prove the uniqueness of the solution bounded by $(\widehat{P}_{24})^{(4)} e^{(\widehat{M}_{24})^{(4)}t}$ and $(\widehat{Q}_{24})^{(4)} e^{(\widehat{M}_{24})^{(4)}t}$ respectively of \mathbb{R}_+ .

If instead of proving the existence of the solution on \mathbb{R}_+ , we have to prove it only on a compact then it suffices to consider that $(a''_i)^{(4)}$ and $(b''_i)^{(4)}$, $i = 24, 25, 26$ depend only on T_{25} and respectively on (G_{27}) (and not on t) and hypothesis can be replaced by a usual Lipschitz condition..340

Remark 2: There does not exist any t where $G_i(t) = 0$ and $T_i(t) = 0$

From 19 to 24 it results

$$G_i(t) \geq G_i^0 e^{-\int_0^t \{(a'_i)^{(4)} - (a''_i)^{(4)}\} (T_{25}(s_{(24)}), s_{(24)}) ds_{(24)}} \geq 0$$

$$T_i(t) \geq T_i^0 e^{-(b'_i)^{(4)}t} > 0 \text{ for } t > 0.341$$

Definition of $(\widehat{M}_{24})^{(4)}_1, (\widehat{M}_{24})^{(4)}_2$ and $(\widehat{M}_{24})^{(4)}_3$:

Remark 3: if G_{24} is bounded, the same property have also G_{25} and G_{26} . indeed if

$G_{24} < (\widehat{M}_{24})^{(4)}$ it follows $\frac{dG_{25}}{dt} \leq ((\widehat{M}_{24})^{(4)})_1 - (a'_{25})^{(4)} G_{25}$ and by integrating

$$G_{25} \leq ((\widehat{M}_{24})^{(4)})_2 = G_{25}^0 + 2(a_{25})^{(4)} ((\widehat{M}_{24})^{(4)})_1 / (a'_{25})^{(4)}$$

In the same way, one can obtain

$$G_{26} \leq ((\widehat{M}_{24})^{(4)})_3 = G_{26}^0 + 2(a_{26})^{(4)} ((\widehat{M}_{24})^{(4)})_2 / (a'_{26})^{(4)}$$

If G_{25} or G_{26} is bounded, the same property follows for G_{24} , G_{26} and G_{24} , G_{25} respectively..342

Remark 4: If G_{24} is bounded, from below, the same property holds for G_{25} and G_{26} . The proof is analogous with the preceding one. An analogous property is true if G_{25} is bounded from below..343

Remark 5: If T_{24} is bounded from below and $\lim_{t \rightarrow \infty} ((b''_i)^{(4)}((G_{27})(t), t)) = (b'_{25})^{(4)}$ then $T_{25} \rightarrow \infty$.

Definition of $(m)^{(4)}$ and ε_4 :

Indeed let t_4 be so that for $t > t_4$

$$(b_{25})^{(4)} - (b''_i)^{(4)}((G_{27})(t), t) < \varepsilon_4, T_{24}(t) > (m)^{(4)} \quad .344$$

Then $\frac{dT_{25}}{dt} \geq (a_{25})^{(4)}(m)^{(4)} - \varepsilon_4 T_{25}$ which leads to

$$T_{25} \geq \left(\frac{(a_{25})^{(4)}(m)^{(4)}}{\varepsilon_4} \right) (1 - e^{-\varepsilon_4 t}) + T_{25}^0 e^{-\varepsilon_4 t} \text{ If we take } t \text{ such that } e^{-\varepsilon_4 t} = \frac{1}{2} \text{ it results}$$

$$T_{25} \geq \left(\frac{(a_{25})^{(4)}(m)^{(4)}}{2} \right), \quad t = \log \frac{2}{\varepsilon_4} \text{ By taking now } \varepsilon_4 \text{ sufficiently small one sees that } T_{25} \text{ is unbounded. The same property}$$

holds for T_{26} if $\lim_{t \rightarrow \infty} (b''_{26})^{(4)}((G_{27})(t), t) = (b'_{26})^{(4)}$

We now state a more precise theorem about the behaviors at infinity of the solutions ANALOGOUS inequalities hold also for $G_{29}, G_{30}, T_{28}, T_{29}, T_{30}$.345

.346

It is now sufficient to take $\frac{(a_i)^{(5)}}{(\widehat{M}_{28})^{(5)}}, \frac{(b_i)^{(5)}}{(\widehat{M}_{28})^{(5)}} < 1$ and to choose

$(\widehat{P}_{28})^{(5)}$ and $(\widehat{Q}_{28})^{(5)}$ large to have

.347

$$\frac{(a_i)^{(5)}}{(\widehat{M}_{28})^{(5)}} \left[(\widehat{P}_{28})^{(5)} + ((\widehat{P}_{28})^{(5)} + G_j^0) e^{-\left(\frac{(\widehat{P}_{28})^{(5)} + G_j^0}{G_j^0} \right)} \right] \leq (\widehat{P}_{28})^{(5)} \quad .348$$

$$\frac{(b_i)^{(5)}}{(\widehat{M}_{28})^{(5)}} \left[((\widehat{Q}_{28})^{(5)} + T_j^0) e^{-\left(\frac{(\widehat{Q}_{28})^{(5)} + T_j^0}{T_j^0} \right)} + (\widehat{Q}_{28})^{(5)} \right] \leq (\widehat{Q}_{28})^{(5)} \quad .349$$

In order that the operator $\mathcal{A}^{(5)}$ transforms the space of sextuples of functions G_i, T_i into itself.350

The operator $\mathcal{A}^{(5)}$ is a contraction with respect to the metric

$$d \left(((G_{31})^{(1)}, (T_{31})^{(1)}), ((G_{31})^{(2)}, (T_{31})^{(2)}) \right) =$$

$$\sup_i \left\{ \max_{t \in \mathbb{R}_+} |G_i^{(1)}(t) - G_i^{(2)}(t)| e^{-(\widehat{M}_{28})^{(5)}t}, \max_{t \in \mathbb{R}_+} |T_i^{(1)}(t) - T_i^{(2)}(t)| e^{-(\widehat{M}_{28})^{(5)}t} \right\}$$

Indeed if we denote

Definition of $(\widehat{G}_{31}), (\widehat{T}_{31})$: $(\widehat{G}_{31}), (\widehat{T}_{31}) = \mathcal{A}^{(5)}((G_{31}), (T_{31}))$

It results

$$|\widehat{G}_{28}^{(1)} - \widehat{G}_i^{(2)}| \leq \int_0^t (a_{28})^{(5)} |G_{29}^{(1)} - G_{29}^{(2)}| e^{-(\widehat{M}_{28})^{(5)}s_{(28)}} e^{(\widehat{M}_{28})^{(5)}s_{(28)}} ds_{(28)} +$$

$$\int_0^t \{ (a'_{28})^{(5)} |G_{28}^{(1)} - G_{28}^{(2)}| e^{-(\bar{M}_{28})^{(5)} s_{(28)}} e^{-(\bar{M}_{28})^{(5)} s_{(28)}} + (a''_{28})^{(5)} (T_{29}^{(1)}, s_{(28)}) |G_{28}^{(1)} - G_{28}^{(2)}| e^{-(\bar{M}_{28})^{(5)} s_{(28)}} e^{(\bar{M}_{28})^{(5)} s_{(28)}} + G_{28}^{(2)} | (a''_{28})^{(5)} (T_{29}^{(1)}, s_{(28)}) - (a''_{28})^{(5)} (T_{29}^{(2)}, s_{(28)}) | e^{-(\bar{M}_{28})^{(5)} s_{(28)}} e^{(\bar{M}_{28})^{(5)} s_{(28)}} \} ds_{(28)}$$

Where $s_{(28)}$ represents integrand that is integrated over the interval $[0, t]$
 From the hypotheses it follows.351

352

$$|(G_{31})^{(1)} - (G_{31})^{(2)}| e^{-(\bar{M}_{28})^{(5)} t} \leq \frac{1}{(\bar{M}_{28})^{(5)}} ((a_{28})^{(5)} + (a'_{28})^{(5)} + (\bar{A}_{28})^{(5)} + (\bar{P}_{28})^{(5)} (\bar{k}_{28})^{(5)}) d((G_{31})^{(1)}, (T_{31})^{(1)}; (G_{31})^{(2)}, (T_{31})^{(2)})$$

And analogous inequalities for G_i and T_i . Taking into account the hypothesis (35,35,36) the result follows.353

Remark 1: The fact that we supposed $(a''_{28})^{(5)}$ and $(b''_{28})^{(5)}$ depending also on t can be considered as not conformal with the reality, however we have put this hypothesis, in order that we can postulate condition necessary to prove the uniqueness of the solution bounded by $(\bar{P}_{28})^{(5)} e^{(\bar{M}_{28})^{(5)} t}$ and $(\bar{Q}_{28})^{(5)} e^{(\bar{M}_{28})^{(5)} t}$ respectively of \mathbb{R}_+ .

If instead of proving the existence of the solution on \mathbb{R}_+ , we have to prove it only on a compact then it suffices to consider that $(a''_i)^{(5)}$ and $(b''_i)^{(5)}$, $i = 28, 29, 30$ depend only on T_{29} and respectively on (G_{31}) (and not on t) and hypothesis can be replaced by a usual Lipschitz condition..354

Remark 2: There does not exist any t where $G_i(t) = 0$ and $T_i(t) = 0$

From GLOBAL EQUATIONS it results

$$G_i(t) \geq G_i^0 e^{-\int_0^t \{ (a'_i)^{(5)} - (a''_i)^{(5)} (T_{29}(s_{(28)}), s_{(28)}) \} ds_{(28)}} \geq 0$$

$$T_i(t) \geq T_i^0 e^{-(b'_i)^{(5)} t} > 0 \text{ for } t > 0.355$$

Definition of $((\bar{M}_{28})^{(5)})_1, ((\bar{M}_{28})^{(5)})_2$ and $((\bar{M}_{28})^{(5)})_3$:

Remark 3: if G_{28} is bounded, the same property have also G_{29} and G_{30} . indeed if

$$G_{28} < (\bar{M}_{28})^{(5)} \text{ it follows } \frac{dG_{29}}{dt} \leq ((\bar{M}_{28})^{(5)})_1 - (a'_{29})^{(5)} G_{29} \text{ and by integrating}$$

$$G_{29} \leq ((\bar{M}_{28})^{(5)})_2 = G_{29}^0 + 2(a_{29})^{(5)} ((\bar{M}_{28})^{(5)})_1 / (a'_{29})^{(5)}$$

In the same way, one can obtain

$$G_{30} \leq ((\bar{M}_{28})^{(5)})_3 = G_{30}^0 + 2(a_{30})^{(5)} ((\bar{M}_{28})^{(5)})_2 / (a'_{30})^{(5)}$$

If G_{29} or G_{30} is bounded, the same property follows for G_{28} , G_{30} and G_{28} , G_{29} respectively..356

Remark 4: If G_{28} is bounded, from below, the same property holds for G_{29} and G_{30} . The proof is analogous with the preceding one. An analogous property is true if G_{29} is bounded from below..357

Remark 5: If T_{28} is bounded from below and $\lim_{t \rightarrow \infty} ((b''_i)^{(5)} ((G_{31})(t), t)) = (b'_{29})^{(5)}$ then $T_{29} \rightarrow \infty$.

Definition of $(m)^{(5)}$ and ε_5 :

Indeed let t_5 be so that for $t > t_5$

$$(b_{29})^{(5)} - (b''_i)^{(5)} ((G_{31})(t), t) < \varepsilon_5, T_{28}(t) > (m)^{(5)}.358$$

359

Then $\frac{dT_{29}}{dt} \geq (a_{29})^{(5)} (m)^{(5)} - \varepsilon_5 T_{29}$ which leads to

$$T_{29} \geq \left(\frac{(a_{29})^{(5)} (m)^{(5)}}{\varepsilon_5} \right) (1 - e^{-\varepsilon_5 t}) + T_{29}^0 e^{-\varepsilon_5 t} \text{ If we take } t \text{ such that } e^{-\varepsilon_5 t} = \frac{1}{2} \text{ it results}$$

$$T_{29} \geq \left(\frac{(a_{29})^{(5)} (m)^{(5)}}{2} \right), t = \log \frac{2}{\varepsilon_5} \text{ By taking now } \varepsilon_5 \text{ sufficiently small one sees that } T_{29} \text{ is unbounded. The same property}$$

holds for T_{30} if $\lim_{t \rightarrow \infty} (b''_{30})^{(5)} ((G_{31})(t), t) = (b'_{30})^{(5)}$

We now state a more precise theorem about the behaviors at infinity of the solutions

Analogous inequalities hold also for $G_{33}, G_{34}, T_{32}, T_{33}, T_{34}$.360

.361

It is now sufficient to take $\frac{(a_i)^{(6)}}{(M_{32})^{(6)}}, \frac{(b_i)^{(6)}}{(M_{32})^{(6)}} < 1$ and to choose

$(\bar{P}_{32})^{(6)}$ and $(\bar{Q}_{32})^{(6)}$ large to have.362

$$\frac{(a_i)^{(6)}}{(M_{32})^{(6)}} \left[(\bar{P}_{32})^{(6)} + ((\bar{P}_{32})^{(6)} + G_j^0) e^{-\left(\frac{(\bar{P}_{32})^{(6)} + G_j^0}{G_j^0} \right)} \right] \leq (\bar{P}_{32})^{(6)}.363$$

$$\frac{(b_i)^{(6)}}{(M_{32})^{(6)}} \left[((\bar{Q}_{32})^{(6)} + T_j^0) e^{-\left(\frac{(\bar{Q}_{32})^{(6)} + T_j^0}{T_j^0} \right)} + (\bar{Q}_{32})^{(6)} \right] \leq (\bar{Q}_{32})^{(6)}.364$$

In order that the operator $\mathcal{A}^{(6)}$ transforms the space of sextuples of functions G_i, T_i into itself.365

The operator $\mathcal{A}^{(6)}$ is a contraction with respect to the metric

$$d\left(\left((G_{35})^{(1)}, (T_{35})^{(1)}\right), \left((G_{35})^{(2)}, (T_{35})^{(2)}\right)\right) = \sup_i \left\{ \max_{t \in \mathbb{R}_+} |G_i^{(1)}(t) - G_i^{(2)}(t)| e^{-(M_{32})^{(6)}t}, \max_{t \in \mathbb{R}_+} |T_i^{(1)}(t) - T_i^{(2)}(t)| e^{-(M_{32})^{(6)}t} \right\}$$

Indeed if we denote

Definition of $(\widehat{G_{35}}, \widehat{T_{35}}) : (\widehat{G_{35}}, \widehat{T_{35}}) = \mathcal{A}^{(6)}((G_{35}), (T_{35}))$

It results

$$|\widehat{G_{32}}^{(1)} - \widehat{G_i}^{(2)}| \leq \int_0^t (a_{32})^{(6)} |G_{33}^{(1)} - G_{33}^{(2)}| e^{-(M_{32})^{(6)}s_{(32)}} e^{(M_{32})^{(6)}s_{(32)}} ds_{(32)} + \int_0^t \{(a'_{32})^{(6)} |G_{32}^{(1)} - G_{32}^{(2)}| e^{-(M_{32})^{(6)}s_{(32)}} e^{-(M_{32})^{(6)}s_{(32)}} + (a''_{32})^{(6)} (T_{33}^{(1)}, s_{(32)}) |G_{32}^{(1)} - G_{32}^{(2)}| e^{-(M_{32})^{(6)}s_{(32)}} e^{(M_{32})^{(6)}s_{(32)}} + G_{32}^{(2)} | (a''_{32})^{(6)} (T_{33}^{(1)}, s_{(32)}) - (a''_{32})^{(6)} (T_{33}^{(2)}, s_{(32)}) | e^{-(M_{32})^{(6)}s_{(32)}} e^{(M_{32})^{(6)}s_{(32)}}\} ds_{(32)}$$

Where $s_{(32)}$ represents integrand that is integrated over the interval $[0, t]$

From the hypotheses it follows.366

367

$$|(G_{35})^{(1)} - (G_{35})^{(2)}| e^{-(M_{32})^{(6)}t} \leq \frac{1}{(M_{32})^{(6)}} \left((a_{32})^{(6)} + (a'_{32})^{(6)} + (\widehat{A}_{32})^{(6)} + (\widehat{P}_{32})^{(6)} (\widehat{k}_{32})^{(6)} \right) d\left(\left((G_{35})^{(1)}, (T_{35})^{(1)}\right); \left((G_{35})^{(2)}, (T_{35})^{(2)}\right)\right)$$

And analogous inequalities for G_i and T_i . Taking into account the hypothesis the result follows.368

Remark 1: The fact that we supposed $(a''_{32})^{(6)}$ and $(b''_{32})^{(6)}$ depending also on t can be considered as not conformal with the reality, however we have put this hypothesis ,in order that we can postulate condition necessary to prove the uniqueness of the solution bounded by $(\widehat{P}_{32})^{(6)} e^{(M_{32})^{(6)}t}$ and $(\widehat{Q}_{32})^{(6)} e^{(M_{32})^{(6)}t}$ respectively of \mathbb{R}_+ .

If instead of proving the existence of the solution on \mathbb{R}_+ , we have to prove it only on a compact then it suffices to consider that $(a''_i)^{(6)}$ and $(b''_i)^{(6)}$, $i = 32, 33, 34$ depend only on T_{33} and respectively on (G_{35}) (and not on t) and hypothesis can be replaced by a usual Lipschitz condition..369

Remark 2: There does not exist any t where $G_i(t) = 0$ and $T_i(t) = 0$

From 69 to 32 it results

$$G_i(t) \geq G_i^0 e^{-\int_0^t \{(a'_i)^{(6)} - (a''_i)^{(6)}\} (T_{33}(s_{(32)}), s_{(32)}) ds_{(32)}} \geq 0$$

$$T_i(t) \geq T_i^0 e^{-(b'_i)^{(6)}t} > 0 \text{ for } t > 0.370$$

Definition of $((\widehat{M}_{32})^{(6)})_1, ((\widehat{M}_{32})^{(6)})_2$ and $((\widehat{M}_{32})^{(6)})_3 :$

Remark 3: if G_{32} is bounded, the same property have also G_{33} and G_{34} . indeed if

$$G_{32} < (\widehat{M}_{32})^{(6)} \text{ it follows } \frac{dG_{33}}{dt} \leq ((\widehat{M}_{32})^{(6)})_1 - (a'_{33})^{(6)} G_{33} \text{ and by integrating}$$

$$G_{33} \leq ((\widehat{M}_{32})^{(6)})_2 = G_{33}^0 + 2(a_{33})^{(6)} ((\widehat{M}_{32})^{(6)})_1 / (a'_{33})^{(6)}$$

In the same way , one can obtain

$$G_{34} \leq ((\widehat{M}_{32})^{(6)})_3 = G_{34}^0 + 2(a_{34})^{(6)} ((\widehat{M}_{32})^{(6)})_2 / (a'_{34})^{(6)}$$

If G_{33} or G_{34} is bounded, the same property follows for G_{32} , G_{34} and G_{32} , G_{33} respectively..371

Remark 4: If G_{32} is bounded, from below, the same property holds for G_{33} and G_{34} . The proof is analogous with the preceding one. An analogous property is true if G_{33} is bounded from below..372

Remark 5: If T_{32} is bounded from below and $\lim_{t \rightarrow \infty} ((b''_i)^{(6)} ((G_{35})(t), t)) = (b'_{33})^{(6)}$ then $T_{33} \rightarrow \infty$.

Definition of $(m)^{(6)}$ and $\varepsilon_6 :$

Indeed let t_6 be so that for $t > t_6$

$$(b_{33})^{(6)} - (b''_i)^{(6)} ((G_{35})(t), t) < \varepsilon_6, T_{32}(t) > (m)^{(6)} \underline{.373}$$

374

Then $\frac{dT_{33}}{dt} \geq (a_{33})^{(6)} (m)^{(6)} - \varepsilon_6 T_{33}$ which leads to

$$T_{33} \geq \left(\frac{(a_{33})^{(6)} (m)^{(6)}}{\varepsilon_6} \right) (1 - e^{-\varepsilon_6 t}) + T_{33}^0 e^{-\varepsilon_6 t} \text{ If we take } t \text{ such that } e^{-\varepsilon_6 t} = \frac{1}{2} \text{ it results}$$

$$T_{33} \geq \left(\frac{(a_{33})^{(6)} (m)^{(6)}}{2} \right), \quad t = \log \frac{2}{\varepsilon_6} \text{ By taking now } \varepsilon_6 \text{ sufficiently small one sees that } T_{33} \text{ is unbounded. The same property}$$

holds for T_{34} if $\lim_{t \rightarrow \infty} (b''_{34})^{(6)} ((G_{35})(t), t) = (b'_{34})^{(6)}$

We now state a more precise theorem about the behaviors at infinity of the solutions .375

376

Behavior of the solutions

If we denote and define

453

Behavior of the solutions

454

If we denote and define

Definition of $(\sigma_1)^{(5)}, (\sigma_2)^{(5)}, (\tau_1)^{(5)}, (\tau_2)^{(5)}$:

(g) $(\sigma_1)^{(5)}, (\sigma_2)^{(5)}, (\tau_1)^{(5)}, (\tau_2)^{(5)}$ four constants satisfying

$$-(\sigma_2)^{(5)} \leq -(a_{28}')^{(5)} + (a_{29}')^{(5)} - (a_{28}'')^{(5)} (T_{29}, t) + (a_{29}'')^{(5)} (T_{29}, t) \leq -(\sigma_1)^{(5)}$$

$$-(\tau_2)^{(5)} \leq -(b_{28}')^{(5)} + (b_{29}')^{(5)} - (b_{28}'')^{(5)} ((G_{31}), t) - (b_{29}'')^{(5)} ((G_{31}), t) \leq -(\tau_1)^{(5)}$$

Definition of $(v_1)^{(5)}, (v_2)^{(5)}, (u_1)^{(5)}, (u_2)^{(5)}, v^{(5)}, u^{(5)}$:

455

(h) By $(v_1)^{(5)} > 0, (v_2)^{(5)} < 0$ and respectively $(u_1)^{(5)} > 0, (u_2)^{(5)} < 0$ the roots of the equations
 $(a_{29})^{(5)}(v^{(5)})^2 + (\sigma_1)^{(5)}v^{(5)} - (a_{28})^{(5)} = 0$
 and $(b_{29})^{(5)}(u^{(5)})^2 + (\tau_1)^{(5)}u^{(5)} - (b_{28})^{(5)} = 0$ and

Definition of $(\bar{v}_1)^{(5)}, (\bar{v}_2)^{(5)}, (\bar{u}_1)^{(5)}, (\bar{u}_2)^{(5)}$: 456

By $(\bar{v}_1)^{(5)} > 0, (\bar{v}_2)^{(5)} < 0$ and respectively $(\bar{u}_1)^{(5)} > 0, (\bar{u}_2)^{(5)} < 0$ the roots of the equations $(a_{29})^{(5)}(v^{(5)})^2 + (\sigma_2)^{(5)}v^{(5)} - (a_{28})^{(5)} = 0$
 and $(b_{29})^{(5)}(u^{(5)})^2 + (\tau_2)^{(5)}u^{(5)} - (b_{28})^{(5)} = 0$

Definition of $(m_1)^{(5)}, (m_2)^{(5)}, (\mu_1)^{(5)}, (\mu_2)^{(5)}, (v_0)^{(5)}$:-

(i) If we define $(m_1)^{(5)}, (m_2)^{(5)}, (\mu_1)^{(5)}, (\mu_2)^{(5)}$ by

$$(m_2)^{(5)} = (v_0)^{(5)}, (m_1)^{(5)} = (v_1)^{(5)}, \text{ if } (v_0)^{(5)} < (v_1)^{(5)}$$

$$(m_2)^{(5)} = (v_1)^{(5)}, (m_1)^{(5)} = (\bar{v}_1)^{(5)}, \text{ if } (v_1)^{(5)} < (v_0)^{(5)} < (\bar{v}_1)^{(5)},$$

and $\boxed{(v_0)^{(5)} = \frac{G_{28}^0}{G_{29}^0}}$

$$(m_2)^{(5)} = (v_1)^{(5)}, (m_1)^{(5)} = (v_0)^{(5)}, \text{ if } (\bar{v}_1)^{(5)} < (v_0)^{(5)}$$

and analogously 457

$$(\mu_2)^{(5)} = (u_0)^{(5)}, (\mu_1)^{(5)} = (u_1)^{(5)}, \text{ if } (u_0)^{(5)} < (u_1)^{(5)}$$

$$(\mu_2)^{(5)} = (u_1)^{(5)}, (\mu_1)^{(5)} = (\bar{u}_1)^{(5)}, \text{ if } (u_1)^{(5)} < (u_0)^{(5)} < (\bar{u}_1)^{(5)},$$

and $\boxed{(u_0)^{(5)} = \frac{T_{28}^0}{T_{29}^0}}$

$(\mu_2)^{(5)} = (u_1)^{(5)}, (\mu_1)^{(5)} = (u_0)^{(5)}, \text{ if } (\bar{u}_1)^{(5)} < (u_0)^{(5)}$ where $(u_1)^{(5)}, (\bar{u}_1)^{(5)}$ are defined respectively

Then the solution satisfies the inequalities 458

$$G_{28}^0 e^{((s_1)^{(5)} - (p_{28})^{(5)})t} \leq G_{28}(t) \leq G_{28}^0 e^{(s_1)^{(5)}t}$$

where $(p_i)^{(5)}$ is defined

$$\frac{1}{(m_5)^{(5)}} G_{28}^0 e^{((s_1)^{(5)} - (p_{28})^{(5)})t} \leq G_{29}(t) \leq \frac{1}{(m_2)^{(5)}} G_{28}^0 e^{(s_1)^{(5)}t} \quad 459$$

$$\left(\frac{(a_{30})^{(5)} G_{28}^0}{(m_1)^{(5)} ((s_1)^{(5)} - (p_{28})^{(5)} - (s_2)^{(5)})} \left[e^{((s_1)^{(5)} - (p_{28})^{(5)})t} - e^{-(s_2)^{(5)}t} \right] + G_{30}^0 e^{-(s_2)^{(5)}t} \right) \leq G_{30}(t) \leq \quad 460$$

$$(a_{30})^{(5)} G_{28}^0 (m_2)^{(5)} (s_1)^{(5)} - (a_{30})^{(5)} 5e^{(s_1)^{(5)}t} - e^{-(a_{30})^{(5)}t} + G_{30}^0 e^{-(a_{30})^{(5)}t} \quad 461$$

$$\boxed{T_{28}^0 e^{(R_1)^{(5)}t} \leq T_{28}(t) \leq T_{28}^0 e^{((R_1)^{(5)} + (r_{28})^{(5)})t}} \quad 462$$

$$\frac{1}{(\mu_1)^{(5)}} T_{28}^0 e^{(R_1)^{(5)}t} \leq T_{28}(t) \leq \frac{1}{(\mu_2)^{(5)}} T_{28}^0 e^{((R_1)^{(5)} + (r_{28})^{(5)})t} \quad 463$$

$$\frac{(b_{30})^{(5)} T_{28}^0}{(\mu_1)^{(5)} ((R_1)^{(5)} - (b_{30})^{(5)})} \left[e^{(R_1)^{(5)}t} - e^{-(b_{30})^{(5)}t} \right] + T_{30}^0 e^{-(b_{30})^{(5)}t} \leq T_{30}(t) \leq \quad 464$$

$$\frac{(a_{30})^{(5)} T_{28}^0}{(\mu_2)^{(5)} ((R_1)^{(5)} + (r_{28})^{(5)} + (R_2)^{(5)})} \left[e^{((R_1)^{(5)} + (r_{28})^{(5)})t} - e^{-(R_2)^{(5)}t} \right] + T_{30}^0 e^{-(R_2)^{(5)}t}$$

Definition of $(S_1)^{(5)}, (S_2)^{(5)}, (R_1)^{(5)}, (R_2)^{(5)}$:- 465

Where $(S_1)^{(5)} = (a_{28})^{(5)}(m_2)^{(5)} - (a'_{28})^{(5)}$

$$(S_2)^{(5)} = (a_{30})^{(5)} - (p_{30})^{(5)}$$

$$(R_1)^{(5)} = (b_{28})^{(5)}(\mu_2)^{(5)} - (b'_{28})^{(5)}$$

$$(R_2)^{(5)} = (b'_{30})^{(5)} - (r_{30})^{(5)}$$

Behavior of the solutions

466

If we denote and define

Definition of $(\sigma_1)^{(6)}, (\sigma_2)^{(6)}, (\tau_1)^{(6)}, (\tau_2)^{(6)}$:

- (j) $(\sigma_1)^{(6)}, (\sigma_2)^{(6)}, (\tau_1)^{(6)}, (\tau_2)^{(6)}$ four constants satisfying
- $$-(\sigma_2)^{(6)} \leq -(a'_{32})^{(6)} + (a'_{33})^{(6)} - (a''_{32})^{(6)}(T_{33}, t) + (a''_{33})^{(6)}(T_{33}, t) \leq -(\sigma_1)^{(6)}$$
- $$-(\tau_2)^{(6)} \leq -(b'_{32})^{(6)} + (b'_{33})^{(6)} - (b''_{32})^{(6)}((G_{35}), t) - (b''_{33})^{(6)}((G_{35}), t) \leq -(\tau_1)^{(6)}$$

Definition of $(v_1)^{(6)}, (v_2)^{(6)}, (u_1)^{(6)}, (u_2)^{(6)}, v^{(6)}, u^{(6)}$:

467

- (k) By $(v_1)^{(6)} > 0, (v_2)^{(6)} < 0$ and respectively $(u_1)^{(6)} > 0, (u_2)^{(6)} < 0$ the roots of the equations
- $$(a_{33})^{(6)}(v^{(6)})^2 + (\sigma_1)^{(6)}v^{(6)} - (a_{32})^{(6)} = 0$$
- and $(b_{33})^{(6)}(u^{(6)})^2 + (\tau_1)^{(6)}u^{(6)} - (b_{32})^{(6)} = 0$ and

Definition of $(\bar{v}_1)^{(6)}, (\bar{v}_2)^{(6)}, (\bar{u}_1)^{(6)}, (\bar{u}_2)^{(6)}$:

468

By $(\bar{v}_1)^{(6)} > 0, (\bar{v}_2)^{(6)} < 0$ and respectively $(\bar{u}_1)^{(6)} > 0, (\bar{u}_2)^{(6)} < 0$ the roots of the equations $(a_{33})^{(6)}(v^{(6)})^2 + (\sigma_2)^{(6)}v^{(6)} - (a_{32})^{(6)} = 0$ and $(b_{33})^{(6)}(u^{(6)})^2 + (\tau_2)^{(6)}u^{(6)} - (b_{32})^{(6)} = 0$

Definition of $(m_1)^{(6)}, (m_2)^{(6)}, (\mu_1)^{(6)}, (\mu_2)^{(6)}, (v_0)^{(6)}$:-

- (l) If we define $(m_1)^{(6)}, (m_2)^{(6)}, (\mu_1)^{(6)}, (\mu_2)^{(6)}$ by

$$(m_2)^{(6)} = (v_0)^{(6)}, (m_1)^{(6)} = (v_1)^{(6)}, \text{ if } (v_0)^{(6)} < (v_1)^{(6)}$$

470

$$(m_2)^{(6)} = (v_1)^{(6)}, (m_1)^{(6)} = (\bar{v}_6)^{(6)}, \text{ if } (v_1)^{(6)} < (v_0)^{(6)} < (\bar{v}_1)^{(6)},$$

$$\text{and } \boxed{(v_0)^{(6)} = \frac{G_{32}^0}{G_{33}^0}}$$

$$(m_2)^{(6)} = (v_1)^{(6)}, (m_1)^{(6)} = (v_0)^{(6)}, \text{ if } (\bar{v}_1)^{(6)} < (v_0)^{(6)}$$

and analogously

471

$$(\mu_2)^{(6)} = (u_0)^{(6)}, (\mu_1)^{(6)} = (u_1)^{(6)}, \text{ if } (u_0)^{(6)} < (u_1)^{(6)}$$

$$(\mu_2)^{(6)} = (u_1)^{(6)}, (\mu_1)^{(6)} = (\bar{u}_1)^{(6)}, \text{ if } (u_1)^{(6)} < (u_0)^{(6)} < (\bar{u}_1)^{(6)},$$

$$\text{and } \boxed{(u_0)^{(6)} = \frac{T_{32}^0}{T_{33}^0}}$$

$(\mu_2)^{(6)} = (u_1)^{(6)}, (\mu_1)^{(6)} = (u_0)^{(6)}, \text{ if } (\bar{u}_1)^{(6)} < (u_0)^{(6)}$ where $(u_1)^{(6)}, (\bar{u}_1)^{(6)}$ are defined respectively

Then the solution satisfies the inequalities

472

$$G_{32}^0 e^{((S_1)^{(6)} - (p_{32})^{(6)})t} \leq G_{32}(t) \leq G_{32}^0 e^{(S_1)^{(6)}t}$$

where $(p_i)^{(6)}$ is defined

$$\frac{1}{(m_1)^{(6)}} G_{32}^0 e^{((S_1)^{(6)} - (p_{32})^{(6)})t} \leq G_{33}(t) \leq \frac{1}{(m_2)^{(6)}} G_{32}^0 e^{(S_1)^{(6)}t}$$

473

$$\left(\frac{(a_{34})^{(6)} G_{32}^0}{(m_1)^{(6)}((S_1)^{(6)} - (p_{32})^{(6)} - (S_2)^{(6)})} \left[e^{((S_1)^{(6)} - (p_{32})^{(6)})t} - e^{-(S_2)^{(6)}t} \right] + G_{34}^0 e^{-(S_2)^{(6)}t} \leq G_{34}(t) \leq \right. \\ \left. (a_{34})^{(6)} G_{32}^0 (m_2)^{(6)} (S_1)^{(6)} - (a_{34}')^{(6)} e^{(S_1)^{(6)}t} - e^{-(a_{34}')^{(6)}t} + G_{34}^0 e^{-(a_{34}')^{(6)}t} \right] \leq G_{34}(t) \leq$$

$$\boxed{T_{32}^0 e^{(R_1)^{(6)}t} \leq T_{32}(t) \leq T_{32}^0 e^{((R_1)^{(6)} + (r_{32})^{(6)})t} \quad 475}$$

$$\frac{1}{(\mu_1)^{(6)}} T_{32}^0 e^{(R_1)^{(6)}t} \leq T_{32}(t) \leq \frac{1}{(\mu_2)^{(6)}} T_{32}^0 e^{((R_1)^{(6)} + (r_{32})^{(6)})t} \quad 476}$$

$$\frac{(b_{34})^{(6)} T_{32}^0}{(\mu_1)^{(6)}((R_1)^{(6)} - (b_{34})^{(6)})} \left[e^{(R_1)^{(6)}t} - e^{-(b_{34}')^{(6)}t} \right] + T_{34}^0 e^{-(b_{34}')^{(6)}t} \leq T_{34}(t) \leq \quad 477}$$

$$\frac{(a_{34})^{(6)} T_{32}^0}{(\mu_2)^{(6)}((R_1)^{(6)} + (r_{32})^{(6)} + (R_2)^{(6)})} \left[e^{((R_1)^{(6)} + (r_{32})^{(6)})t} - e^{-(R_2)^{(6)}t} \right] + T_{34}^0 e^{-(R_2)^{(6)}t}$$

Definition of $(S_1)^{(6)}, (S_2)^{(6)}, (R_1)^{(6)}, (R_2)^{(6)}$:- 478

Where $(S_1)^{(6)} = (a_{32})^{(6)}(m_2)^{(6)} - (a_{32}')^{(6)}$

$$(S_2)^{(6)} = (a_{34})^{(6)} - (p_{34})^{(6)}$$

$$(R_1)^{(6)} = (b_{32})^{(6)}(\mu_2)^{(6)} - (b_{32}')^{(6)}$$

$$(R_2)^{(6)} = (b_{34}')^{(6)} - (r_{34})^{(6)}$$

Proof : From GLOBAL EQUATIONS we obtain 479

$$\frac{dv^{(1)}}{dt} = (a_{13})^{(1)} - \left((a_{13}')^{(1)} - (a_{14}')^{(1)} + (a_{13}'')^{(1)}(T_{14}, t) \right) - (a_{14}'')^{(1)}(T_{14}, t)v^{(1)} - (a_{14})^{(1)}v^{(1)} \quad 480$$

Definition of $v^{(1)}$:- $\boxed{v^{(1)} = \frac{G_{13}}{G_{14}}}$ 481

It follows

$$- \left((a_{14})^{(1)}(v^{(1)})^2 + (\sigma_2)^{(1)}v^{(1)} - (a_{13})^{(1)} \right) \leq \frac{dv^{(1)}}{dt} \leq - \left((a_{14})^{(1)}(v^{(1)})^2 + (\sigma_1)^{(1)}v^{(1)} - (a_{13})^{(1)} \right)$$

From which one obtains

Definition of $(\bar{v}_1)^{(1)}, (v_0)^{(1)}$:-

(a) For $0 < \boxed{(v_0)^{(1)} = \frac{G_{13}^0}{G_{14}^0}} < (v_1)^{(1)} < (\bar{v}_1)^{(1)}$

$$v^{(1)}(t) \geq \frac{(v_1)^{(1)} + (C)^{(1)}(v_2)^{(1)} e^{-(a_{14})^{(1)}(v_1)^{(1)} - (v_0)^{(1)}t}}{1 + (C)^{(1)} e^{-(a_{14})^{(1)}(v_1)^{(1)} - (v_0)^{(1)}t}}, \quad \boxed{(C)^{(1)} = \frac{(v_1)^{(1)} - (v_0)^{(1)}}{(v_0)^{(1)} - (v_2)^{(1)}}$$

it follows $(v_0)^{(1)} \leq v^{(1)}(t) \leq (v_1)^{(1)}$

In the same manner , we get 482

$$v^{(1)}(t) \leq \frac{(\bar{v}_1)^{(1)} + (\bar{C})^{(1)}(\bar{v}_2)^{(1)} e^{-(a_{14})^{(1)}((\bar{v}_1)^{(1)} - (\bar{v}_2)^{(1)})t}}{1 + (\bar{C})^{(1)} e^{-(a_{14})^{(1)}((\bar{v}_1)^{(1)} - (\bar{v}_2)^{(1)})t}}, \quad \boxed{(\bar{C})^{(1)} = \frac{(\bar{v}_1)^{(1)} - (v_0)^{(1)}}{(v_0)^{(1)} - (\bar{v}_2)^{(1)}}$$

From which we deduce $(v_0)^{(1)} \leq v^{(1)}(t) \leq (\bar{v}_1)^{(1)}$

(b) If $0 < (v_1)^{(1)} < (v_0)^{(1)} = \frac{G_{13}^0}{G_{14}^0} < (\bar{v}_1)^{(1)}$ we find like in the previous case, 483

$$(v_1)^{(1)} \leq \frac{(v_1)^{(1)} + (C)^{(1)}(v_2)^{(1)} e^{-(a_{14})^{(1)}(v_1)^{(1)} - (v_2)^{(1)}t}}{1 + (C)^{(1)} e^{-(a_{14})^{(1)}(v_1)^{(1)} - (v_2)^{(1)}t}} \leq v^{(1)}(t) \leq \\ \frac{(\bar{v}_1)^{(1)} + (\bar{C})^{(1)}(\bar{v}_2)^{(1)} e^{-(a_{14})^{(1)}((\bar{v}_1)^{(1)} - (\bar{v}_2)^{(1)})t}}{1 + (\bar{C})^{(1)} e^{-(a_{14})^{(1)}((\bar{v}_1)^{(1)} - (\bar{v}_2)^{(1)})t}} \leq (\bar{v}_1)^{(1)}$$

(c) If $0 < (v_1)^{(1)} \leq (\bar{v}_1)^{(1)} \leq \boxed{(v_0)^{(1)} = \frac{G_{13}^0}{G_{14}^0}}$, we obtain 484

$$(v_1)^{(1)} \leq v^{(1)}(t) \leq \frac{(\bar{v}_1)^{(1)} + (\bar{C})^{(1)}(\bar{v}_2)^{(1)} e^{-(a_{14})^{(1)}((\bar{v}_1)^{(1)} - (\bar{v}_2)^{(1)})t}}{1 + (\bar{C})^{(1)} e^{-(a_{14})^{(1)}((\bar{v}_1)^{(1)} - (\bar{v}_2)^{(1)})t}} \leq (v_0)^{(1)}$$

And so with the notation of the first part of condition (c) , we have

Definition of $v^{(1)}(t)$:-

$$(m_2)^{(1)} \leq v^{(1)}(t) \leq (m_1)^{(1)}, \quad v^{(1)}(t) = \frac{G_{13}(t)}{G_{14}(t)}$$

In a completely analogous way, we obtain

Definition of $u^{(1)}(t)$:-

$$(\mu_2)^{(1)} \leq u^{(1)}(t) \leq (\mu_1)^{(1)}, \quad u^{(1)}(t) = \frac{T_{13}(t)}{T_{14}(t)}$$

485

Now, using this result and replacing it in GLOBAL E486QUATIONS we get easily the result stated in the theorem.

Particular case :

If $(a''_{13})^{(1)} = (a''_{14})^{(1)}$, then $(\sigma_1)^{(1)} = (\sigma_2)^{(1)}$ and in this case $(v_1)^{(1)} = (\bar{v}_1)^{(1)}$ if in addition $(v_0)^{(1)} = (v_1)^{(1)}$ then $v^{(1)}(t) = (v_0)^{(1)}$ and as a consequence $G_{13}(t) = (v_0)^{(1)}G_{14}(t)$ this also defines $(v_0)^{(1)}$ for the special case

Analogously if $(b''_{13})^{(1)} = (b''_{14})^{(1)}$, then $(\tau_1)^{(1)} = (\tau_2)^{(1)}$ and then

$(u_1)^{(1)} = (\bar{u}_1)^{(1)}$ if in addition $(u_0)^{(1)} = (u_1)^{(1)}$ then $T_{13}(t) = (u_0)^{(1)}T_{14}(t)$ This is an important consequence of the relation between $(v_1)^{(1)}$ and $(\bar{v}_1)^{(1)}$, and definition of $(u_0)^{(1)}$.

486

we obtain

487

$$\frac{dv^{(2)}}{dt} = (a_{16})^{(2)} - \left((a'_{16})^{(2)} - (a'_{17})^{(2)} + (a''_{16})^{(2)}(T_{17}, t) \right) - (a''_{17})^{(2)}(T_{17}, t)v^{(2)} - (a_{17})^{(2)}v^{(2)}$$

Definition of $v^{(2)}$:-

$$v^{(2)} = \frac{G_{16}}{G_{17}}$$

488

It follows

489

$$- \left((a_{17})^{(2)}(v^{(2)})^2 + (\sigma_2)^{(2)}v^{(2)} - (a_{16})^{(2)} \right) \leq \frac{dv^{(2)}}{dt} \leq - \left((a_{17})^{(2)}(v^{(2)})^2 + (\sigma_1)^{(2)}v^{(2)} - (a_{16})^{(2)} \right)$$

From which one obtains

490

Definition of $(\bar{v}_1)^{(2)}, (v_0)^{(2)}$:-

$$(d) \text{ For } 0 < (v_0)^{(2)} = \frac{G_{16}^0}{G_{17}^0} < (v_1)^{(2)} < (\bar{v}_1)^{(2)}$$

$$v^{(2)}(t) \geq \frac{(v_1)^{(2)} + (C)^{(2)}(v_2)^{(2)} e^{-(a_{17})^{(2)}(v_1)^{(2)} - (v_0)^{(2)}t}}{1 + (C)^{(2)} e^{-(a_{17})^{(2)}(v_1)^{(2)} - (v_0)^{(2)}t}}, \quad (C)^{(2)} = \frac{(v_1)^{(2)} - (v_0)^{(2)}}{(v_0)^{(2)} - (v_2)^{(2)}}$$

it follows $(v_0)^{(2)} \leq v^{(2)}(t) \leq (v_1)^{(2)}$

In the same manner , we get

491

$$v^{(2)}(t) \leq \frac{(\bar{v}_1)^{(2)} + (\bar{C})^{(2)}(\bar{v}_2)^{(2)} e^{-(a_{17})^{(2)}(\bar{v}_1)^{(2)} - (\bar{v}_2)^{(2)}t}}{1 + (\bar{C})^{(2)} e^{-(a_{17})^{(2)}(\bar{v}_1)^{(2)} - (\bar{v}_2)^{(2)}t}}, \quad (\bar{C})^{(2)} = \frac{(\bar{v}_1)^{(2)} - (v_0)^{(2)}}{(v_0)^{(2)} - (\bar{v}_2)^{(2)}}$$

From which we deduce $(v_0)^{(2)} \leq v^{(2)}(t) \leq (\bar{v}_1)^{(2)}$

492

(e) If $0 < (v_1)^{(2)} < (v_0)^{(2)} = \frac{G_{16}^0}{G_{17}^0} < (\bar{v}_1)^{(2)}$ we find like in the previous case,

493

$$(v_1)^{(2)} \leq \frac{(v_1)^{(2)} + (C)^{(2)}(v_2)^{(2)} e^{-(a_{17})^{(2)}(v_1)^{(2)} - (v_2)^{(2)}t}}{1 + (C)^{(2)} e^{-(a_{17})^{(2)}(v_1)^{(2)} - (v_2)^{(2)}t}} \leq v^{(2)}(t) \leq \frac{(\bar{v}_1)^{(2)} + (\bar{C})^{(2)}(\bar{v}_2)^{(2)} e^{-(a_{17})^{(2)}(\bar{v}_1)^{(2)} - (\bar{v}_2)^{(2)}t}}{1 + (\bar{C})^{(2)} e^{-(a_{17})^{(2)}(\bar{v}_1)^{(2)} - (\bar{v}_2)^{(2)}t}} \leq (\bar{v}_1)^{(2)}$$

(f) If $0 < (v_1)^{(2)} \leq (\bar{v}_1)^{(2)} \leq (v_0)^{(2)} = \frac{G_{16}^0}{G_{17}^0}$, we obtain

494

$$(v_1)^{(2)} \leq v^{(2)}(t) \leq \frac{(\bar{v}_1)^{(2)} + (\bar{C})^{(2)}(\bar{v}_2)^{(2)} e^{-(a_{17})^{(2)}(\bar{v}_1)^{(2)} - (\bar{v}_2)^{(2)}t}}{1 + (\bar{C})^{(2)} e^{-(a_{17})^{(2)}(\bar{v}_1)^{(2)} - (\bar{v}_2)^{(2)}t}} \leq (v_0)^{(2)}$$

And so with the notation of the first part of condition (c) , we have

Definition of $v^{(2)}(t)$:-

495

$$(m_2)^{(2)} \leq v^{(2)}(t) \leq (m_1)^{(2)}, \quad v^{(2)}(t) = \frac{G_{16}(t)}{G_{17}(t)}$$

In a completely analogous way, we obtain

496

Definition of $u^{(2)}(t)$:-

$$(\mu_2)^{(2)} \leq u^{(2)}(t) \leq (\mu_1)^{(2)}, \quad u^{(2)}(t) = \frac{T_{16}(t)}{T_{17}(t)}$$

497

Particular case :

498

If $(a''_{16})^{(2)} = (a''_{17})^{(2)}$, then $(\sigma_1)^{(2)} = (\sigma_2)^{(2)}$ and in this case $(v_1)^{(2)} = (\bar{v}_1)^{(2)}$ if in addition $(v_0)^{(2)} = (v_1)^{(2)}$ then $v^{(2)}(t) = (v_0)^{(2)}$ and as a consequence $G_{16}(t) = (v_0)^{(2)}G_{17}(t)$

Analogously if $(b''_{16})^{(2)} = (b''_{17})^{(2)}$, then $(\tau_1)^{(2)} = (\tau_2)^{(2)}$ and then $(u_1)^{(2)} = (\bar{u}_1)^{(2)}$ if in addition $(u_0)^{(2)} = (u_1)^{(2)}$ then $T_{16}(t) = (u_0)^{(2)}T_{17}(t)$ This is an important consequence of the relation between $(v_1)^{(2)}$ and $(\bar{v}_1)^{(2)}$

499

From GLOBAL EQUATIONS we obtain

500

$$\frac{dv^{(3)}}{dt} = (a_{20})^{(3)} - \left((a'_{20})^{(3)} - (a'_{21})^{(3)} + (a''_{20})^{(3)}(T_{21}, t) \right) - (a''_{21})^{(3)}(T_{21}, t)v^{(3)} - (a_{21})^{(3)}v^{(3)}$$

Definition of $v^{(3)}$:-

$$v^{(3)} = \frac{G_{20}}{G_{21}}$$

501

It follows

$$- \left((a_{21})^{(3)}(v^{(3)})^2 + (\sigma_2)^{(3)}v^{(3)} - (a_{20})^{(3)} \right) \leq \frac{dv^{(3)}}{dt} \leq - \left((a_{21})^{(3)}(v^{(3)})^2 + (\sigma_1)^{(3)}v^{(3)} - (a_{20})^{(3)} \right)$$

502

From which one obtains

(a) For $0 < (v_0)^{(3)} = \frac{G_{20}^0}{G_{21}^0} < (v_1)^{(3)} < (\bar{v}_1)^{(3)}$

$$v^{(3)}(t) \geq \frac{(v_1)^{(3)} + (C)^{(3)}(v_2)^{(3)} e^{[-(a_{21})^{(3)}(v_1)^{(3)} - (v_0)^{(3)}]t}}{1 + (C)^{(3)} e^{[-(a_{21})^{(3)}(v_1)^{(3)} - (v_0)^{(3)}]t}}, \quad (C)^{(3)} = \frac{(v_1)^{(3)} - (v_0)^{(3)}}{(v_0)^{(3)} - (v_2)^{(3)}}$$

it follows $(v_0)^{(3)} \leq v^{(3)}(t) \leq (v_1)^{(3)}$

In the same manner, we get

503

$$v^{(3)}(t) \leq \frac{(\bar{v}_1)^{(3)} + (\bar{C})^{(3)}(\bar{v}_2)^{(3)} e^{[-(a_{21})^{(3)}(\bar{v}_1)^{(3)} - (\bar{v}_2)^{(3)}]t}}{1 + (\bar{C})^{(3)} e^{[-(a_{21})^{(3)}(\bar{v}_1)^{(3)} - (\bar{v}_2)^{(3)}]t}}, \quad (\bar{C})^{(3)} = \frac{(\bar{v}_1)^{(3)} - (v_0)^{(3)}}{(v_0)^{(3)} - (\bar{v}_2)^{(3)}}$$

Definition of $(\bar{v}_1)^{(3)}$:-

From which we deduce $(v_0)^{(3)} \leq v^{(3)}(t) \leq (\bar{v}_1)^{(3)}$

(b) If $0 < (v_1)^{(3)} < (v_0)^{(3)} = \frac{G_{20}^0}{G_{21}^0} < (\bar{v}_1)^{(3)}$ we find like in the previous case,

504

$$(v_1)^{(3)} \leq \frac{(v_1)^{(3)} + (C)^{(3)}(v_2)^{(3)} e^{[-(a_{21})^{(3)}(v_1)^{(3)} - (v_2)^{(3)}]t}}{1 + (C)^{(3)} e^{[-(a_{21})^{(3)}(v_1)^{(3)} - (v_2)^{(3)}]t}} \leq v^{(3)}(t) \leq \frac{(\bar{v}_1)^{(3)} + (\bar{C})^{(3)}(\bar{v}_2)^{(3)} e^{[-(a_{21})^{(3)}(\bar{v}_1)^{(3)} - (\bar{v}_2)^{(3)}]t}}{1 + (\bar{C})^{(3)} e^{[-(a_{21})^{(3)}(\bar{v}_1)^{(3)} - (\bar{v}_2)^{(3)}]t}} \leq (\bar{v}_1)^{(3)}$$

(c) If $0 < (v_1)^{(3)} \leq (\bar{v}_1)^{(3)} \leq (v_0)^{(3)} = \frac{G_{20}^0}{G_{21}^0}$, we obtain

505

$$(v_1)^{(3)} \leq v^{(3)}(t) \leq \frac{(\bar{v}_1)^{(3)} + (\bar{C})^{(3)}(\bar{v}_2)^{(3)} e^{[-(a_{21})^{(3)}(\bar{v}_1)^{(3)} - (\bar{v}_2)^{(3)}]t}}{1 + (\bar{C})^{(3)} e^{[-(a_{21})^{(3)}(\bar{v}_1)^{(3)} - (\bar{v}_2)^{(3)}]t}} \leq (v_0)^{(3)}$$

And so with the notation of the first part of condition (c), we have

Definition of $v^{(3)}(t)$:-

$$(m_2)^{(3)} \leq v^{(3)}(t) \leq (m_1)^{(3)}, \quad v^{(3)}(t) = \frac{G_{20}(t)}{G_{21}(t)}$$

In a completely analogous way, we obtain

Definition of $u^{(3)}(t)$:-

$$(\mu_2)^{(3)} \leq u^{(3)}(t) \leq (\mu_1)^{(3)}, \quad u^{(3)}(t) = \frac{T_{20}(t)}{T_{21}(t)}$$

Now, using this result and replacing it in GLOBAL EQUATIONS we get easily the result stated in the theorem.

Particular case :

If $(a''_{20})^{(3)} = (a''_{21})^{(3)}$, then $(\sigma_1)^{(3)} = (\sigma_2)^{(3)}$ and in this case $(v_1)^{(3)} = (\bar{v}_1)^{(3)}$ if in addition $(v_0)^{(3)} = (v_1)^{(3)}$ then $v^{(3)}(t) = (v_0)^{(3)}$ and as a consequence $G_{20}(t) = (v_0)^{(3)}G_{21}(t)$

Analogously if $(b''_{20})^{(3)} = (b''_{21})^{(3)}$, then $(\tau_1)^{(3)} = (\tau_2)^{(3)}$ and then

$(u_1)^{(3)} = (\bar{u}_1)^{(3)}$ if in addition $(u_0)^{(3)} = (u_1)^{(3)}$ then $T_{20}(t) = (u_0)^{(3)}T_{21}(t)$ This is an important consequence of the relation between $(v_1)^{(3)}$ and $(\bar{v}_1)^{(3)}$

506

: From GLOBAL EQUATIONS we obtain

507

$$\frac{dv^{(4)}}{dt} = (a_{24})^{(4)} - \left((a'_{24})^{(4)} - (a'_{25})^{(4)} + (a''_{24})^{(4)}(T_{25}, t) \right) - (a''_{25})^{(4)}(T_{25}, t)v^{(4)} - (a_{25})^{(4)}v^{(4)}$$

508

Definition of $v^{(4)}$:- $v^{(4)} = \frac{G_{24}}{G_{25}}$

It follows

$$-\left((a_{25})^{(4)}(v^{(4)})^2 + (\sigma_2)^{(4)}v^{(4)} - (a_{24})^{(4)}\right) \leq \frac{dv^{(4)}}{dt} \leq -\left((a_{25})^{(4)}(v^{(4)})^2 + (\sigma_4)^{(4)}v^{(4)} - (a_{24})^{(4)}\right)$$

From which one obtains

Definition of $(\bar{v}_1)^{(4)}, (v_0)^{(4)}$:-

(d) For $0 < \left[(v_0)^{(4)} = \frac{G_{24}^0}{G_{25}^0} \right] < (v_1)^{(4)} < (\bar{v}_1)^{(4)}$

$$v^{(4)}(t) \geq \frac{(v_1)^{(4)} + (C)^{(4)}(v_2)^{(4)} e^{[-(a_{25})^{(4)}(v_1)^{(4)} - (v_0)^{(4)}]t}}{4 + (C)^{(4)} e^{[-(a_{25})^{(4)}(v_1)^{(4)} - (v_0)^{(4)}]t}}, \quad \left[(C)^{(4)} = \frac{(v_1)^{(4)} - (v_0)^{(4)}}{(v_0)^{(4)} - (v_2)^{(4)}} \right]$$

it follows $(v_0)^{(4)} \leq v^{(4)}(t) \leq (v_1)^{(4)}$

In the same manner , we get

509

$$v^{(4)}(t) \leq \frac{(\bar{v}_1)^{(4)} + (\bar{C})^{(4)}(\bar{v}_2)^{(4)} e^{[-(a_{25})^{(4)}(\bar{v}_1)^{(4)} - (\bar{v}_2)^{(4)}]t}}{4 + (\bar{C})^{(4)} e^{[-(a_{25})^{(4)}(\bar{v}_1)^{(4)} - (\bar{v}_2)^{(4)}]t}}, \quad \left[(\bar{C})^{(4)} = \frac{(\bar{v}_1)^{(4)} - (v_0)^{(4)}}{(v_0)^{(4)} - (\bar{v}_2)^{(4)}} \right]$$

From which we deduce $(v_0)^{(4)} \leq v^{(4)}(t) \leq (\bar{v}_1)^{(4)}$

(e) If $0 < (v_1)^{(4)} < (v_0)^{(4)} = \frac{G_{24}^0}{G_{25}^0} < (\bar{v}_1)^{(4)}$ we find like in the previous case,

510

$$(v_1)^{(4)} \leq \frac{(v_1)^{(4)} + (C)^{(4)}(v_2)^{(4)} e^{[-(a_{25})^{(4)}(v_1)^{(4)} - (v_2)^{(4)}]t}}{1 + (C)^{(4)} e^{[-(a_{25})^{(4)}(v_1)^{(4)} - (v_2)^{(4)}]t}} \leq v^{(4)}(t) \leq \frac{(\bar{v}_1)^{(4)} + (\bar{C})^{(4)}(\bar{v}_2)^{(4)} e^{[-(a_{25})^{(4)}(\bar{v}_1)^{(4)} - (\bar{v}_2)^{(4)}]t}}{1 + (\bar{C})^{(4)} e^{[-(a_{25})^{(4)}(\bar{v}_1)^{(4)} - (\bar{v}_2)^{(4)}]t}} \leq (\bar{v}_1)^{(4)}$$

511

512

(f) If $0 < (v_1)^{(4)} \leq (\bar{v}_1)^{(4)} \leq \left[(v_0)^{(4)} = \frac{G_{24}^0}{G_{25}^0} \right]$, we obtain

$$(v_1)^{(4)} \leq v^{(4)}(t) \leq \frac{(\bar{v}_1)^{(4)} + (\bar{C})^{(4)}(\bar{v}_2)^{(4)} e^{[-(a_{25})^{(4)}(\bar{v}_1)^{(4)} - (\bar{v}_2)^{(4)}]t}}{1 + (\bar{C})^{(4)} e^{[-(a_{25})^{(4)}(\bar{v}_1)^{(4)} - (\bar{v}_2)^{(4)}]t}} \leq (v_0)^{(4)}$$

And so with the notation of the first part of condition (c), we have

Definition of $v^{(4)}(t)$:-

$$(m_2)^{(4)} \leq v^{(4)}(t) \leq (m_1)^{(4)}, \quad \left[v^{(4)}(t) = \frac{G_{24}(t)}{G_{25}(t)} \right]$$

In a completely analogous way, we obtain

Definition of $u^{(4)}(t)$:-

$$(\mu_2)^{(4)} \leq u^{(4)}(t) \leq (\mu_1)^{(4)}, \quad \left[u^{(4)}(t) = \frac{T_{24}(t)}{T_{25}(t)} \right]$$

Now, using this result and replacing it in GLOBAL EQUATIONS we get easily the result stated in the theorem.

Particular case :

If $(a_{24}'')^{(4)} = (a_{25}'')^{(4)}$, then $(\sigma_1)^{(4)} = (\sigma_2)^{(4)}$ and in this case $(v_1)^{(4)} = (\bar{v}_1)^{(4)}$ if in addition $(v_0)^{(4)} = (v_1)^{(4)}$ then $v^{(4)}(t) = (v_0)^{(4)}$ and as a consequence $G_{24}(t) = (v_0)^{(4)}G_{25}(t)$ **this also defines $(v_0)^{(4)}$ for the special case .**

513

Analogously if $(b_{24}'')^{(4)} = (b_{25}'')^{(4)}$, then $(\tau_1)^{(4)} = (\tau_2)^{(4)}$ and then

$(u_1)^{(4)} = (\bar{u}_4)^{(4)}$ if in addition $(u_0)^{(4)} = (u_1)^{(4)}$ then $T_{24}(t) = (u_0)^{(4)}T_{25}(t)$ This is an important consequence of the relation between $(v_1)^{(4)}$ and $(\bar{v}_1)^{(4)}$, **and definition of $(u_0)^{(4)}$.**

514
515

From GLOBAL EQUATIONS we obtain

$$\frac{dv^{(5)}}{dt} = (a_{28})^{(5)} - \left((a'_{28})^{(5)} - (a'_{29})^{(5)} + (a''_{28})^{(5)}(T_{29}, t) \right) - (a''_{29})^{(5)}(T_{29}, t)v^{(5)} - (a_{29})^{(5)}v^{(5)}$$

Definition of $v^{(5)}$:- $v^{(5)} = \frac{G_{28}}{G_{29}}$

It follows

$$- \left((a_{29})^{(5)}(v^{(5)})^2 + (\sigma_2)^{(5)}v^{(5)} - (a_{28})^{(5)} \right) \leq \frac{dv^{(5)}}{dt} \leq - \left((a_{29})^{(5)}(v^{(5)})^2 + (\sigma_1)^{(5)}v^{(5)} - (a_{28})^{(5)} \right)$$

From which one obtains

Definition of $(\bar{v}_1)^{(5)}, (v_0)^{(5)}$:-

(g) For $0 < \left(v_0 \right)^{(5)} = \frac{G_{28}^0}{G_{29}^0} < (v_1)^{(5)} < (\bar{v}_1)^{(5)}$

$$v^{(5)}(t) \geq \frac{(v_1)^{(5)} + (C)^{(5)}(v_2)^{(5)} e^{[-(a_{29})^{(5)}(v_1)^{(5)} - (v_0)^{(5)}]t}}{5 + (C)^{(5)} e^{[-(a_{29})^{(5)}(v_1)^{(5)} - (v_0)^{(5)}]t}}, \quad \left(C \right)^{(5)} = \frac{(v_1)^{(5)} - (v_0)^{(5)}}{(v_0)^{(5)} - (v_2)^{(5)}}$$

it follows $(v_0)^{(5)} \leq v^{(5)}(t) \leq (v_1)^{(5)}$

In the same manner , we get

516

$$v^{(5)}(t) \leq \frac{(\bar{v}_1)^{(5)} + (\bar{C})^{(5)}(\bar{v}_2)^{(5)} e^{[-(a_{29})^{(5)}(\bar{v}_1)^{(5)} - (\bar{v}_2)^{(5)}]t}}{5 + (\bar{C})^{(5)} e^{[-(a_{29})^{(5)}(\bar{v}_1)^{(5)} - (\bar{v}_2)^{(5)}]t}}, \quad (\bar{C})^{(5)} = \frac{(\bar{v}_1)^{(5)} - (v_0)^{(5)}}{(v_0)^{(5)} - (\bar{v}_2)^{(5)}}$$

From which we deduce $(v_0)^{(5)} \leq v^{(5)}(t) \leq (\bar{v}_5)^{(5)}$

(h) If $0 < (v_1)^{(5)} < (v_0)^{(5)} = \frac{G_{28}^0}{G_{29}^0} < (\bar{v}_1)^{(5)}$ we find like in the previous case,

517

$$(v_1)^{(5)} \leq \frac{(v_1)^{(5)} + (C)^{(5)}(v_2)^{(5)} e^{[-(a_{29})^{(5)}(v_1)^{(5)} - (v_2)^{(5)}]t}}{1 + (C)^{(5)} e^{[-(a_{29})^{(5)}(v_1)^{(5)} - (v_2)^{(5)}]t}} \leq v^{(5)}(t) \leq$$

$$\frac{(\bar{v}_1)^{(5)} + (\bar{C})^{(5)}(\bar{v}_2)^{(5)} e^{[-(a_{29})^{(5)}(\bar{v}_1)^{(5)} - (\bar{v}_2)^{(5)}]t}}{1 + (\bar{C})^{(5)} e^{[-(a_{29})^{(5)}(\bar{v}_1)^{(5)} - (\bar{v}_2)^{(5)}]t}} \leq (\bar{v}_1)^{(5)}$$

(i) If $0 < (v_1)^{(5)} \leq (\bar{v}_1)^{(5)} \leq \left(v_0 \right)^{(5)} = \frac{G_{28}^0}{G_{29}^0}$, we obtain

518

$$(v_1)^{(5)} \leq v^{(5)}(t) \leq \frac{(\bar{v}_1)^{(5)} + (\bar{C})^{(5)}(\bar{v}_2)^{(5)} e^{[-(a_{29})^{(5)}(\bar{v}_1)^{(5)} - (\bar{v}_2)^{(5)}]t}}{1 + (\bar{C})^{(5)} e^{[-(a_{29})^{(5)}(\bar{v}_1)^{(5)} - (\bar{v}_2)^{(5)}]t}} \leq (v_0)^{(5)}$$

519

And so with the notation of the first part of condition (c) , we have

Definition of $v^{(5)}(t)$:-

$$(m_2)^{(5)} \leq v^{(5)}(t) \leq (m_1)^{(5)}, \quad \left(v \right)^{(5)}(t) = \frac{G_{28}(t)}{G_{29}(t)}$$

In a completely analogous way, we obtain

Definition of $u^{(5)}(t)$:-

$$(\mu_2)^{(5)} \leq u^{(5)}(t) \leq (\mu_1)^{(5)}, \quad \left(u \right)^{(5)}(t) = \frac{T_{28}(t)}{T_{29}(t)}$$

Now, using this result and replacing it in GLOBAL EQUATIONS we get easily the result stated in the theorem.

Particular case :

If $(a''_{28})^{(5)} = (a''_{29})^{(5)}$, then $(\sigma_1)^{(5)} = (\sigma_2)^{(5)}$ and in this case $(v_1)^{(5)} = (\bar{v}_1)^{(5)}$ if in addition $(v_0)^{(5)} = (v_5)^{(5)}$ then $v^{(5)}(t) = (v_0)^{(5)}$ and as a consequence $G_{28}(t) = (v_0)^{(5)}G_{29}(t)$ **this also defines $(v_0)^{(5)}$ for the special case .**

Analogously if $(b''_{28})^{(5)} = (b''_{29})^{(5)}$, then $(\tau_1)^{(5)} = (\tau_2)^{(5)}$ and then $(u_1)^{(5)} = (\bar{u}_1)^{(5)}$ if in addition $(u_0)^{(5)} = (u_1)^{(5)}$ then $T_{28}(t) = (u_0)^{(5)}T_{29}(t)$ This is an important consequence of the relation between $(v_1)^{(5)}$ and $(\bar{v}_1)^{(5)}$, **and definition of $(u_0)^{(5)}$.**

we obtain

520
521

$$\frac{dv^{(6)}}{dt} = (a_{32})^{(6)} - \left((a'_{32})^{(6)} - (a'_{33})^{(6)} + (a''_{32})^{(6)}(T_{33}, t) \right) - (a''_{33})^{(6)}(T_{33}, t)v^{(6)} - (a_{33})^{(6)}v^{(6)}$$

Definition of $v^{(6)}$:- $v^{(6)} = \frac{G_{32}}{G_{33}}$

It follows

$$- \left((a_{33})^{(6)}(v^{(6)})^2 + (\sigma_2)^{(6)}v^{(6)} - (a_{32})^{(6)} \right) \leq \frac{dv^{(6)}}{dt} \leq - \left((a_{33})^{(6)}(v^{(6)})^2 + (\sigma_1)^{(6)}v^{(6)} - (a_{32})^{(6)} \right)$$

From which one obtains

Definition of $(\bar{v}_1)^{(6)}, (v_0)^{(6)}$:-

(j) For $0 < \left[(v_0)^{(6)} = \frac{G_{32}^0}{G_{33}^0} \right] < (v_1)^{(6)} < (\bar{v}_1)^{(6)}$

$$v^{(6)}(t) \geq \frac{(v_1)^{(6)} + (C)^{(6)}(v_2)^{(6)} e^{[-(a_{33})^{(6)}(v_1)^{(6)} - (v_0)^{(6)}]t}}{1 + (C)^{(6)} e^{[-(a_{33})^{(6)}(v_1)^{(6)} - (v_0)^{(6)}]t}}, \quad \left[(C)^{(6)} = \frac{(v_1)^{(6)} - (v_0)^{(6)}}{(v_0)^{(6)} - (v_2)^{(6)}} \right]$$

it follows $(v_0)^{(6)} \leq v^{(6)}(t) \leq (v_1)^{(6)}$

In the same manner , we get

522

$$v^{(6)}(t) \leq \frac{(\bar{v}_1)^{(6)} + (\bar{C})^{(6)}(\bar{v}_2)^{(6)} e^{[-(a_{33})^{(6)}(\bar{v}_1)^{(6)} - (\bar{v}_2)^{(6)}]t}}{1 + (\bar{C})^{(6)} e^{[-(a_{33})^{(6)}(\bar{v}_1)^{(6)} - (\bar{v}_2)^{(6)}]t}}, \quad \left[(\bar{C})^{(6)} = \frac{(\bar{v}_1)^{(6)} - (v_0)^{(6)}}{(v_0)^{(6)} - (\bar{v}_2)^{(6)}} \right]$$

523

From which we deduce $(v_0)^{(6)} \leq v^{(6)}(t) \leq (\bar{v}_1)^{(6)}$

(k) If $0 < (v_1)^{(6)} < (v_0)^{(6)} = \frac{G_{32}^0}{G_{33}^0} < (\bar{v}_1)^{(6)}$ we find like in the previous case,

524

$$(v_1)^{(6)} \leq \frac{(v_1)^{(6)} + (C)^{(6)}(v_2)^{(6)} e^{[-(a_{33})^{(6)}(v_1)^{(6)} - (v_2)^{(6)}]t}}{1 + (C)^{(6)} e^{[-(a_{33})^{(6)}(v_1)^{(6)} - (v_2)^{(6)}]t}} \leq v^{(6)}(t) \leq$$

$$\frac{(\bar{v}_1)^{(6)} + (\bar{C})^{(6)}(\bar{v}_2)^{(6)} e^{[-(a_{33})^{(6)}(\bar{v}_1)^{(6)} - (\bar{v}_2)^{(6)}]t}}{1 + (\bar{C})^{(6)} e^{[-(a_{33})^{(6)}(\bar{v}_1)^{(6)} - (\bar{v}_2)^{(6)}]t}} \leq (\bar{v}_1)^{(6)}$$

(l) If $0 < (v_1)^{(6)} \leq (\bar{v}_1)^{(6)} \leq \left[(v_0)^{(6)} = \frac{G_{32}^0}{G_{33}^0} \right]$, we obtain

525

$$(v_1)^{(6)} \leq v^{(6)}(t) \leq \frac{(\bar{v}_1)^{(6)} + (\bar{C})^{(6)}(\bar{v}_2)^{(6)} e^{[-(a_{33})^{(6)}(\bar{v}_1)^{(6)} - (\bar{v}_2)^{(6)}]t}}{1 + (\bar{C})^{(6)} e^{[-(a_{33})^{(6)}(\bar{v}_1)^{(6)} - (\bar{v}_2)^{(6)}]t}} \leq (v_0)^{(6)}$$

And so with the notation of the first part of condition (c), we have

Definition of $v^{(6)}(t)$:-

$$(m_2)^{(6)} \leq v^{(6)}(t) \leq (m_1)^{(6)}, \quad v^{(6)}(t) = \frac{G_{32}(t)}{G_{33}(t)}$$

In a completely analogous way, we obtain

Definition of $u^{(6)}(t)$:-

$$(\mu_2)^{(6)} \leq u^{(6)}(t) \leq (\mu_1)^{(6)}, \quad u^{(6)}(t) = \frac{T_{32}(t)}{T_{33}(t)}$$

Now, using this result and replacing it in GLOBAL EQUATIONS we get easily the result stated in the theorem.

Particular case :

If $(a''_{32})^{(6)} = (a''_{33})^{(6)}$, then $(\sigma_1)^{(6)} = (\sigma_2)^{(6)}$ and in this case $(v_1)^{(6)} = (\bar{v}_1)^{(6)}$ if in addition $(v_0)^{(6)} = (v_1)^{(6)}$ then $v^{(6)}(t) = (v_0)^{(6)}$ and as a consequence $G_{32}(t) = (v_0)^{(6)}G_{33}(t)$ **this also defines $(v_0)^{(6)}$ for the special case.**

Analogously if $(b''_{32})^{(6)} = (b''_{33})^{(6)}$, then $(\tau_1)^{(6)} = (\tau_2)^{(6)}$ and then $(u_1)^{(6)} = (\bar{u}_1)^{(6)}$ if in addition $(u_0)^{(6)} = (u_1)^{(6)}$ then $T_{32}(t) = (u_0)^{(6)}T_{33}(t)$ This is an important consequence of the relation between $(v_1)^{(6)}$ and $(\bar{v}_1)^{(6)}$, **and definition of $(u_0)^{(6)}$.**

526
527
528

527

We can prove the following

Theorem 3: If $(a_i'')^{(1)}$ and $(b_i'')^{(1)}$ are independent on t , and the conditions

$$\begin{aligned} &(a'_{13})^{(1)}(a'_{14})^{(1)} - (a_{13})^{(1)}(a_{14})^{(1)} < 0 \\ &(a'_{13})^{(1)}(a'_{14})^{(1)} - (a_{13})^{(1)}(a_{14})^{(1)} + (a_{13})^{(1)}(p_{13})^{(1)} + (a'_{14})^{(1)}(p_{14})^{(1)} + (p_{13})^{(1)}(p_{14})^{(1)} > 0 \\ &(b'_{13})^{(1)}(b'_{14})^{(1)} - (b_{13})^{(1)}(b_{14})^{(1)} > 0, \\ &(b'_{13})^{(1)}(b'_{14})^{(1)} - (b_{13})^{(1)}(b_{14})^{(1)} - (b'_{13})^{(1)}(r_{14})^{(1)} - (b'_{14})^{(1)}(r_{14})^{(1)} + (r_{13})^{(1)}(r_{14})^{(1)} < 0 \end{aligned}$$

with $(p_{13})^{(1)}, (r_{14})^{(1)}$ as defined, then the system

529

If $(a_i'')^{(2)}$ and $(b_i'')^{(2)}$ are independent on t , and the conditions

$$\begin{aligned} &(a'_{16})^{(2)}(a'_{17})^{(2)} - (a_{16})^{(2)}(a_{17})^{(2)} < 0 \\ &(a'_{16})^{(2)}(a'_{17})^{(2)} - (a_{16})^{(2)}(a_{17})^{(2)} + (a_{16})^{(2)}(p_{16})^{(2)} + (a'_{17})^{(2)}(p_{17})^{(2)} + (p_{16})^{(2)}(p_{17})^{(2)} > 0 \\ &(b'_{16})^{(2)}(b'_{17})^{(2)} - (b_{16})^{(2)}(b_{17})^{(2)} > 0, \\ &(b'_{16})^{(2)}(b'_{17})^{(2)} - (b_{16})^{(2)}(b_{17})^{(2)} - (b'_{16})^{(2)}(r_{17})^{(2)} - (b'_{17})^{(2)}(r_{17})^{(2)} + (r_{16})^{(2)}(r_{17})^{(2)} < 0 \end{aligned}$$

with $(p_{16})^{(2)}, (r_{17})^{(2)}$ as defined are satisfied, then the system

530.

531

532

Definition and uniqueness of T_{33}^* :-

After hypothesis $f(0) < 0, f(\infty) > 0$ and the functions $(a_i'')^{(6)}(T_{33})$ being increasing, it follows that there exists a unique T_{33}^* for which $f(T_{33}^*) = 0$. With this value, we obtain from the three first equations

$$G_{32} = \frac{(a_{32})^{(6)}G_{33}}{[(a_{32}')^{(6)}+(a_{32}'')^{(6)}(T_{33}^*)]} \quad , \quad G_{34} = \frac{(a_{34})^{(6)}G_{33}}{[(a_{34}')^{(6)}+(a_{34}'')^{(6)}(T_{33}^*)]}$$

569

(e) By the same argument, the equations 92,93 admit solutions G_{13}, G_{14} if

$$\varphi(G) = (b_{13}')^{(1)}(b_{14}')^{(1)} - (b_{13}'')^{(1)}(b_{14}'')^{(1)} - [(b_{13}')^{(1)}(b_{14}'')^{(1)}(G) + (b_{14}')^{(1)}(b_{13}'')^{(1)}(G)] + (b_{13}'')^{(1)}(G)(b_{14}'')^{(1)}(G) = 0$$

Where in $G(G_{13}, G_{14}, G_{15}), G_{13}, G_{15}$ must be replaced by their values from 96. It is easy to see that φ is a decreasing function in G_{14} taking into account the hypothesis $\varphi(0) > 0, \varphi(\infty) < 0$ it follows that there exists a unique G_{14}^* such that $\varphi(G^*) = 0$

570

(f) By the same argument, the equations 92,93 admit solutions G_{16}, G_{17} if

$$\varphi(G_{19}) = (b_{16}')^{(2)}(b_{17}')^{(2)} - (b_{16}'')^{(2)}(b_{17}'')^{(2)} - [(b_{16}')^{(2)}(b_{17}'')^{(2)}(G_{19}) + (b_{17}')^{(2)}(b_{16}'')^{(2)}(G_{19})] + (b_{16}'')^{(2)}(G_{19})(b_{17}'')^{(2)}(G_{19}) = 0$$

571

Where in $(G_{19})(G_{16}, G_{17}, G_{18}), G_{16}, G_{18}$ must be replaced by their values from 96. It is easy to see that φ is a decreasing function in G_{17} taking into account the hypothesis $\varphi(0) > 0, \varphi(\infty) < 0$ it follows that there exists a unique G_{17}^* such that $\varphi((G_{19})^*) = 0$

572

(g) By the same argument, the concatenated equations admit solutions G_{20}, G_{21} if

$$\varphi(G_{23}) = (b_{20}')^{(3)}(b_{21}')^{(3)} - (b_{20}'')^{(3)}(b_{21}'')^{(3)} - [(b_{20}')^{(3)}(b_{21}'')^{(3)}(G_{23}) + (b_{21}')^{(3)}(b_{20}'')^{(3)}(G_{23})] + (b_{20}'')^{(3)}(G_{23})(b_{21}'')^{(3)}(G_{23}) = 0$$

573

Where in $G_{23}(G_{20}, G_{21}, G_{22}), G_{20}, G_{22}$ must be replaced by their values from 96. It is easy to see that φ is a decreasing function in G_{21} taking into account the hypothesis $\varphi(0) > 0, \varphi(\infty) < 0$ it follows that there exists a unique G_{21}^* such that $\varphi((G_{23})^*) = 0$

574

(h) By the same argument, the equations of modules admit solutions G_{24}, G_{25} if

$$\varphi(G_{27}) = (b_{24}')^{(4)}(b_{25}')^{(4)} - (b_{24}'')^{(4)}(b_{25}'')^{(4)} - [(b_{24}')^{(4)}(b_{25}'')^{(4)}(G_{27}) + (b_{25}')^{(4)}(b_{24}'')^{(4)}(G_{27})] + (b_{24}'')^{(4)}(G_{27})(b_{25}'')^{(4)}(G_{27}) = 0$$

575

Where in $(G_{27})(G_{24}, G_{25}, G_{26}), G_{24}, G_{26}$ must be replaced by their values from 96. It is easy to see that φ is a decreasing function in G_{25} taking into account the hypothesis $\varphi(0) > 0, \varphi(\infty) < 0$ it follows that there exists a unique G_{25}^* such that $\varphi((G_{27})^*) = 0$

575

(i) By the same argument, the equations (modules) admit solutions G_{28}, G_{29} if

$$\varphi(G_{31}) = (b_{28}')^{(5)}(b_{29}')^{(5)} - (b_{28}'')^{(5)}(b_{29}'')^{(5)} - [(b_{28}')^{(5)}(b_{29}'')^{(5)}(G_{31}) + (b_{29}')^{(5)}(b_{28}'')^{(5)}(G_{31})] + (b_{28}'')^{(5)}(G_{31})(b_{29}'')^{(5)}(G_{31}) = 0$$

578

Where in $(G_{31})(G_{28}, G_{29}, G_{30}), G_{28}, G_{30}$ must be replaced by their values from 96. It is easy to see that φ is a decreasing function in G_{29} taking into account the hypothesis $\varphi(0) > 0, \varphi(\infty) < 0$ it follows that there exists a unique G_{29}^* such that $\varphi((G_{31})^*) = 0$

579

(j) By the same argument, the equations (modules) admit solutions G_{32}, G_{33} if

$$\varphi(G_{35}) = (b_{32}')^{(6)}(b_{33}')^{(6)} - (b_{32}'')^{(6)}(b_{33}'')^{(6)} - [(b_{32}')^{(6)}(b_{33}'')^{(6)}(G_{35}) + (b_{33}')^{(6)}(b_{32}'')^{(6)}(G_{35})] + (b_{32}'')^{(6)}(G_{35})(b_{33}'')^{(6)}(G_{35}) = 0$$

580

Where in $(G_{35})(G_{32}, G_{33}, G_{34}), G_{32}, G_{34}$ must be replaced by their values It is easy to see that φ is a decreasing function in G_{33} taking into account the hypothesis $\varphi(0) > 0, \varphi(\infty) < 0$ it follows that there exists a unique G_{33}^*

581

such that $\varphi(G^*) = 0$

Finally we obtain the unique solution of 89 to 94 582

G_{14}^* given by $\varphi(G^*) = 0$, T_{14}^* given by $f(T_{14}^*) = 0$ and

$$G_{13}^* = \frac{(a_{13})^{(1)}G_{14}^*}{[(a'_{13})^{(1)} + (a''_{13})^{(1)}(T_{14}^*)]} , G_{15}^* = \frac{(a_{15})^{(1)}G_{14}^*}{[(a'_{15})^{(1)} + (a''_{15})^{(1)}(T_{14}^*)]}$$

$$T_{13}^* = \frac{(b_{13})^{(1)}T_{14}^*}{[(b'_{13})^{(1)} - (b''_{13})^{(1)}(G^*)]} , T_{15}^* = \frac{(b_{15})^{(1)}T_{14}^*}{[(b'_{15})^{(1)} - (b''_{15})^{(1)}(G^*)]}$$

Obviously, these values represent an equilibrium solution

Finally we obtain the unique solution 583

G_{17}^* given by $\varphi((G_{19})^*) = 0$, T_{17}^* given by $f(T_{17}^*) = 0$ and 584

$$G_{16}^* = \frac{(a_{16})^{(2)}G_{17}^*}{[(a'_{16})^{(2)} + (a''_{16})^{(2)}(T_{17}^*)]} , G_{18}^* = \frac{(a_{18})^{(2)}G_{17}^*}{[(a'_{18})^{(2)} + (a''_{18})^{(2)}(T_{17}^*)]} \span style="float: right;">585$$

$$T_{16}^* = \frac{(b_{16})^{(2)}T_{17}^*}{[(b'_{16})^{(2)} - (b''_{16})^{(2)}((G_{19})^*)]} , T_{18}^* = \frac{(b_{18})^{(2)}T_{17}^*}{[(b'_{18})^{(2)} - (b''_{18})^{(2)}((G_{19})^*)]} \span style="float: right;">586$$

Obviously, these values represent an equilibrium solution 587

Finally we obtain the unique solution 588

G_{21}^* given by $\varphi((G_{23})^*) = 0$, T_{21}^* given by $f(T_{21}^*) = 0$ and

$$G_{20}^* = \frac{(a_{20})^{(3)}G_{21}^*}{[(a'_{20})^{(3)} + (a''_{20})^{(3)}(T_{21}^*)]} , G_{22}^* = \frac{(a_{22})^{(3)}G_{21}^*}{[(a'_{22})^{(3)} + (a''_{22})^{(3)}(T_{21}^*)]}$$

$$T_{20}^* = \frac{(b_{20})^{(3)}T_{21}^*}{[(b'_{20})^{(3)} - (b''_{20})^{(3)}(G_{23}^*)]} , T_{22}^* = \frac{(b_{22})^{(3)}T_{21}^*}{[(b'_{22})^{(3)} - (b''_{22})^{(3)}(G_{23}^*)]}$$

Obviously, these values represent an equilibrium solution

Finally we obtain the unique solution 589

G_{25}^* given by $\varphi(G_{27}) = 0$, T_{25}^* given by $f(T_{25}^*) = 0$ and

$$G_{24}^* = \frac{(a_{24})^{(4)}G_{25}^*}{[(a'_{24})^{(4)} + (a''_{24})^{(4)}(T_{25}^*)]} , G_{26}^* = \frac{(a_{26})^{(4)}G_{25}^*}{[(a'_{26})^{(4)} + (a''_{26})^{(4)}(T_{25}^*)]}$$

$$T_{24}^* = \frac{(b_{24})^{(4)}T_{25}^*}{[(b'_{24})^{(4)} - (b''_{24})^{(4)}((G_{27})^*)]} , T_{26}^* = \frac{(b_{26})^{(4)}T_{25}^*}{[(b'_{26})^{(4)} - (b''_{26})^{(4)}((G_{27})^*)]} \span style="float: right;">590$$

Obviously, these values represent an equilibrium solution

Finally we obtain the unique solution 591

G_{29}^* given by $\varphi((G_{31})^*) = 0$, T_{29}^* given by $f(T_{29}^*) = 0$ and

$$G_{28}^* = \frac{(a_{28})^{(5)}G_{29}^*}{[(a'_{28})^{(5)} + (a''_{28})^{(5)}(T_{29}^*)]} , G_{30}^* = \frac{(a_{30})^{(5)}G_{29}^*}{[(a'_{30})^{(5)} + (a''_{30})^{(5)}(T_{29}^*)]}$$

$$T_{28}^* = \frac{(b_{28})^{(5)}T_{29}^*}{[(b'_{28})^{(5)} - (b''_{28})^{(5)}((G_{31})^*)]} , T_{30}^* = \frac{(b_{30})^{(5)}T_{29}^*}{[(b'_{30})^{(5)} - (b''_{30})^{(5)}((G_{31})^*)]} \span style="float: right;">592$$

Obviously, these values represent an equilibrium solution

Finally we obtain the unique solution 593

G_{33}^* given by $\varphi((G_{35})^*) = 0$, T_{33}^* given by $f(T_{33}^*) = 0$ and

$$G_{32}^* = \frac{(a_{32})^{(6)}G_{33}^*}{[(a'_{32})^{(6)} + (a''_{32})^{(6)}(T_{33}^*)]} , G_{34}^* = \frac{(a_{34})^{(6)}G_{33}^*}{[(a'_{34})^{(6)} + (a''_{34})^{(6)}(T_{33}^*)]}$$

$$T_{32}^* = \frac{(b_{32})^{(6)}T_{33}^*}{[(b'_{32})^{(6)} - (b''_{32})^{(6)}((G_{35})^*)]} , T_{34}^* = \frac{(b_{34})^{(6)}T_{33}^*}{[(b'_{34})^{(6)} - (b''_{34})^{(6)}((G_{35})^*)]} \span style="float: right;">594$$

Obviously, these values represent an equilibrium solution

ASYMPTOTIC STABILITY ANALYSIS 595

Theorem 4: If the conditions of the previous theorem are satisfied and if the functions $(a_i'')^{(1)}$ and $(b_i'')^{(1)}$ Belong to $C^{(1)}(\mathbb{R}_+)$ then the above equilibrium point is asymptotically stable.

Proof: Denote

Definition of G_i, T_i :-

$$G_i = G_i^* + G_i , T_i = T_i^* + T_i$$

$$\frac{\partial (a_{14}'')^{(1)}}{\partial T_{14}}(T_{14}^*) = (q_{14})^{(1)} , \frac{\partial (b_i'')^{(1)}}{\partial G_j}(G^*) = s_{ij}$$
596

Then taking into account equations (global) and neglecting the terms of power 2, we obtain 597

$$\frac{dG_{13}}{dt} = -((a'_{13})^{(1)} + (p_{13})^{(1)})G_{13} + (a_{13})^{(1)}G_{14} - (q_{13})^{(1)}G_{13}^*T_{14} \span style="float: right;">598$$

$$\frac{dG_{14}}{dt} = -((a'_{14})^{(1)} + (p_{14})^{(1)})G_{14} + (a_{14})^{(1)}G_{13} - (q_{14})^{(1)}G_{14}^*T_{14} \span style="float: right;">599$$

$$\frac{dG_{15}}{dt} = -((a'_{15})^{(1)} + (p_{15})^{(1)})G_{15} + (a_{15})^{(1)}G_{14} - (q_{15})^{(1)}G_{15}^*T_{14} \span style="float: right;">600$$

$$\frac{dT_{13}}{dt} = -((b'_{13})^{(1)} - (r_{13})^{(1)})T_{13} + (b_{13})^{(1)}T_{14} + \sum_{j=13}^{15} (s_{(13)(j)})T_{13}^*G_j \span style="float: right;">601$$

$$\frac{dT_{14}}{dt} = -((b'_{14})^{(1)} - (r_{14})^{(1)})T_{14} + (b_{14})^{(1)}T_{13} + \sum_{j=13}^{15} (s_{(14)(j)})T_{14}^*G_j \span style="float: right;">602$$

$$\frac{dT_{15}}{dt} = -((b'_{15})^{(1)} - (r_{15})^{(1)})T_{15} + (b_{15})^{(1)}T_{14} + \sum_{j=13}^{15} (s_{(15)(j)})T_{15}^*G_j \span style="float: right;">603$$

If the conditions of the previous theorem are satisfied and if the functions $(a_i'')^{(2)}$ and $(b_i'')^{(2)}$ Belong to $C^{(2)}(\mathbb{R}_+)$ then the above equilibrium point is asymptotically stable 604

Denote 605

Definition of G_i, T_i :-

 \end{aligned}$$

And as one sees, all the coefficients are positive. It follows that all the roots have negative real part, and this proves the theorem.

Acknowledgments:

The introduction is a collection of information from various articles, Books, News Paper reports, Home Pages Of authors, Journal Reviews, Nature 's Letters, Article Abstracts, Research papers, Abstracts Of Research Papers, Stanford Encyclopedia, Web Pages, Ask a Physicist Column, Deliberations with Professors, the internet including Wikipedia. We acknowledge all authors who have contributed to the

same. In the eventuality of the fact that there has been any act of omission on the part of the authors, we regret with great deal of compunction, contrition, regret, trepidation and remorse. As Newton said, it is only because erudite and eminent people allowed one to piggy ride on their backs; probably an attempt has been made to look slightly further. Once again, it is stated that the references are only illustrative and not comprehensive

24. There is usually more than one possible way to define a field energy, because any field can be made to couple to gravity in many different ways. By general scaling arguments, the correct answer at everyday distances, which are long compared to the quantum gravity scale, should be minimal coupling, which means that no powers of the curvature tensor appear. Any non-minimal couplings, along with other higher order terms, are presumably only

determined by a theory of quantum gravity, and within string theory, they only start to contribute to experiments at the string scale.

Privileged Cryptography

Abhishek Dhull*, Priti**

*(Department of Computer Science & Applications, M.D. University, India)

** (Asstt. Prof., Department of Computer Science & Applications, M.D. University, India)

ABSTRACT: Cryptography is the practice and study of techniques for secure communication in the presence of third parties (called adversaries). More generally, it is about constructing and analyzing protocols that overcome the influence of adversaries and which are related to various aspects in information security such as data confidentiality, data integrity, and authentication. This paper presents the way of protecting the information from:

- Intruders: those who capture the packet and alter the information.
- Cryptanalysts: those who decrypt cipher text into plain text without key.

Keywords: Cryptanalyst, Decryption, Encryption, Intruder, Private key, Public key.

I. INTRODUCTION

Modern cryptography is heavily based on mathematical theory and computer science practice. Cryptographic algorithms are designed around computational hardness assumptions, making such algorithms hard to break in practice by any adversary. It is theoretically possible to break such a system but it is infeasible to do so by any known practical means. These schemes are therefore termed computationally secure; theoretical advances (e.g., improvements in integer factorization algorithms) and faster computing technology require these solutions to be continually adapted. There exist information-theoretically secure schemes that provably cannot be broken even with unlimited computing power—an example is the one-time pad—but these schemes are more difficult to implement than the best theoretically breakable but computationally secure mechanisms. Until modern times cryptography referred almost exclusively to *encryption*, which is the process of converting ordinary information (called plaintext) into unintelligible gibberish (called cipher text). Decryption is the reverse, in other words, moving from the unintelligible cipher text back to plaintext. A *cipher* (or *cypher*) is a pair of algorithms that create the encryption and the reversing decryption. The detailed operation of a cipher is controlled both by the algorithm and in each instance by a "key" [6]. This is a secret parameter (ideally known only to the communicants) for a specific message exchange context. A "cryptosystem" is the ordered list of elements of finite possible plaintexts, finite possible cipher texts, finite possible keys, and the encryption and decryption algorithms which correspond to each key[2]. Keys are important, as ciphers without variable keys can be trivially broken with only the knowledge of the cipher used

and are therefore useless (or even counter-productive) for most purposes. Historically, ciphers were often used directly for encryption or decryption without additional procedures such as authentication or integrity checks.

In colloquial use, the term "code" is often used to mean any method of encryption or concealment of meaning. However, in cryptography, *code* has a more specific meaning. It means the replacement of a unit of plaintext (i.e., a meaningful word or phrase) with a code word (for example, wallaby replaces attack at dawn). Codes are no longer used in serious cryptography—except incidentally for such things as unit designations (e.g., Bronco Flight or Operation Overlord)—since properly chosen ciphers are both more practical and more secure than even the best codes and also are better adapted to computers.

Cryptanalysis is the term used for the study of methods for obtaining the meaning of encrypted information without access to the key normally required to do so; i.e., it is the study of how to crack encryption algorithms or their implementations.

II. EXISTING WAYS OF CRYPTOGRAPHY

Some use the terms *cryptography* and *cryptology* interchangeably in English, while others (including US military practice generally) use *cryptography* to refer specifically to the use and practice of cryptographic techniques and *cryptology* refer to the combined study of cryptography and cryptanalysis [3]. English is more flexible than several other languages in which *cryptology* (done by cryptologists) is always used in the second sense above.

2.1 Symmetric-key cryptography

Symmetric-key cryptography refers to encryption methods in which both the sender and receiver share the same key (or, less commonly, in which their keys are different, but related in an easily computable way). This was the only kind of encryption publicly known until June 1976 One round (out of 8.5) of the patented IDEA cipher, used in some versions of PGP for high-speed encryption of, for instance, e-mail Symmetric key ciphers are implemented as either block ciphers or stream ciphers. A block cipher enciphers input in blocks of plaintext as opposed to individual characters, the input form used by a stream cipher.

The Data Encryption Standard (DES) and the Advanced Encryption Standard (AES) are block cipher designs which have been designated cryptography standards by the US government (though DES's designation was finally withdrawn after the AES was adopted). Despite its

deprecation as an official standard, DES (especially its still-approved and much more secure triple-DES variant) remains quite popular; it is used across a wide range of applications, from ATM encryption to e-mail privacy and secure remote access. Many other block ciphers have been designed and released, with considerable variation in quality.

Stream ciphers, in contrast to the 'block' type, create an arbitrarily long stream of key material, which is combined with the plaintext bit-by-bit or character-by-character, somewhat like the one-time pad. In a stream cipher, the output stream is created based on a hidden internal state which changes as the cipher operates. That internal state is initially set up using the secret key material. RC4 is a widely used stream cipher. Block ciphers can be used as stream ciphers.

2.2 Symmetric-key algorithms

Symmetric-key algorithms are a class of algorithms for cryptography that use trivially related, often identical, cryptographic keys for both encryption of plaintext and decryption of cipher text. Symmetric algorithms, sometimes called Conventional algorithms, are algorithms where the encryption key can be calculated from the decryption key and vice versa [1, 4]. The encryption key is trivially related to the decryption key, in that they may be identical or there is a simple transformation to go between the two keys. The keys, in practice, represent a shared secret between two or more parties that can be used to maintain a private information link. Other terms for symmetric-key encryption are secret-key, single-key, shared-key, one-key, and private-key encryption. Use of the last and first terms can create ambiguity with similar terminology used in public-key cryptography. Symmetric-key cryptography is to be contrasted with asymmetric-key cryptography [8].

2.3 Types of symmetric-key algorithms:

Symmetric-key encryption can use either stream ciphers or block ciphers.

- Stream ciphers encrypt the bits of a message one at a time.
- Block ciphers take a number of bits and encrypt them as a single unit. Blocks of 64 bits have been commonly used. The Advanced Encryption Standard (AES) algorithm approved by NIST in December 2001 uses 128-bit blocks [7].

2.3.1 Basic algorithm and terminology

RSA encryption and decryption are essentially mathematical operations. They are what are termed *exponentiation, modulo* a particular number. Because of this, RSA keys actually consist of numbers involved in this calculation, as follows:

- the public key consists of the modulus and a public exponent; the private key consists of that same modulus plus a private exponent.

2.3.2 Security of Public Key Schemes

- like private key schemes brute force exhaustive search attack is always theoretically possible
- but keys used are too large (>512bits)
- The public-key algorithms are based on a known hard problem. The its just made too hard to do in practise
- RSA Problem: Given $n=pq$, with p and q primes. Find p and q .
- requires the use of very large numbers, hence is slow compared to private key schemes

2.3.3 Existing Cryptography

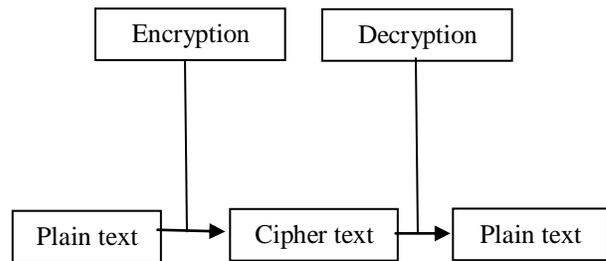

Fig. 1 Existing Cryptography

III. PROPOSED MODEL

3.1 Construction of Symmetric Ciphers

Many modern block ciphers are based on a construction proposed by Horst Feistel. Feistel's construction makes it possible to build invertible functions from other functions that are themselves not invertible.

3.2 Security of Symmetric Ciphers

Construction of the functions for each round can greatly reduce the chances of a successful attack.

3.3 Key Generation

When used with asymmetric ciphers for key transfer, pseudorandom key generators are nearly always used to generate the symmetric cipher session keys. However, lack of randomness in those generators or in their initialization vectors is disastrous and has led to cryptanalytic breaks in the past. Therefore, it is essential that an implementation uses a source of high entropy for its initialization. Symmetric ciphers have historically been susceptible to known-plaintext attacks, chosen plaintext attacks, differential cryptanalysis and linear cryptanalysis.

3.3.1 Detection of Intruder's Activity

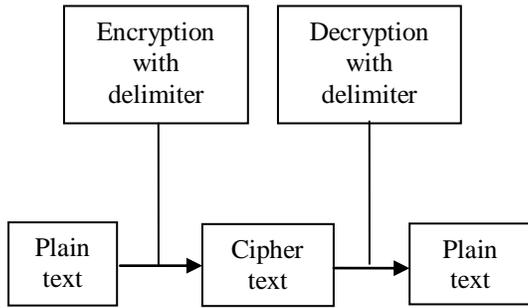

Fig.2 Encryption and Decryption with delimiter

Some time intruder make change in cipher text as a result it becomes difficult to know. Information becomes meaningless. A delimiter can be set with plain text during encryption so that at the time of decryption user could know whether cipher text was altered or not. If it is altered delimiter will not be visible at receiving end and packet will be retransmitted

3.3.2 Privileged Cryptography with IP Filtering

To protect information from cryptanalyst IP Filter would be attached in decryption module

Sometime cryptanalyst decrypt information without key, this problem can be solved using IP filtering

If there is decryption request from different IP then packets will be deleted.

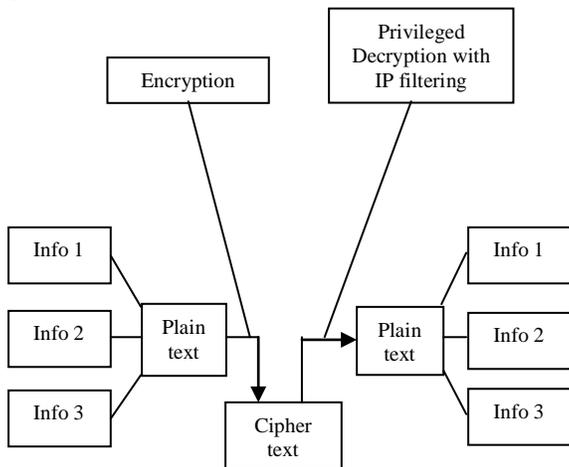

Fig. 3 Decryption with IP filtering

IV. CONCLUSION

It will improve the security of the text while sending it from sender to receiver. A delimiter can be set during encryption and decryption to know whether the data has been altered by an intruder or not. We can also protect our information from cryptanalyst, who can decrypt information without using key, by attaching IP filter during decryption. Hence our data becomes more secure when transmitted from sender to receiver.

Shape Recognition based on Features matching using Morphological Operations

Shikha Garg¹, Gianetan Singh Sekhon²

¹(Student, M.Tech Department of Computer Engineering, YCOE, Punjabi University, Patiala, India)

²(Assistant Professor, M.Tech Department of Computer Engineering, YCOE, Punjabi University, Patiala, India)

ABSTRACT: This paper presents the implementation of method of shape recognition among different regular geometrical shapes using morphological operations. Many algorithms have been proposed for this problem but the major issue that has been enlightened in this paper is over segmentation dodging among different objects. After an introduction to shape recognition concept, we describe the process of extracting the boundaries of objects in order to avoid over segmentation. Then, a shape recognition approach is proposed. It is based on some mathematical formulae. Our new algorithm detects the shapes in the following cases when (i) There are distinct objects in the given image. (ii) The objects are touching in the given image. (iii) The objects are overlapping in the given image. (iv) One object is contained in the other in the given image. Then with the help of boundaries concentrate and shape properties, classification of the shapes is done.

Keywords: Edge detection, geometrical shapes, morphological operations, over segmentation, Shape recognition.

I. Introduction

In an image, shape plays a significant role. Shape of an image is one of the key information when an eye recognizes an object. Shape of an image does not change when colour of image is changed. Shape recognition finds its applications in robotics, fingerprint analysis, handwriting mapping, face recognition, remote sensors etc [6]. In pattern recognition shape is one of the significant research areas. Main focus of the pattern recognition is the classification between objects.

In a computer system, shape of an object can be interpreted as a region encircled by an outline of the object. The important job in shape recognition is to find and represent the exact shape information. Many algorithms for shape representation have been proposed so far.

Many methods for 2D shape representation and recognition have been reported. Curvature scale space (CSS), dynamic programming, shape context, Fourier descriptor, and wavelet descriptor are as the example of these approaches [8]. There are two methods for shape recognition, area based and boundary based technique. In area based technique, all pixels within the region of image are taken into consideration to get shape representation. Common area based technique uses moment descriptors to depict the shape. Whereas boundary based technique focuses mainly on object boundary. Boundary based technique represents shape feature of object more clearly as compared to area based technique. It is fast in processing and needs less computation than area based

technique. Due to fast processing and easy computation it is widely used in real time and practical applications. In this paper we consider just the boundary based technique.

In the previous work of shape recognition, object detection approaches based on color/texture segmentation or image binarization and foreground extraction is proposed, which can be used in this case. Other shape detection solutions are based on edge-detection, sliding-windows or generalized Hough transforms. The identified image objects are then recognized by their shapes. The focus of this paper is shape recognition by edge detection using morphological operations. In this paper the problem of over segmentation among different objects has been taken into consideration for shape recognition. The different objects in the given image are processed one by one and then they are clustered together to form the output image. This process is executed in two stages: firstly, the image is read in from the user and objects which are touching one another are segmented. Then we will match the features of the current object with the preloaded features in the database or we can say training set for recognition.

II. Materials and methods

The computation of proposed method can be briefly summarised in 2 steps (1) Avoidance of over segmentation among different objects like circle, rectangle, square etc with the use of morphological operations (2) Labelling the objects after recognition of various objects within the image.

2.1 Over segmentation avoidance

The proposed method is trying to prevent the over segmentation and segment some overlapping areas to extract the boundaries of various objects within the image. For this, read the RGB image in from the user and convert the RGB (coloured) image to gray scale and then to binary image. Invert the binary image in order to speed up the time of processing. Then morphological operation is implemented so that all the objects are eroded from all the sides and then the boundaries of small radius are enhanced along the edges of the objects.

```
se = strel('disk', 1);  
dummy1=imerode(dummy,se);
```

SE = strel('disk', R,) creates a flat, disk-shaped structuring element, where R specifies the radius. R must be a nonnegative integer. Here the value of R is 1. Imerode performs binary erosion; otherwise it performs gray scale erosion. If SE is an array of structuring element objects,

imerode performs multiple erosions of the input image, using each structuring element in SE in succession.

2.2 Recognition and labelling of objects

In this algorithm when the objects are being segmented from each other, the final stage is to identify the shape of the objects. This is done by using filtering technique. Some properties like sensitivity factor and corners of the objects are needed to predict the shapes of varying objects. Then with these mathematical parameters, objects of input image are matched with the preloaded features of the objects in the database or we can say training set and thus we can recognize the shape of the objects.

CIRCLE > Number of corners = 0 > Absolute difference b/w length and breadth < 25 > Sensitivity Factor = 0.24	TRIANGLE > Number of corners = 3 > Sensitivity Factor = 0.24	SQUARE > Number of corners = 4 > Absolute difference b/w length and breadth < 10 > Sensitivity Factor = 0.24
RECTANGLE > Number of corners = 4 > Absolute difference b/w length and breadth > 10 > Sensitivity Factor = 0.24	POLYGON > Number of corners > 4 > Absolute difference b/w length and breadth > 10 > Sensitivity Factor = 0.2	

Fig.1 filters used to distinguish objects

III. Experiments

We have performed numerous experiments using the described shape recognition approach. The proposed technique has been tested on various image datasets and satisfactory results have been obtained. A high recognition rate, of approximately 95 %, is achieved by our method. It represents a better rate that those of many other object recognition approaches.

An indexed image consists of an array and a colormap matrix. The pixel values in the array are direct indices into a colormap. An indexed image uses direct mapping of pixel values to colormap values. The color of each image pixel is determined by using the corresponding value of X as an index. As RGB image is having an index value of 255 therefore we set this parameter to a scalar between 250 and 0 and in loop this scalar value go on decrementing with a value 5. As this scalar value matches with the index value of object, the particular object is identified. The image is then converted in the binary form, then the binary image is processed using some morphological operations, to eliminate the over segmented area and retain only the important image regions.

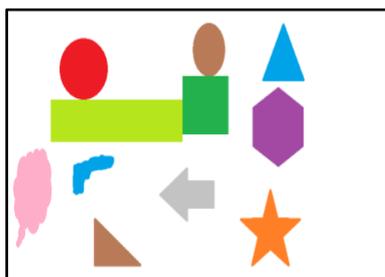

Fig.2 Image containing several objects

A shape recognition example is described in the next figures. Thus, in Fig.3 there is an displayed image containing objects which are segmented. Each object is marked with the *obj_i* value in the picture, $i = 2 \dots, 12$.

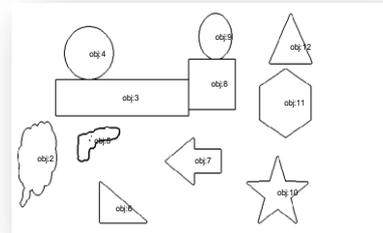

Fig.3 segmented objects

The connected components of the enhanced binary image are detected, thus the image foreground, containing the main objects, being extracted. The feature extraction process is then applied on the detected shapes. The obtained shapes are then classified using the presented shape recognition algorithm. The shape names corresponding to the image from Fig. 2 are represented in Fig. 4. As one can see in that figure, each object is labelled with the name matched with its features defined in Fig. 1. The final recognition result are, circle{obj4,obj6}, square{obj8}, rectangle{obj3}, triangle{obj5,obj12}, polygon{obj11}.

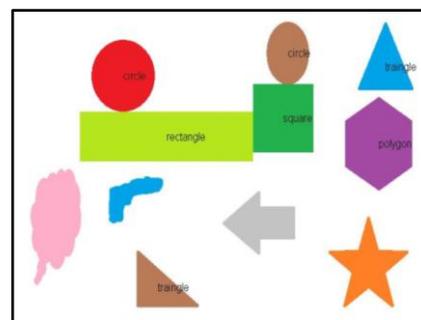

Fig.4 The resulted labelled objects

IV. Conclusion

In this study, a new method of shape recognition is proposed which takes into account the problem of over segmentation. By integrating the structural features like distance measure and centroid, the proposed method extracts the structural information of shapes. Based on those properties, various shapes can be recognized. The identification of the appropriate name of shape clusters automatizes the classification method, which represents a very important thing. That means our recognition technique can be used successfully for very large sets of images, containing a high number of shapes.

Experiments have shown that this method produces accurate and fast results with different images provided. The results of this provided recognition technique can be applied successfully in important domains, such as object recognition and segmentation.

Performance of Symmetrical and Asymmetrical Multilevel Inverters

K. Lakshmi Ganesh, U. Chandra Rao

**(Department of Electrical and Electronics Engineering, Sri Vasavi Engineering College, India)*

*** (Department of Electrical and Electronics Engineering, Sri Vasavi Engineering College, India)*

ABSTRACT: *Distributed Energy Resources (DER) are systems that produce electrical power at the site where the power is needed. If only electrical power is used then the technology is called Distributed Generation (DG). The objective of this paper is to study a novel more than five level multistring inverter topology for DERs based DC/AC conversion system. The distributed energy resource based single-phase inverter is usually adopted in the microgrid system. In order to reduce the conversion losses, the key is to saving costs and size by removing any kind of transformer as well as reducing the power switches. In this study, a high step-up converter is introduced as a front-end stage to improve the conversion efficiency of conventional boost converters and to stabilize the output DC voltage of various DERs such as photovoltaic for use with the simplified multilevel inverter. In addition, two active switches are operated under line frequency. In this project a novel asymmetrical configuration is proposed. The proposed asymmetrical configuration uses less number of switches to get more levels. It will reduce the cost, reduce the number of sources, complexity, losses and improves reliability. The proposed converter is simulated by Matlab/Simulink software and simulation results are presented.*

Key words: *DC/AC power conversion, multilevel inverter, harmonic analysis and Total Harmonic Distortion (THD).*

I. INTRODUCTION

The continuous economic development of many countries and the environmental issues (gas emissions and the green house effect) observed in the last decades forced an intense research in renewable energy sources. Distributed energy resources are small, modular, energy generation and storage technologies that provide electric capacity or energy where you need it. Typically producing less than 10 megawatts (MW) of power, DER systems can usually be sized to meet your particular needs and installed on site.

DER technologies include wind turbines, photo voltaic (PV), fuel cells, micro turbines, reciprocating engines, Hydro, combustion turbines and energy storage systems are the most explored technologies due to their considerable advantages [1],[2], such as reliability, reasonable installation and energy

production costs, low environmental impact, capability to support micro grid [3].

The renewable energy resources consists of photovoltaic, fuel cells are generate the voltage are dc voltage. But I want the ac voltage because of mostly used the loads are ac loads. So we are convert the dc power to ac power processing interface is required and is Commercial, homes, factories and utility grid standards [4],[7].

Differing converter topographies have been acquired DERs establish effectual power flow control performance of DERs. DER systems may be either connected to the local electric power grid or isolated from the grid in stand-alone applications [7], [10].

The dc-dc converters are two types. They are without galvanic isolation and with galvanic isolation (high frequency transformer).The with galvanic isolation converter (high power applications) are used corresponding to size, weight, expense reduces. So low and medium power applications without galvanic isolation means make no use of transformers corresponding to reduces the size, weight expense [7], [8].

The next procedure the output voltage level increases of the inverter output then automatically harmonic component of the output voltage of inverter reduces and also corresponding to small size of filters are used simultaneously the cost reduces. The differing multilevel topographies are usually characterizing by strong reduction of switching power losses and electromagnetic interference (EMI) [6], [7], [8].

A new simplified single-phase multistring five-level multilevel inverter topography of dc/ac power conversion with auxiliary circuit proposed [8], [9]. This topography are used, the number of switching devices and output harmonics are reduced. The THD of the multistring five-level inverter is much less than the conventional multistring three-level inverter because of additional auxiliary circuit has high switching losses [9].

The objective of this paper is to study a newly constructed transformerless five level multistring inverter topology for DERS. In this letter aforesaid GZV-based inverter is reduced to a multistring multilevel inverter topography that require only 6 active switches instead of existing cascaded H-bridge multilevel inverter have eight switches[10].Multi string multilevel inverter have six active switches. They are middle two switches are operated

fundamental frequency and remaining four switches are operated switching frequency. A high efficiency dc-dc boost converter reduction of transformer and device voltage and current stresses with continuous input current leakage inductance energy recovery, and avoiding the use of electrolytic capacitor due to reduced ripple current[13]. Operation of the system configuration of operation is shown below. The performance of symmetrical and asymmetrical single phase multilevel inverter with respect to harmonics content and number of switches and input voltage source is DC is simulated by MATLAB/Simulink. A detailed harmonic analysis is done on the multilevel inverter by considering up to 23rd harmonics for 7 levels to 13 levels operation.

II. SYSTEM CONFIGURATION OF OPERATION PRINCIPLES

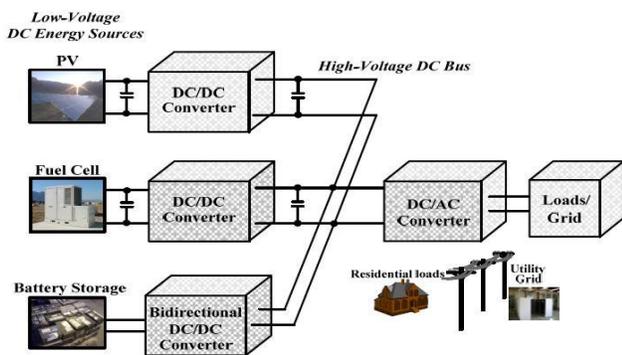

Fig.1 Different type of DERs are system configuration of Multistring Inverter

The above Fig.1 shows the DERs have photovoltaics or Fuel cell inverter are taken as [14]. The individual dc/dc boost converter are connected to the photovoltaic modules or Fuel cell. The bidirectional (buck-boost) dc/dc converter is connected to the only for battery storage. The individual dc/dc boost converter is connected to the multistring inverter. These common inverter for interface with all dc/dc converters of DERs [15]. The two modes of operation above Fig.1. They are standalone mode and grid connected mode. In grid connected mode, the battery storage energy is not connected to the grid. In standalone operation, the battery storage energy is connected to the load.

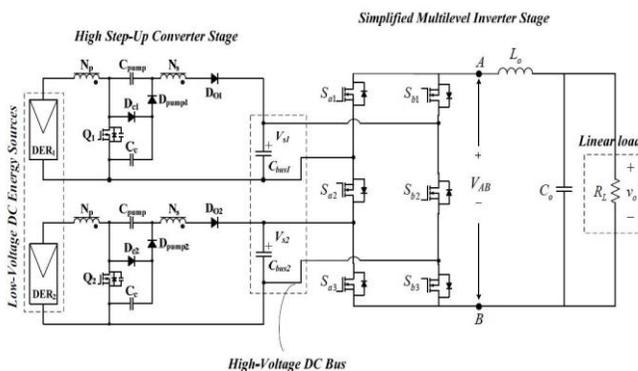

Fig.2 Single phase simplified multistring five-level inverter topography for high stepup converter from DERs

The above Fig.2 shows DER module-1 is connected to the high step up dc/dc converter and DER module-2 is connected to high step up dc/dc converter. These two converters are connected to their individual dc-bus capacitor and a simplified multilevel inverter. The resistive load is connected output of the simplified multilevel inverter from DER through high step up dc/dc converter. The input sources of DERs are photovoltaic or Fuel cells. The basic circuit have eight switches of cascaded H-bridge Multilevel inverter (CHB) with phase shift carrier pulse width modulation scheme are used. The simplified multilevel inverter have six switches then best merits of improved output waveforms, reduced the filter size, low EMI and THD [11],[12]. It should be noted that, by using independent voltage regulation control of the individual high step-up converter, voltage balance control for the two bus capacitors C_{bus1} , C_{bus2} can be achieved normally.

2.1. High Step-Up Converter Stage

In this study, High Efficiency Converter with Charge Pump and Coupled Inductor for Wide Input Photovoltaic AC Module Applications [13]. This simplified multilevel inverter combines the behavior of three different converter topologies: boost, flyback and charge pump. The flyback aspect of the topology allows the design to be optimized in terms of the transformer turns-ratio, allowing for much higher voltage gains than would be possible with a boost converter. However, flyback converters are notoriously inefficient and are very sensitive to leakage inductance, which can cause undue voltage-stress on switches and diodes. By using a clamp-circuit- identical to the output of a boost-converter- after the main switch, much of the efficiency issues can be resolved and the transformer design becomes less complicated. Finally, adding a charge-pump capacitor across the primary and secondary windings of the transformers gives higher converter voltage-gain and reduced peak current stress by allowing the current of the primary-windings to continuous.

The equivalent circuit of the proposed converter is shown in Fig.3. The coupled inductor is modeled as a magnetizing inductor L_m an ideal transformer with a turn's ratio of $N_s : N_p$ primary leakage inductor L_{Lk1} and secondary leakage inductor L_{Lk2} . C_c is the clamp capacitor, S is the Active switch, D_0 is the output diode C_{pump} is the charge pump capacitor.

According to voltage-seconds balance condition of the magnetizing inductor, the voltage of the primary winding can be derived as

$$V_{pri} = V_{in} \frac{D}{1-D} \tag{1}$$

Where V_m represents each the low-voltage dc energy input sources and voltage of the secondary winding is

$$V_{sec} = \frac{N_S}{N_P} \cdot V_{pri} = \frac{N_S}{N_P} \cdot V_{in} \frac{D}{1-D} \quad (2)$$

Similar to that of the boost converter, the voltage of the charge-pump capacitor C_{pump} and clamp capacitor C_c can be expressed as

$$V_{C_{pump}} = V_{C_c} = V_{in} \cdot \frac{1}{1-D} \quad (3)$$

Hence, the voltage conversion ratio of the high step-up converter, named input voltage to bus voltage ratio, can be derived as [13].

$$\frac{V_0}{V_{in}} = \frac{\left(2 + \frac{N_S}{N_P} \cdot D\right)}{1-D} \quad (4)$$

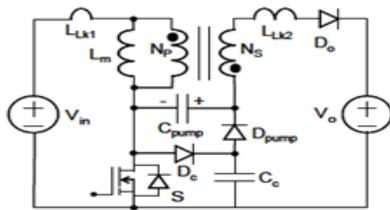

Fig.3. Equivalent circuit of the high step-up boost converter

2.2 Simplified Multilevel Inverter Stage

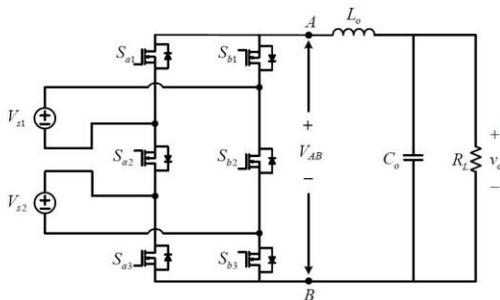

Fig.4 Basic Five-level inverter Circuitry of six switches

The simplified multilevel inverter is the conventional circuit of five level inverter Fig.4 shows above. A new single phase multistring topography, as a new basic circuitry in Fig.4. Referring to Fig.2, it is should assumed that, in this configuration, the two capacitors in the capacitive voltage divider are connected directly across the dc bus and all switching combinations are activated in an output cycle. The dynamic voltage balance between the two capacitors is automatically controlled by the preceding high step-up converter stage. Then, we can assume $V_{s1} = V_{s2} = V_s$.

This circuit has six power switches compare the basic circuit of cascaded H-bridge has eight power switches which drastically reduces the power circuit complexity and simplifies modulation circuit design and implementation. The phase disposition (PD) pulse width modulation (PWM) control scheme is introduced to generate switching signals

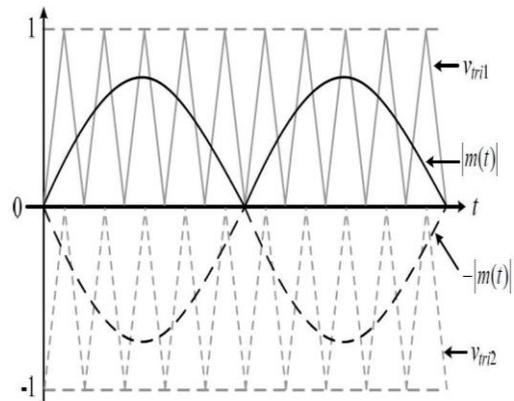

and to produce five output voltage levels: $0, V_s, 2V_s, -V_s$ and $2V_s$

This inverter topology uses two carrier signals and one reference signal to generate the PWM signals for the switches the modulation strategy and its implemented logic scheme in Fig.5 (a) and (b) area widely used alternative for Phase disposition modulation. With the exception of an offset value equivalent to the carrier signal amplitude. Two comparators are used in this scheme with identical carrier signals V_{tri1} and V_{tri2} to provide high-frequency switching signals

for S_{a1}, S_{b1}, S_{a3} and S_{b3} . Another comparator is used for zero-crossing detection to provide line-frequency switching signals for switches S_{a2} and S_{b2} .

For Fig.4 the switching function of the switch defined as follows.

- $S_{aj} = 1, S_{aj}$ ON
- $S_{aj} = 0, S_{aj}$ OFF for $j=1, 2, 3$
- $S_{bj} = 1, S_{bj}$ ON
- $S_{bj} = 0, S_{bj}$ OFF for $j=1, 2, 3$

(a)

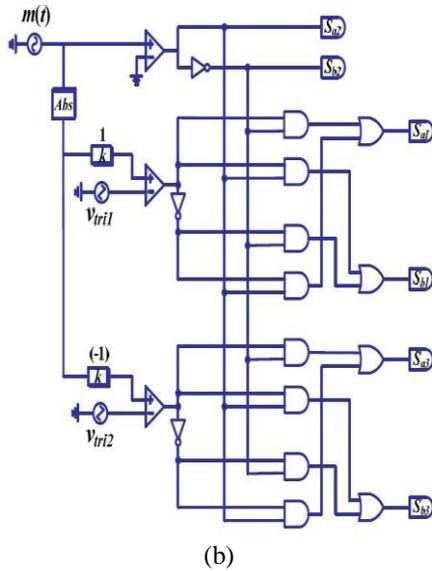

Fig.5. Modulation strategy a) Carrier/reference signals
 (b) modulation logic

Table-I

Simplified Five Level Inverter Switching Combination

S_{a1}	S_{a2}	S_{a3}	S_{b1}	S_{b2}	S_{b3}	V_{AB}
0	1	0	1	0	1	$2V_S$
0	1	1	1	0	0	V_S
1	1	0	0	0	1	V_S
1	1	1	0	0	0	0
0	0	0	1	1	1	0
1	0	0	0	1	1	$-V_S$
0	0	1	1	1	0	$-V_S$
1	0	1	0	1	0	$-2V_S$

Table-I lists switching combinations that generate the required five output levels. The corresponding operation modes of the simplified multilevel inverter stage are described clearly as follows.

1) Maximum positive output voltage ($2V_S$): Active switches S_{a2} , S_{b3} and S_{b1} are ON. The voltage applied to the LC output filter is $2V_S$.

2) Half level positive output voltage ($+V_S$): The two switching combinations are there. One switching combination is that active switches S_{a2} , S_{a3} and S_{b1} are ON, the other is active switches S_{a2} , S_{a1} and S_{b3} are ON. During this operating stage, the voltage applied to the LC output filter $+V_S$.

3) Zero Output, (0): This output condition either one of the leg are left or right all switches are ON. The load is short-circuited, and the voltage applied to the load terminals zero.

4) Half level negative output voltage ($-V_S$): the two switching combinations are there. One switching combination is such that active switches S_{a1} , S_{b2} and S_{b3} are ON, the other switching is active switches S_{b2} , S_{b1} and S_{a3} .

5) Maximum negative output ($-2V_S$): During this stage, active switches S_{a1} , S_{a3} and S_{b2} are ON, and the output voltage applied to the LC output filter $-2V_S$.

In these circuit operations, it can be observed that the open voltage stress of the active power switches S_{a1} , S_{b1} , S_{a3} and S_{b3} is equal to input voltage V_S and the main active switches S_{a2} and S_{b2} are operated at the line frequency. Hence, the switching losses are reduced in the new topology and the overall conversion efficiency is improved.

In Fig.5 control circuit diagram as shown, $m(t)$ is the sinusoidal modulation signal. Both V_{ri1} and V_{ri2} are two carrier signals. The magnitude value and frequency of the sinusoidal modulation signal are given as $m_{peak}=0.7$ and $f_m=60\text{Hz}$. The peak to peak value of the triangular modulation signals is equal to 1 and the switching frequency f_{ri1} and f_{ri2} are both given as 18.06 kHz.

The two input voltage sources feeding from the high step up converter is controlled at 100V that is $V_{s1} = V_{s2} = 100\text{V}$. The five level output of the phase voltage of the simulation waveform is shown in Fig.6.

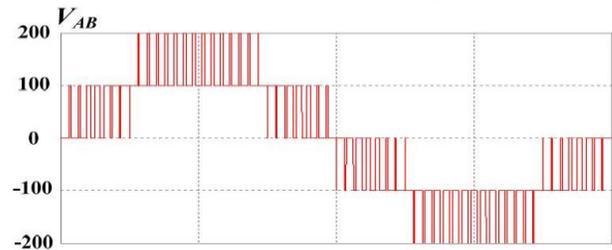

Fig.6 Simplified multilevel five level output phase voltage of simulation waveform V_{AB}

2.3 Basic circuit of Cascaded H-Bridge (CHB) Inverter

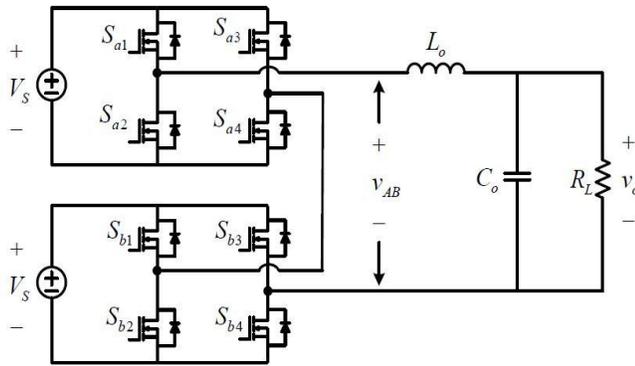

Fig.7 Basic circuit of five-level inverter topology of CHB inverter have eight switches

The above figure shows the Basic circuit of five level inverter CCHB inverter have eight switches. The carrier based sinusoidal phase shift carrier pulse width modulations are used in the basic circuit of CHB inverter. The eight switches are operated of the switching frequency. The CHB inverter are operate at the switching frequency is same as 18.06kHz the same modulation index $m_a=0.7$.

The simplified multilevel inverter and Cascaded H-bridge inverter are operated the same switching frequency and same modulation index m_a , the same input voltage $V_s=100V$ and output L-C filter, $L_o=20mH, C_o=200\mu F, R-load=100\Omega$. Table VII and Table VIII shows the harmonic component and THD Cascaded H-Bridge Inverter and Simplified multilevel inverter. The simplified multilevel inverter have the lesser THD compare to the Cascaded H-bridge inverter. So the low values of LC filter.

The symmetrical multilevel inverters are Cascaded H-bridge inverter and Simplified multilevel inverter. These are taken the equal voltage values. The symmetrical multilevel inverters above are operated with PWM method. The Proposing methods of asymmetrical multilevel inverters are repeating sequence is used for Seven, Nine, Eleven and Thirteen levels. The seven level have 6 switches and Nine, Eleven and Thirteen level have 8 switches. The Seven, Nine, Eleven and Thirteen levels are get by using 12,16,20,24 switches are necessity in symmetrical configuration of Cascaded H-bridge inverter. So the less number of switches are in asymmetrical configuration to get more number of voltage levels, lesser the THD, low cost, reducing the DC sources, reduce the complexity and driving circuits.

III. PROPOSED SYTEM

3.1 Seven Level Multi Level Inverter (MLI)

Table- II
Seven Level Multilevel Inverter (MLI)

1	0	0	0	0	1	1	1	$-V_s$
0	0	1	1	1	1	0	0	$-2V_s$
1	0	1	1	0	1	0	0	$-3V_s$
0	0	1	0	1	1	0	1	$-4V_s$
1	0	1	0	0	1	0	1	$-5V_s$

3.5 Different voltages are taken as the source voltages of the asymmetrical multilevel inverters

TABLE VI
DIFFEERENT VOLTAGES

No of levels	No of Switches	V1	V2	V3	Output Voltage in V
7	6	V_s	$2V_s$	-	$3V_s$
9	8	V_s	V_s	$2V_s$	$4V_s$
11	8	V_s	$2V_s$	$2V_s$	$5V_s$
13	8	V_s	$2V_s$	$3V_s$	$6V_s$

The above Table VI is shows the active switches operation of eight switches with eleven level, 1 means the switch is ON, the 0 means the switch is OFF. Then we will get the eleven level output voltage from the eight switches only.

3.4 Thirteen Level multi Level inverter

Table-V
Thirteen level multi level inverter (MLI)

S_1	S_2	S_3	S_4	S_5	S_6	S_7	S_8	V_0
0	1	0	1	1	0	1	0	$6V_s$
0	1	0	0	1	0	1	1	$5V_s$
1	1	0	1	0	0	1	0	$4V_s$
1	1	0	0	0	0	1	1	$3V_s$
0	1	1	1	1	0	0	0	$2V_s$
0	0	0	1	1	1	1	0	V_s
1	1	1	1	0	0	0	0	0
0	0	0	0	1	1	1	1	0
1	1	1	0	0	0	0	1	$-V_s$
1	0	0	0	0	1	1	1	$-2V_s$
0	0	1	1	1	1	0	0	$-3V_s$
0	0	1	0	1	1	0	1	$-4V_s$
1	0	1	1	0	1	0	0	$-5V_s$
1	0	1	0	0	1	0	1	$-6V_s$

The above Table V is shows the active switches operation of eight switches with thirteen level, 1 means the switch is ON, the 0 means the switch is OFF. Then we will get the thirteen level output voltage from the eight switches only.

The seven level output voltage are get only from six switches only. The nine level, eleven level and thirteen level output voltage are get only from eight switches corresponding to respective voltage sources are taken.

The above table VI shows different voltages are taken for asymmetrical multilevel inverters. The asymmetrical multilevel inverters are simulated the output voltage are designed by using 200V. The seven level output voltage are get by using $V_1=66.66V$, $V_2=133.33V$. The nine level output voltage are get by using $V_1=50V$, $V_2=50V$, $V_3=100V$. The eleven level output voltage are get by using $V_1=40V$, $V_2=80V$, $V_3=80V$. The thirteen level output voltage are get by using $V_1=66.66V$, $V_2=99.99V$, $V_3=33.33V$. The asymmetrical multilevel inverters are simulate the above written voltage values.

The Table VIII shows the simplified five level inverter operating two modulation indexes. They are 0.7 and 0.8 without and with LC filter.

The modulating frequency (Switching frequency) is 18060Hz.

The CHB five level inverter operated with $m_a=0.7$ and $m_a=0.8$ with phase shift carrier pulse width modulation technique then I would get the fundamental component voltage increases and THD value decreases when modulation index $m_a=0.8$ compare to the $m_a=0.7$. The simplified five level inverter operated the same modulation index with phase disposition pulse width modulation technique then I would get the fundamental component voltage increases and THD value decreases compare to the CHB inverter. After clearly understand reduce the number of switches, improved output waveforms, smaller filter size and lower EMI of simplified multistring five level inverter compared to the CHB inverter.

V. CONCLUSION

This work reports a Performance analysis of symmetrical and asymmetrical multilevel inverters, so reduce the number of switching devices, reduce the number of DC sources, driving circuits and cost reduces and also THD decreases.

Multistring multilevel inverters have low stress, high conversion efficiency and can also be easily interfaced with renewable energy sources (PV, Fuel cell). Asymmetrical multilevel inverter uses least number of devices to produce higher voltage level. As number of level increases, the THD content approaches to small value as expected. Thus it eliminates the need for filter. Though, THD decreases with increase in number of levels, some lower or higher harmonic contents remain dominant in each level. These will be more dangerous in induction drives.

Hence the future work may be focused to determine the pwm techniques of seven to thirteen level asymmetrical multilevel inverters.

ABSTRACT: Magnesium nickel ferrites were synthesized by employing sol gel technique at 1473 K sintering temperature. A critical Rietveld analysis of XRD reveals that the presence of a very small amount of NiO phase along with the ferrite phase. It indicates that almost a stoichiometric (Mg,Ni)-ferrite phase has been obtained at 1473 K. SEM image shows that of (MgNi)-ferrite is regular in shape have granular in structure, compact and well connected grain to each others. The ac conductivity increases with increase in applied frequency. The magnesium nickel ferrite ($MgNiFe_2O_4$) shows σ_{ac} conductivity of 1.2×10^{-4} S/cm. This is may be attributed to the dipole polarization i.e., the rotation of dipoles between two equivalent equilibrium positions is involved. The high value of dielectric constant of the sample $MgNiFe_2O_4$ may be the structural changes associated with the magnesium nickel ferrite when the grain size is reduced. Therefore, this ferrites material is attracted to use in many science and technological applications.

Keywords: Ac conductivity, (MgNi) ferrite, dielectric constant, Impedance spectra, X-ray diffraction.

I. INTRODUCTION

Small ferrimagnetic oxides, technically known as ferrites have attracted considerable attention not only from a fundamental scientific interest but also from a practical point of view for growing applications in the magnetic, electronic and microwave fields [1-3]. Simultaneous presence of magnetic and dielectric nature of ferrites is vastly exploited in a variety of applications at different frequencies. The special feature of these materials is that the properties can be tailored over wide ranges by appropriate substitution of various ions in the chemical formula unit and control of processing procedures. Ferrites are extensively used in magnetic recording, information storage, colour imaging, bio-processing, magnetic refrigeration and in magneto optical devices [4, 5].

Ferrites also have great promise for atomic engineering of materials with functional magnetic properties. The formation of corrosion product on the out of core surfaces in pressurized heavy water reactors (PHWRs) are major problem. Ferrite having spinal structure such as magnetic and nickel etc play a major role to prevent such problem. Thus attempts are being made to study the various ferrites to evaluate the impact of substitution of the divalent metal ions to modify the properties of these oxides [6-8].

In the present study authors, report synthesis, characterization and dielectric studies of $MgNiFe_2O_4$. A critical Rietveld analysis of XRD reveals that the presence of a very small amount of NiO phase along with the ferrite

phase. It indicates that almost a stoichiometric (Mg,Ni)-ferrite phase has been obtained at 1473 K. SEM image shows that of (MgNi) ferrite is regular in shape have granular in structure, compact and well connected grain to each others. The ac conductivity increases with increase in applied frequency and dielectric constant decreases. Therefore, this ferrites material is attracted to use in many science and technological applications.

II. EXPERIMENTAL

All Chemicals used were analytical grade (AR). The magnesium chloride, nickel chloride (purity 99.99%) and dehydrated ferric chloride were procured and were used as received.

1.1 SYNTHESIS OF MAGNESIUM NICKEL FERRITE

The chloride salts of magnesium, nickel chloride and ferric chloride are mixed in calculated stoichiometric with oxalic acid in equimolar ratio so as to form nickel ferric oxalate precursor. The precursor is then filtered and dried at 323K to achieve constant weight. The precursor is mixed with polyethylene glycol (PEG) in the ratio 1:5 and is ignited. The combustion propagates throughout the precursor. After completion of combustion nickel ferrite ($MgNiFe_2O_4$) is formed. The $MgNi$ -ferrite is sonicated in acetone media for 20min and then calcinated at 1473 K to remove the impurities. Finally, fine graded nanosized nickel ferrite particles are formed [9, 10].

The pellets of 10 mm diameter are prepared with thickness varying up to 2 mm by applying pressure of 10 Tons in a UTM – 40 (40 Ton Universal testing machine). For temperature dependent conductivity and sensor studies, the pellets are coated with silver paste on either side of the surfaces to obtain better contacts.

1.2 CHARACTERIZATION

The X-ray diffraction (XRD) pattern of the $MgNiFe_2O_4$ was recorded at room temperature by employing an x-ray powder diffractometer (Rigaku Miniflex) with $CuK\alpha$ radiation ($\lambda=1.5405\text{\AA}$) in the 2θ (Bragg angles) range ($2^\circ \leq 2\theta \leq 10^\circ$) at a scan speed of $0.5^\circ \text{ minute}^{-1}$.

The percentage transmittances for the entire sample are measured from 300 to 4000 cm^{-1} . The SEM images of $MgNiFe_2O_4$ were recorded using Philips XL-30 (ESEM) scanning electron microscopy. The set up used for measuring ac conductivity is Hioki 3050 impedance analyzer, which is in turn interfaced to the computer.

III. RESULTS AND DISCUSSION

2.1 X-RAYS DIFFRACTION

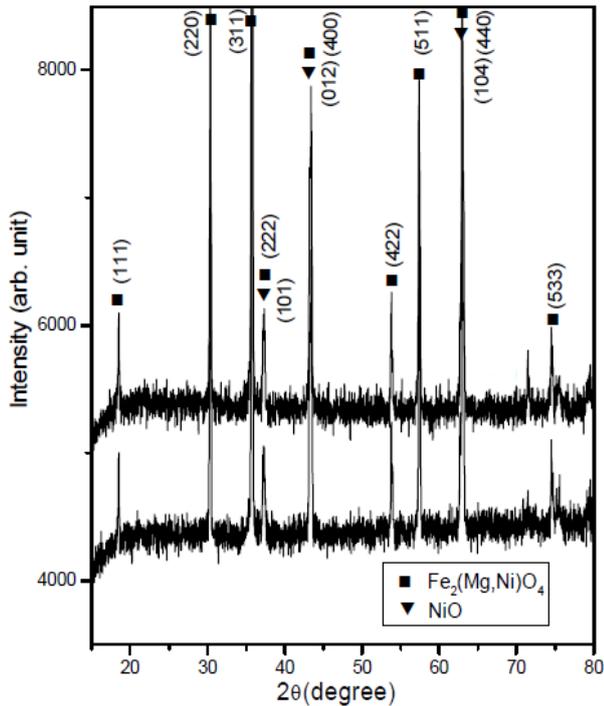

Figure 1 shows the XRD patterns of Mg,Ni)-ferrite annealed at temperature 1473 K.

It seems that the (Mg,Ni)-ferrite phase is formed completely after this heat-treatment. However, a critical rietveld analysis reveals the presence of a very small amount of NiO phase along with the ferrite phase. It indicates that almost a stoichiometric (Mg,Ni)-ferrite phase has been obtained at 1473 K. This indicates that the amount of ferrite phase formation is dependent of annealing time. By measuring particle size we actually measure the coherently diffracting zone of a grain. The particle or crystallites re separated from each other by grain boundaries and the grain boundaries are nothing but bulk crystal imperfections in a crystal [11]. The size of the crystallite in the nanometer range. As can be seen from the experiment, annealing the sample increases the size of the particles. Heat energy helps to annihilate the deformations in the crystals. As a result of grain boundaries started to vanish during annealing and the small crystallites agglomerate together to form larger particles due to intra-grain diffusion.

2.2 SCANNING ELECTRON MICROSCOPY

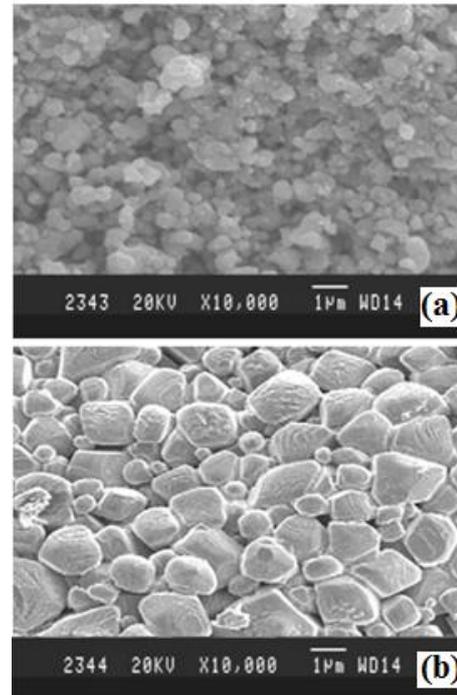

Figure 2 shows the SEM image of (a) NiO and (b) MgNi-ferrite at 1473 K.

Figure 2 (a) shows that SEM image of nickel oxide. It is clearly observed from the image they are agglomerated, highly branched and porous in nature. The average grain size was calculated by using line intercept formula and it is found to be 0.21µm.

Figure 2 (c) shows that SEM image of (MgNi) ferrite. It is found that the image is regular in shape have granular in structure, compact and well connected grain to each others. The average grain size was calculated by using line intercept formula and it is found to be 0.7µm.

2.3 AC CONDUCTIVITY

The variation of σ_{ac} of $MnNiFe_2O_4$ as a function of frequency as shown in figure 3. The conductivity of nickel ferrites is increases with increase in frequency. The magnesium nickel ferrite ($MnNiFe_2O_4$) shows σ_{ac} conductivity of 1.2×10^{-4} S/cm.

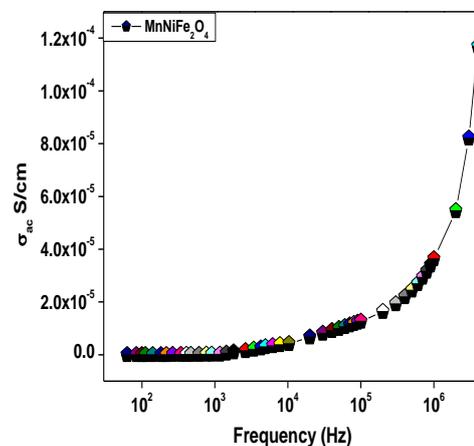

Figure 3 shows the variation of σ_{ac} of $MnNiFe_2O_4$ as a function of frequency.

This is may be attributed to the dipole polarization i.e., the rotation of dipoles between two equivalent equilibrium positions is involved. It is the spontaneous alignment of dipoles in one of the equilibrium positions that give rise to the nonlinear polarization behavior of this composition.

This behaviour of $MnNiFe_2O_4$ obeys the universal power law, $\sigma(\omega) = \sigma_0 \sigma_{dc} \sigma_{ac} \omega^{-n}$ (the solid line is the fit to the expression), where σ_0 is the dc conductivity (frequency independent plateau in the low frequency region), A is the pre-exponential factor, and n is the fractional exponent between 0 and 1 [12]. On crystallization, the conductivity spectrum remains similar as that of the nickel ferrite except dispersion in the low frequency region, where the deviation from σ_{dc} (plateau region) is more prominent. The deviation from σ_{dc} (plateau region) value in the conductivity spectrum (in the low frequency region) is due to the electrode polarization effect. The values of σ_0 , A , and n were obtained by fitting the $\sigma(\omega)$ to $\sigma(\omega) = \sigma_0 \sigma_{dc} \sigma_{ac} \omega^{-n}$. The overall behavior of σ_{ac} follows the universal dynamic response, which has widely been observed in disordered materials like ionically conducting glasses and also doped crystalline solids, and is generally believed to be reflected in the mechanism of charge transport behavior of charge carriers.

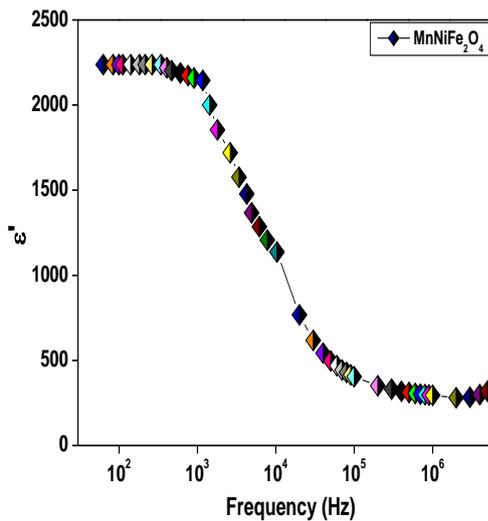

Figure 4 shows the variation real permittivity (ϵ') of nickel ferrite as a function of frequency.

Figure 4 shows the variation real permittivity (ϵ') of nickel ferrite of various composition as a function of logarithmic frequency. It is found that in all these nickel ferrite compositions, as frequency increases, dielectric constant decreases up to the frequency range of 10^5 Hz and after that it remains constant for further increasing in frequency [13]. The strong frequency dispersion of permittivity is observed in the low frequency region followed by a nearly frequency independent behaviour above 10^3 Hz. It is observed that Debye type relaxation mechanism is responsible for higher value of $MnNiFe_2O_4$.

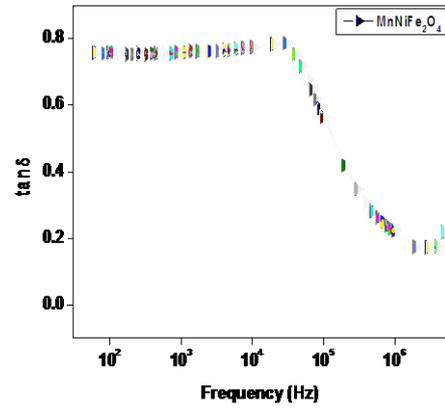

Figure 5 shows the variation of dielectric constant as a function of frequency of $MnNiFe_2O_4$

Figure 5 shows the variation of dielectric constant as a function of frequency for $MnNiFe_2O_4$. The high value of dielectric constant of the sample $MnNiFe_2O_4$ may be explained on the basis of the structural changes associated with the magnesium nickel ferrite when the grain size is reduced. Magnesium nickel ferrite crystallizes into a cubic close-packed arrangement of oxygen ions. It belongs to the class of ferrites with an inverse spinel structure having structural formula, $Fe^{3+}[Mg^{2+}Ni^{3+}]O_4$. The metal ions given in the square bracket are called octahedral (B site) ions and that outside the square bracket are called tetrahedral (A site) ions. The nickel ions (Ni^{2+}) together with half of the iron ions (Fe^{3+}) occupy the B site and the Mg^{2+} occupy the remaining half of the iron ions reside in A site. The presence of Mg^{2+} and Ni^{3+} ions gives rise to p-type carriers (holes) whereas Fe^{2+} and Fe^{3+} ions produce n-type carriers (electrons). Therefore, both electrons and holes that are present in the B sites are due to the presence of Mg and Ni ions. Since Mg ions are present in A sites, electrons are the carriers in A sites. The distance between the ions in A sites (0.357 nm) is larger than the distance between the ions in B site (0.292 nm) [14-16]. Also, the degree of covalency for the A site ions is higher than that of the B site ions. All the above factors result in a high activation energy for the A sites compared to the B sites. Hence, in ordinary magnesium nickel ferrite with an inverse spinel structure the electron movement in B sites dominates compared to that in A sites.

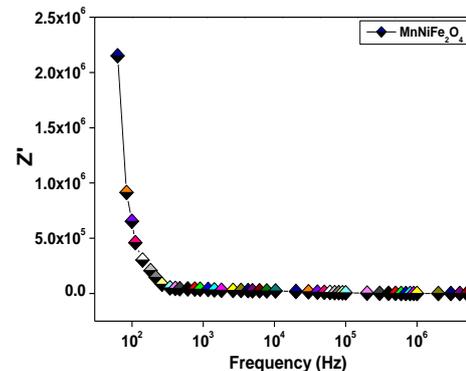

Figure 6 the variation of real part of impedance as a function of frequency

The variation of real part of impedance of MnNiFe₂O₄ is shown in figure 6 as a function of increasing frequency. It is observed that the real part of impedance decreases with increase in frequency. The initial decrease in impedance value due to the increase in conductivity at lower frequency region up to 10³ Hz and further increases in applied frequency, the impedance value remains constant. This indicates that after 10³ Hz the ferrite acts as lossless materials. Therefore, these ferrites can be used in many technological applications such as memory device, microwave, sensor, transducer, solar cell etc.

IV. CONCLUSION

Sol-gel technique was employed to prepare the magnesium nickel ferrites were at 1473 K sintering temperature. A critical Rietveld analysis of XRD reveals that the presence of a very small amount of NiO phase along with the ferrite phase. It indicates that almost a stoichiometric (Mg,Ni)-ferrite phase has been obtained at 1473 K. SEM image shows that of (MgNi) ferrite is regular in shape have granular in structure, compact and well connected grain to each others. The ac conductivity increases with increase in applied frequency. The magnesium nickel ferrite (MnNiFe₂O₄) shows σ_{ac} conductivity of 1.2×10^{-4} S/cm. This is may be attributed to the dipole polarization i.e., the rotation of dipoles between two equivalent equilibrium positions is involved. The high value of dielectric constant of the sample MnNiFe₂O₄ may be the structural changes associated with the magnesium nickel ferrite when the grain size is reduced. It is observed that the real part of impedance decreases with increase in frequency. The initial decrease in impedance value due to the increase in conductivity at lower frequency region up to 10³ Hz and further increases in applied frequency, the impedance value remains constant. Therefore, this ferrites material is attracted to use in many science and technological applications.

The Effects of Different Temperatures and Temperature Cycling on Breakdown Voltages of Tantalum Capacitors

Johanna Virkki

Department of Electronics/Tampere University of Technology, Finland

ABSTRACT: *This study focuses on the effects of different temperatures and temperature cycling on breakdown voltages of tantalum capacitors. High and low temperature tests and temperature cycling tests were done. In all tests the used temperatures were inside component's operating temperature limits. After the tests, capacitors were tested for their breakdown voltage. According to results of this research, high or low temperature testing inside component's operating temperature limits does not have an effect on the breakdown voltage of tantalum capacitors. However, temperature cycling inside component's operating temperature limits can lower the breakdown voltage of tantalum capacitors.*

Keywords: *accelerated testing, reliability, tantalum capacitors, temperature, temperature cycling*

I. INTRODUCTION

In today's competitive market, it is important for a company to know the reliability of its products and to be able to control it for continued production at optimum reliability. Sometimes there is a need to examine the performance of a specific electronic component: it may be radically redesigned, or there may be an individual reliability specification for that component. That is why reliability testing of components has become a concern for electronics manufacturers. Also, in many cases, component-level reliability testing is undertaken to begin characterizing a product's reliability when full system-level test units are unavailable.

Electronic components are often stored and used at high or low temperatures, and sometimes temperature can change radically during component's lifetime. Temperature and temperature changes can have various, often unpredictable effects on components. Reliability tests seek to simulate the component's use environment in order to find the effects of environmental stresses. Because such testing is very time-consuming, accelerated testing becomes necessary. Accelerated testing is a procedure in which conditions are intensified to cut down the time required to obtain a weakening effect similar to one encountered in normal service conditions [1].

High Temperature Storage Life (HTSL), JESD22-A103C, and Low Temperature Storage Life (LTSL), JESD22-A119, tests "are applicable for evaluation, screening, monitoring, and/or qualification of all solid state devices and typically used to determine the effect of time and temperature, under storage conditions, for thermally activated failure mechanisms of solid state electronic

devices [2, 3].“ The standard HTSL test is run for 1000 hours (42 days) and the standard LTSL test for 168 hours (7 days) [2, 3]. During the tests, increased/reduced temperatures (test conditions) are used without electrical stress.

Temperature cycling, according to the standard JESD22-A104D, "is conducted to determine the ability of components and solder interconnects to withstand mechanical stresses induced by alternating high- and low-temperature extremes. Permanent changes in electrical and/or physical characteristics can result from these mechanical stresses [4]." This standard test includes numerous temperature cycling conditions. The test usually lasts 500 or 1000 cycles.

These standard accelerated tests are commonly used for testing reliability of electronics and were used in this research. The object of this research was to test the effects of low temperature, high temperature, and the effects of temperature cycling on tantalum capacitors.

II. TANTALUM CAPACITORS

Surface mount solid tantalum capacitors (henceforth referred to as "tantalum capacitors", shown in Fig. 1) of a maximum voltage of 50V, a capacitance of 10 μ F, and an operating and non-operating temperature of -55 $^{\circ}$ C to 125 $^{\circ}$ C were used in this research. The structure of these capacitors is presented more detailed in Fig 2.

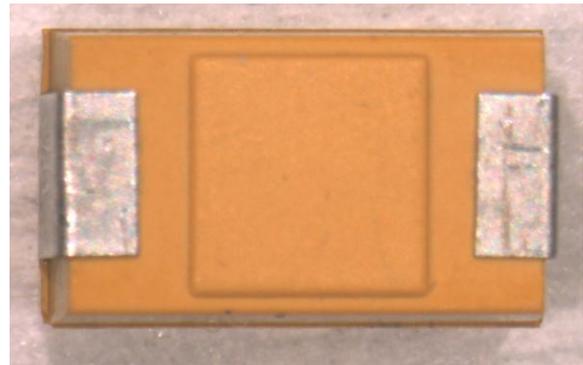

Figure 1. Bottom side of a surface mount tantalum capacitor used in this research.

A. Structure of tantalum capacitors

A tantalum capacitor (structure shown in Fig. 2) consists of three main elements: anode, cathode, and a dielectric layer of tantalum pentoxide that separates them. The capacitor contains an embedded tantalum pellet (anode), surrounded by a tantalum pentoxide, amorphous dielectric layer. The

cathode is a semiconductor, manganese dioxide. This pellet is coated with carbon and then with silver to provide the final connecting layer to the cathode terminal. The tantalum wire passes through these layers and connects the positive termination to the tantalum pellet. The negative termination of the capacitor is attached with a silver adhesive to the silver paint layer. Next sections focus on possible failure mechanisms caused by temperature and changes in it.

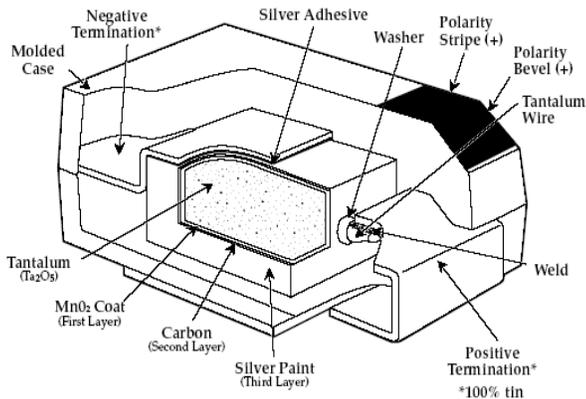

Figure 2. Structure of a tantalum capacitor [5].

B. Effects of temperature and temperature cycling on tantalum capacitors

Temperature, whether generated externally or internally, degrades the performance and reliability of tantalum capacitors. The use of tantalum capacitors at high temperatures has been studied, and manufacturing tantalum capacitors for high-temperature applications is found to be challenging [6, 7]. Mechanical stresses related to the temperature changes during reflow-manufacturing and use of surface mount tantalum capacitors at high temperatures affect their performance and reliability and can account for their breakdowns. Due to mismatch of the coefficients of thermal expansion between the constituent materials, significant mechanical stresses develop in the bulk of materials and at the interfaces. During heating, shear forces are exerted on the anode wire. The molded case pushes on the lead frame in one direction and the pellet in another, generating forces that pull the wire away from the anode structure. Once the device has passed through high temperatures and its elements are shrinking while cooling, they may not fit together as they did before the expansion. Compressive forces may appear on the pellet structure and produce fractures. In addition, these stresses may cause cracking in the tantalum pentoxide dielectric and/or delaminations at the interfaces, resulting in different failure modes of the components. A crack in the dielectric at a corner or edge, when exposed to high stress, may lead to failure [9-11]. The cracking increases leakage current, decreases breakdown voltage, and may cause short-circuits. On the other hand, delaminations can raise the effective series resistance and thus increase power dissipation and temperature of the capacitor, which can decrease its reliability. Severe delaminations may result in intermittent contacts and open-circuit failures of the components [11].

Temperature has also a specific effect inside a tantalum capacitor, known as crystal growth [12-14]. The tantalum pentoxide dielectric is considered an amorphous material. An amorphous state tends to order and crystallize to reduce its internal energy. Surface impurities can induce direct growth of tantalum pentoxide crystals and any imperfection in the dielectric structure is a potential site for crystals to grow. Once the dielectric crystallizes, conductivity and leakage current increase. The presence of impurities is not the only mechanism that may lead to a growth of crystals; Crystal growth can also be initiated in small areas of crystalline order in the dielectric. The conductivity of the crystallized structure has been reported to be higher than that of a dielectric in an amorphous state [14]. However, the latest findings suggest that the crystals themselves are good insulators with very limited conductivity [12, 13]. The exact conductivity mechanism related to the crystal phase is not yet fully understood. The increase in leakage current may still be caused by other mechanisms accelerated by the crystal growth. However, studies show that field crystallization may have only a limited impact on the end use of tantalum capacitors [12].

The temperature cycling of tantalum capacitors has been studied before [11, 15] with capacitors subjected to temperature cycling in a range from -40°C to 85°C [15], -65°C to 125°C , and -65°C to 150°C [11]. Results indicate that tantalum capacitors are capable of withstanding up to 500 cycles of temperature ranging from -65°C to 150°C . However, different lots show different robustness under cycling conditions, and though parts may not fail formally by exceeding specified limits, a significant degradation in the leakage current and breakdown voltages indicates an increased propensity of some lots to failure after temperature cycling. Cracking in the tantalum pentoxide dielectric, which develops during temperature cycling, results not only in increased leakage current, but also increases the probability of scintillation breakdowns [11]. The results suggested that a harmful temperature cycling effect can be achieved in a much shorter time than in 500 cycles [15].

III. RELIABILITY TESTING

Testing was divided into five tests, hereafter called Tests A, B, C, D, and E. Test A was a low temperature test in -40°C temperature and lasted for 168h. Tests B and C were high temperature tests, Test B was done in 85°C and Test C was done in 125°C . Both tests lasted for 1000h. Tests D and E were temperature cycling tests. Both tests lasted for 500 cycles and one cycle lasted for 0.5h. In test D, the temperature changed between -40°C and 85°C and in Test E, temperature changed between -40°C and 125°C . In all tests, 18 capacitors were tested. Because the capacitors were rated for an operating and non-operating temperature of -55°C to 125°C , they were tested here within their operating limits. This was done in order to get information on their usability in such field conditions and to compare the effects of different temperatures and temperature

voltages. More testing work needs be done in order to collect statistical data for conclusions. Such results would be useful in addition to these results, where conclusions are mostly done based on literature review.

An Algorithm for Image Compression Using 2D Wavelet Transform

Mr. B. H. Deokate¹, Dr. P. M. Patil²

Shri Jagdishprasad Jhabarmal Tibrewala University (JJTU)

Abstract: Wavelet Transform has been successfully applied in different fields, ranging from pure mathematics to applied sciences. Numerous studies carried out on Wavelet Transform have proven its advantages in image processing and data compression. Recent progress has made it the basic encoding technique in data compression standards. Pure software implementations of the Discrete Wavelet Transform, however, appear to be the performance bottleneck in real-time systems. Therefore, hardware acceleration of the Discrete Wavelet Transform has become a topic of interest. The goal of this paper is to investigate the feasibility of hardware acceleration of Discrete Wavelet Transform for image compression applications, and to compare the performance improvement against the software implementation. In this paper, a design for efficient hardware acceleration of the Discrete Wavelet Transform is proposed. The hardware is designed to be integrated as an extension to custom-computing platform and can be used to accelerate multimedia applications as JPEG2000.

Keywords: Wavelet transforms, Image compression, Haar wavelet.

I. INTRODUCTION

A majority of today's Internet bandwidth is estimated to be used for images and video [4]. Recent multimedia applications for handheld and portable devices place a limit on the available wireless bandwidth. The bandwidth is limited even with new connection standards. JPEG image compression that is in widespread use today took several years for it to be perfected. Wavelet based techniques such as JPEG2000 for image compression has a lot more to offer than conventional methods in terms of compression ratio. Currently wavelet implementations are still under development lifecycle and are being perfected. Flexible energy-efficient hardware implementations that can handle multimedia functions such as image processing, coding and decoding are critical, especially in hand-held portable multimedia wireless devices.

II. BACKGROUND

Computer data compression is, of course, a powerful, enabling technology that plays a vital role in the information age. Among the various types of data commonly transferred over networks, image and video data comprises the bulk of the bit traffic. For example, current estimates indicate that image data take up over 40% of the volume on the Internet. [4] The explosive growth in demand for image and video data, coupled with delivery bottlenecks has kept compression technology at a premium. Among the several 1 compression standards available, the JPEG image compression standard is in wide spread use today. JPEG

uses the Discrete Cosine Transform (DCT) as the transform, applied to 8-by-8 blocks of image data. The newer standard JPEG2000 is based on the Wavelet Transform (WT). Wavelet Transform offers multi-resolution image analysis, which appears to be well matched to the low level characteristic of human vision. The DCT is essentially unique but WT has many possible realizations. Wavelets provide us with a basis more suitable for representing images. This is because it can represent information at a variety of scales, with local contrast changes, as well as larger scale structures and thus is a better fit for image data. Field programmable gate arrays (FPGAs) provide a rapid prototyping platform. FPGAs are devices that can be reprogrammed to achieve different functionalities without incurring the non-recurring engineering costs typically associated with custom IC fabrication. In this work, DWT architecture is implemented on a reconfigurable FPGA hardware. The target platform is the Xilinx Virtex FPGA. The design is based on the multi-level decomposition implementation of the Discrete Wavelet Transform. The design utilizes various techniques and specific features of the Xilinx Virtex XSV FPGA to accelerate the computation of the transform. Performance analysis includes the investigation of the performance enhancement due to the hardware acceleration. It is expected that the proposed design can substantially accelerate the DWT and the inherent scalability can be exploited to reach a higher performance in the future. The implementation can be easily modified to act as a co-processing environment for wavelet compression/decompression or even as a part of the algorithms to be used in future mobile devices for image encoding/decoding using wavelets. One drawback of the FPGA, however, is that due to the rather coarse grained reconfigurable blocks, an implementation on an FPGA is often not as efficient, in terms of space and time, as on a custom IC.

III. WAVELET TRANSFORM BASED IMAGE COMPRESSION

III.1 Introduction

Image compression is different from binary data compression. When binary data compression techniques are applied to images, the results are not optimal. In lossless compression, the data (such as executables, documents, etc.) are compressed such that when decompressed, it gives an exact replica of the original data. They need to be exactly reproduced when decompressed. For example, the popular PC utilities like Winzip or and Adobe Acrobat perform lossless compression. On the other hand, images need not be reproduced exactly. A 'good' approximation of the original image is enough for most purposes, as long as the error between the original and the compressed image is

tolerable. Lossy compression techniques can be used in this application. This is because images have certain statistical properties, which can be exploited by encoders specifically designed for them. Also, some of the finer details in the image can be sacrificed for the sake of saving bandwidth or storage space. In digital images the neighboring pixels are correlated and therefore contain redundant information. Before the image is compressed, the pixels, which are correlated is to be found. The fundamental components of compression are redundancy and irrelevancy reduction. Redundancy means duplication and irrelevancy means the parts of signal that will not be noticed by the signal receiver, which is the Human Visual System (HVS). There are three types of redundancy that can be identified:

Spatial Redundancy is the correlation between neighboring pixel values.

Spectral Redundancy is the correlation between different color planes or spectral bands.

Temporal Redundancy is the correlation between adjacent frames in a sequence of images (in video applications). Image compression focuses on reducing the number of bits needed to represent an image by removing the spatial and spectral redundancies. Since our work focuses on still image compression, therefore temporal redundancy is not discussed.

III.2 Principles of Image Compression

A typical lossy image compression scheme is shown in Figure 3.2.1. The system consists of three main components, namely, the source encoder, the quantizer, and the entropy encoder. The input signal (image) has a lot of redundancies that needs to be removed to achieve compression. These redundancies are not obvious in the time domain. Therefore, some kind of transform such as discrete cosine, fourier, or wavelet transform is applied to the input signal to bring the signal to the spectral domain. The spectral domain output from the transformer is quantized using some quantizing scheme. The signal then undergoes entropy encoding to generate the compressed signal. The wavelet transform mainly applies on the source encoder component portion.

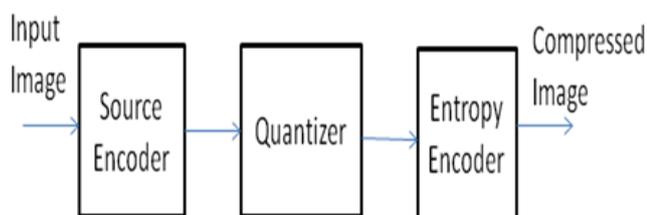

Figure 3.2.1 Image compression scheme

Source Encoder

An encoder is the first major component of image compression system. A variety of linear transforms are available such as Discrete Fourier Transform (DFT), Discrete Cosine Transform (DCT), and Discrete Wavelet Transform (DWT). The Discrete Wavelet Transform is main focus of my work.

Quantizer

A quantizer reduces the precision of the values generated from the encoder and therefore reduces the number of bits required to save the transform co-coefficients. This process is lossy and quantization can be performed on each individual coefficient. This is known as Scalar Quantization (SQ). If it is performed on a group of coefficients together then it is called Vector Quantization (VQ).

Entropy Encoder

An entropy encoder does further compression on the quantized values. This is done to achieve even better overall compression. The various commonly used entropy encoders are the Huffman encoder, arithmetic encoder, and simple run-length encoder. For improved performance with the compression technique, it's important to have the best of all the three components.

III.4 JPEG 2000

JPEG 2000 is a wavelet-based image compression standard created by the Joint Photographic Expert Group (JPEG) committee in 2000 with the aim of replacing the original discrete cosine transform-based JPEG. This part specifies the core and minimal functionality and is known as JPEG2000 codec.[5]

The main advantages of JPEG2000 against the classical JPEG are:

- Superior compression performance: specially at low bitrate (e.g. less than 0.25 bits/pixel).
- Multiple resolution representation.
- Progressive transmission: after a smaller part of the whole file has been received, the viewer can see a lower quality version of the final picture.
- Lossless and lossy compression.
- Random codestream access and processing: different grades of compression could be given to some Regions of Interest (ROI) of the image.
- Error resilience: small independent block avoid error propagation.

The JPEG2000 algorithm flow shown in Figure 3.4.1 reveals the first and simple stages: The whole raw image in divided in the three Red-Green-Blue (RGB) components. Each component is divided in equal smaller pieces called tiles, which are coded independently. The RGB components are transformed in YUV model that requires less memory. The last stages: Discrete Wavelet Transform (DWT) and T1 Entropy Encoding.

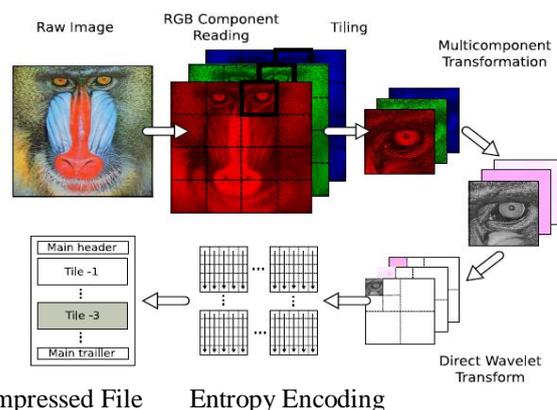

Figure 3.4.1 JPEG 2000 algorithm flow.

IV. WAVELET TRANSFORM AS THE SOURCE ENCODER

Just as in any other image compression schemes the wavelet method for image compression also follows the same procedure. The discrete wavelet transform constitutes the function of the source encoder. The theory behind wavelet transform is discussed below.

IV.1 Measuring Frequency Content by Wavelet Transform

Wavelet transform is capable of providing the time and frequency information simultaneously. Hence it gives a time-frequency representation of the signal. When we are interested in knowing what spectral component exists at any given instant of time, we want to know the particular spectral component at that instant. In these cases it may be very beneficial to know the time intervals these particular spectral components occur. Wavelets are functions defined over a finite interval and having an average value of zero. The basic idea of the wavelet transform is to represent any arbitrary function $f(t)$ as a superposition of a set of such wavelets or basis functions. These basis functions are obtained from a single wave, by dilations or contractions (scaling) and translations (shifts). The discrete wavelet transform of a finite length signal $x(n)$ having N components, for example, is expressed by an $N \times N$ matrix similar to the discrete cosine transform .

V. WAVELET-BASED COMPRESSION

Digital image is represented as a two-dimensional array of coefficients, each coefficient representing the brightness level in that point. We can differentiate between coefficients as more important ones, and lesser important ones. Most natural images have smooth color variations, with the fine details being represented as sharp edges in between the smooth variations. Technically, the smooth variations in color can be termed as low frequency variations, and the sharp variations as high frequency variations.

The low frequency components constitute the base of an image, and the high frequency components add upon them to refine the image, thereby giving a detailed image. Hence, the smooth variations are more important than the details. Separating the smooth variations and details of the image can be performed in many ways. One way is the decomposition of the image using the discrete wavelet transform. Digital image compression is based on the ideas of discrete wavelet transforms. Wavelets which refer to a set of basis functions are defined recursively from a set of scaling coefficients and scaling functions. The DWT is defined using these scaling functions and can be used to analyze digital images with superior performance than classical short-time Fourier-based techniques, such as the DCT. The basic difference between wavelet-based and Fourier-based techniques is that short-time Fourier-based techniques use a fixed analysis window, while wavelet-based techniques can be considered using a short window at high spatial frequency data and a long window at low spatial frequency data. This makes DWT more accurate in analyzing image signals at different spatial frequency, and thus can represent more precisely both smooth and dynamic regions in image. The compression system includes forward wavelet transform, a quantizer, and

a lossless entropy encoder. The corresponding decompressed image is formed by the lossless entropy decoder, a de-quantizer, and an inverse wavelet transform.

V.1 Wavelet Decomposition

There are several ways wavelet transforms can decompose a signal into various sub bands. These include uniform decomposition, octave-band decomposition, and adaptive or wavelet-packet decomposition. Out of these, octave-band decomposition is the most widely used.

The procedure is as follows: wavelet has two functions “wavelet” and “scaling function”. They are such that there are half the frequencies between them. They act like a low pass filter and a high pass filter. The decomposition of the signal into different frequency bands is simply obtained by successive high pass and low pass filtering of the time domain signal. This filter pair is called the analysis filter pair. First, the low pass filter is applied for each row of data, thereby getting the low frequency components of the row. But since the low pass filter is a half band filter, the output data contains frequencies only in the first half of the original frequency range. By Shannon's Sampling Theorem, they can be sub-sampled by two, so that the output data now contains only half the original number of samples. Now, the high pass filter is applied for the same row of data, and similarly the high pass components are separated.

This is a non-uniform band splitting method that decomposes the lower frequency part into narrower bands and the high-pass output at each level is left without any further decomposition. This procedure is done for all rows. Next, the filtering is done for each column of the intermediate data. The resulting two-dimensional array of coefficients contains four bands of data, each labeled as LL (low-low), HL (high-low), LH (low-high) and HH (high-high). The LL band can be decomposed once again in the same manner, thereby producing even more sub bands. This can be done up to any level, thereby resulting in a pyramidal decomposition as shown in figure 5.1.1

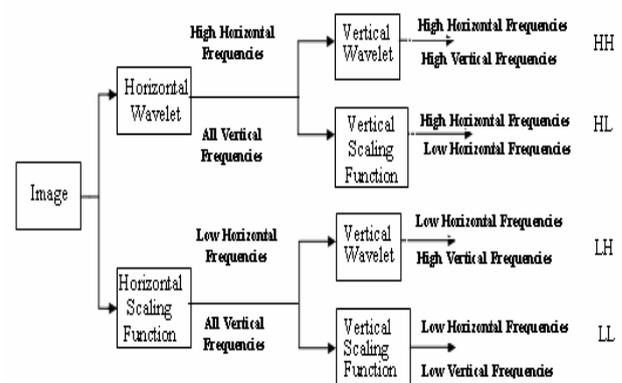

Figure 5.1.1 Pyramidal Decomposition of an image

V.2 Haar Wavelet Transform

The first DWT was invented by the Hungarian mathematician Alfréd Haar. For an input represented by a list of $2n$ numbers, the Haar wavelet transform may be considered to simply pair up input values, storing the difference and passing the sum. This process is repeated recursively, pairing up the sums to provide the next scale: finally resulting in $2n - 1$ differences and one final sum (The Haar scaling function) Let be defined by

$$\emptyset : R \rightarrow R$$

Define as

$$\emptyset(t) = \begin{cases} 1 & t \in [0,1) \\ 0 & t \in [1,2) \end{cases} \quad (1)$$

$$\emptyset_i^j : R \rightarrow R$$

$$\emptyset_i^j(t) = \sqrt{2^j} \emptyset(2^j t - i) \quad j=0,1,\dots \quad (2)$$

$i=0,1,\dots, 2^j - 1$

Defines the vector space

$$V^j = sp \{ \emptyset_i^j \} \quad i = 0, \dots, 2^j - 1$$

For encoding the transform image used various type. For example Huffman coding, EZW coding, Run length encoding, thresholding technique is also used for encoding. In this scheme i used soft & hard thresholding technique

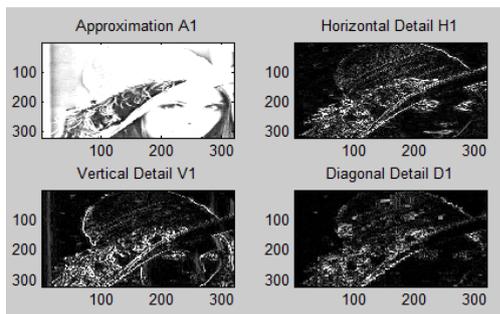

VI. EXPERIMENTAL RESULT

Original image of Lena of size 320 x 320 pixel which is compressed by using Harr wavelet & thresholding technique. By developing a code in Matlab for compression of image using wavelet transform results are shown in following figure.

VII. CONCLUSION

This paper introduced the basic wavelet theory used for wavelet transform based image compression. Wavelet based image compression is ideal for adaptive compression since it is inherently a multi-resolution scheme. Variable levels of compression can be easily achieved. The number of waveletting stages can be varied, resulting in different number of sub bands. Different filter banks with different characteristics can be used. Efficient fast algorithm for the computation of discrete wavelet coefficients makes a wavelet transform based encoder computationally efficient. BY using this method the compression ratio is 23.60% and this will be increase more using different entropy encoding technique.

ABSTRACT: In this paper, vehicle terminal system is proposed to realize continuous monitoring and tracking the location of cargos or goods loaded on board for digital logistics. The embedded design of the terminal system is combines both the RFID with GPS technologies. The ultra-low power 16-bit RISC microcontroller is used as the central control unit considering both small size and high efficiency. The vehicle terminal system can give the automatic identification of cargos loaded, the real-time vehicle location, the data and voice communication, and continuous monitoring. The results specify that the combination of RFID and GPS can provide the reliability of the system, which further improve the accuracy and efficiency of digital logistics management.

Keywords: digital Logistics; vehicular communications; RFID; GPS; vehicle terminal system

I. INTRODUCTION

In recent years, the RFID (Radio Frequency Identification) technology is known for real-time identification and tracking. Because of its accurate and fast identification, RFID is used extensively to improve the logistics management, supply chain operation and asset tracking. The GPS (Global Positioning System) is the most popular technology to acquire the position information in outdoor environments. Always GPS is used for tracking of vehicles over a wide geographic area. With simultaneous data received from four satellites and ideal conditions and minimal Ionosphere, users can calculate an object's location including mainly latitude, longitude, and altitude. The powerful combination of information and intelligent technologies will advance the supply chain monitoring and management capabilities from the origin to final destination. There have been some related works that are focused on the integration of RFID and GPS in certain fields. A hybrid RFID-GPS system was explored and tested in, which allowed for the real-time location of human resources both indoors and outdoors. In, an embedded pedestrian navigation system comprising a self-contained sensor, the GPS and an active RFID tag system was presented, and a method of complementary compensation algorithm for the GPS/RFID localization was proposed. From we find a new integrated solution, which makes the cargos and container monitored and located through moving RFID and GPS equipment. Using both RFID and DGPS technique, solved the limitations of existing yield mapping systems for manual fresh fruit harvesting, which was also tested in the field. In a

stray prevention system that integrated RFID, GPS, GSM, and GIS technologies was constructed for elderly patients without interfering their activities of daily livings. In mobile supply chain management, it is also very necessary to propose an advanced, flexible, intelligent and ultra-low-power vehicle terminal system to ensure logistics goods and transport vehicles against damage, loss or theft. Cooperating with the remote monitoring centre, the mobile vehicles and cargos loaded can be localized quickly, which will improve management visibility and centralized control energetically. The main components of the terminal system are composed of the ultra-low power 16-bit MCU LPC 2148, the acquisition unit of RFID tags information, the receiver module of GPS information, the GSM wireless communication module, and the temperature sensor. The RFID-GPS-based tracking vehicle terminal system can provide identify, monitor, track, localize and manage key mobile supply chain assets, even though in the hard environmental conditions. Moreover, the system can perform real-time stock checks, locate missing stock soon, position drivers quickly and protect drivers from danger in case of emergency. Experimental results show that the vehicle terminal device can distinguish correctly RFID tags and receive accurately GPS information. The RFID tags information and the GPS data can be processed in time. The processing results can be transmitted to the logistics monitoring center via the GSM mobile networks. The performances indicate that the system can improve the real-time management of movable supply chains. The organization of this paper is as follows. Section II depicts an overall framework of the vehicle terminal system. In section III, the system architecture and prototype design are presented. Section IV describes the prototype system test and evaluation. Finally, conclusive remarks are made in Section V.

II. OVERVIEW OF THE SYSTEM FRAMEWORK

II.1 System Description

During logistics management, one of the constant challenges is to ensure the celerity, accuracy, security and safety of consignment. When cargos or goods are loaded in vehicles, Transport Company should know immediately a detailed product description, which will act as the identification information of different cargos or goods. During the transportation, the logistics management center need to know whether the products are security and safety, whether the

products are damaged or stolen, and what is the real-time geographic position of the vehicle. When the vehicle arrives at the destination, transport company should know how many and what kind of products should be unloaded. Thus the logistics management center has to monitor more closely the supply chain using the real-time automatic visibility afforded by expert and advanced technologies such as RFID and GPS. RFID technology is stable and evolving, and it cannot be easily replicated. Therefore, RFID is becoming increasingly available in variety of fields, including manufacture, transportation, warehousing, distribution, retail, healthcare, and security. RFID systems play a key role in managing updates of stocks, transportation and logistics of the product, which enables counterfeit identification, parcel tracking, shipment monitoring and tracing, access controlling, and so on. A typical RFID system consists of a reader, tags, antennas and a connection to database management system. The reader can receive the information (a unique ID) of tags in the available range of the reader. Using the merit of accurate and fast identification and tag reading from a greater distance, all kinds of related messages can be received by the RFID reader when the tagged products are loaded or unloaded. Hence RFID can improve movable asset management accuracy and efficiency. GPS technology has provided major breakthroughs in transportation fleet management (vehicle tracking, speed, waiting time, etc.). Through GPS, the object position coordinates and the time of the determination, which is related to a value referred to as clock bias, can be obtained by picking up signals from four satellites and measure the time. So GPS is used extensively to trace, locate and navigate. Considering the advantages of RFID and GPS, we proposed to design and develop a hybrid RFID/GPS vehicle terminal system for mobile supply chain assets tracking and monitoring.

II.2 Overall System Framework

To solve accurate consignment and realize real-time monitoring service in the transport management, the overall framework of the digital logistics management system can be proposed as figure 1. Working in coordination, the system can implement corresponding function to track goods and vehicle movement in real time. Once the position and the product ID information are captured through GPS and RFID, the vehicle terminal can send the messages to the logistics monitoring center through GSM/GPRS base stations.

The system operating procedures consist of three basic stages. Firstly, when the products leave the warehouse and are handed over to transport company, the product identification data can be found by the RFID reader. Meanwhile, the product's departure and arrival information can be automatically registered as well. The transporting information of goods is sent to transport company momentarily. Then, the GPS module achieves the message (latitude, longitude, and altitude) of vehicle position; RFID reader detects whether a product data is changed. Both the product information and the combined GPS position information are sent in real time. Once the information is

inconsistent with the present manifest, the vehicle terminal system raises the alarm to ask for help towards the logistics monitoring center. Finally, when the vehicle gets to the destination and the goods are unloaded, the information database is updated immediately.

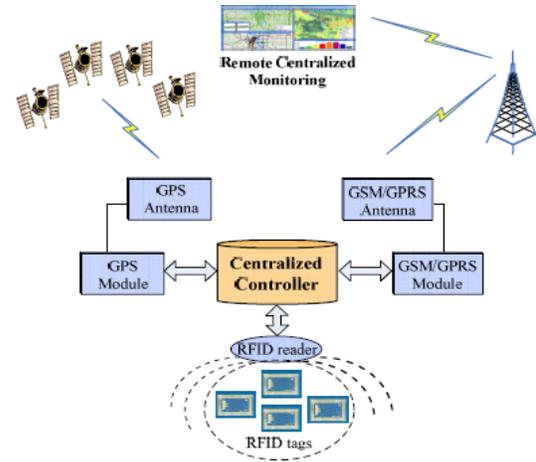

Figure 1. The overall system framework.

III. System Structure and Prototype Design

III.1 Analysis of hardware Structure

The hardware structure of the vehicle terminal system is depicted as Fig. 2. The main components are described as follows.

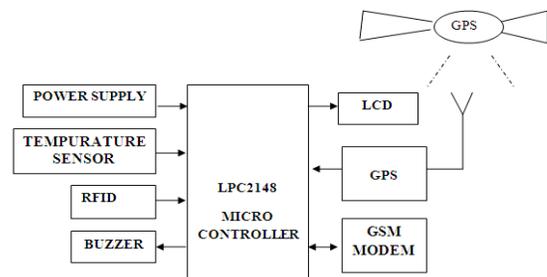

Figure 2. Block diagram of the vehicle terminal system.

III.1.1 Micro controller: The LPC2148 micro controller is based on a 32-bit/16-bit ARM7TDMI-S CPU with real-time emulation and embedded trace support, that combine microcontroller with embedded high speed flash memory ranging from 32 kB to 512 kB. A 128-bit wide memory interface and unique accelerator architecture enable 32-bit code execution at the maximum clock rate. For critical code size applications, the alternative 16-bit Thumb mode reduces code by more than 30% with minimal performance penalty. Due to their tiny size and low power consumption, LPC2146/48 are ideal for applications where miniaturization is a key requirement, such as access control and point-of-sale. Serial communications interfaces ranging from a USB 2.0 Full-speed device, multiple UARTs, SPI, SSP to I2C-bus and on-chip SRAM of 8 kB up to 40 kB, make these devices very well suited for communication gateways and protocol converters, soft modems, voice recognition and low end imaging, providing both large buffer size and high

processing power. Various 32-bit timers, single or dual 10-bit ADC(s), 10-bit DAC, PWM channels and 45 fast GPIO lines with up to nine edge or level sensitive external interrupt pins make these microcontrollers suitable for industrial control and medical systems.

III.1.2 RFID reader Module: This is used to automatically identify the products tagged within the communication range of the reader, which will be able to provide the accurate consignments and real-time automatically manifest, and improve movable asset management accuracy and efficiency.

III.1.3 GPS Module: It is used to provide satellite localization information to trace and locate the vehicle of transportation, such as WGS84 coordinates (latitude, longitude and altitude), time, speed, and direction.

III.1.4 GSM Module: It provides a communication channel to transmit product tag messages, geography location messages or emergency rescue messages, and receives commands from the transport company or the remote monitor center.

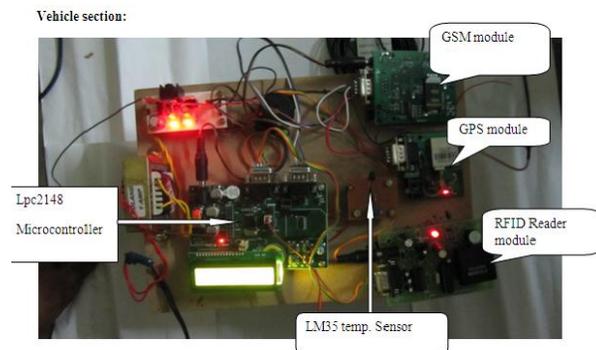

Figure 3. Prototype of the vehicle terminal system.

III.2 Building the Prototype System

As is depicted in Fig. 3, the vehicle terminal prototype system consists of a low-power microcontroller, a RFID reader, GPS module, a GSM module, power management, and other interface circuits. The LPC 2148 micro controller is chosen as the centralized control unit due to its ultra-low power.

The MCU power consumption of active mode is $280\mu\text{A}$ and only $1.6\mu\text{A}$ in standby mode. The RFID reader of the vehicle terminal is performed by a TI TRF7960 13.56MHz RFID reader, which supports the ISO 14443A/B, ISO 15693, ISO 18000-3 standards, and TI's Tag-It RFID protocol. The GPS and GSM functions of the vehicle terminals are performed by a FALCOM JP7-T GPS receiver module and a Siemens TC35-i GSM module. JP7-T is a standard receiver using the L1 band and C/A coding by stand alone positioning with 12 channels, 10m position accuracy, 0.1m/s velocity accuracy and its power consumption is 200mW in continues mode. Working in coordination, the vehicle terminal system provides the ability to capture and trace supply chain assets movement in real time. The system supports combined RFID

and GPS message reporting. We can also create custom rules associated with products or vehicles passing into or out of the zone that may trigger further actions or messages.

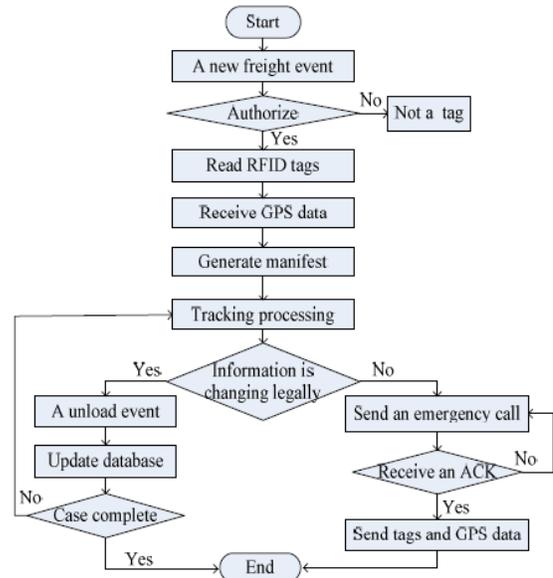

Figure 4. The operation flow of the vehicle terminal system.

III.3 System operation flow

The vehicle terminal system operation flow is depicted as Fig.4. Once a new freight event occurs, the RFID reader will continuously read RFID tags. Then the data combined with GPS position are sent to the remote monitor center for further processing through GSM communication module. Meanwhile a real-time automatic manifest is generated, including data from RFID tags with a unique ID which describes a tagged product's manufacturer, type, and serial number. When a legal unload event happens, related database will be updated. If a transportation case is completed, the system will enter standby mode and wait for a next freight event.

Whenever an abnormal situation happens, the vehicle Terminal system will immediately send out a message Containing the product's status and GPS information to the remote monitor center. After the monitor center receives the data packet, it will manage or convert the longitude and latitude coordinates, and combine this location with other basic information such as product characteristics, type, material, shape and size to generate the complete information needed for search and assistance tasks.

IV. EXPERIMENTS AND RELATED RESULTS

We have conducted related experiments and evaluations in a simulation transportation scene. The vehicle terminal system was mounted at an automobile carrier. Each product has a fixed RFID tag working at 13.56MHz band, which supports ISO15693 protocol and provides 9600bps communication link. When the products tagged enter the operational zone of the RFID reader, each of unique ID is acquired. Meanwhile,

the reader can get the detected time of the product tagged. One of the experiment results is shown in Fig. 5.

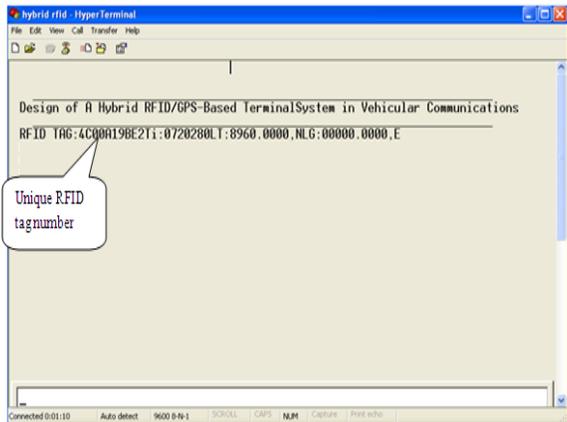

Figure 5. RFID Testing Experiment.

During the experiment run, the GPS module receives the longitude, latitude values which will give the real-time location message from different satellites shown in figure 6.

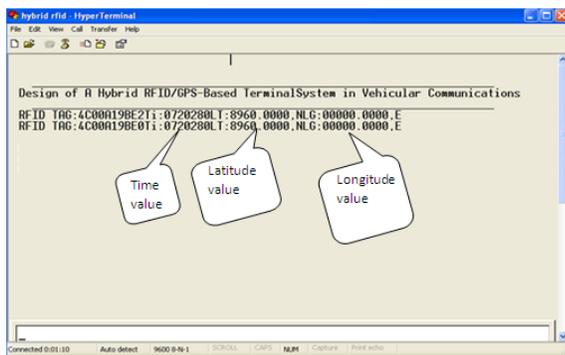

Figure 6. Locating the longitude & latitude values.

Fig.7 shows that when the temperature exceeds more than 50°C then the message “fire accident occurred” is sent to the control section.

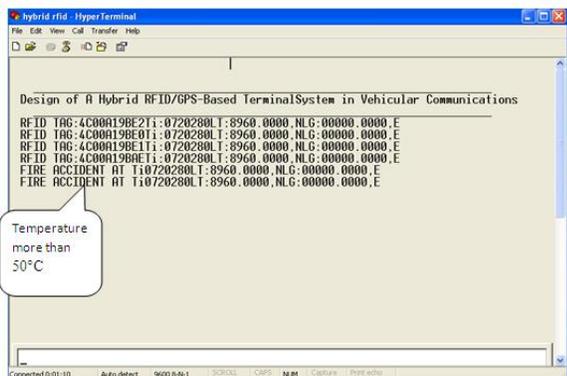

Figure 7. The message when temperature more than 50°C.

V. CONCLUSIONS

A new solution that integrates RFID identifying and GPS tracking is proposed and implemented, which can enhance automatic management, information security, real-time trace and location, and anti-theft in digital logistics management. Experimental results show that the vehicle terminal system can identify quickly mobile supply chain assets, trace and locate mobile equipment in real time, reduce loss and theft and enhance management control as well. Soon the system will be further improved through the integration with GIS technology, which will enhance the visibility of the supply chain. It is conceivable that this research will bring more efficient and intelligent logistic transportation.

ABSTRACT: The dynamic voltage restorer (DVR) is one of the modern devices used in distribution systems to protect consumers against sudden changes in voltage amplitude. In this paper, emergency control in distribution systems is discussed by using the proposed multifunctional DVR control strategy. Also, the multi loop controller using the Posicast and P+Resonant controllers is proposed in order to improve the transient response and eliminate the steady-state error in DVR response, respectively. The proposed algorithm is applied to some disturbances in load voltage caused by induction motors starting, and a three-phase short circuit fault. Also, the capability of the proposed DVR has been tested to limit the downstream fault current. The current limitation will restore the point of common coupling (PCC) (the bus to which all feeders under study are connected) voltage and protect the DVR itself. The innovation here is that the DVR acts as virtual impedance with the main aim of protecting the PCC voltage during downstream fault without any problem in real power injection into the DVR. Simulation results show the capability of the DVR to control the emergency conditions of the distribution systems.

Keywords: Dynamic voltage restorer (DVR), emergency control, voltage sag, voltage swells.

I. INTRODUCTION

Voltage sag and voltage swell are two of the most important power-quality (PQ) problems that encompass almost 80% of the distribution system PQ problems. According to the IEEE 1959–1995 standard, voltage sag is the decrease of 0.1 to 0.9 p.u. in the rms voltage level at system frequency and with the duration of half a cycle to 1 min. Short circuits, starting large motors, sudden changes of load, and energization of transformers are the main causes of voltage sags [3]. According to the definition and nature of voltage sag, it can be found that this is a transient phenomenon whose causes are classified as low- or medium-frequency transient Events. In recent years, considering the use of sensitive devices in modern industries, different methods of compensation of voltage sags have been used. One of these methods is using the DVR to improve the PQ and compensate the load voltage. Previous works have been done on different aspects of DVR performance, and different control strategies have been found. These methods mostly depend on the purpose of using DVR. In some methods, the main purpose is to detect and compensate for the voltage sag with minimum DVR active power injection.

Also, the in-phase compensation method can be used for sag and swell mitigation. The multiline DVR can be used for eliminating the battery in the DVR structure and controlling more than one line. Moreover, research has been made on using the DVR in medium level voltage. Harmonic mitigation and control of DVR under frequency variations are also in the area of research. The closed-loop control with load voltage and current feedback is introduced as a simple method to control the DVR in Also, Posicast and P+Resonant controllers can be used to improve the transient response and eliminate the steady-state error in DVR. The Posicast controller is a kind of step function with two parts and is used to improve the damping of the transient oscillations initiated at the start instant from the voltage sag. The P+Resonant controller consists of a proportional function plus a resonant function and it eliminates the steady-state voltage tracking error. The state feed forward and feedback methods, symmetrical components estimation, robust control, and wavelet transform have also been proposed as different methods of controlling the DVR. In all of the aforementioned methods, the source of disturbance is assumed to be on the feeder which is parallel to the DVR feeder. In this paper, a multifunctional control system is proposed in which the DVR protects the load voltage using Posicast and P+Resonant controllers when the Source of disturbance is the parallel feeders. On the other hand, during a downstream fault, the equipment protects the PCC voltage, limits the fault current, and protects itself from large fault current. Although this latest condition has been described in using the flux control method, the DVR proposed there acts like a virtual inductance with a constant value so that it does not receive any active power during limiting the fault current. But in the proposed method when the fault current passes through the DVR, it acts like series variable impedance (unlike where the equivalent impedance was a constant).

The basis of the proposed control strategy in this paper is that when the fault current does not pass through the DVR, an outer feedback loop of the load voltage with an inner feedback loop of the filter capacitor current will be used. Also, a feed forward loop will be used to improve the dynamic response of the load voltage. Moreover, to improve the transient response, the Posicast controller and to eliminate the steady-state error, the P+Resonant controller are used. But in case the fault current passes

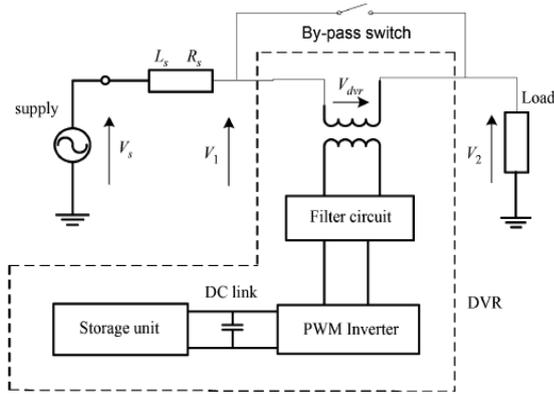

Fig. 1. Typical DVR-connected distribution system.

Through the DVR, using the flux control algorithm, the series voltage is injected in the opposite direction and, therefore, the DVR acts like series variable impedance. The remainder of this paper is organized as follows: The general operation of DVR and its state space description are provided in Section II. The closed-loop control using Posicast and P+Resonant controllers has been presented in Section III. In Section IV, the multifunctional DVR is introduced. The basis of the proposed control method is described in Section V. Finally, the simulation results are provided in Section VI which shows that the control capability of the proposed DVR system is satisfactory.

II. DVR COMPONENTS AND ITS BASIC OPERATIONAL PRINCIPLE

A. DVR Components

A typical DVR-connected distribution system is shown in Fig. 1, where the DVR consists of essentially a series-connected injection transformer, a voltage-source inverter, an inverter output filter, and an energy storage device that is connected to the dc link. Before injecting the inverter output to the system, it must be filtered so that harmonics due to switching function in the inverter are eliminated. It should be noted that when using the DVR in real situations, the injection transformer will be connected in parallel with a bypass switch (Fig. 1). When there is no disturbances in voltage, the injection transformer (hence, the DVR) will be short circuited by this switch to minimize losses and maximize cost effectiveness. Also, this switch can be in the form of two parallel thyristors, as they have high on and off speed. A financial assessment of voltage sag events and use of flexible ac transmission systems (FACTS) devices, such as DVR, to mitigate them is provided in. It is obvious that the flexibility of the DVR output depends on the switching accuracy of the pulse width modulation (PWM) scheme and the control method. The PWM generates sinusoidal signals by comparing a sinusoidal wave with a saw tooth wave and sending appropriate signals to the inverter switches.

B. Basic Operational Principle of DVR

The DVR system shown in Fig. 1, controls the load voltage by injecting an appropriate voltage phasor in series with the

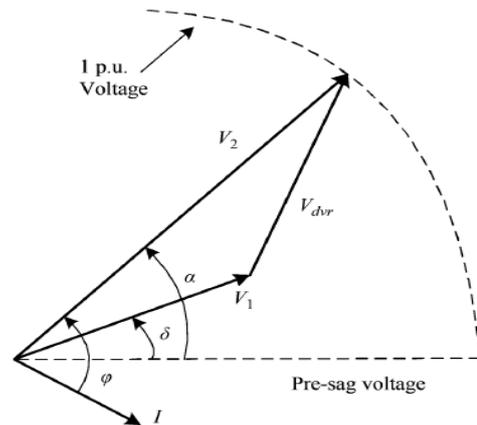

Fig. 2. Phasor diagram of the electrical conditions during voltage sag.

System using the injection series transformer. In most of the sag compensation techniques, it is necessary that during compensation, the DVR injects some active power to the system. Therefore, the capacity of the storage unit can be a limiting factor in compensation, especially during long-term voltage sags. The phasor diagram in Fig. 2 shows the electrical conditions during voltage sag, where, for clarity, only one phase is shown. Voltages V_1 , V_2 and V_{dvr} are the source-side voltage, the load side voltage, and the DVR injected voltage, respectively. Also, the operators I , ϕ , δ and α are the load current, the load power factor angle, the source phase voltage angle, and the voltage phase advance angle, respectively. It should be noted that in addition to the in-phase injection technique, another technique, namely “the phase advance voltage compensation technique” is also used. One of the advantages of this method over the in-phase method is that less active power should be transferred from the storage unit to the distribution system. This results in compensation for deeper sags or sags with longer durations. Due to the existence of semiconductor switches in the DVR inverter, this piece of equipment is nonlinear. However, the state equations can be linearized using linearization techniques.

The dynamic characteristic of the DVR is influenced by the filter and the load. Although the modeling of the filter (that usually is a simple LC circuit) is easy to do, the load modeling is not as simple because the load can vary from a linear time invariant one to a nonlinear time-variant one. In this paper, the simulations are performed with two types of loads: 1) a constant power load and 2) a motor load. As Fig. 3 shows, the load voltage is regulated by the DVR through injecting V_{dvr} . For simplicity, the bypass switch shown in Fig. 1 is not presented in this figure. Here, it is assumed that the load has a resistance R_L and an inductance L_L . The DVR harmonic filter has an inductance of L_f , a resistance of R_f , and a capacitance of C_f . Also, the DVR injection transformer has a combined winding resistance of R_t , a leakage inductance of L_t , and turns ratio of 1: n.

The Posicast controller is used in order to improve the transient response. Fig. 4 shows a typical control block diagram of the DVR. Note that because in real situations, we are dealing with multiple feeders connected to a common bus, namely “the Point of Common Coupling (PCC),” from now on, V_1 and V_2 will be replaced with V_{pcc}

and V_L , respectively, to make a generalized sense. As shown in the figure, in the open-loop control, the voltage on the source side of the DVR is compared with a load-side reference voltage (V_L^*) so that the necessary injection voltage (V_{inv}^*) is derived. A simple method to continue is to feed the error signal into the PWM inverter of the DVR. But the problem with this is that the transient oscillations initiated at the start instant from the voltage sag could not be damped sufficiently.

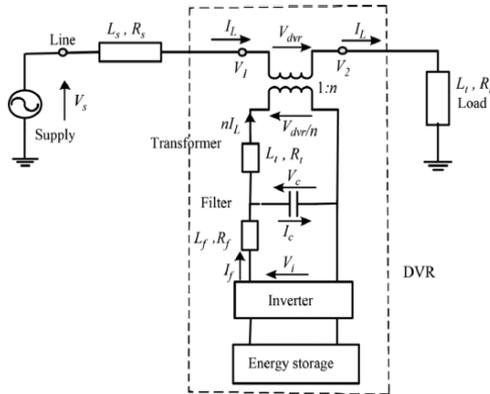

Fig. 3. Distribution system with the DVR

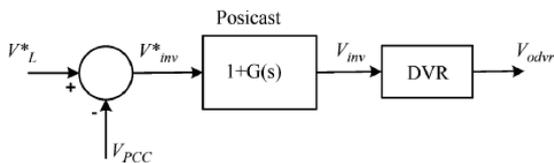

Fig. 4. Open-loop control using the Posicast controller.

To improve the damping, as shown in Fig. 4, the Posicast controller can be used just before transferring the signal to the PWM inverter of the DVR. The transfer function of the controller can be described as follows:

$$1 + G(s) = 1 + \frac{\delta}{1 + \delta} \left(e^{-sT_d/2} - 1 \right) \quad (1)$$

Where δ and T_d are the step response overshoot and the period of damped response signal, respectively. It should be noted that the Posicast controller has limited high-frequency gain; hence, low sensitivity to noise.

To find the appropriate values of δ and T_d and, first the DVR model will be derived according to Fig. 3, as follows:

$$\begin{aligned} V_i &= V_c + I_f R_f + L_f \frac{dI_f}{dt} \\ I_f &= I_c + n \cdot I_t \\ I_c &= C_f \frac{dV_c}{dt} \end{aligned}$$

$$V_{dvr} = n \left[V_c - n \left(R_t I_t + L_t \frac{dI_t}{dt} \right) \right]$$

$$V_2 = V_1 + V_{dvr}$$

Then, according to (2) and the definitions of damping and the delay time in the control literature, and are derived as follows:

$$\begin{aligned} T_d &= \frac{2\pi}{\omega_r} = \frac{\pi}{\sqrt{\frac{1}{L_f C_f} - \frac{R_f^2}{4L_f^2}}} \\ \delta &= e^{\xi\pi/\sqrt{1-\xi^2}} = e^{-R_f\pi\sqrt{C_f}/\sqrt{4L_f - R_f^2 C_f}} \end{aligned} \quad (3)$$

The Posicast controller works by pole elimination and proper regulation of its parameters is necessary. For this reason, it is sensitive to inaccurate information of the system damping resonance frequency. To decrease this sensitivity, as is shown in Fig. 5, the open-loop controller can be converted to a closed loop controller by adding a multi loop feedback path parallel to the existing feed forward path. Inclusion of a feed forward and a feedback path is commonly referred to as two-degrees-of freedom (2-DOF) control in the literature. As the name implies, 2-DOF control provides a DOF for ensuring fast dynamic tracking through the feed forward path and a second degree of freedom for the independent tuning of the system disturbance compensation through the feedback path. The feedback path consists of an outer voltage loop and a fast inner current loop. To eliminate the steady-state voltage tracking error, a computationally less intensive P+Resonant compensator is added to the outer voltage loop. The ideal P+Resonant compensator can be mathematically expressed as

$$G_R(s) = k_p + \frac{2k_I s}{s^2 + \omega_0^2} \quad (4)$$

Where k_p and k_I are gain constants and ω_0 is the controller resonant frequency. Theoretically, the resonant controller compensates by introducing an infinite gain at the resonant frequency of 50 Hz to force the steady-state voltage error to zero. The ideal resonant controller, however, acts like a network with an infinite quality factor, which is not realizable in practice. A more practical (non ideal) compensator is therefore used here, and is expressed as

$$G_R(s) = k_p + \frac{2k_I \omega_{cut} s}{s^2 + 2\omega_{cut} s + \omega_0^2} \quad (5)$$

Where ω_{cut} is the compensator cutoff frequency which is 1 rad/s

III. PROPOSED MULTIFUNCTIONAL DVR

In addition to the aforementioned capabilities of DVR, it can be used in the medium-voltage level (as in Fig. 6) to protect a group of consumers when the cause of disturbance is in the downstream of the DVR's feeder and the large fault current passes through the DVR itself. In this case, the equipment can limit the fault current and protect the loads in parallel feeders until the breaker works and disconnects the faulted feeder. The large fault current will cause the PCC voltage to drop and the loads on the other feeders connected to this bus will be affected. Furthermore, if not controlled properly, the DVR might also contribute to this PCC voltage sag in the process of compensating the missing voltage, hence further worsening the fault situation.

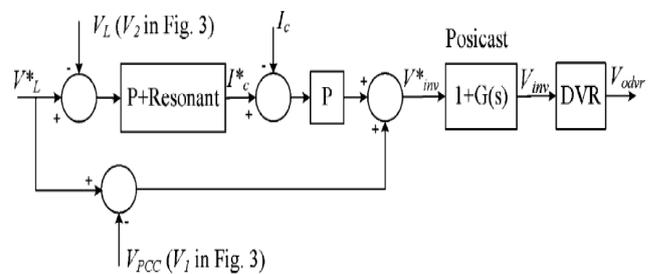

Fig. 5. Multiloop control using the Posicast and P+Resonant controllers.

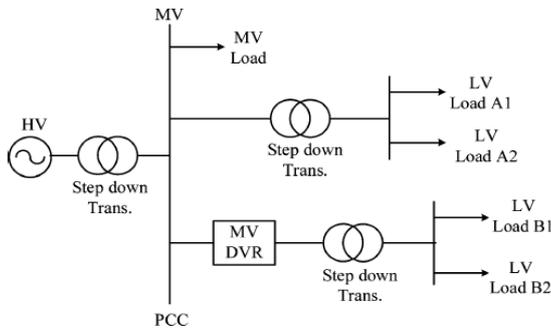

Fig. 6DVR connected in a medium-voltage level power system.

To limit the fault current, a flux-charge model has been proposed and used to make DVR act like a pure virtual inductance which does not take any real power from the external system and, therefore, protects the dc-link capacitor and battery as shown in Fig.1. But in this model, the value of the virtual inductance of DVR is a fixed one and the reference of the control loop is the flux of the injection transformer winding, and the PCC voltage is not mentioned in the control loop. In this paper, the PCC voltage is used as the main reference signal and the DVR acts like a variable impedance. For this reason, the absorption of real power is harmful for the battery and dc-link capacitor. To solve this problem, impedance including a resistance and an inductance will be connected in parallel with the dc-link capacitor. This capacitor will be separated from the circuit, and the battery will be connected in series with a diode just when the downstream fault occurs so that the power does not enter the battery and the dc-link capacitor. It should be noted here that the inductance is used mainly to prevent large oscillations in the current. The active power mentioned is, therefore, absorbed by the impedance.

IV. PROPOSED METHOD FOR USING THE FLUX-CHARGE MODEL

In this part, an algorithm is proposed for the DVR to restore the PCC voltage, limit the fault current, and, therefore, protect the DVR components. The flux-charge model here is used in a way so that the DVR acts as a virtual inductance with a variable value in Series with the distribution feeder. To do this, the DVR must be controlled in a way to inject a proper voltage having the opposite polarity with respect to usual cases. It should be noted that over current tripping is not possible in this case, unless additional Communication between the DVR and the downstream side over current circuit breaker (CB) is available. If it is necessary to operate the over current CB at PCC, communication between the DVR and the PCC breaker might have to be made and this can be easily done by sending a signal to the breaker when the DVR is in the fault-current limiting mode as the DVR is just located after PCC.

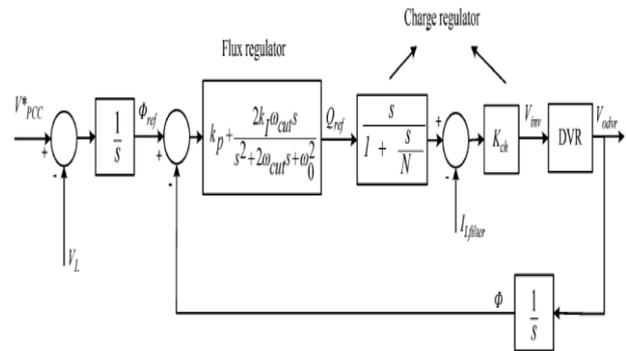

Fig. 7. Proposed method.

The proposed DVR control method is illustrated in Fig. 7. It should also be noted that the reference flux (ϕ_{ref}) is derived by integration of the subtraction of the PCC reference voltage (V_{pcc}^*) and the DVR load-side voltage. In this control strategy, the control variable used for the outer flux model is the inverter-filtered terminal flux defined as:

$$\Phi = \int V_{odvr} dt \tag{6}$$

Where is the filter capacitor voltage of the DVR (at the DVR power converter side of the injection transformer). The flux error is then fed to the flux regulator, which is a P+Resonant controller, with a transfer function given in (6). On the other hand, it can be shown that a single flux-model would not damp out the resonant peak of the LC filter connected to the output of the inverter.

To stabilize the system, an inner charge model is therefore considered. In this loop, the filter inductor charge, which is derived by integration of its current, tracks the reference charge Output Q_{ref} of the flux regulator. The calculated charge error is then fed to the charge regulator with the transfer function

$$G_{charge}(s) = k_{ch} \frac{S}{1 + \frac{S}{N}} \tag{7}$$

Which is actually a practical form of the derivative controller. In this transfer function, the regulator gain is limited to at high frequencies to prevent noise amplification. The derivative term in $S/(1+(S/N))$ neutralizes the effects of voltage and current integrations at the inputs of the flux-charge model, resulting in the proposed algorithm having the same regulation performance as the multiloop voltage-current feedback control, with the only difference being the presence of an additional low-pass filter in the flux control loop in the form of $1/(1+(S/N))$. The bandwidth of this low-pass filter is tuned (through varying) with consideration for measurement noise attenuation, DVR LC-filter transient resonance attenuation, and System stability margins.

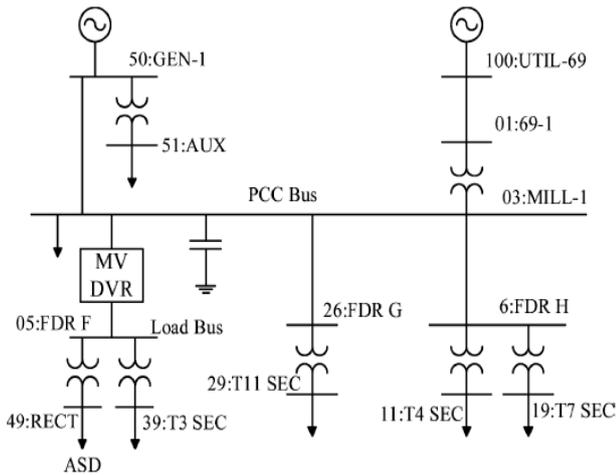

Fig. 8. Under Study test system.

V. SIMULATION RESULTS

In this part, the proposed DVR topology and control algorithm will be used for emergency control during the voltage sag. The three-phase short circuit and the start of a three-phase large induction motor will be considered as the cause of distortion in the simulations.

A. Under Study Test System

In this paper, the IEEE standard 13-bus balanced industrial system will be used as the test system. The one-line diagram of this system is shown in Fig. 9. The test system is modeled in MATLAB SIMULINK software. Control methods of Figs. 5 and 7 were applied to control the DVR, and the voltage, current, flux, and charge errors were included as the figures show. A 12-pulse inverter was used so that each phase could be controlled separately. Detailed specifications of the DVR components are provided in the Appendix.

The plant is fed from a utility supply at 69 kV and the Local plant distribution system operates at 13.8 kV. The local (in-plant) generator is represented as a simple Thevenin equivalent. The internal voltage, determined from the converged power-flow solution, is $13.8 \angle -1.52^\circ$ kV. The equivalent impedance is the subtransient impedance which is $0.036 + j1.3651 \Omega$. The plant power factor correction capacitors are rated at 6000 kvar. As is typically done, leakage and series resistance of the bank are neglected in this study. The detailed description of the system can be found in [1]. In the simulations, the DVR is placed between buses "03: MILL-1" and "05: FDR F."

B. Three-Phase Short Circuit

In this part, the three-phase short circuit is applied on bus "26: FDR G," and the capability of the DVR in protecting the voltage on bus "05: FDR F" will be studied. The DVR parameters and the control system specifications are provided in Appendices A and B. At $t=205$ ms, the fault is applied at $t=285$ ms, and the breaker works and separates the line between buses "03: MILL-1" and "26: FDR G" from the system. At $t=305$ ms, the fault will be recovered and, finally, at $t=310$ ms, the separated line will be rejoined to the system by the breaker. The simulation results are shown in Fig. 9. As can be seen in the figure, the rms voltage of PCC drops to about 0.25 p.u. during the fault.

The DVR will start the compensation just after the detection of sag.

C. Starting the Induction Motor

A large induction motor is started on bus "03: MILL-1." The motor specifications are provided in Appendix C. The large motor starting current will cause the PCC voltage (bus "03: MILL-1" voltage) to drop. The simulation results in the case of using the DVR are shown in Fig. 10. In this simulation, the motor is started at $t=405$ ms. As can be seen in Fig. 10, at this time, the PCC rms voltage drops to about 0.8 p.u. The motor speed reaches the nominal value in about 1 s. During this period, the PCC bus is under voltage sag. From $t=1.4$ s, as the speed approaches nominal, the voltage also approaches the normal condition.

D. Fault Current Limiting

The last simulation is run for a symmetrical downstream fault, and the capability of the DVR to reduce the fault current and restore the PCC voltage is tested. For this purpose, a three-phase short circuit is applied on bus "05: FDR F". In Fig. 11, the fault current, without the DVR compensation, is shown. For the simulation with DVR compensation, the three-phase fault is applied at $t=205$ ms and then removed after 0.1 s. Also, a breaker will remove the faulted bus from the entire system at $t=300$ ms. Fig. 12 shows the DVR operation during the fault. As can be seen, the rms load bus voltage reaches zero during the fault, and as the enlarged figure shows, in about half a cycle, the DVR has succeeded in restoring the PCC voltage wave shape to the normal condition.

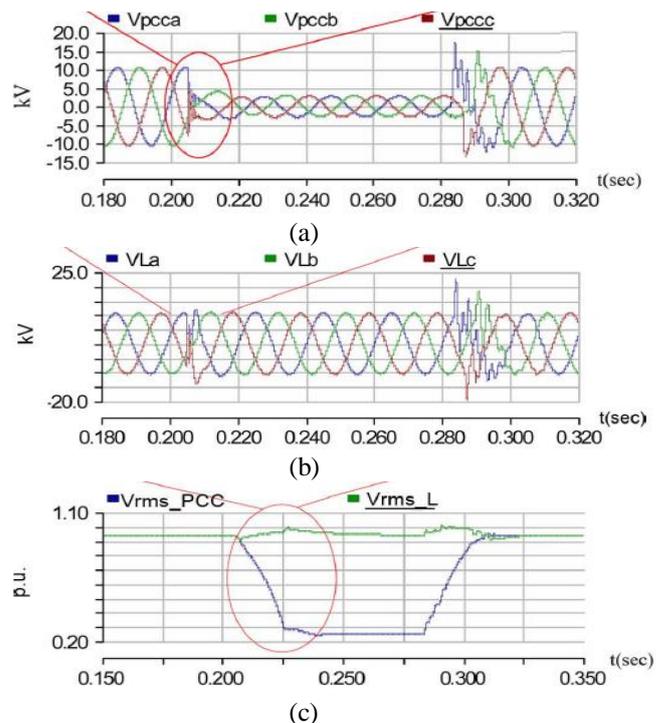

Fig. 9. Three-phase fault compensation by DVR. (a) Three-phase PCC voltages. (b) Three-phase load voltages. (c) RMS voltages of PCC and load.

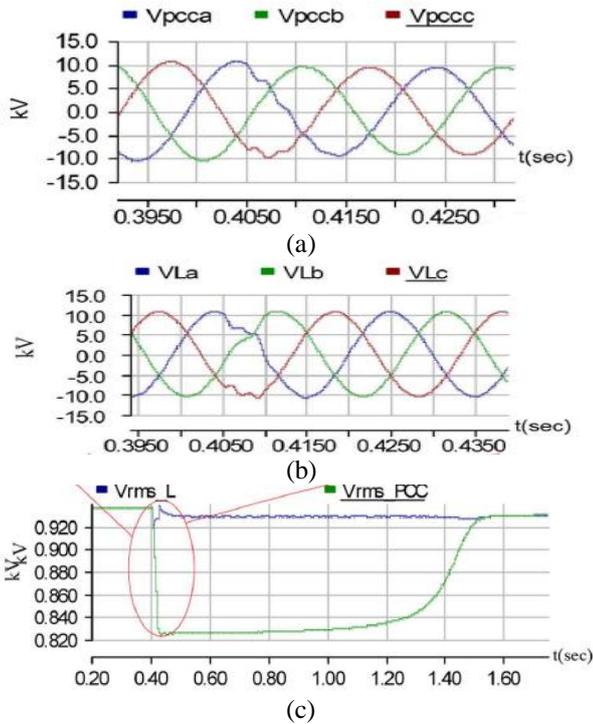

Fig. 10. Starting of an induction motor and the DVR compensation. (a) Three phase PCC voltages. (b) Three-phase load voltages. (c) RMS voltages of PCC and load.

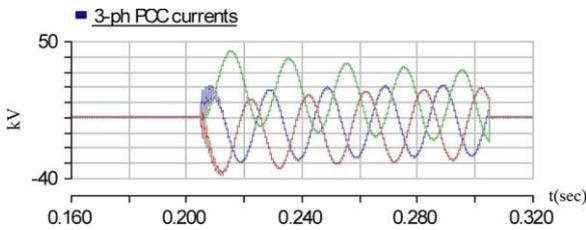

Fig. 11. Current wave shape due to the three-phase short-circuit fault without DVR compensation.

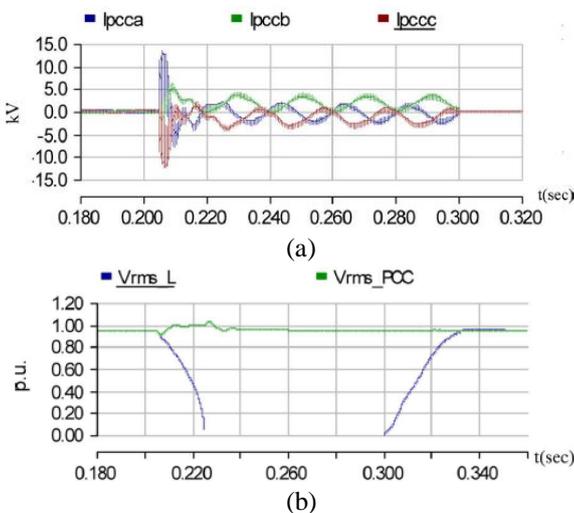

Fig. 12. Fault current limiting by DVR. (a) Three-phase currents. (b) RMS voltages of the PCC and load.

VI. CONCLUSION

In this paper, for improving the transient response and eliminating the steady-state error, the Posicast and P+Resonant controllers are used. As the second function of this DVR, using the flux-charge model, the equipment is controlled so that it limits the downstream fault currents and protects the PCC voltage during these faults by acting as variable impedance. The simulation results verify the effectiveness and capability of the proposed DVR in compensating for the voltage sags caused by short circuits and the large induction motor starting and limiting the downstream fault currents and protecting the PCC voltage.

APPENDIX

DVR Parameters:

Filter inductance (L_f) = 1mH
 Filter capacitance (C_f) = 700 μ F
 Inverter modulation ratio = 21
 Kind of DVR inverter: 12 Pulse
 DC-link capacitance: 26 mF
 Entered resistance for current limiting: 3 ohms
 Entered inductance for current limiting: 2 mH
 Supply battery: 12 kV.

Control System Parameters:

$\delta = 1$
 $T_d = 41.56$
 $K_p = 1$
 $K_i = 100$
 $\omega_0 = 314$ rad/s
 $\omega_{cut} = 1.0$ rad/s

Induction Motor Parameters:

Rated power: 2.4 MVA
 Rated voltage: 13.8 kV
 Moment of inertia: 3.7267 sec
 Number of rotor squirrel cages: 1
 Base frequency: 50 Hz
 Stator resistance: 0.0034 p.u.
 Rotor resistance: 0.298 p.u.
 Stator inductance: 0.0102 p.u.
 Rotor inductance: 0.05 p.u.
 Magnetizing inductance: 0.9 p.u.

²Principal, MGIT, Gandipet, Hyderabad-75

Abstract: *Finite element simulations are often required to reduce the experimental cost and time by reducing number of trials in the product development cycle. Metal forming is one of such area where a lot of trials are required to arrive at the die design to produce defect free parts. Hence in this paper the authors review the literature on finite element analysis in the area of metal forming*

Key Words: *Metal Forming, Finite Element Analysis, Simulations*

The term simulation is derived from the Latin word “simulare” what means “to pretend”. However, the technical meaning of simulation is the description and reproduction of physical and technical processes by use of mathematical and physical models. In comparison with practical tests, the simulation often is cheaper and not so dangerous. Combined with modern methods of computation, the simulation is a powerful tool which gains more and more importance for describing and developing new processing methods. Because of higher requirements on the quality of products and narrow tolerances of measures, optimizing, planning and simulating of forming processes becomes more and more important. As the computational power has increased during the last years, numerical methods play an outstanding roll. The most important numerical method is the method of finite elements (FEM). Numerous finite element programmes have been developed which are able to solve linear, non linear, static, dynamic, elastic, plastic, elastic – plastic, steady state, transient, isothermal as well as non isothermal problems [1].

The deep drawing process is applied with the intention of manufacturing a product with a desired shape and no failures. The final product shape after deep drawing is defined by the tools, the blank and the process parameters. An incorrect design of the tools and blank shape or an incorrect choice of material and process parameters can yield a product with a deviating shape or with failures. A deviating shape is caused by elastic springback after forming and retracting the tools. The most frequent types of failure are wrinkling, necking (and subsequently tearing), scratching and orange peel. Wrinkling may occur in areas with high compressive strains, necking may occur in areas with high tensile strains, scratching is caused by defects of the tool surface and orange peel may occur after excessive deformations, depending on the grain size of the material. The deformation patterns of the sheet material are influenced by the material properties and the processing and tooling variables. Generally, sheet material behaves anisotropically which means that the material shows a different deformation behavior in different directions because of the rolling process. An example of anisotropy is the development of ‘ears’ in cylindrical cup drawing. The friction conditions during forming depend on the lubricant, the presence of coatings on the blank, surface roughness of the tools and the blank, blank holder pressure and process velocity. Without extensive knowledge of the influences of all these variables on the deep drawing process, it is hardly possible to design the tools adequately and make a proper choice of blank material and lubricant to manufacture a product with the desired shape and performance. As a result, after the first design of the tools and choice of blank material and lubricant, an extensive and time consuming trial and error process is started to determine the proper tool design and all other variables, leading to the desired product. This trial and error process can yield an unnecessary number of deep drawing strokes, or may even require redesigning the expensive tools. To reduce this waste of time and cost, process modeling for computer simulation can be used to replace the experimental trial and error process by a virtual trial and error process. The prime objective of an analysis is to assist in the design of a product. To design or select the tools and the equipment, such design essentially consists of predicting the material flow, determining whether it is possible to form the part without surface or internal defects, predicting the forces necessary to execute the forming operation and stresses induced during the operation.

Analytical study of Metal forming processes was started in the mid of 20th century [2,3]. Later a number of analyzing methods have been developed and applied to various forming processes. Some of these methods are the slab method, the slip-line field method, the viscoplasticity method, upper and lower bound techniques and Hill’s general method. These methods have been useful in qualitatively predicting forming loads, overall geometry changes of the deformed blank and material flow and approximate optimum process conditions. Numerical procedures (finite difference method) were applied to analyze axisymmetric deep drawing process in 1960s[4] Although the work contributed to greatly to the development of theory of sheet metal forming analysis, that could not be applicable to the industrial components. However, a more accurate determination of the effects of various process parameters on the deep drawing process has become possible only, when the non linear finite element method was developed for these analyses [5-7]. Later, three dimensional auto body panel forming process was simulated using elasto-plastic finite element method by Arlinghaus [8] and Tang [9]. They simulated the drawing process of and left window outer and binder wrapping process of deck lid. But they were in the state of testing and evaluation. Because finite element analysis by that time is was still extremely time consuming and unreliable tool to the engineers in the press shop.

Rapid developments in computer hardware make the finite element analysis of complex deformation responses increasingly applicable. The finite element method is used worldwide to simulate the deep drawing process and has become a reliable numerical simulation technology. For an accurate simulation of a real-life deep drawing process an accurate numerical description of the tools is necessary, as well as an accurate description of material behavior, contact behavior and other process variables. The numerical description of the tools is provided by CAD packages which are generally used by tool designers. The description of material behavior, contact behavior and other process variables evolved from rather simple models in the earlier days to more and more sophisticated models nowadays. Developments have been made in the field of finite element types, mesh adaptivity, material laws, failure criteria, wrinkling and surface defects, springback, contact algorithms, friction, and simulation of new processes (optimization and process design). The conventional finite element codes are based on implicit time integration. This involves repeated solutions of large systems of equations. Furthermore, equilibrium must be fulfilled after each incremental step. As a result, implicit codes are computational time and memory consuming. Hence, a new class of finite element codes based on explicit time integration was developed, resulting in a drastic decrease of computational time. Honecker et.al [10] first demonstrated the deep drawing of an oil pan and a radiator part by explicit method, obtaining deeply drawn shapes including wrinkle on the flange. After this several dynamic explicit codes specialized to the sheet metal forming were developed and many automotive industries started to develop these codes. In an explicit code no system of equations needs to be solved and static equilibrium is not checked after each incremental step, as the algorithm assumes an inertia dominated process. The explicit procedure is conditionally stable with a critical time step, which is proportional to the smallest element in the mesh [11]. However, in most sheet metal forming processes inertia effects can be neglected. In order to apply the explicit algorithms in these processes, it is necessary to assume artificially high velocities and accelerations or artificially high mass density, which seems rather unrealistic [12]. On the other hand one step method proposed by Batoz et.al [13] was developed based on the idea of Chung and Lee [14] in which single time step was used, deforming the sheet inversely from final part configuration to initial blank configuration. A major advantage of this method is very short computation time. Mean while there were several activities to develop codes based on static implicit incremental approach [15-19]. But convergence is the basic problem of this approach. To avoid the convergence problem static explicit codes were developed [20,21].

In a nutshell all these codes may be classified into five categories based on the formulation and solution strategy used. These are dynamic explicit codes, static explicit codes, Static implicit incremental codes, Static implicit large step code and Static implicit one step code.

The dynamic explicit approach was originally developed for the problems in which dynamic effects are important, such as impact problems and crash simulation, and includes inertia in the equilibrium equations. The reasons for using a method like this in metal forming are two fold. The method is extremely robust and it is very efficient for large scale problems. In this approach the central difference explicit scheme is used to integrate the equations of motion. Lumped mass matrices are used, which implies that the mass matrix is diagonal, and no system equations has to be solved. A typical time step is of the order of a micro seconds and the number of time steps in typical sheet forming simulation are normally several tens of thousands. In spite of its success for industrial applications, it has also some intrinsic drawbacks i.e. in order to achieve significant computational advantage several numerical artifacts have to be introduced into the explicit solution procedure. In particular the parameters like mass density, punch velocity, loading history etc are to be modified. Since the maximum permissible time step, as defined by the current stability limit is directly proportional to the square root of the material density, this parameter is increased, usually by at least one order of magnitude. In order to reduce the total number of time steps necessary to model the sheet metal forming process, the punch velocity is increased, again by at least one order of magnitude. Since increase in both the material density and punch velocity results in increased inertia forces, the punch travel must be suitably controlled so as to minimize the inertia effects. Thus, the very nature of the dynamic explicit method, the simulation of forming defects requires a considerable experience on the user side for adequately designing the finite element mesh and choosing the scaling parameters of mass, velocity and damping. Other issues that must be given attention in the dynamic explicit analysis is the simulation of the spring back. One way of improving reliability of spring back is to combine the dynamic explicit analysis with quasi -static implicit simulation.

In the static explicit method, the system of equations representing the rate of equilibrium is integrated with a simple forward Euler scheme, involving no iterations. This implies that equilibrium equations are satisfied only in rate form and the obtained solution can gradually drift away from the true one. In order to reduce the error involved vary small incremental steps have to be taken. An ordinary simulations normally involves several thousand steps. The main advantage of this approach is the robustness, since there are no iterative processes.

The Static implicit incremental approach may seem ideally suited for metal forming problems, since the static equilibrium equations are solved iteratively, ensuring that the equilibrium conditions are full filled in every step. However, in practice complex nonlinear problems involving many contacts may results in slow or even lack of convergence. The method is also inefficient for solving large scale problems, since time taken for solving the system of equations increases approximately quadratically with the number of degrees of freedom.

Static implicit large step codes employ large incremental time step under special contact treatment, uncoupled bending and stretching solution algorithm, and adoptive mesh refinement of refinement levels. These features, specialized for the simulations of thin sheet metal forming renders code extremely efficient ,but unfortunately also make the results approximate in respects. For instance, the contact and discontact process are not accurately simulated and there fore wrinkling and buckling are poorly predicted.

In static implicit one step codes use a single time step, usually taking the deformation process from the final part configuration to the initial flat blank configuration, assuming a linear strain path and neglecting the history of contact.

Although, this method incorporates significantly drastic simplifications, its major advantage is a very short computation time and less input data. These features enable the use of these codes at the product design stage, in the absence of information of the stamping tools.

Currently, the accuracy and reliability of numerical simulations of sheet metal forming processes do not yet satisfy the industrial requirements. One of the limitations of numerical simulations is still the high computational time for complex deep drawing parts, despite the development of iterative solvers, fast contact algorithms and the ever ongoing progress in computer hardware. Another limitation is the lack of detailed knowledge of material physics such as material behavior at high deformations and contact behavior. Therefore extensive research in the field of sheet metal forming is and will be necessary to decrease the existing gap between the real-life deep drawing process and the predictions obtained from deep drawing simulations.

Deep drawing, even though is one of the most basic processes in sheet metal working, it involves very complicated deformation mechanics. The numerical difficulty in the finite element analysis of the deep drawing processes arises due to the existence of compressive stress in the sheet plane and the occurrence of unloading. The drawing load increases with the punch displacement. As the punch moves, the flange part of the sheet is drawn into the die cavity. The punch load decreases after a critical point because less resisting force to drawing is developed in the flange. In the range of decreasing punch load, unloading occurs at the wall of a drawn cup. Therefore, in analyzing the bending-dominant processes like deep drawing, the effect of unloading should be also considered. The state of stress at the wall and at the flange is basically tensile stress in axial or radial direction and compressive stress in the circumferential direction. As the sheet metal has relatively a small dimension in the thickness direction, the compressive stress may cause wrinkling in the actual process or numerical buckling in simulation [22]. The numerical buckling is the mesh buckling phenomenon occurring in the finite element analysis at the region of high compressive stress like actual buckling.

The modeling of the blank elements can be done by two alternative approaches [23] namely a structural based elasto-plastic / elasto-viscoplastic approach or rigid-plastic/ rigid-visco- plastic approach. Elastic-plastic analysis of sheet metal forming can be broadly classified into three categories according to the element types; membrane analysis, continuum analysis and shell analysis. Membrane analysis done by Wang [24] Arlinghaus [25], Mattiason [26], Massoni (27), Saran (28) and Batoz (29), has been widely applied to various sheet metal forming problems because of small computation time and small memory size. However, it provides insufficient information when treating the bending-dominant processes. Continuum analysis by Wifi (30), Anderson (31), Stalman (32), Makinouchi (33,34), Keck (35) has several merits; e.g. the bending effect can be considered and the formulation is much simpler than other methods of analysis using different element types. The continuum analysis, however, involves extremely large computation time and enormous memory size when three-dimensional problems are to be treated for any practical purposes. The shell analysis by Tatenami (36), Wang (37, 38), Gelin (39), Honnor (40), Batoz (29) and Honecker (41) may be regarded as a compromise between the continuum analysis and the membrane analysis. It is possible to consider the effect of bending with much less computation time and less memory size than the continuum analysis. However, most of the applications using shell elements are limited to the axisymmetric and plane strain problems because of the difficulty in treating kinematics of three-dimensional shells, computation time and memory size etc. Recently, the effect of bending has been studied through the comparison between the membrane analysis, the continuum analysis and the shell analysis. Wang and Tang (38) analyzed stretching and deep drawing with axisymmetric membrane elements and axisymmetric shell elements. In the analysis of stretching, both theories do not show any appreciable discrepancy, while the discrepancy between two theories becomes apparent in the analysis of deep drawing. Hambrecht et al. (42) studied the effect of bending in the plane strain punch stretching and axisymmetric stretching by the comparison of above-mentioned three kinds of approaches. Through the study, the continuum or shell theory is necessary in analyzing deep drawing and above three kinds of approaches do not give any difference in analyzing stretching. Yang et al. (22) analyzed stretching of a square plate as well as deep drawing of a cylindrical cup with the rigid-plastic finite element analyses using membrane and then they have investigated the effect of bending in the stretch dominant process and draw-dominant processes. Now, the effect of bending has become significant in the modelling of sheet metal forming process in order to obtain more accurate information for the die design of deep drawing. Shim and Yang [43] analysed deep drawing of cylindrical and square cups using membrane and shell elements. They found that both theories are in good agreement with each other in case of load-displacement curve. However in the neighborhood of punch round, the thinning appearing in the experiment can not be predicted by membrane analysis. In the shell analysis the thickness strain distribution is better predicted over whole range of sheet. It is due to the fact that bending of sheet effects considerably the thickness strain distribution and bending has no significant affect in load-displacement curve. So shell element is considered to be most suitable for the analysis in deep drawing process.

Finite Element models for rigid visco-plastic thin sheet problems was presented by Bellet et.al.[44]. A viscous shell formulation was introduced by Onate et.al [28] , who considered visco-plastic deformation of the work material as well as frictional affects of punch and die. Onate et.al [45]discussed viscous shell approach based on bending and membrane shell elements.

Shift variance behavior for different sub-band coding systems, Biorthogonal, Orthogonal and Bspline wavelets

Gamal Fahmy

Electrical Engineering Dept., Majmaah University, KSA

Abstract: Sub-band coding has long been utilized and adopted in different compression, coding and reconstruction techniques in most signal processing applications. It has wide applications in communications, bit rate codec's, sampling, and compression for images, videos and speech. However sub-band coding systems in general suffer from a certain amount of shift variance of the output reconstructed signal, due to the frequency overlap between different sub-bands in the analysis stage. This overlap is known as non-ideal anti-aliasing.

In this paper we simplify the shift variance analysis of sub-band coding systems in general, and we present different metrics that have been reported in the literature to measure the bounds of shift variance for Perfect Reconstruction (PR) sub-band systems, we simplify its mathematical analysis and illustrate with graphs the reasons for these bounds and compare them. We apply these metrics on Biorthogonal, Orthogonal and Bspline wavelets and present the worst case scenario for different input signals in terms of shift variance for all these sub-band coding systems, both numerically and graphically. We finally compare the shift variance behavior for different sub-band PR systems for different types of input signals.

Keywords: Shift variance, Bspline, multirate system

1. Introduction

Multirate systems employ by definition sampling rate conversion which introduces an amount of linear periodical shift variance (LPSV) in the output reconstructed signal [1-3], in spite of the fact that the adopted sub-band filters are linear shift invariant (LSI). This LPSV can be noticed in different applications such as block transform, fractional sampling rate converters, multirate filter banks, sub-band quantization, and motion estimation. Several approaches in the literature tried to reduce or prevent LPSV has adopted Complex wavelets [4], cycle spinning [5], and circular shifted wavelets [6]. In [7-9] several effects of shift variance, and some of its consequences like cyclostationarities on re-sampled data and images, were presented.

In this paper we present a quantitative measure for shift variance in different sub-band coding systems. We derive the worst case scenario for the amount of shift introduced in the output reconstructed signal from different types of input signals (such as a narrow band input signal or a wide band one). We analyze different metrics for shift variance that has been reported in the literature [10] in a simplified form and we apply it on different PR sub-band coding systems that have different orthogonality characteristics (Biorthogonal, Orthogonal and Bspline wavelets). We selected Bspline wavelets to be included in our comparison as they are well known of being semi orthogonal, as they are orthogonal across different scales/channels, but not orthogonal within the same channel, in other words they are orthogonal across time shifts but not across time scale. We present an upper bound for shift variance for these systems mathematically and experimentally. Finally we discuss our results and provide a tradeoff analysis between different sub-band coding structures. We claim that our main contribution is presenting the shift variance metrics reported in [10-13] in a much simplified forms, as well as applying and comparing it on different sub-band systems.

Section 2 analyzes different shift variance bounds and metrics for multirate sub-band coding systems in general. Section 3 presents the bounds on shift variance for two channel (2-CH) PR sub-band coding systems for either orthogonal or biorthogonal systems. Section 4 presents our own developed shift variance bounds on Bspline PR sub-band coding systems. Finally a comparative result analysis of different bounds of shift variance on Biorthogonal, Orthogonal and Bspline wavelets is presented in section 5. Discussion and Conclusion in section 6 & 7, respectively

2. Shift variance for subband coding system

In this paper we will note the following, for a M band multirate filter bank, Fig. 1, if the input signal is $s[n]$, and the output of $s[n]$ is $y[n]$, then when the input signal is shifted by m samples so that the input is $s[n-m]$, the output is denoted by $x^m[n]$, while $y^m[n] = y[n-m]$. Hence for a system to be fully shift invariant $x^m[n]$ should be equal to $y^m[n]$. We denote $r^m[n] = x^m[n] - y^m[n]$. The residual energy for any band, which is the energy for the difference signal $r^m[n]$ for a given input $s[n]$, which is proportional to the amount of shift variance in the band, would be,

$$E_r[m] = \|r^m[z]\|_2^2 = \frac{1}{2\pi} \int_{-\pi}^{\pi} |R^m(e^{j\omega})|^2 d\omega = \frac{1}{2\pi} \int_{-\pi/M}^{\pi/M} \|r_M^m(e^{j\omega})\|_2^2 d\omega \quad (1)$$

Where $r_M^m[z]$, which is the modulation vector for the difference signal $r^m[n]$, is

$$r_M^m(z) = X_M^m(z) - Y_M^m(z) = \frac{z^{-m}}{M} [g_M(z)h_M^T(z)D^{-m} - D^{-m}g_M(z)h_M^T(z)]s_M(z) = T(m, z)s_M(z) \quad (2)$$

Where $D \in C^{M \times M}$ a diagonal matrix $\text{diag} [1, W, W^2, \dots, W^{M-1}]$, Hence, $D^{-m} = \text{diag} [1, W^{-m}, W^{-2m}, \dots, W^{-m(M-1)}]$

The norm of $r_M^m[z]$ would be

$$\|r_M^m(z)\|_2^2 = (r_M^m(z))^T \overline{r_M^m(z)} = s_M^*(z)T^*(m, z)T(m, z)s_M(z) = s_M^*(z)A(m, z)s_M(z) \quad (3)$$

Where the matrices $T(m, z), A(m, z) \in C^{M \times M}$. Thus the residual energy would be

$$E_r[m] = \frac{1}{2\pi} \int_{-\pi/M}^{\pi/M} s_M^*(z)A(m, z)s_M(z)d\omega \quad (4)$$

In any subband coding system for a filter bank K , if the output $x^m[n]$ which is because of the shifted input $s[n-m]$ can be expressed as $x^m = K \circ \tau_m(s)$, where K, \circ are the filter bank and the concatenation process, and τ_m is the shift operator.

Then, the shifted output signal $y^m[n]$ can be expressed as $y^m = \tau_m \circ K(s)$. Hence for a the filter bank K to be fully shift variant, $[K, \tau_m] = K \circ \tau_m - \tau_m \circ K$ should be zero for any input. This last term $[K, \tau_m]$ is known as a commutator [10-13], and

$$it\ should\ be\ proportional\ to\ the\ mean\ square\ error\ between\ x^m[n]\ and\ y^m[n].\ Thus,\ E_r[m] = \|[K, \tau_m](s)\|_2^2 \quad (5)$$

We note here that in any subband coding system channel, fig.2, even if the analysis and synthesis filters are fully shift invariant, the processing inside the band (decimators and interpolators) causes a certain amount of shift variance. Even though this analogy may seem strange, as for any band M the decimation and interpolation by factor M shouldn't lose any data and is completely reversible in a any PR system [3,14], but if we remember that there is an amount of overlap between different channels (overlap of frequency between High Pass and Low Pass filters in a 2-CH system) that causes this data alteration (shift variance), we justify why the PR system is shift variant.

Hence in an ideal scenario, where all analysis (or synthesis) filters are ideal with sharp transition and no overlap between the filters, there PR system would be fully shift invariant in spite of the processing in the band. This can be verified in the result section where we see that most amount of shift variance is at frequency overlap regions in the filter frequency response graph, fig. 3-10.

Since we are interested in finding the worst shift variance behavior for a PR system, the error energy $E_r[m]$ should be maximum, this will happen if the residual input signal is $\|s[n]\|_2 \leq 1$ for any input. Hence because of eq. 1-5, [10-13], the

max eigenvalue of the operator norm $\|r_M^m(z)\|_2^2$, would be the upper bound of $E_r[m]$, which is the worst case scenario for shift variance in a M band multirate filter bank channel. The upper bound of $E_r[m]$ is denoted $E[m]$, where $E[m] = \sup E_r[m]$ and sup stands for supremum which is the least upper bound.

$$Hence \quad E[m] = \|[K, \tau_m](s)\|_\infty^2 = \max \lambda_1(m, e^{j\omega}) \quad (6)$$

Example of shift variance in a subband PR system (2-CH)

For a single channel case of a 2-CH PR filter bank, D and T would be,

$$D^{-1} = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \text{ and } T_i(z) = z^{-1} \begin{bmatrix} 0 & -G_i(z)H_i(-z) \\ G_i(-z)H_i(z) & 0 \end{bmatrix} \quad (7)$$

Resulting in

$$\lambda_{i1}(e^{j\omega}) = \max(|G_i(-e^{j\omega})H_i(e^{j\omega})|^2, |G_i(e^{j\omega})H_i(-e^{j\omega})|^2) \quad (8)$$

,which is the max eigenvalue for channel i . For a 2-CH multi-rate system, the PR property would imply

$$s_M(z) = \frac{1}{2}(g_{0M}(z)h_{0M}(z)^T + g_{1M}(z)h_{1M}(z))s_M(z) \quad (9)$$

$$\text{where } G(z) = \begin{bmatrix} G_0(z) & G_1(z) \\ G_0(-z) & G_1(-z) \end{bmatrix} \quad H(z) = \begin{bmatrix} H_0(z) & H_0(z) \\ H_1(z) & H_1(z) \end{bmatrix}. \text{ Hence, } G_0(z) = \frac{2H_1(-z)}{\det(H(z))} \text{ and } G_1(z) = \frac{2H_0(-z)}{\det(H(z))}$$

$$\text{So, } \lambda_{01}(e^{j\omega}) = \max\left(\frac{2H_1(e^{j\omega})H_0(e^{j\omega})}{|\det(H(-e^{j\omega}))|^2}, \frac{2H_1(-e^{j\omega})H_0(-e^{j\omega})}{|\det(H(e^{j\omega}))|^2}\right) \text{ and } \lambda_{01}(e^{j\omega}) = \lambda_{11}(e^{j\omega}) \quad (10)$$

In the last equation, the 2 eigenvalues of the norm of the 2-CH system were equal, as it is a perfect reconstruction system. This would lead to the following equation

$$\|[K_0, \tau_1]\|_\infty = \|[K_1, \tau_1]\|_\infty \quad (11)$$

Fig. 3-6 shows examples of the worst case scenario of shift variance in different 2-Ch PR systems, we also show the frequency response of the associated analysis filters. It can be easily noticed that the max amount of shift variance exists around the overlap area.

3. Bounds of Shift variance for 2-CH orthogonal and biorthogonal systems

As orthogonal subband PR system are more restrictive by definition and nature [1,3,14] and they also have less overlap between the Low Pass and High Pass regions, it is normal to expect that they introduce an amount of shift variance that is less than biorthogonal ones.

Since the max amount of shift variance for a 2-CH PR system, as in eq. 10, is

$$\lambda_{01}(e^{j\omega}) = \max\left(\frac{2H_1(e^{j\omega})H_0(e^{j\omega})}{|\det(H(-e^{j\omega}))|^2}, \frac{2H_1(-e^{j\omega})H_0(-e^{j\omega})}{|\det(H(e^{j\omega}))|^2}\right)$$

and since $\frac{2H_1(e^{j\omega})H_0(e^{j\omega})}{|\det(H(-e^{j\omega}))|^2}$ or $\frac{2H_1(-e^{j\omega})H_0(-e^{j\omega})}{|\det(H(e^{j\omega}))|^2}$ typically equals a value of 1 for orthogonal 2-CH PR systems

[3,14]. It can be easily proved that the max amount of shift variance for an orthogonal system would not exceed a value of 1 in a normalized frequency response graph, fig.3-6

For biorthogonal systems due to their more degrees of freedom nature, their maximum eigenvalue (commutator) would exceed the value of 1, fig.5-6. For bi-orthogonal 2-CH PR systems, the $\lambda_1(m, e^{j\omega})$ function has a maximum higher than that of unitary (orthogonal) filter banks and corresponds to worst case scenario for shift variance for this band. The areas under both curves $\lambda_1(m, e^{j\omega})$ and $\lambda_2(m, e^{j\omega})$ for the bi-orthogonal systems are equal, and their worst case shift variance frequency is not center at $\pi/2$, but around it. The higher the maximum value of the curve in fig.4, the more shift variance it has. Table 1, lists the $E_r[m]$ values for different 2-CH PR filter banks. It can be realized that the shift variance behavior for all orthogonal systems tends to be the same for different filter types, this also applies for biorthogonal filter banks. Hence we can conclude that the worst case scenario for shift variance is more dependent of the filter bank structure (orthogonal or bi-orthogonal) rather than the filter type. We can also see that the higher the order of the utilized filter, the less is the $\lambda_1(m, e^{j\omega})$ value for the same filter type, which means less shift variance, as the filter frequency response is more ideal with sharper transition (and less overlap).

Wide band Input signals

It can be seen in fig. 3-7, that the worst case scenario of shift variance or near maximizers, is a narrow band signal around the transition frequency. To complement this worst case shift variance behavior, and to capture more of the filter properties rather than properties of the filter banks structure, we can apply an additional bound for shift variance, under the assumption that the input signal for the subband PR system exhibit a given amplitude spectra. Similar to earlier work in [10-13], we will use a wide band model spectra as the input signal, like a signal with a flat spectrum

If we specify an amplitude spectrum $|S(e^{j\omega})| = \Phi(e^{j\omega})$ we would also be specifying absolute values of the entries of the

modulation vector $s_M(e^{j\omega})$. Hence, from the weight function $\omega(e^{j\omega}) = \sum_{m=0}^{M-1} |\Phi(W^m e^{j\omega})|^2$ formed from the modulated

versions $\Phi(e^{j\omega})$, we can define this wide band input signal additional measure of shift variance by

$$\tilde{E}_w[m] = \frac{1}{2\pi} \int_{-\pi/M}^{\pi/M} \lambda_1(m, e^{j\omega}) \omega(e^{j\omega}) d\omega \quad (12)$$

Hence, for these types of signals, the worst case scenario for shift variance corresponds to a weighted integration of the max eigenvalue of the commutator, $\sqrt{\lambda_1(m, e^{j\omega})}$, rather than its peak height as eq. 1-5. Similarly to eq.6 & 12, this additional

measure $\tilde{E}_w[m]$ is also is the same for both channels $\tilde{E}_w[m]$, as $\| [K, \tau_m](s) \|_2^2 = \tilde{E}_w[m]$

For a 2-CH PR filter bank, we would have: $\tilde{E}_w[1] = \| [K, \tau_1](s) \|_2^2$, for every signal s with $|S(e^{j\omega})| = \Phi(e^{j\omega})$. By choosing $\Phi(e^{j\omega})$ to be wide band, this would correspond to the additional measure of shift variance for wide band signals. This additional bound corresponds to the area under $\lambda_1(m, e^{j\omega})$ and would typically decrease with the increase of the filter length, which would imply less width of either of the 2 curves in fig.4-7.

Table 1 also lists the $\tilde{E}_w[m]$ values for the same orthogonal and biorthogonal PR system of the previous subsection. It can be seen that this additional shift variance measure is more dependent on the filter type, rather than the filter structure. It is also eliminated when there is no overlap in the frequency response between the analysis filters in different channels, as it represents the area of the overlap, while the previous narrow band shift variance measure $E_r[m]$ corresponds to the max

value in the overlap region. Hence, the wide band input shift variance measure $\tilde{E}_w[m]$ is a stronger measure than narrow band shift variance measure $E_r[m]$, as it assumes that the input signal has a wide band flat spectrum.

4. Shift variance bounds on Bspline PR sub-band coding systems

The m^{th} order Bspline function $B_m(t)$, has a finite support and equals zero at $t=0, m$, and is represented by a polynomial of order $m-1$ at the knots $1, 2, \dots, m$. It satisfies the recurrence relation:

$$B_m(t) = \frac{t}{m-1} B_{m-1}(t) + \frac{m-t}{m-1} B_{m-1}(t-1) \tag{13}$$

$$\frac{\partial B_m(t)}{\partial t} = B_{m-1}(t) - B_{m-1}(t-1)$$

The m^{th} order Bspline time domain equivalent function would imply

$$B_m(t) = B_1(t) * B_1(t) * \dots * B_1(t) \quad \leftarrow \text{---} \quad m \text{ times} \quad \text{---} \rightarrow \tag{14}$$

$$B_m(t) \text{ is also symmetric about } m/2; \text{ i.e. } B_m\left(\frac{m}{2} + t\right) = B_m\left(\frac{m}{2} - t\right) \tag{15}$$

In [15], a Bspline based PR multi-scale representation was introduced and for a 2-CH system, as in fig.2, it was shown that the analysis and synthesis filters are:

$$H_0 = \frac{B_m(\omega)}{B_m(\omega/2)} = \frac{1}{2^m} \sum_{k=0}^m \binom{m}{k} z^{-k} = \left(\frac{1+z^{-1}}{2}\right)^m, \quad z = e^{j\frac{\omega}{2}} \tag{16}$$

$$H_1 = -E(-z)\tilde{H}_0(-z), \quad E(z) = \sum_{k=1}^{2m-1} B_{2m}(k)z^{-(k-1)} \quad F_0 = z \frac{E(z)}{E(z^2)} \tilde{H}_0(z) \quad \text{and} \quad F_1 = z^{-1} \frac{\tilde{H}_0(-z^{-1})}{E(z^2)} \tag{17}$$

As shown before the shift variance for a Bspline PR sub-band coding system, could be assessed by a single channel case for either H_0 & G_0 or H_1 & G_1 , Fig.1.

Hence, the max eigenvalue for either channel in a Bspline based 2-CH PR system, would be:

$$\lambda_{11} = \frac{|H_0(z)H_1(-z)|^2}{|\det H(z)|^2} = \frac{\left(\frac{1+z^{-1}}{2}\right)^m \left(\frac{1+(-z)^{-1}}{2}\right)^m \sum_{k=1}^{2m-1} B_{2m}(k)z^{-k-1}}{|\det H(z)|^2} \tag{18}$$

Where m in this case represents the Bspline order used, rather than the PR channel index as in section 3. As shown in eq.18, the eigenvalue of the operator norm would depend on the Bspline order m . We note here that the area under the operator norm curve for either channel is the same for any Bspline order, as in the case of orthogonal and bi-orthogonal filters. We also note that the worst case behavior of shift variance for narrow band input signals would be represented in the peak of the operator norm and would be around $\pi/2$ as the biorthogonal one. The additional bound of shift variance which is for wide band input signals, would correspond to the area under the max eigenvalue curve.

5. Result Analysis

We carried out extensive simulation tests to measure both metrics $E_r[m]$ and $\tilde{E}_w[m]$ for different types of orthogonal, Bi-orthogonal and Bspline PR filters banks. Table 1, compares the numerical values of them for all utilized filters banks. Fig.3-9, shows the maximum Eigen value for both channels λ_0 and λ_1 for the whole frequency band for different orthogonal, bi-orthogonal and Bsplined based systems. As proven in sections 2, 3, and 4, the worst case scenario for shift variance for narrow band signals for a Bspline based PR system, would correspond to the peak point in the curves, while the worst case scenario for shift variance for wide band input signals would correspond to the range of frequencies inside the curve.

6. Discussion

It can be easily proven both experimentally and mathematically that the worst case scenario for narrow band input shift variance signal for orthogonal PR subband coding systems won't exceed the unity value for a normalized frequency response graph, fig. 3, as proven in eq.10. For bi-orthogonal systems this narrow band input shift variance signal gets higher than 1 due to the more overlap between the high and Low bands. For the additional shift variance bound of wide band input signal, orthogonal PR systems in general has a less area under the curve and less $\tilde{E}_w[m]$ value, which implies that their shift variance behavior is much less compared to biorthogonal PR systems.

For different Bspline orders, (sometimes) the higher the B-spline order, the higher is the pulse at the worst case scenario frequency (which would imply more shift variance). This is unexpected due to the increased filter length, which is supposed to imply less shift variance. However, the interpolating nature of Bsplines that is not suited for narrow band signals [16] can justify for us this behavior, also the wide band input signal behavior, which is the area under the operator norm

curve, λ_0 or λ_1 , can make this small increase eliminated. For higher B-spline orders, this width of the operator norm curve is smaller, (which would imply less shift variance). From analyzing fig 5-7, it can be realized that the amount of increase in the frequency peak at the worst case scenario for the error norm is negligible compared to the amount of reduction of the width of the curve, for different Bspline orders. Hence the higher the B-spline order for this 2-Ch PR multi-rate system, the more shift invariant it is. Bsplines are also more suitable for wideband spectrum input signals. We note here that the average number of taps for an analysis/synthesis filter was 14 for the cubic Bspline, 25 for the quadratic Bspline and 35 for the 5th order B-spline. Typically for an ideal shift invariant Bspline filter, $\tilde{E}_w[m]$ tends to go to zero, while $E_r[1]$ tends to be 1. This analogy has been verified experimentally as in fig 4-6; however it was not possible to prove mathematically, eq.18. The cubic B-spline (order 3) tends to outperform some of the well known orthogonal or bi-orthogonal filter banks in terms of $E_r[1]$ or $\tilde{E}_w[1]$ values. It is obvious from comparing fig.3-9, that Bspline decomposition filters exhibits much less shift variance for similar filters lengths of other structures. We note here that this improvement for shift variance behavior with a Bspline subband coding PR system in general, is mainly due to the nature of Bsplines that are semi orthogonal, as they are orthogonal across different scales/channels, but not within the same channel [17] (orthogonal across time shifts, but not across time scale). Hence the overlap between different channels is reduced than in similar bi-orthogonal filters bank systems. This justifies their shift variance behavior improvement, it can also be seen in the frequency response High Pass and Low Pass graphs, fig 8-10.

7. Conclusion and Acknowledgement

In this paper we presented some of the most popular metrics for shift variance, previously reported in [10-13] in a clear manner. Mathematical proof as well experimental simulations are illustrated to prove the achieved results and the shift variance worst bounds for different input scenarios on different decomposition structures (i.e. orthogonal and biorthogonal systems). We also applied the proposed shift variance bounds on a Bspline 2-CH multirate PR systems. Our analysis and testing implied that a higher order Bspline would correspond to less shift variance and would have a larger impact in reducing the shift variance behavior than higher corresponding orders for other PR systems such as orthogonal or biorthogonal systems. The author would like to acknowledge the help received from Prof. Til Aach, RWTH Aachen University, for the extensive help and simulation code. Joint Watermarking and Compression for Images in Transform Domain

Gamal Fahmy

Electrical Engineering Dept., Majmaah University, KSA

Abstract: Image watermarking, authentication and encryption have gained an increased importance during the last decade. This is due to the widespread use of visual media over the Internet and in several digital media applications. Several watermarking techniques have been proposed, some in spatial domain, and more recently in the transform/frequency domain and have been reported to be robust against different attacks, namely compression. It is also well known the importance and effectiveness of compression techniques to store transmit and retrieve visual information. However, the creation or development of a joint watermarking and compression framework for images has yet to be explored, where watermarking and compression could be pursued jointly on a trade-off manner. In other words, watermarking embedding/extraction can be performed on compressed domain data, while compression parameters could be used as watermarking keys. The primary focus of this paper is to explore this novel/unique idea. We propose a joint watermarking and compression (JWC) technique in the transform domain. This transform domain is based on the Natural Preserve Transform and can be utilized to achieve a balance between watermarking and compression for visual information. Watermarking performance is evaluated blindly for different compressed domain data scenarios, while compression performance is analyzed for other watermarking cases. Extensive simulation results that demonstrate the efficiency of the proposed joint watermarking and compression technique are presented.

Keywords: Image Watermarking, Natural Preserve Transform, Image Compression; Hartley Transform

I. Introduction

The rapid growth of visual media based applications necessitates sophisticated compression techniques in order to store, transmit and retrieve audio-visual information. The recent MPEG 4 and JPEG 2000 standards address the need for content based coding and manipulation of visual media. With the widespread use of the Internet and the rapid and massive development of multimedia, there is an impending need for efficient and powerfully effective copyright protection techniques [1-3]. Digital watermarking schemes are typically classified into three categories. (1) Private watermarking which requires the prior knowledge of the original information and secret keys, at the receiver, (2) Semi-private or semi-blind watermarking where the watermark information and secret keys may be available at the receiver, and (3) public or blind watermarking where the receiver must only know the secret keys [4]. The robustness of private watermarking schemes is high to endure signal processing attacks. While private watermarking is suitable for high security applications such as financial or defense data, it is not feasible in real applications, such as DVD copy protection where the original information may not be available for watermark detection. On the other hand, semi-blind and blind watermarking schemes are more feasible in that situation [5], but they have lower robustness than the private watermarking schemes [6]. Hence, while private watermarking is mainly utilized for authentication and verification, blind or public watermarking is for copy protection applications. In general, the requirements of a watermarking system fall into three categories: robustness, visibility, and capacity [7]

A variety of image watermarking methods have been proposed mostly based on transform domain [7-9]. In spite of the successful performance of most watermarking techniques reported in the literature, they still suffer from being semi-fragile due to the energy concentration of their transform domains (DCT and Wavelets), which makes them discard much of the mid and high frequency watermarked data in compression [10-13].

Watermarking compressed domain data will obviate the need for it to be decompressed for watermark extraction, while compressing watermarks would store and transmit visual data efficiently. Hence, there is an impending need for sophisticated joint watermarking and compression techniques that could compress, protect and watermark data simultaneously. While compression aims at concentrating data in the least possible information, watermarking aims at distributing and hiding logos and parameters. Hence, compression and watermarking are inversely related and they have to be treated on a trade-off manner. The amount of extracted/retrieved watermarked data is affected by the compression degree of the host data, while the efficiency of compression is affected by the amount of data that needs to be embedded and extracted.

In this paper we propose a transform domain based technique for data watermarking that has been previously reported in [14], and [15]. This transform domain is based upon the Natural Preserve Transform (NPT) originally reported in [16]. We utilized this transform domain to present our main contribution in this paper, which is to develop a joint compression and watermarking system based on the NPT and wavelet domains for visual data. We try to achieve a framework/equation that includes both compression and watermarking jointly in our proposed system. The organization of this paper is as follows. Section 2 contains necessary mathematical background about the NPT based watermarking approach. Section 3 briefly explains the watermarking embedding and extraction process in the NPT domain. Section 4 shows the robustness of the watermarking technique against several attacks. Section 5 shows our proposed joint

watermarking and compression framework, analysis and results. Discussion is in section 6, followed by conclusions in section 7.

2. Mathematical Background for NPT based Watermarking

The NPT was first used as a new orthogonal transform that holds some unusual properties that can be used for encoding and reconstructing lost data from images. The NPT transform of an image S of size $N \times N$ is given by:

$$S_{tr} = \psi(\alpha) S \psi(\alpha) \quad (1)$$

As $\psi(\alpha)$ is the transformation kernel defined as in [17-18].

$$\psi(\alpha) = \alpha I_N + (1 - \alpha) H_N \quad (2)$$

I_N is N^{th} order identity matrix, $0 \leq \alpha \leq 1$, and H_N is any orthogonal transform, like Hadamard, DCT, Hartley, etc. Throughout this paper, we use the 2-D Hartley transform, defined by

$$H_N(k, j) = \frac{1}{\sqrt{N}} \left(\cos \left(\frac{2(k-1)\pi}{N} \right) + \sin \left(\frac{2(j-1)\pi}{N} \right) \right) \quad (3)$$

We note here that the Hartley transform was utilized due to its circular symmetry performance, as it evenly distributes the energy of the original image in the 4 corners of the orthogonally projected transform image, Fig. 1(a). Hence the Hartley transform achieves a trade-off point between the energy concentration feature (which is crucial for any transform domain for compression purposes) and the even distribution and spreading feature (which is crucial for watermarking and data hiding applications).

After the transformation kernel ψ is calculated in eq. 2, it is multiplied by the input image as a separable 2-D kernel, eq.1. The value of α in eq. 2, gives a balance between the original domain (that would be multiplied by the identity matrix) and the transform domain (that would be multiplied by the Hartley basis). Clearly, when $\alpha = 1$, the transformed image is the original image, whereas when $\alpha = 0$, it is its orthogonal projection (which is the Hartley transform as in this paper). Hence the NPT transform is capable of concentrating energy of the image while still preserving its original sample values on a trade-off basis. This makes the NPT transform domain image has both almost original pixel values (that can not be visually distinguished from the original image) and a capability feature of retrieving the logo watermark image from a small part of the transformed image (provided that this small part has enough energy concentration in it).

The original image can be retrieved from the transformed image S_{tr} , using

$$S = \psi^{-1}(\alpha) S_{tr} \psi^{-1}(\alpha) \quad (4)$$

If H is symmetric, as in Hartley matrices, the matrix $\psi^{-1}(\alpha)$ can be computed as follows:

$$\psi^{-1}(\alpha) \equiv \phi = \frac{1}{\alpha} \left[I - \frac{1-\alpha}{\alpha} H + \left(\frac{1-\alpha}{\alpha} H \right)^2 - \left(\frac{1-\alpha}{\alpha} H \right)^3 + \dots \right] \quad (5)$$

Fig. 1(b-c) shows the Lena image and its NPT transformed image. α is adjusted to a value of 0.994, which yields a nominal PSNR of around 45 dB. The high similarity between the original and transformed images, suggests that NPT is very convenient for watermarking and data hiding.

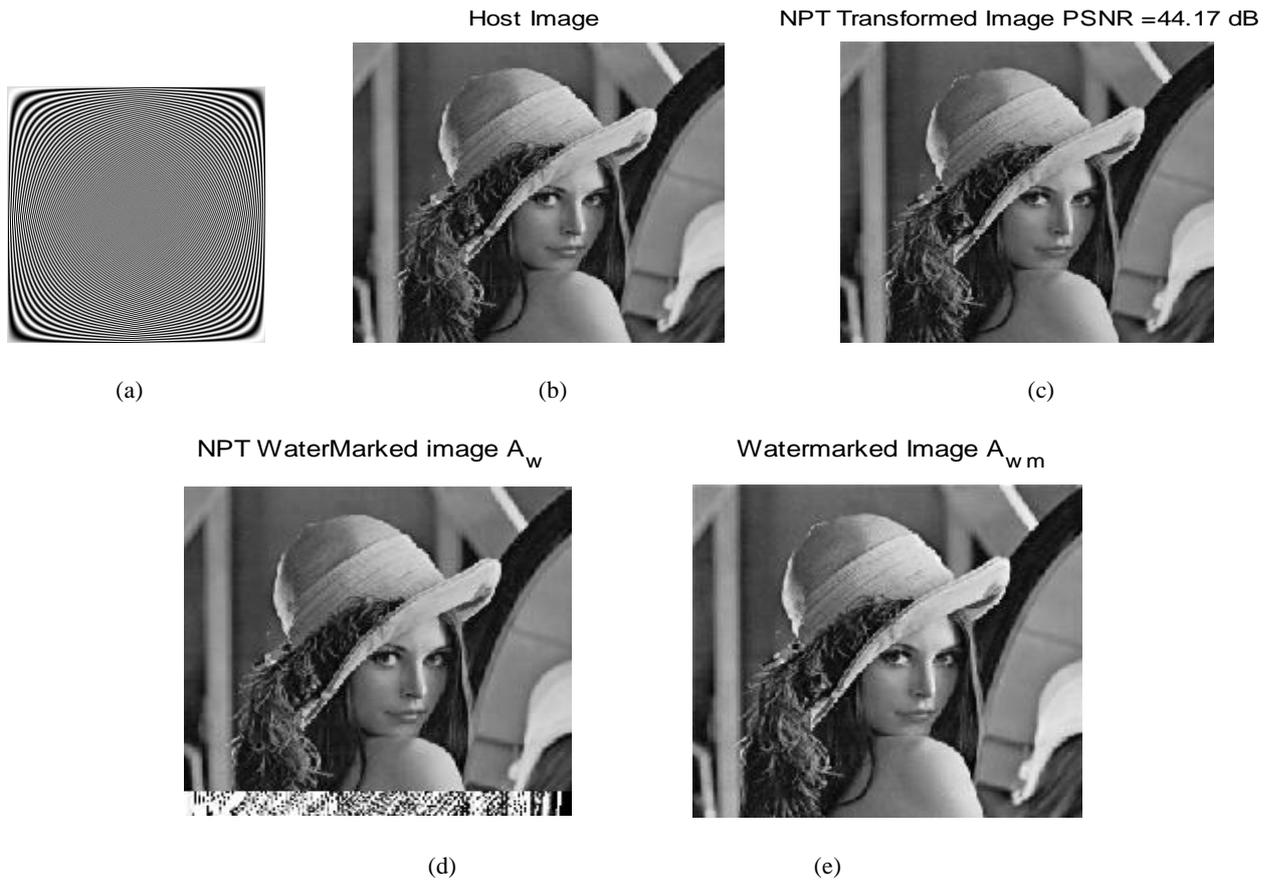

Fig. 1. (a) Transform basis of the Hartely. (b-c) Original image and its NPT image, computed with $\alpha = 0.994$. (d) NPT watermarked image with logo in last r rows. (e) NPT watermarked image with last r rows replace with last r rows of original image

3.1 Watermark Embedding

Let the host image S , (size $N \times N$) be watermarked by a watermarking logo (image) w , of size $(m \times n)$. In the bottom embedding technique [14-15], the logo is embedded to S as the last r bottom lines. Hence, the logo matrix is reshaped to be a matrix w_l (of size $r \times N$, $r = \frac{mn}{N}$). Then, the last r rows of S are replaced by the reshaped logo w_l , as in Fig. 1(d). This would

yield a watermarked image S_{wm} , $S_{wm} = \begin{bmatrix} S_1 \\ w_l \end{bmatrix}$, $S_1 = S(1 : N - r, :)$. Then the NPT of S_{wm} is obtained as:

$$A_w = \psi(\alpha) S_{wm} \psi(\alpha) \equiv \begin{bmatrix} A_{0w} \\ z \end{bmatrix} \begin{matrix} \updownarrow (N-r) \\ \updownarrow r \end{matrix} \begin{matrix} \leftarrow N \rightarrow \end{matrix} \quad (6)$$

This step in eq. 6, would register the watermark (distribute its energy) over the entire host image. In order to make the watermarking logo invisible, we replace the last r rows z of A_w with the last r of the original image S , Fig 1(e).

$$A_{wm} = \begin{bmatrix} A_{0w} \\ S(N-r+1 : N, :) \end{bmatrix} \quad (7)$$

3.2 Watermark Extraction

The watermarking extraction process is divided into a non-blind case, and a blind case. In the non blind case the original host image is known at the receiver side and we only try to extract the logo from the watermarked image. In the blind case the host image is not known at the receiver side, and we try to extract both the host and logo images from the watermark image, A_{wm} .

3.2.1 The Non Blind Case

Assuming that the original image S , the parameter α of eq. 1 and the type of the orthogonal transformation H_N , are known at the receiver, the extraction of the watermark from the received A_{wm} proceeds as follows:

1. Since the size of the watermark $m \times n$ is known at the receiver side, as well as the number of rows of w . Form

$$Y = A_{wm} \phi \equiv \begin{bmatrix} Y_1 \\ Y_2 \end{bmatrix} = \psi S_{wm} = \psi \begin{bmatrix} S_1 \\ w_1 \end{bmatrix}. \quad (8)$$

$$2. \text{ Partition } \psi = \begin{bmatrix} \psi_{11} & \psi_{12} \\ \psi_{21} & \psi_{22} \end{bmatrix} \begin{matrix} \Downarrow (N-r) \\ \Downarrow r \end{matrix}. \quad (9)$$

$$\leftarrow N \rightarrow \leftarrow r \rightarrow$$

Then, as long as $N-r \geq r$, the watermark w is the least squares solution of the system

$$Y_1 - \psi_{11} S_1 = \psi_{12} w_1 \quad (10)$$

The quality of extraction is judged by computing the normalized correlation $NCORR$ between the original and extracted

$$\text{logo, i.e. } NCORR = \frac{\sum_{i=1}^m \sum_{j=1}^n w_{ij} w_{exij}}{\|w\| \cdot \|w_{ex}\|} \quad (11)$$

w_{ex} is the extracted watermark. The non-blind extracted logo, in our experiments achieved a $NCORR = 1$ performance factor.

3.2.2 The Quasi Blind Case

When the prior knowledge of the host image S is not available, the following quasi blind technique is proposed for watermarking extraction of an NPT-based watermarked image. The proposed technique can be described as follows:

$$1. \text{ Partition } \psi = \begin{bmatrix} \psi_{11} & \psi_{12} \\ \psi_{21} & \psi_{22} \end{bmatrix} \begin{matrix} \Downarrow (N-r) \\ \Downarrow r \end{matrix} \quad (12)$$

$$\leftarrow N \rightarrow \leftarrow r \rightarrow$$

As $A_w \phi = \psi S_{wm}$ from eq. (6, 7, and 8), we can show that

$$\begin{bmatrix} A_{0w} \\ S(N-r+1:N,:) \end{bmatrix} \phi = \begin{bmatrix} \psi_{11} & \psi_{12} \\ \psi_{21} & \psi_{22} \end{bmatrix} \begin{bmatrix} S_1 \\ w_1 \end{bmatrix} \quad \text{i.e. } A_{0w} \phi = \psi_{11} S_1 + \psi_{12} w_1 \quad (13)$$

2. To cancel the effect of S_1 in eq. 13, construct an $(N-r)$ square matrix V such that $V^t \psi_{12} = 0$. This matrix can be easily constructed by expressing its k^{th} vector V_k as follows :

$$V_k = I_{N-r,k} - \sum_{j=1}^r \alpha_{jk} \psi_{12}(:, j), \quad \text{and } I_{N-r,k} \equiv I_{N-r}(:, k), \quad 1 \leq k \leq N-r \quad (14)$$

The α_{jk} are obtained by solving a set of r linear equations satisfying the following condition:

$$\text{Since } \psi_{12} \text{ is an } (N-r) \times r \text{ matrix, } V_k^t \psi_{12}(:, j) = 0 \quad 1 \leq j \leq r$$

then its maximum rank is r . Consequently, the rank of the matrix V is $(N-2r)$, [19].

$$3. \text{ Pre-multiply Equation (13) by } V^t \text{ to yield } V^t A_{0w} \phi = V^t \psi_{11} S_1 \quad (15)$$

As the rank of ψ_{11} is $(N-r)$, the rank of $V^t \psi_{11}$ is $(N-2r)$. So, to have a unique solution of eq.15, r arbitrary parameters of every column of S_1 have to be known at the receiver/extractor. This can be achieved if in the watermarked image A_w , we choose the matrix z (eq. 6), to be $S(N-2r+1:N-r,:)$ instead of $S(N-r+1:N,:)$. (it basically means replicating the r last rows of the image as in Fig. 2 (a)).

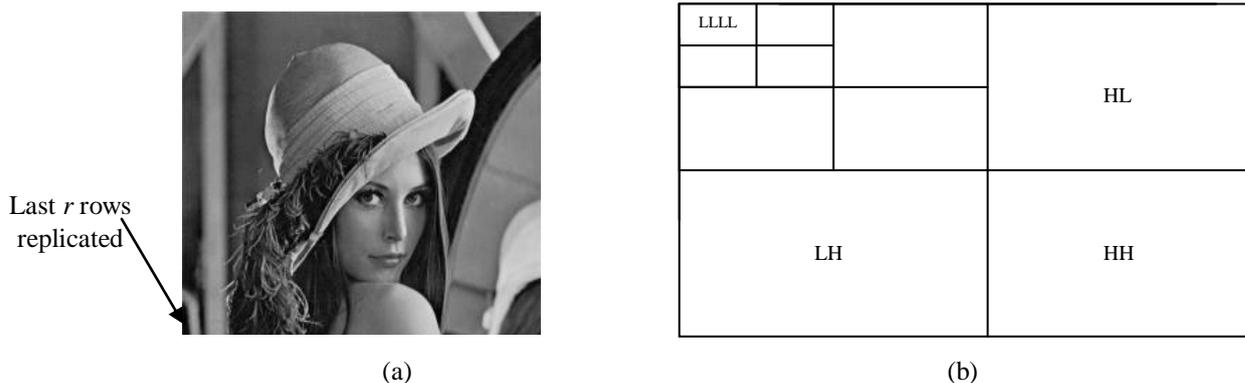

Fig.2. (a) Example of host images with last r rows replicated, $N=256$, $r=8$

(b) LLLL is the lowest band in a 2 layer wavelet decomposition

Having obtained S_j as the unique solution of eq.15, w_j (the logo) is extracted as in the non-blind case, and subsequently reshaped to regain the original watermark w . We used the terminology quasi blind, as a minor amount of information has to be known (r parameters of every column) at the receiver side. We note here that having r rows of the host image known at the receiver side as a mandatory condition for our blind technique is a slight draw back. However if we replicate the r rows of our host image, $S(N-2r+1:N-r,:)$, as the last r rows, our host image would be like fig.4(a) with negligible effect for this replication process, especially if the host image has a large size compared to r , as $N \gg r$.

4. Robustness against attacks (compression, noise and cropping)

The proposed watermarking techniques has been reported to be robust against compression (which is mainly shown in the next section), cropping and noise attacks [14-15]. Although this paper is primarily aimed at introducing a joint compression and watermarking system, we report here the performance against different attacks and compare it with other literature performances.

Regarding the cropping attack [14], if we crop the host watermarked image up to 50% of its original size, full extraction of the watermarked logo is shown to be possible, as in the non blind case, provided that the remaining watermarked size is at least the logo size. This ratio outperforms most of the other watermarking techniques against this kind of attack.

Regarding the noise attack, as reported in [15], we mixed the watermarked image with different amounts of noise such as the salt and pepper noise and the AWGN noise, so that the PSNR value of the original image went as low as 22-25 dB. The watermarking logo was correctly extracted with a correlation rate higher than 90%, which is very competitive with the recent literature [8].

We note here that studying the compression attack's impact on the proposed watermarking scheme is thoroughly examined in the next section, as it is part of the proposed joint compression and watermarking system, but we briefly state that the proposed watermarking approach can fully extract the hidden logo (more than 90% NCORR value) with up 1.0 bpp compression using the SPIHT compression approach.

5. NPT based joint watermarking and Compression

In our proposed system, we watermark our host image with a logo image to obtain a watermarked image. Then we compress the watermarked image through any transform based image compression standard. In our case we selected the SPIHT wavelet based image codec [20], to compress and then decompress (at the receiver side) the watermarked image, and then the extraction process takes place for the host and logo images. In our system we measure the compression performance by the PSNR quality of the reconstructed image (with respect to the original image) for a specific bit rate, while we measure the watermarking performance by the PSNR quality of the extracted image (host and logo) for a specific bit rate with a specific logo size. It can also be easily proven that the target compression bit rate would significantly affect the watermarking extraction quality, as shown next.

We also watermark compressed domain data, by watermarking the LL band image in the wavelet transform of any compression process, Fig. 2(b). It can also be shown that the amount of watermarked data (with its target extraction quality) would significantly affect the compression reconstruction performance; it is also dependent on which wavelet level (number of layers) its LL band is being watermarked as also shown in the next section. We note here that the higher the LL band (more layers) that is being watermarked, the less the quality of the reconstructed image from wavelet based compression theories. This is due to the fact that more data would be concentrated in LL band of the highest layer; therefore any manipulation to the band coefficients, as what happens by NPT, would more deteriorate the reconstructed image, also as a larger number of high band frequencies are dependent on it as in SPIHT or EBCOT [20-21]. We note here that if there is no watermark, zero number of embedded bottom lines, then increasing the number of wavelet layers would definitely enhance the PSNR of reconstructed image from enhanced resolution, but if there is a watermark, even if it is small (5 rows), it will affect (negatively) the reconstructed host image, and hence increasing the number of wavelet decomposition layers would further deteriorate the PSNR of the reconstructed host image. Increasing the number of wavelet layers would also

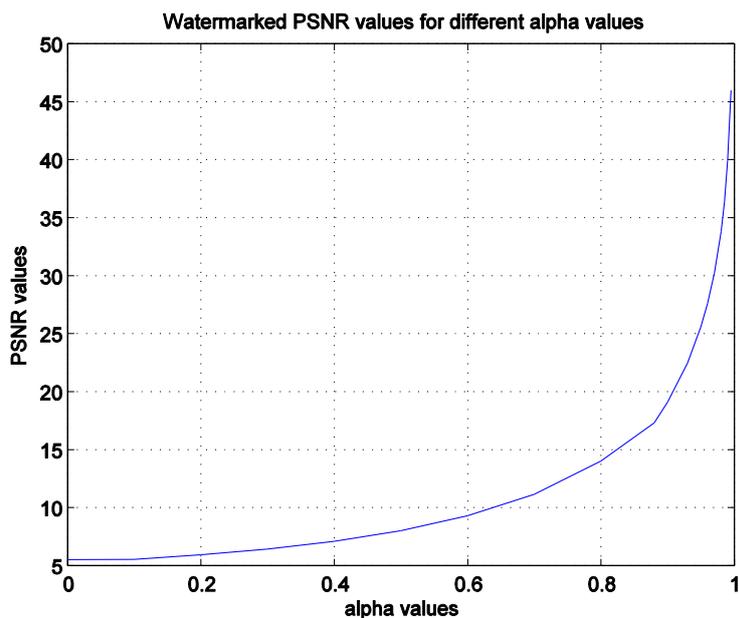

double the number of r rows in the bottom embedding process, as the logo (watermark) has a fixed size and the last LL band would be half the number of rows and columns of the previous case for every decomposition level. This would provide us with one more justification for the deteriorated PSNR reconstruction quality of the host image for increasing the number of wavelet layers from this joint watermarking and compression process.

For a watermarking system that is based on section 3, Fig.3 shows the PSNR values of the watermarked image for different values of alpha (α), along with the corresponding NCORR values of the extracted image, when the watermarked image is compressed using SPIHT with bpp (bits per pixel) =2.5, and no wavelet decomposition layers. It can be seen in the figure, that the smaller the value of alpha, the less contribution of the original image in eq.2, and the lower the PSNR, but the more contribution of the Hartley basis, which means more energy distribution, which will yield better extraction, better NCORR, and vice versa. A value of alpha in the range 0.985-0.99, is the optimal trade-off point between the 2 curves for this watermarking case, as in Fig. 3.

Fig. 4, shows a block diagram for our proposed joint watermarking and compression system. There are primarily three parameters that can significantly affect the performance of both watermarking and compression. The alpha parameter (α) as in eq.2, the number of wavelet layers and the target bit-rate in compression in the adopted SPIHT.

While it can be easily proven that the higher the bit-rate, the better is the PSNR of the extracted image (both host and logo) and the lower is the compression performance from basic rate-distortion theories [20-22]. The higher the value of α the more weight of the original image would be in eq.2, which would imply less contribution of the Hartley basis, which means lower amount of energy distribution, which means less watermarking performance.

On the other hand, more wavelet decomposition layers, which would imply more resolutions levels, and would lead to better compression performance as well known from successful wavelet based coders [20, 21]. Since in our system we watermark the LL band in the last wavelet layer, increasing the number of layers would deteriorate the compression reconstruction quality of watermarking extracted images, as higher band frequencies are added to it in reconstruction, as in Fig. 6. Therefore increasing the number of wavelet layers in our system would imply less PSNR for the reconstructed image (that has been watermarked and extracted). Hence, while increasing the bit rate would enhance the reconstruction quality of watermarking an extracted image, increasing the number of wavelet decomposition layers would deteriorate it in our joint watermarking and compression system, and the lower the value of alpha, the better the watermarking extraction as the NCORR curve in Fig. 3. Since the number of wavelet decomposition layers and the bit rate are two compression parameters and they have an inverse impact on the watermarking performance, they could be jointly combined in a single variable C , according to this relation, $C=K_1 * bpp + (1/K_2 * No. \text{ of wavelet layers})$

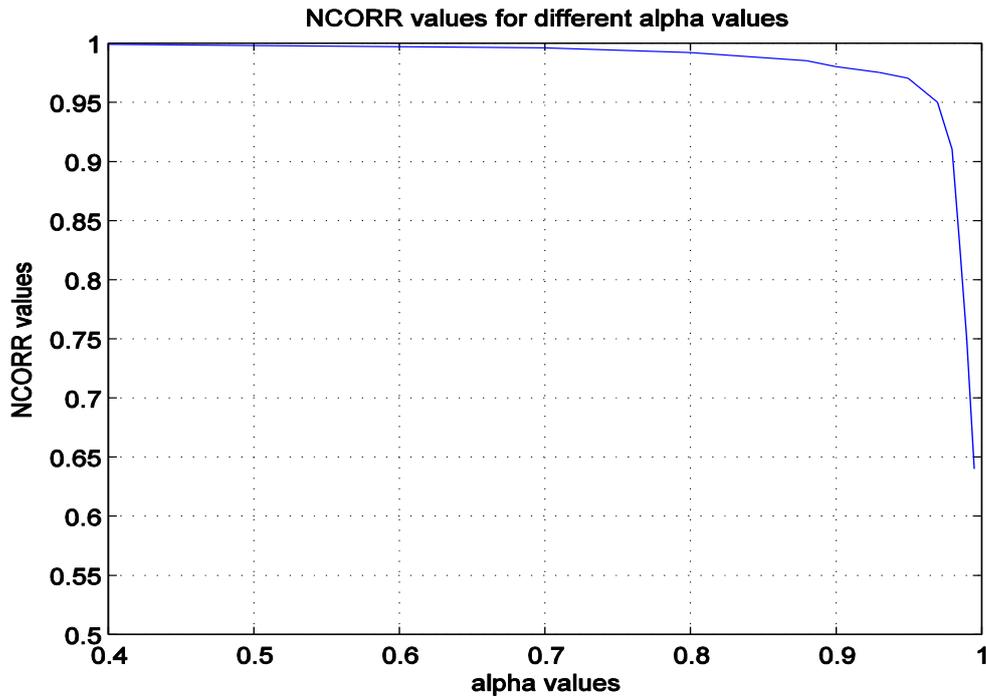

Fig. 3 PSNR and NCORR values for differential alpha values for different

From all above, we can identify the two variables of alpha and C as the parameters that affect the performance of our proposed joint watermarking and compression system. As shown above, each of them can significantly affect the performance of both watermarking and compression (JWC) on an inverse manner. Hence these two parameters can be combined into a single equation with a Lagrange multiplier as in eq. 16. The Lagrange multiplier can be adjusted to control both alpha (α) and C on a trade-off manner. JWC stand for performance of our joint system.

$$JWC = \alpha + \lambda * C \tag{16}$$

Fig.4 shows a block diagram of the proposed joint watermarking and compression system with a Lagrange multiplier as an adjustor that controls the trade-off between both. Fig. 5 shows the PSNR and the NCORR values for different alpha values on the same curve, it can be shown that an alpha value of 0.985 is optimal on that curve's trade-off.

Fig.6 shows the reconstructed PSNR quality of host images from watermarking the LL band for different number of layers, with an alpha (α) value of 0.985 and 2.5 target bpp. Fig. 7 shows the reconstructed PSNR quality of host images for different bit rates from one wavelet decomposition layer with an alpha value of 0.985.

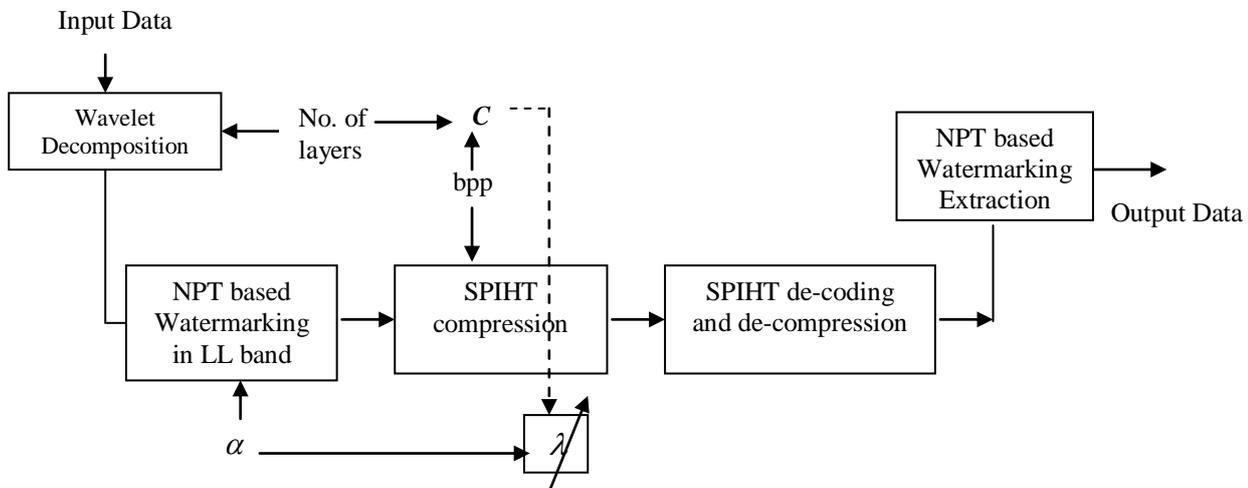

Fig. 4 Block diagram of a joint watermarking and compression system

We note here the variables of K_1 , K_2 and λ are image dependent, and can be adjusted according to the needed point on the compression and watermarking trade-off.

Fig. 8 shows the PSNR of the reconstructed and extracted host image with a bpp 2.5 with different numbers of bottom embedding rows, which imply different logo sizes. It is obvious that the increased number of bottom rows of the logo image, would deteriorate the PSNR of the reconstructed host image.

Fig. 9 shows the compression performance (PSNR reconstruction quality of watermarked host image) and the watermarking performance (NCORR correlation of the extracted logo), both against different alpha (α) values as well as different C values, a higher C value would imply high bit rate and less number of wavelet decomposition layers. It can be shown that the compression and watermarking performances are inversely affected by changing the value of either alpha or C ; hence they have to be treated on a trade-off manner.

5. Discussion

In this paper we presented a joint watermarking and compression system that can both compress and watermark a host image on a trade-off manner. We note here that our primary objective was to present the idea of joint compression and watermarking, rather than a regular single watermarking or compression technique like the recent literature, or our work in [14-15].

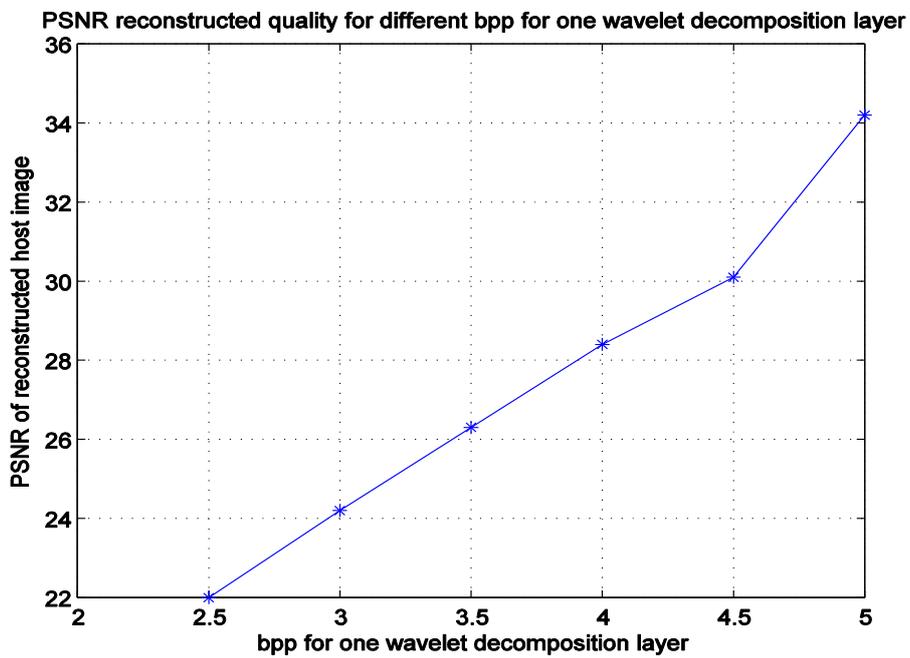

Fig. 7 PSNR reconstructed quality for different bpp for one wavelet decomposition layer

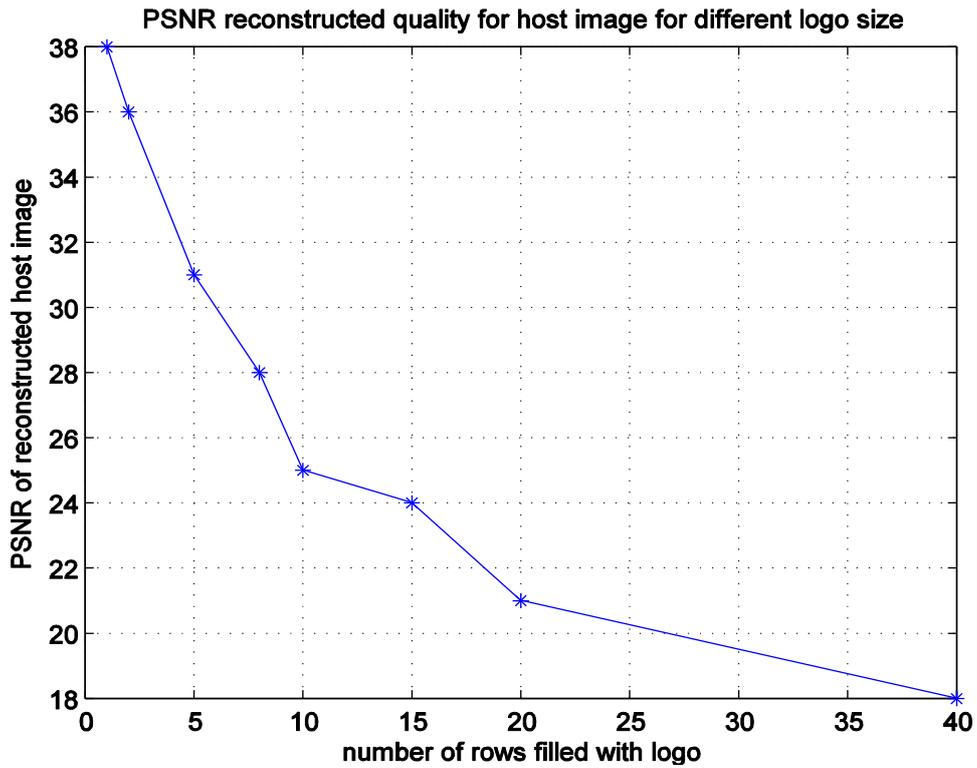

Fig. 8 PSNR reconstructed quality for host for different logo sizes

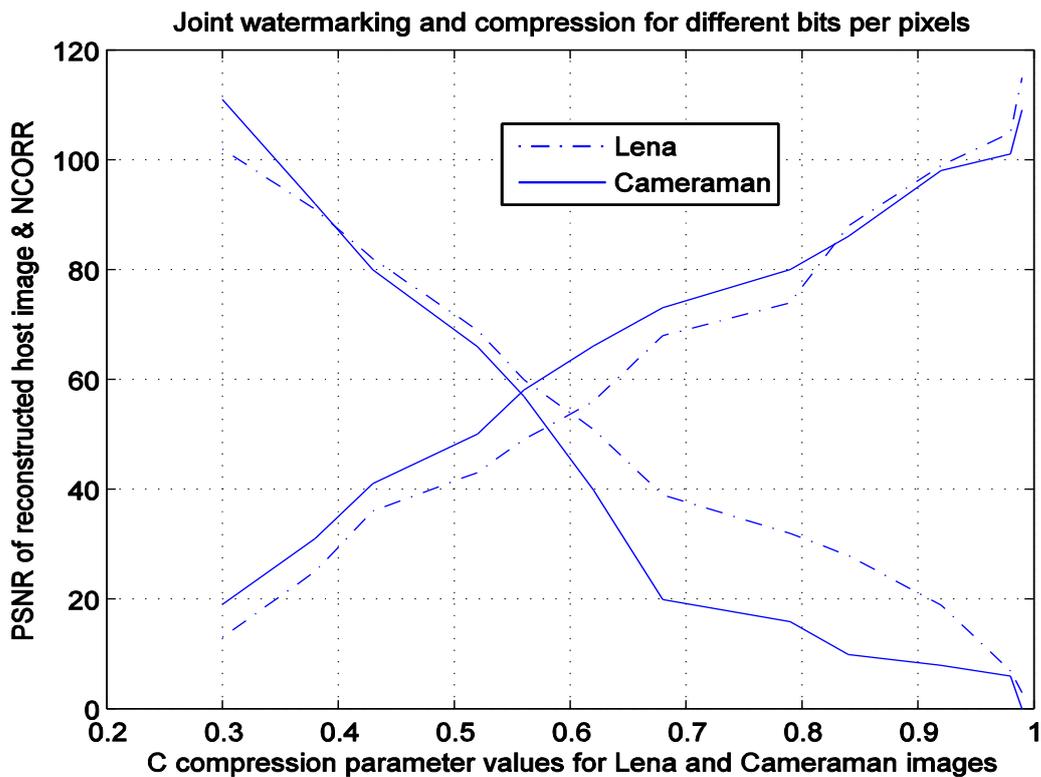

Fig. 9 Joint watermarking and Compression for different alpha values for Lena and Cameraman images

When treating compression and watermarking jointly, compression parameters can be treated as security keys, while watermarking data or keys can be considered as compression indices. Our proposed simulation results showed that there were three variables that could significantly affect the performance of both watermarking and compression. Bit rate, number of wavelet decomposition layers and the alpha value, which controls the balance between energy concentration (compression) and energy distribution (watermarking). The number of wavelet decomposition layers and the bit rate are two compression parameters that are typically defined in any wavelet-based compression process and they were combined in a single compression parameter C . Since both the alpha value and the C compression parameter had inverse impact on the performance of both compression and watermarking, a Lagrange multiplier equation was introduced that controls the balance between alpha and C on a trade-off manner. We note here the Lagrange multiplier value would depend on both the image class/type/content in addition to the desired point between compression and watermarking performances.

7. Conclusions

Our proposed system can be utilized in joint watermarking and compression applications that exploits compression parameters as watermarking variables, while compression indices could be used as watermarking actuators/adjustors. Our illustrated simulation results support our hypotheses and analogies in joint watermarking and compression, that they are inversely related and there is a trade-off relation between them, hence they should be treated jointly to achieve the optimal point of them. This work is funded by the ministry of Communication and Information Technology, Egypt, ITIDA. It has also been funded partly by the Alexander von Humboldt foundation, Germany.

India.

Abstract: Friction stir welding (FSW), a solid state joining technique is widely used for joining Aluminum alloys in marine, aerospace, automotive and many other applications of commercial importance. In the present study, dissimilar Aluminum alloy (AA 6262-T6 and AA 7075-T6) plates were FS welded by varying the weld parameters such as Tool rotational speed, weld speed and axial force with square tool pin profile. The mechanical properties (hardness and tensile strength) of the Dissimilar Friction Stir welded (DFS welded) specimens were tested and compared with the base materials. The observations have been elaborated in detail along with microstructures of parent and welded specimens through Optical Microscopy and it is observed that the weld parameters have a significant effect on mechanical and micro structural properties of the welds.

Keywords: Aluminum alloys, Friction stir welding, dissimilar welds, mechanical properties and microstructure.

INTRODUCTION

The marine and the aeronautic industries are definitely the most Wanted, interested and focused fields of research now-a-days predominantly on joining techniques. Actually, mechanical strength and performances, corrosion resistance, residual stress state, and weight reduction are some of the most significant issues which are painstaking in the assembly of aeronautical components and also in transport industry [1]. Heat treatable wrought aluminium-magnesium-silicon alloy conforming to AA6262 is of medium strength and possess good welding characteristics over the high strength aluminium alloys and also have similar chemistry to AA6061 except small addition of lead and bismuth to enhance machinability whereas aluminium-zinc-magnesium alloy namely AA7075[2] is of high strength and possess low welding characteristics. Both the materials AA6262 and AA7075 are extensively employed in marine fittings, couplings, hinge pins, camera parts, screw machine products, automobiles and aircraft applications [3,4,5].

In contrast to many of the fusion welding processes that are routinely used for joining structural alloys, FSW is an emerging solid state joining process in which the material that is being welded does not melt and recast. FSW was invented at The Welding Institute (TWI), UK in 1991 [6-13]. FSW is a continuous, hot shear, autogenous process involving a non-consumable rotating tool of harder material than the substrate material [14, 15]. Defect-free welds with good mechanical

properties have been made in a variety of aluminium alloys. When alloys are friction stir welded, phase transformations that occur during the cooling of the weld are of a solid-state type. Due to the absence of parent metal melting, the new FSW process is observed to offer several advantages over fusion welding. The material flow behavior is predominantly influenced by the FSW tool profiles, FSW tool dimensions and FSW process parameters namely tool rotational speed, weld speed and axial force [16-19].

In the present study, the dissimilar Aluminum alloys AA 6262-T6 and AA 7075-T6 of 6mm thick plates were joined by FSW considering welding parameters as tool rotational speed (1000rpm, 1200 rpm and 1400rpm), weld speed (0.4 mm/sec, 0.6 mm/sec and 0.8 mm/sec) and axial force (8kN, 9kN and 10kN) with a square tool pin profile made of H13 tool steel.

EXPERIMENTAL WORK

Plates of 6mm thick of 6262-T6 and 7075-T6 Al alloys were friction stir butt welded using a tool made of H13 tool steel having 18mm shoulder diameter and the swept diameter of the square pin measuring 6mm. AA 6262 was kept on the advancing side (AS) of the tool and AA 7075 was kept on retreating side (RS).

Chemical compositions in weight percentage and mechanical properties at room temperature of base metals (BMs) AA 6262 and AA 7075 are presented in Table 1 and Table 2 respectively. Square butt joint configuration was prepared to fabricate the FSW joints. The initial joint configuration was obtained by securing the plates in position using mechanical clamps. The direction of welding was normal to the rolling direction. Single pass welding procedure was adopted to fabricate the joints. An indigenously designed and developed FSW machine (15 HP; 3000 RPM; 25 kN) was used to fabricate the joints. The welding parameters considered and tool geometry are presented in Table 3.

Macro and micro structural analysis were carried out using a light optical microscope (Make: Union Opticals, Japan; Model: VERSAMET-3). The specimens for metallographic examinations were sectioned to the required dimension from the joint comprising stirred zone (SZ), thermo mechanically affected zone (TMAZ), and base metal (BM) regions and were polished using different grades of emery papers. Final polishing was done using the diamond paste on the disc polishing machine. Specimens were etched with Keller's reagent to reveal the macro and microstructures.

Hardness testing was carried out using Vickers pyramid hardness testing machine (Make: Leco and LV

700) with a load of 5 kg. Hardness survey along the transverse direction of the weld was conducted with hardness measurements at regular intervals of 2 mm from the centerline of the weld on both sides of the weld.

The tensile test specimens were prepared by Electro Discharge Machining and tested according to ASTM-E8 standards on 10tonne, computer controlled Universal Testing Machine at an initial strain rate of $6.7 \times 10^{-5} \text{ s}^{-1}$ at room temperature. The tensile properties of the joint were evaluated using three tensile specimens in each condition prepared from the same joint. All the specimens were mechanically polished before tests in order to eliminate the effect of possible surface irregularities [20, 21]. The specimen finally fails after necking and the load versus displacement was recorded. The Ultimate Tensile Strength (UTS), Yield Strength (YS), and percentage of Elongation (%E) were evaluated.

Table 1 Chemical composition (wt %) of BM's

Elements	Si	Cu	Mn	Mg	Zn	Al
AA6262	0.640	0.262	0.096	0.88	0.048	Bal
AA7075	0.104	1.560	0.063	2.32	5.950	Bal

Table 2 Mechanical properties of BM's

Material	UTS (MPa)	YS (MPa)	%E	Hardness (VHN)
AA6262-T6	346	319	22.8	108
AA7075-T6	589	471	20.8	195

Table 3 Welding Parameters and Tool geometry

S.no	Process Parameters	Values
1	Tool rotational Speed(rpm)	1000,1200, 1400
2	Weld Speed(mm/sec)	0.4,0.6, 0.8
3	Axial Force (kN)	8,9,10
4	Tool shoulder diameter (mm)	18
5	Tool Pin swept diameter (mm)	6
6	Pin Length (mm)	5.8

RESULTS AND DISCUSSIONS

3.1 Macro and Microstructural observations

The FSW joints were successfully produced. The obtained joints shown no porosity or other defects in both top and root weld surface in all the welding conditions. Fig.1 shows the macrograph of the produced weld after thoroughly etched with the Keller's reagent marked as "SZ", "TMAZ" and "BM". From the different etching response of each material the AA6262 Al alloy appeared darker colored than the AA7075 one. It is clear that the microstructure of the SZ is mainly composed of the AA6262 fixed on the AS than AA7075 fixed on RS.

The SZ is the region that experienced the highest strain and undergoes recrystallization. Its microstructure is due to the mechanical action of the tool probe that generates a continuous dynamic recrystallization process. The higher temperature and the severe plastic deformation during the welding in the SZ result in a new equiaxed fine grain structure.

Fig.2 shows the Optical microstructures of the BM's and that of the welds at SZ and TMAZ. The left-hand side micrograph of the BM region indicates that microstructure consists of Mg_2Si precipitates and that on right side indicates Al_2Zn precipitates. The SZ has equiaxed grains with both the precipitates. The appreciable variation in grain size and distribution of strengthening particles in TMAZ region was observed on both AS and RS compared to SZ, which is due to various reasons such as FSW parameters, tool geometry, work piece composition & temperature, vertical pressure and active cooling.

3.2 Hardness observations

Table 4 shows the micro hardness values in SZ, tensile test results of all the DFS welded specimens and also the position of tensile failure considering all the conditions. It is observed that out of all the

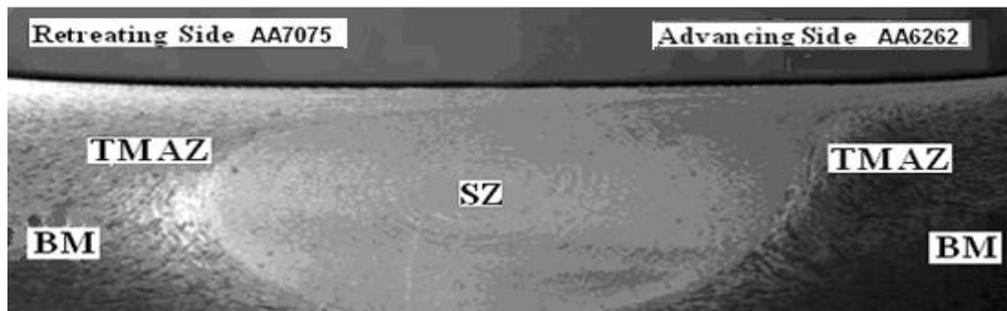

Fig.1 Typical macrograph showing various regions of the FS welded plates on AS, RS.

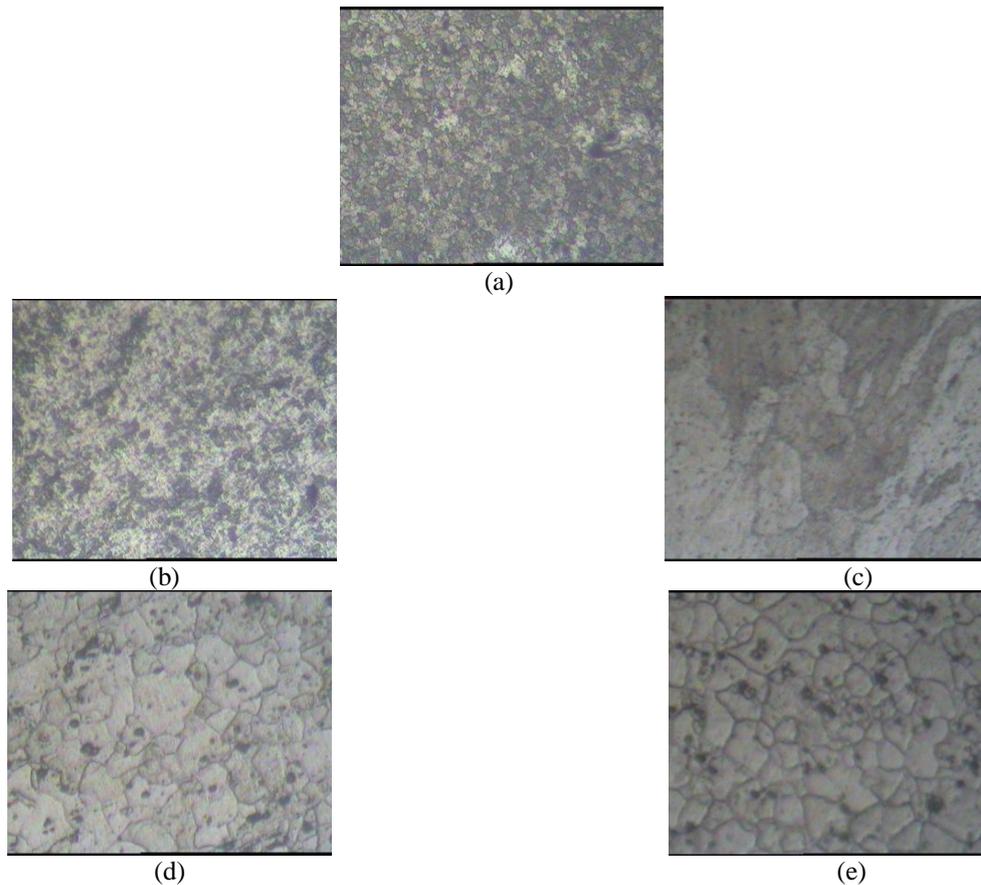

Fig. 2 Optical micrographs with main distinct regions of a dissimilar FS weld: (a) Stirred Zone (SZ) (b) TMAZ on AA6262 side (c) TMAZ on AA7075 side (d) Base metal AA6262 and (e) Base Metal AA7075.

DFS welded plates, the plate welded with 1200 rpm tool rotational speed, 0.6mm/sec weld speed and 9 kN axial force showed better micro hardness value at the SZ. Fig 3 shows the effect of tool rotational speed on the hardness variation across the weld line of the DFS welded plate with 0.6mm/sec weld speed and 9 kN axial force as it showed better hardness value. It is observed that the plates welded with 1200 rpm tool rotational speed shows better results

compared to the other two tool rotational speeds and also the hardness in the region of tool pin interaction with the plates is found to be higher than the hardness of AA6262 BM whereas lower than that of AA7075 BM. Hardness gradually decreases to the TMAZs on both the sides of SZ and then increases towards the ends (BMs) of the DFS welded plate.

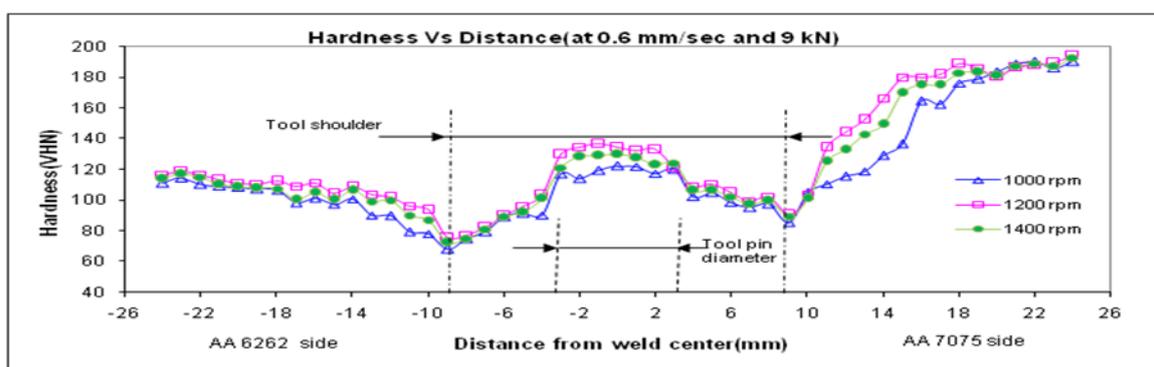

Fig.3 Hardness variation at 0.6mm/sec feed rate, 9kN axial force

3.3 Tensile Observations

Traverse tensile properties of DFS welded joints fabricated using square tool pin profile with all possible conditions were evaluated. Three specimens were tested for each condition and average of these is reported in Table 4. The results show that Tool rotational speed is having significant influence on tensile properties of the welded specimens and also it is observed that most of the

specimens failed in the HAZ region of retreating side i.e. AA6262 side and a few of them failed in SZ region. The joints fabricated with 1200 rpm tool rotational speed, 0.6 mm/sec weld speed and 9kN axial force showed highest tensile strength, where as joints fabricated using 1000 rpm tool rotational speed with 0.8 mm/sec weld speed and 8kN axial force showed lowest tensile strength.

CONCLUSIONS

- The Friction stir welding used successfully to join dissimilar aluminium alloys (AA6262 and AA7075).
- Better mechanical properties (hardness and tensile strength) were obtained with the FSW plate fabricated with 1200 rpm tool rotational speed, 0.6 mm/sec weld speed and 9kN axial force compared to all other conditions.
- The SZ region shows a new equiaxed fine grain structure compared to the base metals.

ABSTRACT: This paper attempts to enhance the dynamic performance of a shunt-type active power filter. The predictive and adaptive properties of artificial neural networks (ANNs) are used for fast estimation of the compensating current. The dynamics of the dc-link voltage is utilized in a predictive controller to generate the first estimate followed by convergence of the algorithm by an adaptive ANN (adaline) based network. Weights in adaline are tuned to minimize the total harmonic distortion of the source current. Extensive simulations and experimentations confirm the validity of the proposed scheme for all kinds of load (balanced and unbalanced) for a three-phase three-wire system.

Keywords: Adaline, current control, nonlinear load, shunt active power filter (APF), total harmonic distortion (THD), voltage source inverter.

I. INTRODUCTION

Harmonic compensations have become increasingly important in power systems due to the widespread use of adjustable-speed drives, arc furnace, switched-mode power supply, uninterruptible power supply, etc. Harmonics not only increase the losses but also produce unwanted disturbance to the communication network, more voltage and/or current stress, etc. Different mitigation solutions, e.g., passive filter, active power line conditioner, and also hybrid filter, have been proposed and used [1]–[8]. Recent technological advancement of switching devices and availability of cheaper controlling devices, e.g., DSP-/field-programmable-gate-array-based system, make active power line conditioner a natural choice to compensate for harmonics. Shunt-type active power filter (APF) is used to eliminate the current harmonics.

The dynamic performance of an APF is mainly dependent on how quickly and how accurately the harmonic components are extracted from the load current. Many harmonic extraction techniques are available, and their responses have been explored. Proposed techniques include traditional $d-q$ [2] and $p-q$ theory [3]–[5] based approaches and application of adaptive filters [6], wavelet [7], genetic algorithm (GA), artificial neural network (ANN), etc., for quick estimation of the compensating current [8]. A critical evaluation of such techniques is recently reported by the authors [8].

Recently, ANNs have attracted much attention in different applications, including the APF [9]–[20], [22]. Dash *et al.* [14] computed the Fourier coefficients of the signal by using *adaline*, and Chen and O'Connell [15] used an ANN that is trained with GA and back

propagation. Lai *et al.* [16] used a Hopfield neural network for real-time computation of frequency and harmonic content of the signal. Improved performance has been observed compared to discrete Fourier transform, fast Fourier transform, or Kalman- Tey *et al.* [17] reported a modified version of [10]. An additional PI controller is used to regulate the dc-link voltage. A full “neuromimetic” strategy involving several *adalines* has been reported by Abdeslam *et al.* [18]. The controller can adapt for unbalance and change in working conditions. Lin [19] proposed an intelligent neural-network-based harmonic detection, which is first trained with enough data (1400 patterns). The working model could compute the harmonic components with only onehalf of the distorted wave. An *adaline*-based harmonic compensation is reported by Singh *et al.* [20]. Weights are computed online by the LMS algorithm. Luo *et al.* [21] demonstrated a 200-kVA laboratory prototype for a combined system for harmonic suppression and reactive power compensation using an optimal nonlinear PI controller, whereas a two-stage recursive least square based *adaline* is reported by Chang *et al.* [22] for harmonic measurement.

Note that parallel developments on predictive control techniques are reported for power controllers. These are also applied to APF [23], [24]. The implementation of APF using power balance at the dc link is reported by Singh *et al.* [25]. The dc-link voltage has been used to find the peak magnitude of the supply current for self-supporting dc bus. However, no detail analysis of the dynamics of the dc-link voltage is available. This paper is an integration of predictive and adaptive control techniques for fast convergence and reduced computations. Two ANN-based controllers are used for such purpose. The predictive controller generates the first estimate of the compensating current quickly after the change in load is detected. The change in voltage across the capacitor is used for this purpose. This is followed by an *adaline*-based controller to fast converge to the steady value. This paper is organized in Eight sections. Section II deals with the Basic Block Diagram. Section III Estimation of Current Reference. Regulation of DC link Voltage in APF is covered in Section IV. Fast estimation of compensating current using ANN is presented in Section V. Section VI presents the Adaptive Current Detection Technique, Section VII presents the MATLAB Model and Simulation results. Section VIII concludes the work.

II. BASIC BLOCK DIAGRAM

A general block diagram of a APF with a non-linear load is shown below. Two ANN-based controllers are used for such purpose. The predictive controller generates the first

estimate of the compensating current quickly after the change in load is detected. The change in voltage across the capacitor is used for this purpose. This is followed by an *adaline*-based controller to fast converge to the steady value.

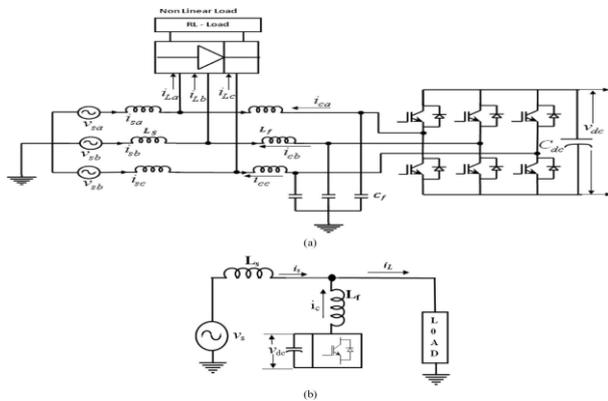

Fig. 1. (a) APF to compensate for a nonlinear load. (b) Single phase of shunt APF.

III. ESTIMATION OF CURRENT REFERENCE

Fig. 1(a) shows the APF compensating a nonlinear load. Fig. 1(b) shows the corresponding schematic diagram. A general expression for the load current [corresponding to Fig. 1(b)] is

$$iL(t) = i\alpha 1(t) + i\beta 1(t) + ih(t). \tag{1}$$

The in-phase and quadrature components of the phase current at fundamental frequency are $i\alpha 1$ and $i\beta 1$, respectively. All other harmonics are included in ih . The per-phase source voltage and the corresponding in-phase component of the load current may be expressed as

$$v_s(t) = V_m \cos \omega t \tag{2}$$

$$i\alpha 1(t) = I\alpha 1 \cos \omega t. \tag{3}$$

Assuming that the APF will compensate for harmonic and reactive power, the compensating current becomes

$$i_c(t) = iL(t) - i\alpha 1(t) = iL(t) - I\alpha 1 \cos \omega t \tag{4}$$

where $I\alpha 1$ is the peak magnitude of the in-phase current that the mains should supply and hence needs to be estimated. Once $I\alpha 1$ estimation is over, the reference current for the APF may easily be set as per (4)

IV. REGULATION OF DC-LINK VOLTAGE IN APF

The dynamics of the dc-link voltage is an indirect measure of the performance of the APF. Whenever there is a change in the load, the voltage across the dc-link capacitor also undergoes a corresponding change. A controller is used to keep the voltage regulated at a desired value. In this section, a simple analysis of the dynamics of the dc-link voltage is first carried out. Parameters that govern the dynamics are identified, following which an algorithm is developed to estimate the compensating current of the APF.

To maintain the dc-bus voltage to a desired magnitude, the capacitor draws in-phase (i.e., in phase with

the source voltage) current i_{sa} . This is in addition to the compensating current i_c . From the power balance equation

$$P_{dc} = C_{dc} v_{dc} \frac{dv_{dc}}{dt} \tag{5}$$

where p_{dc} is the power required to maintain the voltage v_{dc} across the dc link. From the power balance equation

$$\sum_{i=a,b,c} v_{si}(t) i_{sai}(t) - \sum_{i=a,b,c} R_f (i_{sai}^2(t) + i_{ci}^2(t)) - \frac{1}{2} \sum_{i=a,b,c} L_f \frac{d}{dt} (i_{sai}^2(t) + i_{ci}^2(t)) = i_{dc}(t) v_{dc}(t) = P_{dc}$$

where R_f and L_f are the resistance and inductance of the inductor that is connected in between the point of common coupling and the voltage source inverter. Note that i_{sa} supplies the system loss at the steady state and charges/discharges the capacitor during transient to maintain the dc-link voltage. Considering that “power” is a scalar quantity, (6) for a balanced three-phase system may be expressed as

$$3v_s(t) i_{sa}(t) - 3R_f (i_{sa}^2(t) + i_c^2(t)) - \frac{3}{2} L_f \frac{d}{dt} (i_{sa}^2(t) + i_c^2(t)) = i_{dc}(t) v_{dc}(t) = P_{dc} \tag{7}$$

Applying small perturbations in i_c , i_{sa} , v_{dc} , and v_s , around

an operating point, the following new set of variables may be obtained:

$$i_c(t) = I_c + \Delta i_c \tag{8}$$

$$i_{sa}(t) = I_{sa} + \Delta i_{sa} \tag{9}$$

$$v_{dc}(t) = V_{dc} + \Delta v_{dc} \tag{10}$$

$$v_s(t) = V_s + \Delta v_s \tag{11}$$

where I_c , I_{sa} , and V_s are rms and V_{dc} is the dc value of the corresponding quantities at the operating point. Again, in steady state

$$3V_s I_{sa} - 3R_f (I_{sa}^2 + I_c^2) = 0 \tag{12}$$

Substituting (8)–(12) in (7), the following equation is obtained:

$$3(\Delta v_s I_{sa} + V_s \Delta i_{sa}) - 6R_f (I_{sa} \Delta i_{sa} + I_c \Delta i_c) + 3L_f (I_{sa} \frac{d\Delta i_{sa}}{dt} + I_c \frac{d\Delta i_c}{dt}) = C_{dc} V_{dc} \frac{d\Delta v_{dc}}{dt} \tag{13}$$

Converting the variables to s -domain and after rearranging, (13) may be expressed as

$$\Delta V_{dc}(s) = \frac{K G_2(s) G_1(s) G_2(s)}{1 + K G_2(s) G_1(s) G_2(s)} \Delta V_{dc}^*(s) - \frac{G_2(s) G_3(s)}{1 + K G_2(s) G_1(s) G_2(s)}$$

$$\Delta I_c(s) + \frac{G_2(s) G_4(s)}{1 + K G_2(s) G_1(s) G_2(s)} \Delta V_s(s) \quad (14)$$

where K is the small-signal gain.

$$\Delta V_{dc}(s) = - \frac{G_2(s) G_3(s)}{1 + K G_2(s) G_1(s) G_2(s)} \Delta I_c(s) \quad (15)$$

This explores the possibility of extracting an estimate of the compensating current from the change in vdc.

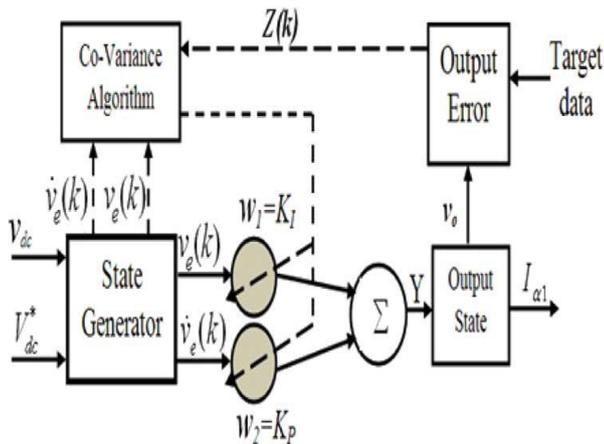

Fig 2. Block Diagram of ANN-Based Peak Value Predictor

$$I_s < \frac{C_{dc} V_{dc}^*}{3 K_P L_f} \quad (16)$$

$$I_s \leq \frac{K_P V_s}{2 R_f K_P + L_f K_i} \quad (17)$$

All the ac quantities in (16) and (17) are expressed as rms value. I_s , V_{dc}^* , and V_s are the source current, reference dc-link voltage, and source voltage, respectively. Equations (16) and (17) are used to generate an initial guess of K_P and K_I and also to set their limits.

V. FAST ESTIMATION OF COMPENSATING CURRENT USING ANN

An ANN-based PI controller plays a dual role. It ensures faster reference generation and is also accountable for better regulation of dc-bus voltage. The structure of the system (i.e., ANN-tuned adaptive PI controller) is shown in Fig. 2. To reduce computational burden, a single-layer ANN structure is used. The input vector as expressed in (18) is fed to the state exchanger. In our scheme, error voltage and its gradient are chosen as the state of the system to ensure faster corrective action

$$u = [V_{dc}^* \ v_{dc}]^T \quad (18)$$

The task of the state generator block is to generate states x_1 and x_2 as follows:

$$x_1 = v_e(k) \quad x_2 = \frac{\delta x_1}{\delta k} \quad (19)$$

where $v_e(k) = V_{dc}^* - v_{dc}(k)$. The output error $z(k)$ is represented as

$$z(k) = v_o(k) - v_o(k-1) \quad (20)$$

The output $v_o(k)$ is fed to output state to estimate I_{a1} . Neuron cell generates controlling signal through interrelated gathering [27], [28] as

$$u(k) = u(k-1) \sum_{i=1}^n w_i(k) x_i(k) \quad (21)$$

where w_i is the weight of the system

Here, a neuron is trained by Hebb's rule [27], [28]. Therefore, the change of weight of the neuron cell at k th instant may be represented as

$$w_i(k+1) = (1-c)w_i(k) + \eta r_i(k) \quad (22)$$

$$r_i(k) = z(k)u(k)x_i(k) \quad (23)$$

where r_i is the progressive signal, η is Hebb's studying ratio

(learning rate), and " c " is a constant. Substituting (22) and (23) in (21), the following equation may be obtained:

$$\Delta w_i(k) = w_i(k+1) - w_i(k) = -c[w_i(k) - \eta z(k)u(k)x_i(k)/c] \quad (24)$$

$\Delta w_i(k)$ is the change of weight at k th step. Weights of the neuron are tuned according to Hebb's assumption. Hebb's assumption is popularly known as the covariance algorithm.

$$\Delta w_i(k) = F_i(y_1(k), x_i(k)) \quad (25)$$

where $F_i(*)$ is a function of both postsynaptic and presynaptic signals and y_1 is the output of the individual neuron. If $F_i(*)$ is differentiable, then $\delta F_i / \delta w_i$ may be represented as

$$\frac{\delta F_i}{\delta w_i} = w_i(k) - \frac{\eta}{c} z(k)u(k)x_i(k) \quad (26)$$

From (26), the change of weight in k th sample may be expressed as

$$\Delta w_i(k) = -c \frac{\delta F_i(k)}{\delta w_i(k)} \quad (27)$$

Thus, by adjusting the values of $w_i(k)$, K_P and K_I are tuned.

The weights $w_i(k)$ are searched according to the negative slope of function $F_i(*)$. Equations (26) and (27) are used to tune the parameter used in (28) and (29). Finally, for the PI controller, the weights are represented by

$$w_1(k+1) = w_1(k) + \eta_1 z(k)x_1(k) \quad (28)$$

$$w_2(k+1) = w_2(k) + \eta_2 z(k)x_2(k) \quad (29)$$

Whenever the ANN is initiated, it starts with a set of controller gains to generate the first estimate of the compensating current. These initial values of controller parameters are set by offline training of the ANN. The controller parameters are then adjusted following (28) and (29) to regulate the dc-link voltage.

VI. ADAPTIVE CURRENT DETECTION TECHNIQUE

The ANN in Section IV provides an initial guess for any change in system dynamics. To generate more accurate reference for APF, load current samples are fed to the *adaline*-based network shown in Fig. 3. *Adaline* is designed to minimize the total harmonic distortion (THD) of source current. Uncompensated source current sample $s(k)$ may be represented as

$$s(k) = I_{\alpha 1} \cos(\omega k t_s) + I_{\beta 1} \sin(\omega k t_s) + \sum_{n=2}^R I_n \cos(n\omega k t_s + \phi_n) \tag{30}$$

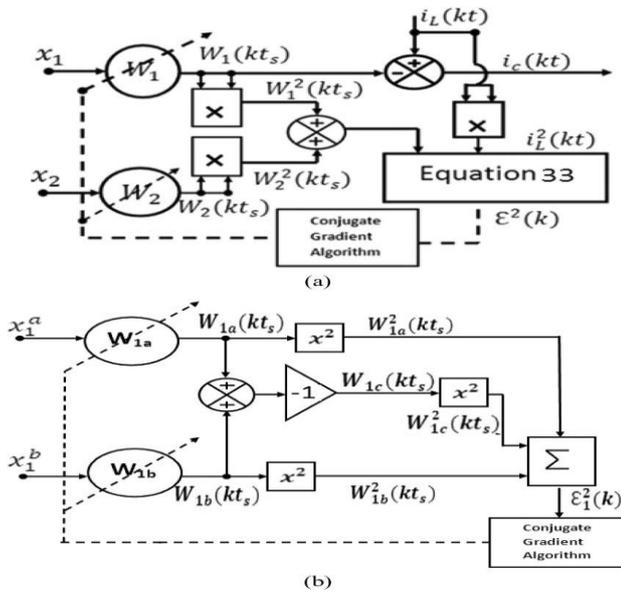

Fig 3: a) Adaline Based Harmonic Extraction for a Three Phase Balanced Network b) Adaline Based Harmonic Extraction for a Three Phase UnBalanced Network

The error terms for k th sample may be expressed as

$$\epsilon^2(k) = \left[\frac{(s^2(k) - 2s(k)\bar{a}(k))}{a^2(k)} + 1 \right] \tag{31}$$

Where

$$a^2(k) = I_{\alpha 1}^2(k) \cos^2(\omega k t_s) + I_{\beta 1}^2(k) \sin^2(\omega k t_s) \tag{32}$$

Equation (31) may also be represented as

$$\epsilon^2(k) = \left[\frac{(s^2(k) - 2s(k)\bar{a}(k))}{X^T(k)\bar{a}(k)\bar{a}^T(k)X(k)} + 1 \right] \tag{33}$$

where the vector

$$\bar{a}(k) = [I_{\alpha 1}(k), I_{\beta 1}(k)] \tag{34}$$

and the input vector

$$X(k) = [\cos \omega k t_s, \sin \omega k t_s]^T \tag{35}$$

Equation (33) is further modified to fit in terms of a quadratic equation as

$$A[\bar{a}^T(k)X(k)]^T[\bar{a}^T(k)X(k)] - B[\bar{a}^T(k)X(k)] + C = 0 \tag{36}$$

Equation (36) is minimized by *conjugate gradient* (CG) method [27]–[29].

Thus, the error function (i.e., THD) is minimized to calculate the in-phase component of the fundamental

load current. The compensating current is then calculated according to (4). Fig. 3(a) shows the details of current detection for a three phase balanced system, while Fig. 3(b) shows the same for an unbalanced (three-phase and three-wire) network. $W1a$, $W1b$, and $W1c$ are the corresponding in-phase components of the current for phase-a, phase-b and phase-c, respectively.

VII. MATLAB MODELLING

Block Diagram

A general block diagram of the ANN model Simulink is given in Fig.4. Simulations have been conducted for balanced and unbalanced loads using SIMULINK for different controller configurations. The whole system is built in SIMULINK where the ANN routine is called whenever necessary.

First, simulation study is made for the case with only predictive algorithm. A quick estimate helped, the waveform quality is poor due to the lack of any corrective mechanism in the system. The simulation results obtained. Next, the adaptive algorithm is tried. Simulation have done to check the performance of the system for a step change in load. Balance three-phase nonlinear load is considered similar to the case with predictive algorithm.

Now, to have the advantage of predictive and adaptive controllers, the system is run with both the algorithms. Fig4 show the situation with both the predictive and adaptive controllers in operation. The results have confirmed very satisfactory performance in terms of waveform quality and response time.

The controller is found to operate satisfactorily. The source current, load current, and compensating current are shown in top-to-bottom order. The controller took 51 s to converge, whereas the proposed controller with predictive and adaptive algorithm converged within less than one-quarter of a cycle with acceptable current quality.

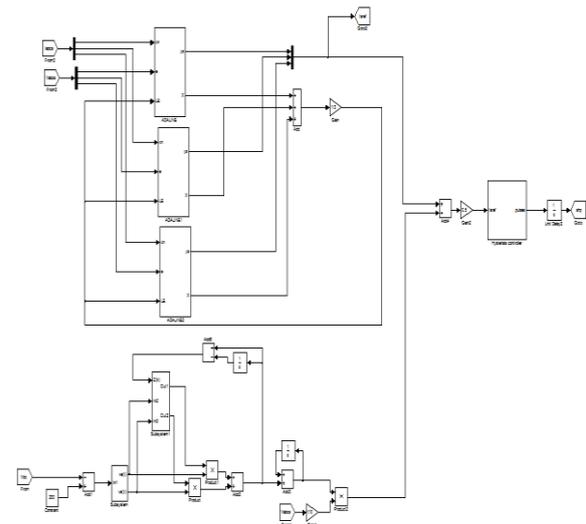

Fig 4: Operational functional block diagram of the ANN Model

VIII. RESULTS AND DISCUSSION

Simulations have been conducted for balanced and unbalanced loads. First simulation study is made for the case of only predictive algorithm Fig 5 gives simulation results with predictive ANN. Fig 6 gives simulation results of APF with adaline. Fig 7. Performance of the APF with predictive and adaptive controllers.

(scale: 20 A/div). (c) Compensating current of phase A (scale: 5 A/div). Time scale: 10 ms/div.

IX. CONCLUSION

An integration of predictive and adaptive ANN-based controller for a shunt-type APF has been presented in this paper to improve the convergence and reduce the computational requirement. The predictive algorithm is derived from an ANN based PI controller used to regulate the dc-link voltage in the APF. This is followed by an *adaline*-based THD minimization technique. *Adaline* is trained by CG method to minimize THD. Use of only two weights and two input vectors makes the convergence very fast. The system is extensively simulated in MATLAB/SIMULINK.

Analytical Study on Seismic Performance of Hybrid (DUAL) Structural System Subjected To Earthquake

Nabin Raj .C¹, S.Elavenil²

Department of civil engineering, Faculty of engineering and technology,
SRM UNIVERSITY, Kattankulathur- 603203, Chennai,

Abstract: Steel braced frame is one of the structural systems used to resist earthquake loads in multi-storeyed buildings. Many existing reinforced concrete (RC) buildings can be retrofitted to overcome deficiencies, to resist seismic loads at the same time steel bracings can be incorporated with RC frames which in combine can be called as dual system to resist lateral force in the new buildings. Steel bracing is economical, easy to erect, occupies less space and has flexibility to design for meeting the required strength and stiffness. In the present study, the seismic performance of reinforced concrete buildings using concentric steel bracing is investigated. The bracings are provided at peripheral columns. A six, twelve and eighteen storied buildings are analysed for seismic zone V as per IS 1893: 2002 using SAP 2000 software. Response spectrum analysis is performed for the buildings. For getting eigen values and eigen vectors the MathCAD Prime software is used. And hence storey shear and base shear are computed. The seismic performance of the building is evaluated in terms of storey drifts.

I. INTRODUCTION

This paper presents a study of three dimensional elastic behaviour of medium rise and high rise buildings having combination of rigid frame and vertical steel bracings which combine can be called as dual system. In present the parameters taken for analysis are displacements, reinforcement demands of frame members, moments, drift pattern for different types of bracing systems. As the height of the structure increases, effect of lateral load becomes more and more predominant and additional structure materials are required to resist it.

+ PG student, SRM University, Chennai.

++ Professor, SRM University, Chennai

Steel bracing of RC frames has received some attention in recent years both as retrofitting to increase shear capacity of the existing building and as a shear resisting element in seismic design of new buildings. The direct bracing of RC frames has received more attention since it is less costly, and can be used not for retrofitting but also as viable alternative to RC shear walls at pre-construction design level.

II. DUAL SYSTEM

In present contest many buildings are provided with more than one type of seismic resisting systems. Usually in these days structures are designed in such a way that it lateral force resistance is provided by frames and shear walls, frames and infill and frames and bracings. This combined system can be said as dual system.

Dual system may combine the advantages of the constituent elements. Ductile frames, interacting with steel bracings, can provide a significant amount of energy dissipation when required particularly in upper stories of the building. On other hand as result of large stiffness of frame, good story drift during earthquake can be achieved.

Despite the attractiveness and prevalence of dual system, it is only recently that research effort has been directed toward the developing relevant seismic design methodologies. This paper involves the analytical studies of proposed new apartment building, using dynamic analysis and the overall response of braced frame.

III. RC STRUCTURES WITH STEEL BRACINGS

Steel bracing is a highly efficient and economical method of resisting horizontal forces in a frame structure. Bracing has been used to stabilize laterally, the majority of the world's tallest building structures as well as one of the major retrofit measures. Bracing is efficient because the diagonals work in axial stress and therefore call for minimum member sizes in providing stiffness and strength against horizontal shear. A number of researchers have investigated various techniques such as infilling walls, adding walls to existing columns, encasing columns, and adding steel bracing to improve the strength and/or ductility of existing buildings and new buildings

Bracing system improves the seismic performance of the frame by increasing its lateral stiffness and capacity. Through the addition of the bracing system, load could be transferred out of the frame and into the braces, bypassing the weak columns. Steel braced frames are efficient structural systems for buildings subjected to seismic or wind lateral loadings. Therefore, the use of steel bracing systems for both retrofitting as well as in newly constructed reinforced concrete frames with adequate lateral resistance is attractive.

IV. TYPES OF BRACINGS

There are two types of bracing systems, Concentric Bracing System and Eccentric Bracing System.

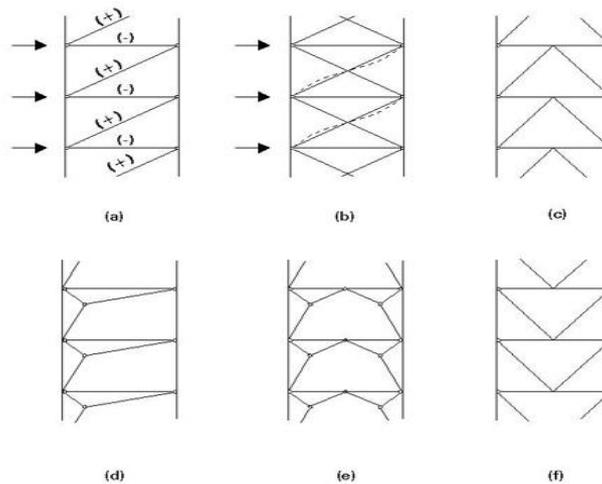

Fig. 1 Type of bracings

The steel braces are usually placed in vertically aligned spans. This system allows obtaining a great increase of stiffness with a minimal added weight, and so it is very effective for structure for which the poor lateral stiffness is the main problem. The concentric bracings increase the lateral stiffness of the frame, thus increasing the natural frequency and also usually decreasing the lateral drift. However, increase in the stiffness may attract a larger inertia force due to earthquake. Further, while the bracing decrease the bending moments and shear forces in columns, they increase the axial compression in the columns to which they are connected. Since reinforced concrete columns are strong in compression, it may not pose a problem in RC frame using concentric steel bracings.

Eccentric Bracings reduce the lateral stiffness of the system and improve the energy dissipation capacity. Due to eccentric connection of the braces to beams, the lateral stiffness of the system depends upon the flexural stiffness of the beams and columns, thus reducing the lateral stiffness of the frame. The vertical component of the bracing forces due to earthquake causes lateral concentrated load on the beams at the point of connection of the eccentric bracings.

V. MODELING

The SAP2000 software is utilized to create 3D model and carry out the analysis. The buildings are modelled as a series of load resisting elements. The dead load, live load and lateral loads to be applied on the buildings are based on the Indian standards. The study is performed for seismic zone V as per IS 1893:2002. The buildings adopted consist of reinforced concrete and brick masonry elements. The frames are assumed to be firmly fixed at the bottom and the soil–structure interaction is neglected.

The six, twelve, and eighteen storied buildings are analysed for zone V without bracing and with diagonal and X type bracings at peripheral columns only.

MODEL DATA OF BUILDING

Structure OMRF	
Plan dimension:	16.229m*11.275m

VI. RESULTS

Lateral displacements

The lateral displacements of non braced building for the cases of dead live and earthquake load for seismic analysis in all the three directions are presented in Table. The results are compared with that of buildings with various types of concentric bracings. It is observed that the maximum lateral displacements are reduced due to the presence of bracings. It is observed that the lateral displacements are reduced to the largest extent for X type of bracing systems then diagonal one.

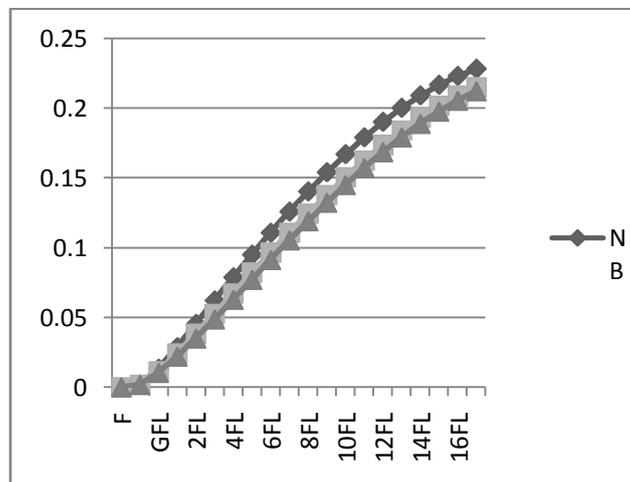

Fig. 3 Lateral deformation curves in X direction (18-Storey)

From the results obtained from building frame, it is observed that among concentric bracing system the X intersection type of bracing system is the most effective type of bracing system which can reduce the lateral displacements and moments in the structures. Therefore, the X type of bracing system can be used for seismic minimizing part of multi storied buildings. For all analysis of six twelve and eighteen storied building frames; X type of bracing system is considered. These buildings are analyzed for earthquake zone V. The lateral displacement is obtained for these structures, for the seismic load along with load combinations. The percentage reduction in lateral displacements is found out for increase in the number of stories. It is observed that the X bracing system reduces the displacements considerably than diagonal one.

VII. CONCLUSION

- Based on the observation made from analysis of the example buildings, various conclusions may be drawn.
- Stiffness: The bracings in bare frame increases the overall stiffness of the structure Hence performance of braced frame is much better than bare frame.
- Lateral displacement: The lateral displacement in bare frame is more in comparison to the frame with bracings .The bracings prevent the excessive damage in non structural elements. The percent reduced in lateral displacement between DB and XB is from 15% to 8%, similarly in 12 storey frame it reduces by 8% to 9% and so on in 18 storeys.
- Member forces: Significant reduction in moment in case of frame with bracings in comparison to bare frame .Moment reduced by
- 40% to 60% in 6 storey, 20 %to 30% in 12 storey and 35% to 45% in 18 storeys. So comparatively in XB the reduction of member force is higher.
- Reinforcement detailing: Significant reduction in reinforcement demand by the frame members other than the one associated with bracings. The bare frame steel demand is nearly 4% in 18 storey which is not practically possible so it is reduced to 2.58% with (DB) and 2.18% with (XB) similarly in 12 storeys and 6 storey it is reduced as shown in table above.
- Inter storey drift: The performance of frame with bracings is better and within the limit.
- The inter-storey drift is very important parameter in analysis and design of buildings. If the inter-storey drift values at each floor level reach their maximum allowable limits, then the roof displacement will reach undesirable values.
- Maximum ISD for frame without bracings is in storey just above the GF between 2nd and 3rd storey, it is because the frame structure deflects in shear configuration where the rate of change of deflection goes on reducing with height.
- For frame with bracings maximum ISD is found at height nearly to 30%-40% height of the building .Deflection pattern is of flexure shape at lower heights in which rate of deflection increase and follows the shear configuration in upper heights.
- This means the bracings governs flexural deflection, so it is desirable.

Abstract: In this paper a novel modulated power filter compensator (MPFC) is used for power quality improvement on transmission side for the smart grid stabilization and efficient utilization. The MPFC is controlled by a novel tri-loop dynamic error driven inter coupled fuzzy controller. The Fuzzy logic controller based on fuzzy logic provides a means of converting a linguistic control strategy based on expert knowledge into automatic control strategy. This paper presents a Digital validation conducted for different cases of load, excursions and fault conditions using the Mat lab/Simulink/Sim-Power software environment without and with the modified power Filter Compensator scheme with fuzzy controller for effective voltage stabilization, power factor correction and transmission line loss reduction.

Keywords: FACTS, Dynamic Voltage stabilization, fuzzy controller, Smart Grid, Stabilization, Efficient, Utilization.

I. INTRODUCTION

The proliferation of microelectronics processors in a wide range of equipments, from home VCRs and digital clocks to automated industrial assembly lines and hospital diagnostics systems has increased the vulnerability of such equipment to power quality problems [1]. These problems include a variety of electrical disturbances, which may originate in several ways and have different effects on various kinds of sensitive loads. As a result of this vulnerability, increasing numbers of industrial and commercial facilities are trying to protect themselves by investing in more sophisticated equipment to improve power quality [2]. Harmonics, voltage sag/swell and persistent quasi steady state harmonics and dynamic switching excursions can result in electric equipment failure, malfunction, hot neutral, ground potential rise, fire and shock hazard in addition to poor power factor and inefficient utilization of electric energy manifested in increase reactive power supply to the hybrid load, poor power factor and severely distorted voltage and current waveforms. To improve the efficiency, capacitors are employed which also leads to the improvement of power factor of the mains [3]. Between the different technical options available to improve power quality, active power filters have proved to be an important alternative to compensate for current and voltage disturbances in power distribution systems [4], [5], [6]. Different active power filters topologies have been presented in the technical literature, [7] [8] and many of them are already available in the market [1], [2]. Modern active filters are superior in filtering performance smaller in physical size, and more flexible in application, compared to traditional passive filters [9], [10]. The shunt active filters are used for

providing compensation of harmonics, reactive power and/or neutral current in ac networks, regulation of terminal voltage, suppression of the voltage flicker, and to improve voltage balance in three-phase system [11], [12]. Hybrid filters effectively mitigate the problems of both passive filters and pure active filter and provide cost effective and practical harmonic compensation approach, particularly for high power nonlinear loads. The combination of low cost passive filters and control capability of small rating active filter effectively improve the compensation characteristics of passive filters and hence reduce the rating of the active filters, compared to pure shunt or series active filter solutions [13]-[15]. Many power filter compensation configurations are proposed in literature to enhance power quality and to improve power factor [16]-[18]. This paper explores design and analysis of a novel modulated power filter compensator along with fuzzy controller (Mamdani rule base) for efficient stabilization and utilization. Fuzzy inference systems have been successfully applied in fields such as automatic control, data classification, decision analysis, expert systems, and computer vision [19], [20]. Because of its multidisciplinary nature, fuzzy inference systems are associated with a number of names, such as fuzzy-rule-based systems, fuzzy expert systems, and fuzzy logic controllers [21]. The Mamdani rule base is a crisp model of a system, i.e. it takes crisp inputs and produces crisp outputs. It does this with the use of user-defined fuzzy rules on user-defined fuzzy variables. The idea behind using a Mamdani rule base to model crisp system behavior is that the rules for many Systems can be easily described by humans in terms of fuzzy variables. Thus we can effectively model a complex non-linear system, with common-sense rules on fuzzy variables [22], [23]. The proposed scheme proved success in improving the power quality, enhancing power factor, reduce transmission losses and limit transient over voltage and inrush current conditions. The paper is organized in seven sections. Section II deals with the Modified power filter compensator. Section III Tri loop error driven fuzzy controller with mat lab models. Ac study system is presented in Section IV. Section V presents the Digital simulation results when different loads are applied, Section VI concludes the work.

II. MODIFIED POWER FILTER COMPENSATOR

The low cost modulated dynamic series-shunt power filter and compensator is a switched type filter, used to provide measured filtering in addition to reactive Compensation. The modulated power filter and compensator is controlled by the on-off timing sequence of the Pulse Width Modulation (PWM)

switching pulses that are generated by the dynamic tri loop error driven fuzzy controller. The fuzzy controller is equipped with a error and error-sequenced compensation loop for fast effective dynamic response in addition to modified PID activation. This scheme of MPFC structure comprises a aeries fixed capacitor bank and two shunt fixed capacitor banks are connected to a

modulated PWM switched tuned arm filter through six pulse uncontrolled rectifier. The mat lab model of this scheme structure is shown in Fig. 1

III. T R I L O O P E R R O R D R I V E N F U Z Z Y C O N T R O L L E R

The tri-loop error-driven fuzzy controller is a novel dual action control used to modulate the power filter compensator [24], [25]. The global error signal is an input to the fuzzy controller to regulate the modulating control signal to the PWM switching block as shown in Figs. 2a & 2b. The fuzzy controller includes an error sequential activation supplementary loop to ensure fast dynamic response and affective damping of large excursion, in addition to modified PID structure.

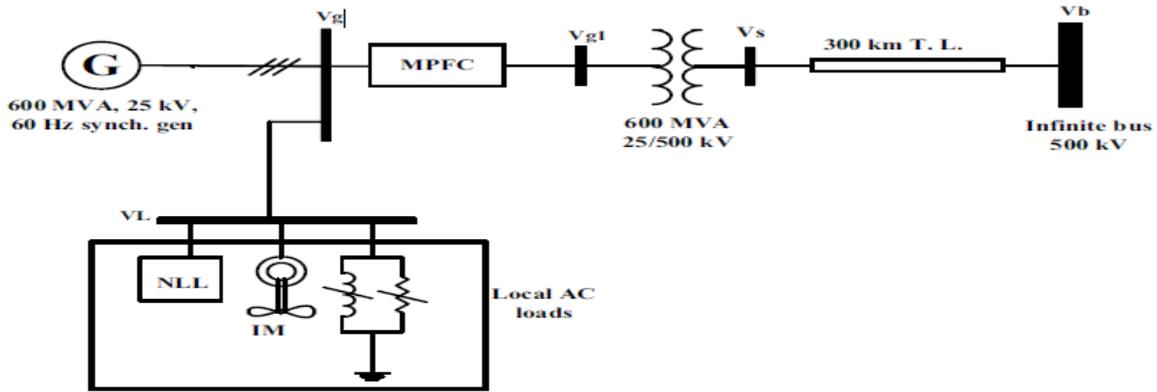

Fig. 3 The single line diagram of the unified EHV study AC system

IV. AC STUDY SYSTEM

The sample study AC grid network is shown in Fig. 3. It comprises a synchronous generator (driven by steam turbine) delivers the power to a local hybrid load (linear, non-linear and induction motor load) and is connected to an infinite bus through 300 km transmission line. The system, compensator parameters are given in the Appendix.

V. DIGITAL SIMULATION RESULTS

The Mat lab digital simulation results using MATLAB/SIMULINK/Sim-power Software Environment for proposed MPFC Scheme under three different study cases are:

A. Normal Loading Operating Case:

The dynamic responses of voltage, current, reactive power, power factor, $(THD)_V$, $(THD)_i$, $(FFT)_V$ and $(FFT)_i$ at generator bus (V_g), load bus (V_L) and infinite bus (V_b) under normal operation are shown Figs. 4-13. The RMS of voltage and current waveforms of the MPFC are shown in Fig. 14 and Fig. 15. The modulated tuned power filter switching signals that are generated by the dynamic tri loop error driven fuzzy controller are shown in Fig16. The stable voltage signal of synchronous generator power system stabilization (PSS) is depicted in Fig. 17. The Transmission line losses are shown in Table I.

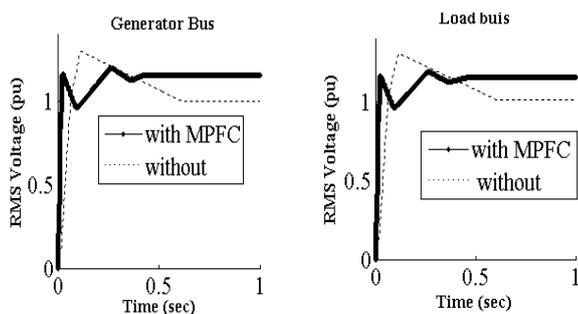

Fig. 4 The RMS voltage at AC buses under normal operation

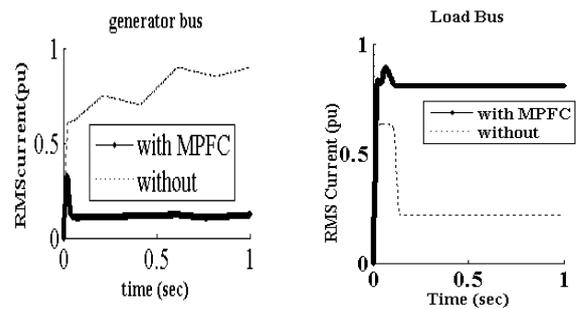

Fig. 5 The RMS current at AC buses under normal operation

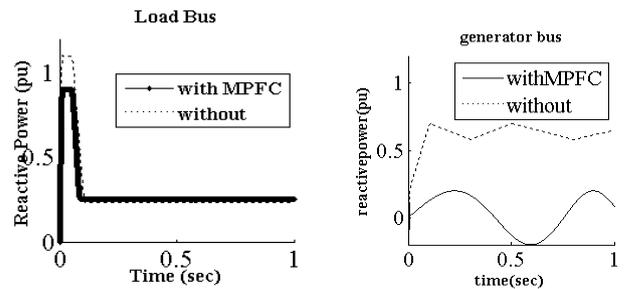

Fig. 6 The reactive power at AC buses under normal operation

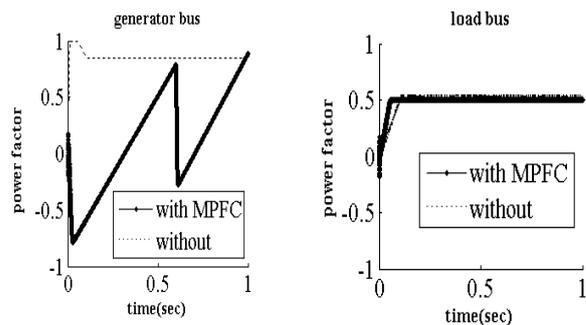

Fig. 7 The power factor at AC buses under normal operation

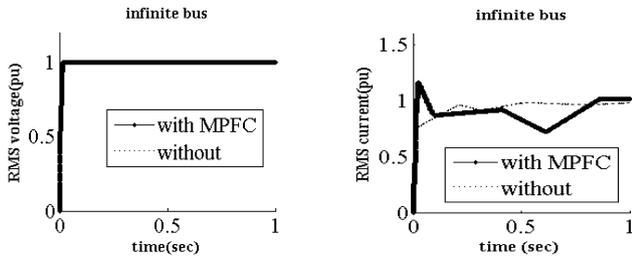

Fig. 8 The RMS voltage and current at the infinite bus under normal operation.

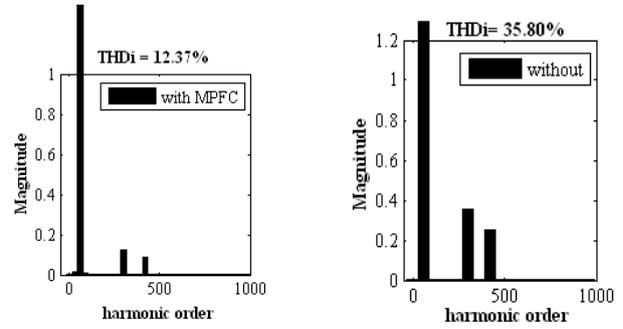

Fig. 13 THD and FFT of current waveforms at the infinite bus

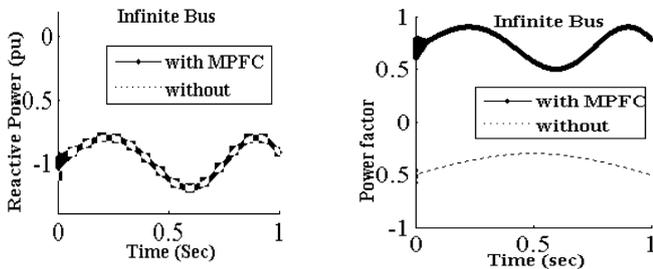

Fig. 9 The reactive power and power factor at the infinite bus under normal operation.

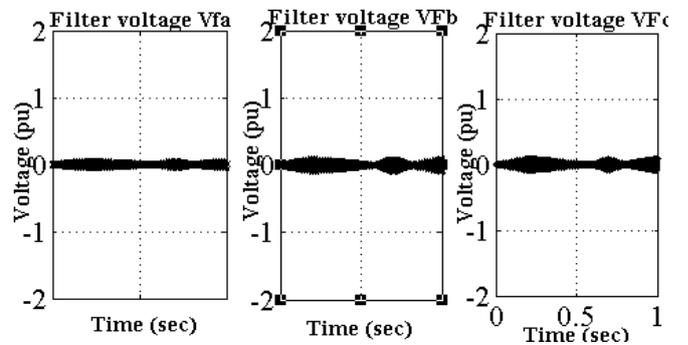

Fig. 14 The voltage waveforms of MPFC

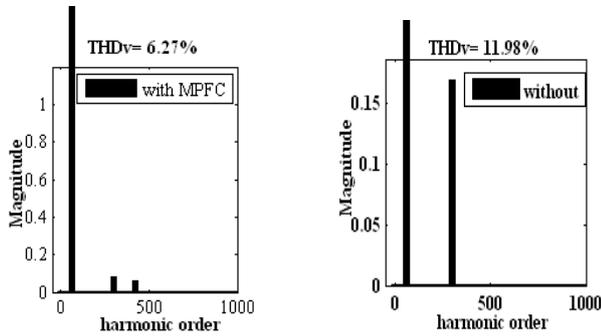

Fig. 10 THD and FFT of voltage waveforms at the load bus

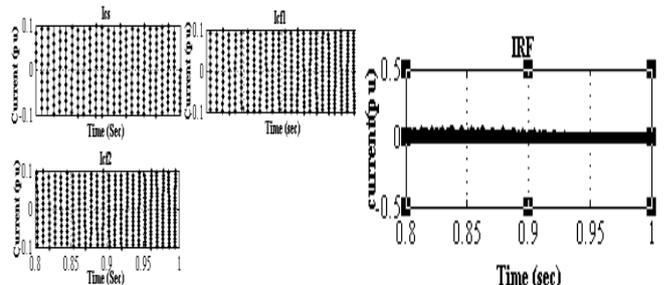

Fig. 15 The current waveforms of MPFC

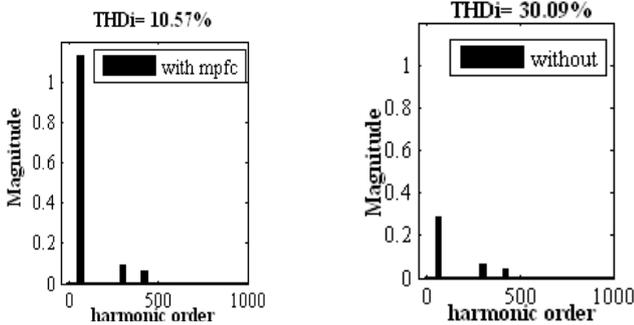

Fig. 11 THD and FFT of current waveforms at the load bus

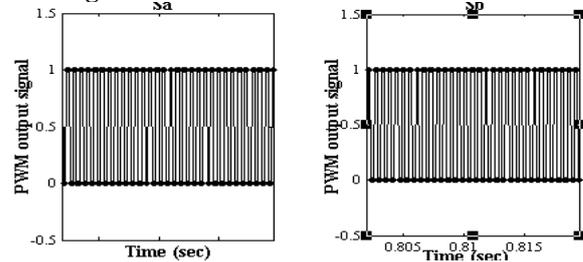

Fig. 16 Sa and Sb pulsing signals method

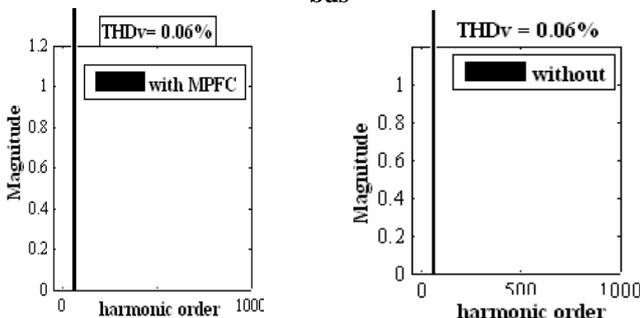

Fig. 12 THD and FFT of voltage waveforms at the infinite bus

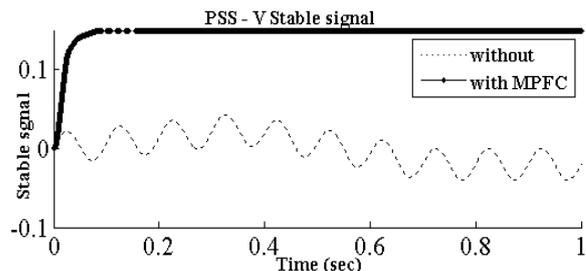

Fig. 17 PSS stable voltage signal

The previous figures confirm the compensation effectiveness as well as the harmonic filtering of the proposed MPFC.

B Short Circuit Fault Condition Case:

A three phase short circuit (SC) fault is occurred at bus V_s as shown in Fig. 3, for a duration of 0.1sec, from t=0.2 sec to t=0.3 sec. The RMS of voltage and current waveforms at generator and load buses are depicted in Figs. 18 & 19.

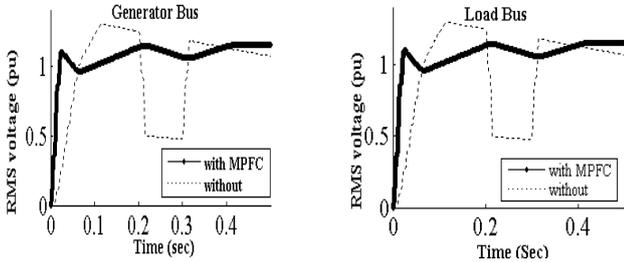

Fig. 18 The RMS Voltage at generator and load buses under short circuit (SC) fault condition at bus V_s

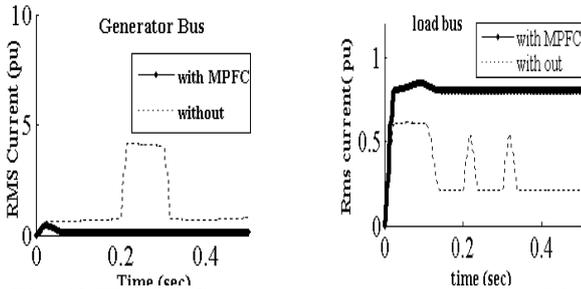

Fig. 19 The RMS current at generator and load buses under short circuit (SC) fault condition at bus V_s

As shown in figs.18&19, with using the proposed MPFC scheme, the remote short circuit fault has not any effect on the values of RMS voltage and RMS current of generator and load buses, so these schemes can be considered a good power quality mitigation method.

C Hybrid Local Load Excursions Case:

The real time dynamic responses of the system for a load excursion are obtained for the following time sequences

- At t = 0.1 sec, linear load is disconnected for a duration of 0.05 sec
- At t = 0.2 sec, nonlinear load is disconnected for a duration of 0.05 sec
- At t = 0.3 sec, the induction motor torque is decreased by 50% for a duration 0.05 sec.
- At t = 0.4 sec, the induction motor torque is Increased by 50% for duration 0.05 sec.

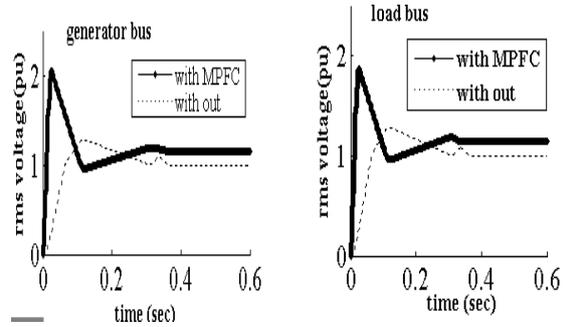

Fig. 20 The RMS voltage waveform at the generator and load buses under load excursions

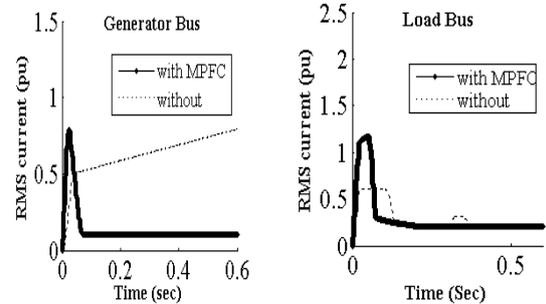

Fig. 21 The RMS current waveform at the generator and load buses Under load excursion

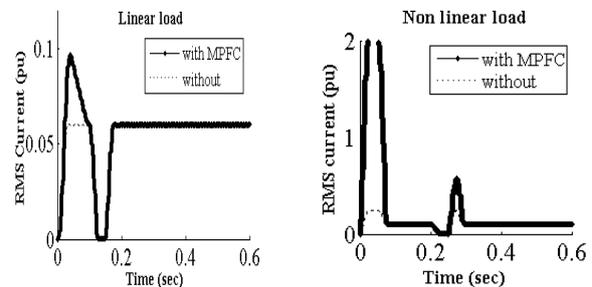

Fig. 22 The linear and nonlinear load RMS current waveforms

The RMS of voltage and current waveforms at generator and load buses under load excursions are depicted in Figs 20 & 21. The linear and nonlinear load RMS current waveforms are shown in Fig. 22 and the speed-torque relationship of induction motor (IM) is shown in Fig. 23.

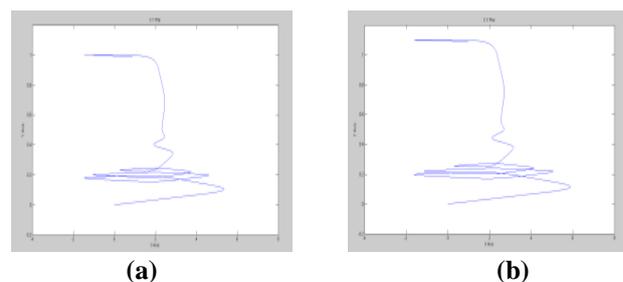

Fig. 23 The speed-torque relationship of the induction motor with (a) and without mpfc (b)

TABLE I THE TRANSMISSION LINE LOSSES

		PLoss	Qloss	Sloss
Case 1	without	0.0832	0.1542	0.1752
	with	0.008	0.005	0.005064
Case 2	without	0.1954	0.3467	0.398
	with	0.0008	0.005	0.005064
Case 3	without	0.1018	0.1869	0.2128
	with	0.0009	0.0045	0.004589

Comparing the dynamic response results without and with using the proposed MPFC under three study cases; normal operation, short circuit fault conditions and hybrid load excursion, it is quite apparent that the proposed MPFC enhanced the power quality, improved power factor voltage and reduced the transmission line losses.

VI. CONCLUSION

This paper presents a novel modulated switched power filter compensator (MPFC) scheme is controlled by a dynamic tri-loop dynamic error driven fuzzy controller. The proposed FACTS based scheme can be extended to other distributed/dispersed renewable energy interface and utilization systems and can be easily modified for other specific compensation requirements, voltage stabilization and efficient utilization. The proposed MPFC scheme has been validated for effective power quality improvement, voltage stabilization, and power factor correction and transmission line loss reduction when the system is extensively simulated in MATLAB/SIMULINK.

APPENDIX

1) Steam turbine

$P_{out} = 600$ MW, speed = 3600 rpm.

2) Synchronous generator

3 phase, 1 pair of poles, $V_g = 25$ kV (L-L), $S_g = 600$ MVA, $X_d = 1.79$, $X_d' = 0.169$, $X_d'' = 0.135$, $X_q = 1.71$, $X_q' = 0.228$, $X_q'' = 0.2$, $X_l = 0.13$.

3) Local Hybrid AC Load (90 MVA)

Linear load: 30 MVA, 0.85 lag pf.

Non-linear load: $P = 20$ kW, $Q = 22.4$ MVAR. Induction motor: 3phase, 30 MVA, no of poles=4, Stator resistance and leakage inductance (Pu)

$R_s = 0.01965$, $L_s = 0.0397$

Rotor resistance and leakage inductance (Pu)

$R_r = 0.01909$, $L_r = 0.0397$

Mutual inductance L_m (Pu) = 1.354

4) Transmission Line

$V_{L-L} = 500$ kV, 300 km length, $R/km = 0.01273$ Ω , $L/km = 0.9337$ mH

5) Infinte Bus: $V_{L-L} = 500$ kV

6) MPFC: $C_s = 30\mu F$, $C_{f1} = C_{f2} = 125\mu F$, $R_f = 0.25\Omega$, $L_f = 3mH$

(physics department ,LETS Laboratory /Faculty of Science/, Mohammed V University/Morocco)

ABSTRACT: MRI images are often subject to noise (artifacts). We evaluated the performance of DT-CWT combined to Bayesian MAP Estimator to restore those images.

We chose the images from two of four sequences commonly used in coronal and axial MRI with and without contrast agent. The image with contrast agent was used as a reference, and the image without where we added artificially noise was subjected to de-noising by forward Dual-Tree Wavelet Transform (DT-CWT) combined to Bayesian MAP estimator. A test was submitted to radiologists for an assessment of the de-noised images to compare the proposed algorithm to other effective techniques from the recent literature using MRI images. Our approach contributed effectively to the MRI images de-noising, with better results. In general, wavelets and Bayesian estimator contributed effectively to the de-noising process and to other image processing methods, but ranging from classic to complex wavelet transforms, the results gradually improved.

Keywords: Bayesian MAP, Complex Wavelet, Dual-Tree Wavelet transform, Image de-noising, MRI images.

I. INTRODUCTION

The digital representation of images has been controversial since the early days of computing. Because images are innately strong in semantic content, they quickly became a frequently used communication medium.

Images are also an essential tool in the fields of biomedicine and satellite and astronomical imaging, among others.

Medical imaging has revolutionized medicine by allowing doctors to retrieve potentially vital information from inside the human body in a noninvasive manner, as is the case for MRI that we focused on in our study. In Magnetic resonance, the practical limits of the acquisition time impose a trade-off between the SNR and the image resolution [1,2,3]

In this paper, we address the problem of MRI images de-noising.

In MRI, acquisition protocols lead to image quality loss, particularly with contrast, because of the presence of artifacts that make their interpretation difficult [4,6] and this noise in the MRI image magnitude is Rician [5], having a signal dependent mean.

Many challengers have been made to remove this noise using wavelet transform as described briefly.

WiemFourati and Mohammed Salim. B (2007) proposed a de-noising method based on the statistical dependency of wavelet coefficients and on the application of an adaptive Bivshrink type MAP filter (Maximum Posterior Estimator) [7].

From a method described by Donoho, Alendru in [9]. I and al. have proposed a de-noising scheme based on a wavelet transform named discrete wavelet transform with enriched diversity (TODDE), combining several families of wavelets and various estimators in Bishrink occurrence to eliminate the noise (speckle) in the images, which also applies to ultrasound images [8].

Previously proposed wavelet domain filtering techniques were based on different thresholding schemes where the coefficient selection was based on inter-scale correlations [5,11,12],

It was noted that due to the signal dependent mean of the Rician noise, both wavelet and scaling coefficients of a noisy MRI image are biased estimates of their noise-free counterparts [5].

In addition it was shown that one can efficiently overcome this problem by filtering the square of the MRI image in wavelet domain.

In the wavelet domain, the Discrete Wavelet Transform (DWT) has a limits and major disadvantages that undermines its application for some image processing as; lack of shift invariance, poor directional selectivity for diagonal features and other.. [10].

A comprehensive review of previous work shows the performance of these tools for image de-noising, although performance suffers from the classical wavelet limits of certain processing treatments, especially for the specificity of medical images.

The objective of this study was to use the DT-CWT and Bayesian approach that is based on a Symmetric Normal Inverse Gaussian (SNIG) [13] this model is useful for smoothing disease relative risk estimates.

The object is to de-noise images, in which the use of contrast agents could have affected the distinct visualization of healthy and pathological tissues.

The images with contrast agent were used as controls, and the images without contrast were used as images to restore, with the aim of obtaining images similar to the ones with contrast agent. In spite of existing mathematical methods, such as PSNR, correlation, and so forth, we used a human visual system (HSV), consisting of a blind test based on specific and precise criteria such as quality, sharpness, and the clinicians' ability to arrive at a correct diagnosis.

The paper is organized as follows: In the next section, we first described briefly the DT-CWT with has advantages in noise study, Section III provides some necessary preliminaries on Bayesian MAP Estimator, as Symmetric Normal Inverse Gaussian (SNIG) processes and presents results on the modeling that indicating their heavy-tailed nature. The design of a Bayesian estimator that exploits the signal. The proposed method and choice of MRI is described in section IV. Section V compares the performance of our proposed algorithm with the performance of current de-noising methods, and quantifies the achieved performance improvement. Finally we conclude.

II. DUAL-TREE COMPLEX WAVELET TRANSFORM (DT-CWT).

Remember that the classical discrete wavelet transform (DWT) provides a means of implementing a multiscale analysis, based on a critically sampled filter bank with perfect reconstruction [14] [15].

However, questions arise regarding the good qualities or properties of the wavelets and the results obtained using these tools, the standard DWT suffers from the following problems described as below:

Shift sensitivity: it has been observed that DWT is seriously disadvantaged by the shift sensitivity that arises from down samples in the DWT implementation [16,17].

Poor directionality: an m-dimension transform (m>1) suffers poor directionality when the transform coefficients reveal only a few feature in the spatial domain.

Absence of phase information: filtering the image with DWT increases its size and adds phase distortions; human visual system is sensitive to phase distortion [18]. Such DWT implementations cannot provide the local phase information.

In other applications, and for certain types of images, it is necessary to think of other, more complex wavelets, who gives a good way, because the complex wavelets filters which can be made to suppress negative frequency components. As we shall see the CWT has improved shift-invariance and directional selectivity [19].

The discrete complex dual tree wavelet transform (DT-CWT) was introduced by N. Kingsburg around in 1990.

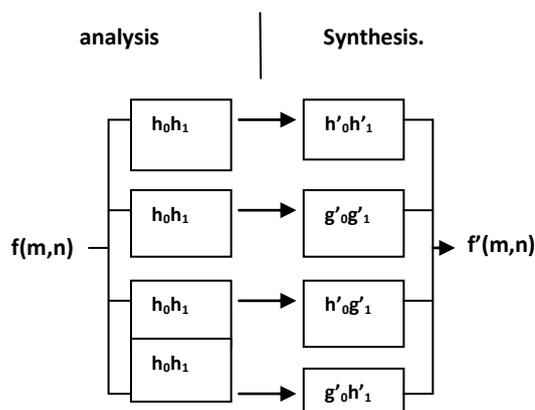

This implementation uses consists in analyzing the signal by two different DWT trees, with filters chosen so that at the end, the signal returns with the approximate decomposition by an analytical wavelet.

The dual-tree structure has an extension of conjugate filtering in 2-D case; this structure is shown in "Fig.1".

This structure needs four trees for analysis as well as for synthesis. The pairs of conjugate filters are applied to two dimensions (0 and 1), which can be expressed as:

$$(h_0 + jg_0)(h_1 + jg_1) = (h_0h_1 - g_0g_1) + j(h_0g_1 + g_0h_1) \tag{1}$$

The synthesis of filters suitable for this structure was performed by several people.

Imaginary trees

Figure.1. Filter bank structure for DT-DWT

The wavelet corresponding to the tree's "imaginary part" is very close to the Hilbert transform of the wavelet corresponding to the tree's "real part" [20].

For J level decomposition, the corresponding details subbands at leven η are denoted :HLη^{real},

$$HLη^{im}, LHη^{real}, LHη^{im}, HHη^{real} and HHη^{im}.$$

Where η = 1,2,...,J.

Because of the existence of two trees, it appears that the second noise coefficients moments from such decomposition can be precisely characterized.

The DT-CWT ensures filtering of the results without distortion and with a good ability for the localization function and the perfect reconstruction (PR) of signal.

In the noise study, as with any redundant frame analysis, when a stationary noise, even if white, is subject to a dual decomposition tree, statistical dependencies appear between coefficients [12,18,19], because of the existence of two trees, it appears that the second noise coefficients moments from such decomposition can be precisely characterized.

We observe a de-correlation between primal and dual coefficients located at the same spatial position and an inter-scale correlation, which allows us to choose between several estimators, taking this phenomenon into account.

If we consider an image degraded by a Gaussian n, white, and centered, additive Gaussian noise with a spectral density, the decomposition coefficients are also affected by that same noise as part of the linearity property [22, 20, and 28].

With this advantage we can choose an appropriate estimator for de-noising and the case of DT-DWT

The mathematical expression for a signal observed at point whose coordinates (x,y) in the image is modeled as follows:

$$g(x,y) = f(x,y) + \epsilon(x,y) \tag{2}$$

With g(x,y), f(x,y) and ε(x,y) are respectively the noise coefficient, the original coefficient, and the

Gaussian independent noise. Our goal is to estimate f from g . To do this, we will use an MPE (Maximum Posterior Estimator) filter [7].

In considering the linearity Property In the noise study, as with any redundant frame analysis, when a stationary noise, even if white, is subject to a dual decomposition tree, statistical dependencies appear between coefficients [26,27].

After applying the DT-CWT on (2), we obtain:

$$g_{\eta}(x, y) = f_{\eta}(x, y) + \varepsilon\eta(x, y) \quad (3),$$

Where, $g_{\eta}(x, y)$, $f_{\eta}(x, y)$ and $\varepsilon\eta(x, y)$ denote (x, y) -th wavelet coefficient at level of a particular detail subband of the DT-CWT of g , f , and ε , respectively and η ($\eta=1, 2, \dots, J$).

III. BAYESIAN MAP ESTIMATOR

It is recognized that parametric Bayesian processing presupposes proper modeling for the prior probability density function (PDF) of the signal.

Bayesian models use prior distributions for parameters, this prior can be multi-level and has distributions can control the model results

In this section we describe the Symmetric Normal Inverse Gaussian (SNIG) distribution and some it proprieties before presenting the model, we refer the reader to a recent work of M. I. H. Bhuiyan et al [13,23]. showed that distributions, a family of heavy-tailed densities, are sufficiently flexible and rich to appropriately mode wavelet coefficients of images in image de-noising applications with better models the prior statistics of the signal components, its probability density function reads as follows [23]:

$$P_f(f) = A \frac{K_1(\alpha\sqrt{\delta^2+f^2})}{\sqrt{\delta^2+f^2}} \quad (4)$$

Where $A = \frac{\alpha \delta \exp(\delta \alpha)}{\pi}$, K_1 denotes the modified Bessel function of second kind with index 1 [24], the parameter α control the shape of the distribution and δ is the a scale parameter. IN additional to illustrate the efficiency of the proposed prior, the generally Gaussian (GG) and SNIG PDFs are fitted to wavelet coefficients of the subbands $HH^{real}1$ for the medical image. Since in DT-CWT, we applied two real DWT, we assure the distribution of the noise coefficients in each DWT is a Gaussian with zero mean and standard deviation σ_{ε}^2 , and denote it by $P_{\varepsilon}(\varepsilon)$.

The Bayesian MAP estimator is given by [8] as follow:

$$\hat{x}(g) = \arg \max P_{\varepsilon}(g - f)P_f(f) \quad (5)$$

To obtain the MAP estimate, the derivative of the logarithm of the in (5) is the st to resulting in:

$$\frac{x-y}{\sigma^2} + p'(f) = 0 \quad (6)$$

Where $p(f) = \ln P_f(f)$ and $p'(f) = \frac{\partial}{\partial f} p(f)$. Using the approach proposed by Hyvarinen [25], an approximate solution of [7] is obtained as:

$$\hat{x}(g) \text{sign}(g) \max(|g| - \sigma_{\eta}^2 |B|, 0) \quad (7) \text{Where}$$

$$B = \frac{2g}{\delta^2+g^2} + \frac{\alpha g}{\sqrt{\delta^2+g^2}} \frac{K_0(\alpha\sqrt{\delta^2+g^2})}{K_1(\alpha\sqrt{\delta^2+g^2})} \quad (8)$$

In this step we need to estimate the parameters α , δ and σ_{η}^2 to obtain the MAP estimates. In order to take noise correction into account for each real DWT tree of the DT-CWT. The corresponding value of σ_{η} is obtained using the coefficients in the corresponding finestsubbands of diagonal orientation as:

$$C = C \frac{D_1+D_2}{2} \quad (9) \text{Where } D_1 = \text{MAD}(g(k,l)) / 0,6745, g(k,l) \in \text{HH1 and}$$

$D_2 = \text{MAD}(g(k,l)) / 0,6745, g(k,l) \in \text{HH2}$, C is a smoothing factor, (MAD is the Median absolute deviation).

To obtain the SNIG parameters for the (k, l) -th coefficient, the estimates of the second and fourth order signal moments denoted by $\widehat{m}_2(k, l)$ and $\widehat{m}_4(k, l)$, respectively, as obtained as:

$$\widehat{m}_2(k, l) = \max((m_2(k, l) - \sigma_{\eta}^2), 0) \quad (10)$$

$$\widehat{m}_4(k, l) = \max((m_4(k, l) - \sigma_{\eta}^2 m_2(k, l) - 3\sigma_{\eta}^4), 0)$$

The values of $m_2(k, l)$ are obtained using a DXD square window as

$$m_2(k, l) = \frac{1}{D^2} \sum_{i=-(M)/2}^{(M)/2} \sum_{j=-(M)/2}^{(M)/2} g(k-i, l-j)^2 \quad (11)$$

$$m_4(k, l) = \frac{1}{D^2} \sum_{i=-(M)/2}^{(M)/2} \sum_{j=-(M)/2}^{(M)/2} g(k-i, l-j)^4$$

Where $M = D-1$. Next, the corresponding second and fourth order cumulants, denoted by \widehat{K}_2 and \widehat{K}_4 respectively, are obtained as:

$$\widehat{K}_2 = \widehat{m}_2$$

$$\widehat{K}_4 = \max((\widehat{m}_4 - 3\widehat{m}_2^2), 0) \quad (12)$$

The parameters α and δ are estimated as

$$\alpha = \sqrt{\frac{3\widehat{K}_2}{\widehat{K}_4}} \delta = \alpha \widehat{K}_2 \quad (13)$$

IV. PROPOSED METHOD

The de-noising diagram involves the following steps shown in diagram "Fig. 2".

- (1) Take the MRI image without contrast agent
- (2) Add noisy into this image (to obtain a noisy MRI image)
- (3) Compute the DT-CWT (dual-tree complex wavelet) of the noisy MRI image,
- (4) Obtain the Bayesian MAP estimator using equation (5)
 - or Compute the threshold value for each pixel for Visu shrink in all sub band details wavelet coefficients [26]
 - or applying Bivariate MAP estimator, in all sub band details wavelet coefficients [27].

- (5) Compute the inverse dual-tree complex (IDT-CWT) using synthesis filter bank forobtained the de-noised image.

where \hat{I} and I denote the noise free and the noised images respectively and N^2 is the total pixels [29].

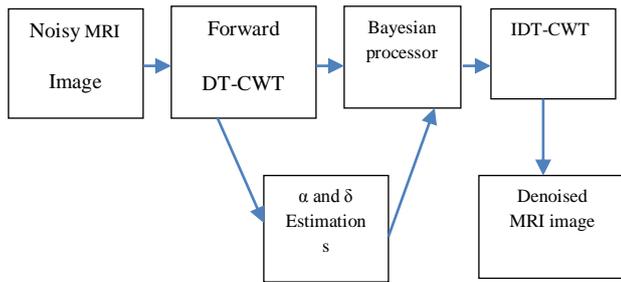

Fig 2. Diagram of proposed de-noising method

Choice of the images

MRI images are diverse and specific. Our study takes into account the behavior of different structures in comparison to contrast agents, because we are convinced that all structures do not react the same way to these agents. Our choice is geared to cranial images, in collaboration with the MRI department of the CHEIK ZHAID International University Hospital, based in Morocco. We selected brain MRI images of two of the four most commonly used sequences, axial and coronal ‘‘Fig. 3’’, for ethical reasons, we decline to identify the patient.

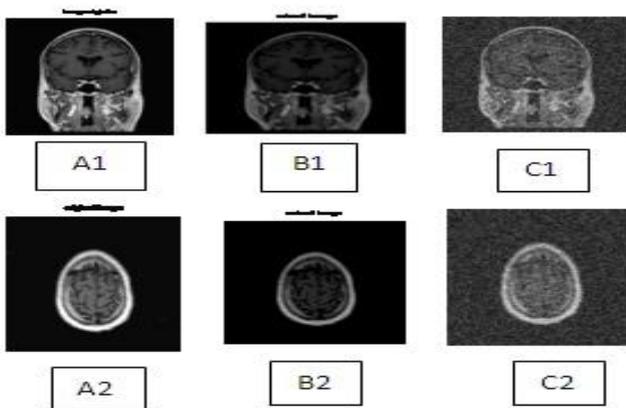

Figure 3.Reference images with contrast agent (A1 and A2.), the same images without contrast (B1 and B2) and noisy images (C1 and C2) respectively.

We compare our proposed algorithm to other effective techniques from the recent literature using MRI images.

From the first category of thresholding, we select the Vusu Shrinkage and Bivariate shrinkage[26], [27], in the second set we used only the adaptive Wiener filter implemented in CWT domain and considered window of size 7x7 within subband.

To quantify the noising performance of each algorithm, we employed the Peak-Signal to-Noise-Ratio (PSNR) defined as

$$PSNR = 20 \log_{10} \left(\frac{256}{\sqrt{\frac{1}{N^2} \sum (\hat{I} - I)^2}} \right) \tag{14}$$

V.Results and Discussion

In the simulations, complex zero mean white Gaussian noise with standard deviation $\sigma \epsilon = 20$, was added to the images without contrast agent (C1 and c2)

The noisy image is decomposed using only the dual tree wavelet transform (DT-CWT), for both the discrete (real DWT) and the complex parts (CWT), because the previous works have sufficiently proved the superiority of DT-CWT over DWT in image de-noising [15,28]

For each decomposition, the number of resolution levels is set in order to obtain equivalent size approximations (as much as possible) at the coarser resolution.

Table 1 give the results obtained the category of thresholding, has, Visu Shrinkage and Bivariate Shrinkage. In Table2, we show results obtained with adaptive Wiener adaptive filter

From the tables it can be seen that our approach achieves the best results in most situations, followed by Bivariate method.

Figure 4 and 5 illustrates the results with the first set of thresholding and Wiener adaptive filter respectively.

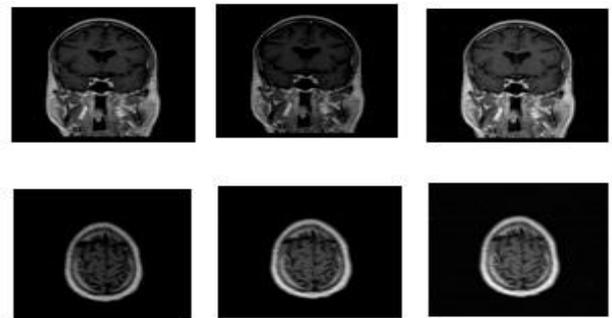

Figure 4. Coronal and Axial images de-noised with Visushrink (left), Bishrink (middle) and proposed method (right) with ($\sigma = 10$)

The PSNRs and Similarity between restored and original image as shown in table1 and2 for each case.

Table 1.PSNR VALUES (dB) OBTAINED BY THE TREE DE-NOISING METHODS

Image	Coronal MRI Image				Axial MRI Image			
	10	15	20	25	10	15	20	25
σ	10	15	20	25	10	15	20	25
Noisy	27.18	23.65	21.14	20.17	28.26	24.55	22.25	20.45
Visushrink	30.76	29.00	28.25	27.44	31.51	30.43	27.92	26.74
Bishrink	32.85	31.00	29.81	28.77	33.77	32.78	30.11	29.43
Proposed method.	33.26	31.22	30.00	29.09	34.75	33.03	31.87	30.01

TABLE 2. PSNR VALUES (dB) OBTAINED BY WIENER FILTER AND PROPOSED METHOD

σ	Axial MRI Image			Coronal MRI Image		
	Noisy	Wiener filter	Proposed Method	Noisy	Wiener filter	Proposed Method
10	28.26	32.51	33.61	27.18	32.34	32.85
15	24.55	30.43	31.63	23.65	30.87	31.90
20	22.55	28.92	30.19	21.14	29.17	30.17
25	20.45	27.74	29.21	20.17	28.10	29.85
30	18.62	26.73	28.51	18.62	26.13	28.87

We observed a decrease of PSNR between the reference images and those subject to de-noising. To assert the difference caused by the use of a contrast agent in the image, the correlation between the two images is lower, as it is to the naked eye. We clearly noticed that some details were quite visible, due to the contrast agent.

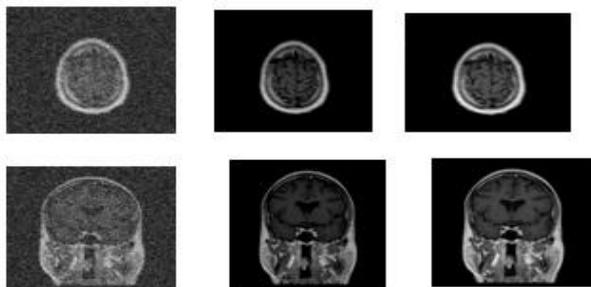

Figure 5. Axial and coronal images de-noised, where noisy images (left), Wiener filter (middle) and proposed method (right) with ($\sigma = 10$)

For the other images with Visu-shrinkage or Bivariate shrinkage (Bishrink), the proposed method shows an even better performance with the Bishrink estimator, where values have improved.

In all cases, the best results were obtained with the proposed method, followed by Bivariate shrinkage with Wiener filter and finally Visu shrinkage, figures and tables shows.

One can also note that the poorer performance was obtained for Visu shrinkage (increased the value of σ , which remains well below the Bivariate threshold as indicated in Table 1.

Here, we focused particularly on the ability of the our processor structure to de-noise MRI images. In comparison with several existing de-noised methods, the proposed approach out performs results in all cases, the obtained results are provided in Tables 1 and Table 2.

When considering the initial PSNR between original images and degraded images, it shown this approach providing a superior gain for each estimator. We then turned our attention to the test addressed to radiologists on the image quality, also obtaining, in their consideration and as a result of the simulations, a better performance for our processor, compared to other techniques.

The test methodology is detailed below:

Considering the brain images of four sequences commonly used in MRI, axial, coronal, presented to four experienced radiologists working in university hospitals and Sino-congolaise hospital.

In a first stage, the anonymous images were given to the radiologists and they were asked whether the image presented to them was original or restored and if it was acceptable for the diagnosis, to which they could answer yes or no.

Secondly, the restored images compared to the reference images were placed side by side and in this case the original was revealed to the observer, blinded to the type of transform used to restore the image to compare. The radiologists were asked to quantify on a scale of 1 to 9, as follows:

- 9 No visible difference
- 7 No loss of diagnostic information
- 5 In the limit of information loss, discrete anomalies may be omitted.
- 3 Important diagnostic information may be omitted, and the degradation affects the interpretation.
- 1 Unsatisfactory for diagnosis; indisputable loss of diagnostic information.

From this test, we obtained the following observations:

For two of four observers, axial sequence images de-noised with Visu shrink estimator ($\sigma > 20$) were considered non-diagnostic cases.

One observer rejected the coronal sequence images restored with Visushrink estimator ($\sigma > 20$).

Axial images were considered acceptable for diagnosis by all observers for all techniques without Visu shrink estimator ($\sigma > 20$)

In the case where the original or reference image is revealed, we obtained the following results:

Axial: 75% of the observers found no significant loss of diagnostic information for the proposed approach. One observer judged the images de-noised with the Visushrink estimator ($\sigma > 15$) estimator too degraded to be reliable.

Coronal: One observer has considered an image de-noised Visushrinkage at the limit of information loss and marked it as a 5.

Axial: All observers agreed on the absence of significant loss of diagnostic information for proposed method, images with the Bivariate estimator and Wiener filter.

Axial: Three observers classified the images in the 5-6 categories, within the diagnostic information loss limit, for Visu Shrinkage.

VI. CONCLUSION

Given the simulation results obtained with our approach, we can state, as described in the literature, this processor is more efficient than others. Its extension to the complex case has especially proved to be interesting and leads to better results than the discrete case. Moreover, the combination with DT-CWT and different MAP estimator offered encouraging results.

Far from the consideration of matching or competing with the use of contrast agents, our study is meant as a statement, indicating that it is possible, with computer processing and the appropriate estimators, to restore a noisy medical image and to highlight certain pathologies the distinction of healthy and pathological tissue.

This can result in a solution on the social level, taking into account the cost of an MRI exam with contrast agents. Finally, the results of the simulation carried out on selected MRI images has allowed us to ascertain that our approach is very favorably positioned compared to the existing medical image de-noising techniques.

ACKNOWLEDGEMENTS

WE WOULD LIKE TO THANK THE RADIOLOGIST RESPONDENTS IN UCH CHEIKZAID AND SINO-CONGOLAISE HOSPITAL FOR THEIR EXCELLENT SCIENTIFIC CONTRIBUTIONS.

On the Estimation of the Software Process Maturity using COCOMO II's Effort Estimation based on CMMI

Yousef Alkouni Alghdr¹, M. Afshar Alam², Mugeem Ahmed³

Department of Computer Science, Jamia Hamdard Delhi India

Department of computer science Jamia Millia Islamia Delhi India

Abstract: Software resource estimation methods and models have had a major impact on successful software engineering practice. They provide milestone budgets and schedules that help projects determine when they are making satisfactory progress and when they need corrective action. The software capability maturity model is a most popular model to enhance software processes with the goal of developing best quality of the software which are under the control of budget and schedule. The last stage of updating of the software cost estimation model, constructive cost model has a different set of seventeen cost drivers and a set of five scale factors. The Process maturity is one of the important five scale factors whose ratings are based on the software capability maturity model. This paper is an attempt to determine the effect of process maturity on the software development effort by deriving a new set of constructive cost model II's process maturity rating values based on the most recent version of CMM, i.e., capability maturity model integration. The effect of the constructive cost model II's process maturity scale factor is determined by considering the ideal scale factor methodology. Precedentedness shows all prediction accuracies compared to the generic, constructive cost model II estimation.

I. Introduction

The Software is one the most important and yet one of the most economically challenging technologies of the current era. As a purely intellectual product, it is among the most labor intensive, complex, and error-prone technologies in human history [1]. The software industry is not untouched by the quality by the quality movement that dramatically affected the product of other industries. But constant demand from the industry for cheaper and better software, make this goal (quality of software) more challenging. Each and every company knows, to remain competitive, it must deliver quality product at time and within budget[2]. Consequently many software companies has turned to software process improvement as a way of enhancing the quality of their products ,reducing the cost and accelerating the development process. The delivery of the software on time, within the budget and with the expected functionalities and quality is a challenge for all software development organizations. Inaccurate estimations in software development industry is one of the most serious problems that cause the software failure[2].It is also well known that the quality of software products depends on the software development capabilities and the quality of the maintenance process to a great extent. Thus an organization have no possesses well-trained developers, it will be difficult to them to build the foundation which supports successful improvement of the software development

process. Therefore, the fundamental way of ensuring the software quality is to improve the software productivity of the enterprises. And the software productivity of the enterprises depends on their software development capability, especially the maturity of software development and production. Software cost estimation is the process of predicting the effort required to develop a software [3].These types of process becomes one of the major challenges which also the most expensive component in software development. While software cost estimation may be simple in concept, it is difficult and complex in reality [4]. The different estimation models have been developed; most of them have disappeared without any kind of rigorous evaluation. The main reason for that was that these types of models were not good and precise enough [5]. The other reason was that the people who are working in the software development prefer to use their own estimation techniques rather than improving and applying the work of the others. The most of the organizations have relied on experience and "Price-to-win" strategies for getting past competitors. Despite the emergence of concepts like because of the rapidly changing technologies, the Software Capability Maturity Model one can never rely completely on experience based estimation in the software industry which renders the experience-based estimates ineffective. The price-to-win strategy is not very favorable for most of the organization [6].Hence the requirement of effective cost model arises to account for the effort spent on the developing software systems. It is an important input to software cost estimation models. The Capability Maturity Model for software was enveloped by Software Engineering Institute to describe the principles and practices underlying software process maturity. Its aim is to help organizations improve their software process maturity through an evolutionary path and process predictability [7]. Despite the fact that the Software Engineering Institute has released the Capability Maturity Model Integration, which is the updated version of the original CMM, COCOMO II still relies on SW-CMM to assess its process maturity scale factor.

This paper is an attempt to describes the effect of process maturity on software development effort by deriving a new set of constructive cost model II's process maturity rating values based on the most recent version of CMMI capability maturity model integration.

II. Review of Literature

The Software development become an important part for many organizations; software estimation is gaining an ever increasing importance in effective software project management. Boehm was the first researcher who considered the software estimation from an economic point

of view, and came up with the cost estimation model, COCOMO in 1981, after investigating a large set of data in the 1970's (Boehm, A, and Chulani,2000). Putnam also developed an early model known as, the Software Lifecycle Management, (Putnam, 1978).The software estimation includes the effort/schedule estimation, quality estimation, risk analysis, etc. The most accurate software estimation can provide powerful assistance for software management decisions (Boehm, 2000). The most new computational techniques are used for cost estimation that are non-algorithmic in the 1990's. The researchers have turned their attention to different approaches which are based on soft computing methods that include artificial neural networks, fuzzy logic models and genetic algorithms. The Artificial neural network is able to generalize from trained data set. Over a known set of training data, a neural-network learning algorithm constructs rules that fit the data and predicts previously unseen data in a reasonable manner (Schofield, 1998). The most popular estimation methods are discussed in detail by Khatibiand J (2011). The COCOMO, SLIM and Albrect's function point methods that measures the amount of functionality in a system were all based on linear regression techniques by collecting data from historical project as the major input to their models. The different algorithmic methods are deliberated as the most popular methods and many researchers used the selected algorithmic methods (Musilek, et al. 2002; Yahiya, et al. 2008; Lavazza and Garavaglia 2009; Yinchuan et al. 2009; Sikka et al. 2010).The Software estimation techniques can support the planning and tracking of software development projects. The efficiently controlling the expensive investment of software development is of prime importance (Gray, MacDonell and Gray, 1997; Jingzhou and Guenther, 2008; Kastro and Bener, 2008; Strike et al., 2001). ImanAttarzadeh and Siew Hock Ow (2010) proposed amodels which is based on COCOMO II and fuzzy logic to the NASA dataset and found that the proposed model performed better than ordinary COCOMO II model and also achieved the results which were closer to the actual effort. The relative error for proposed model using two-side Gaussian membership functions is found to be lower than that of the error obtained using ordinary COCOMO II. A novel neuro-fuzzy Constructive Cost Model is used for software cost estimation and this model carried some of the desirable features of a neuro-fuzzy approach, such as learning ability and good interpretability, while maintaining the merits of the COCOMO model (XishiHuang et al., 2005).

III. Background

A. COCOMO II Model

The COCOMO was originated in 1981[8], and became one of most popular cost estimation models of the 1980s. But the COCOMO faced different difficulties in the 90s, and different complications in cost estimation of software that were developed to a new life cycle processes such as non-sequential and rapid development process models, reuse-driven approaches, and object-oriented approaches [9].Thus, COCOMO II was published initially in the annals of software engineering in 1995 with three sub models; an application-composition model, an early design model and a post-architecture model. The COCOMO II has, as an

input, a set of seventeen Effort Multipliers or cost drivers which are used to adjust the nominal effort to reflect the software product being developed. The seventeen COCOMO II factors are shown in Table 1 [10].

a. Effort Estimation

The equation a is formulated the COCOMO II effort estimation model. The effort estimates by both early design and post-architecture models. The inputs are the size of software development, a constant A , an exponent E , and the number of Effort Multipliers (EM). The number of effort multipliers depends on the model being used.

$$PM = A \times SIZE^E \times \prod_{i=1}^N EM_i \quad (a)$$

Where the constant $A=2.94$, and the exponent E will be described in the bellow.

b. Scale Factors

The study accomplished by [12] presents the conclusion that the most critical input to the COCOMO II model is size, so, a good size estimate is very important for any good model estimation. The Size in COCOMO II is consider as a special cost driver, so it has an exponential factor, E . The exponent E in equation 2 is an aggregation of five scale factors. All scale factors have rating levels. These rating levels are Very Low, Low, Nominal, High, Very High and Extra High. Each rating level has a weight W , which is a quantitative value used in the COCOMO II model. The five COCOMO II scale factors are shown in Table 1

$$E = B + 0.01 \times \sum_{j=1}^N SF_j \quad (b)$$

Where B is a constant = 0.91. A and B are constant values devised by the COCOMO team by calibrating to the actual effort values for the 161 projects currently in COCOMO II database.

Table 1. Scale factors of COCOMO II.

Scale Factor	Description
Precedentedness	Reflects the previous experience of the organization.
Development Flexibility	Reflects the degree of flexibility in the development process.
Risk Resolution (RESL)	Reflects the extent of risk analysis carried out.
Team Cohesion	Reflects how well the development team knows each other and work together.
Process Maturity	Reflects the process maturity of the organization.

Table 2. Cost drivers of COCOMO II.

Cost Driver	Description
RELY	Required Software Reliability
DATA	Data base size
RUSE	Developed for Reusability
DOCU	Documentation needs
CPLX	Product Complexity
TIME	Execution Time Constraints
STOR	Main storage Constraints
PVOL	Platform Volatility
ACAP	Analyst Capability
PCAP	Programmer Capability
APEX	Application Experience
PLEX	Platform Experience
LTEX	Language and Tool Experience
PCON	Personnel Continuity
TOOL	Use of Software Tools
SITE	Multisite Development
SCED	Required Development Schedule

The procedure for determining procedure maturity which is the factor of interest in this study- is organized around the SEI-CMM, Table 3

Table 3. The rating levels ,values, and Process Maturity Scale Factor.

Process maturity Description	CMM	CMM	CMM	CMM	CMM	CMM
	Level 1 (lower)	Level 1 (upper)	Level 2	Level 3	Level 4	Level 5
Rating	Very Low	Low	Nominal	High	Very High	Extra High
Values	7.80	6.24	4.68	3.12	1.56	0.00

The CMM level 1 is for organizations that don't focus on processes or documenting lessons learned. The CMM level 1 is for organizations that have implemented most of the requirements that would satisfy CMM level 2. In CMM's published definition, level 1 (lower half) and (Upper half) are grouped into level 1.

B. The CMM Based Process Maturity

The Software Engineering Institute at Carnegie-Mellon University published the CMM is used to rate an organization's process maturity [11]. It provides a number of requirements that all organizations can use in setting up the software processes used to control software product development. There are five levels of process maturity, level 1 (lowest half) to level 5 (highest). The CMM specifies "what" should be in the software process rather than "when" or "for how long". To be rated at a particular level, the organization should demonstrates capabilities in a set of Key Process Areas associated with a specific CMM level. The capabilities demonstrated in moving from

lower levels to higher levels are cumulative. For example, level 3 organizations should show compliance with all key process areas in levels 2 and 3. The CMM process maturity framework is presented in Table 4

Table 4. The Framework of CMM.

CMM Level	Key Process Area
Level 1	None
Level 2 Repeatable	Requirements Management
	Software Project Planning
	Software Project Tracking and Oversight
	Software Subcontract Management
	Software Quality Assurance
Level 3 Defined	Software Configuration Management
	Organization Process Focus
	Organization Process Definition
	Training Program
	Integrated Software Management
	Software Product Engineering
Level 4 Managed	Intergroup Coordination
	Peer Reviews
	Quantitative Process Management
	Software Quality Management
Level 5 Optimizing	Defect Prevention
	Technology Change Management
	Process Change Management

All the organizations are supposed to start at level 1. Which is known as Initial level? At this level, few processes are defined, and the success depends on individual effort which makes the software process unpredictable because it changes as work progresses. Project Schedules, budgets, functionality, and product quality are also unpredictable. Every key process area has a set of goals, capabilities, key practices, measurements and verification practices. The goals state the scope, boundaries, and intent of a key process area. A key practice describes "what" should happen in that key process area. There are a total of 52 goals and 150 key practices.

IV. Methodology

The methodology of our work is the primary data collection tool was a questionnaire that has been used to collect a data from individual projects, i.e., each and every questionnaire should be applied only on one of the project. The questionnaire is based on "COCOMO II cost estimation"

A. The Data Collection

The data collection procedures 55 questionnaires distributed to 20 software development organizations, 35 questionnaires were returned. Some of the questionnaires could not be verified by project managers or senior project

staff; therefore, 16 questionnaires were rejected and eliminated from this study. Therefore, 40 questionnaires were analyzed. The datasets were returned from different fields like banking, insurance, communication, simulation, web development, etc. The questionnaires were distributed to software organizations that have already achieved one of the CMMI levels, and spanned the range of its levels, from level 1) to level 4, i.e., 8 data points were collected from each level. For each project, there was a meeting with the project manager or team leader for each project, who would be filling out the forms, in order to clarify each question to ensure that it was well understood and each manager would answer consistently.

B. The Data Analysis

The questionnaires were checked for consistency and went through a data validation process, based on some constraints determined in [6]. There are four aspects that would be extracted and computed: for each questionnaire.

- The set of seventeen COCOMO II's cost drivers. To deal with these seventeen cost drivers, we computed their multiplication. A sample of the cost drivers is shown in Table 5.
- The set of five exponential scale factors. To deal with these five scale factors, we computed their summation. A sample of these scale factors is shown in Table 6 (excluding the last row).
- The Actual effort in Person Months, which extracted for the person hours, as shown in Table 7.
- We collected the project size as a thousand lines of code (KLOC), which is the baseline size in COCOMO II.

We applied equation 1 To predict the effort in person month, which is the basic COCOMO II's formula [6]. At last this analysis, we got the estimated effort for the generic COCOMO II as well as the actual effort for this project.

C. Ideal Scale Factor Analysis on Process Maturity

Boehm[7] has described normalization method out contaminating effects of individual cost driver attributes in order to get clear picture of that cost driver's contribution. Since we have relatively similar situation, i.e., we need to normalize out contaminating effects of a scale factor in process maturity rather than a cost driver. Therefore, for the given project P, compute the estimated development effort using the COCOMO II estimation procedure, with one exception: do not include the value for the Scale Factor Attribute being analyzed. Call this estimate PM (P, Scale Factor Attributes). Then the Ideal Scale Factor, for this project/scale-factor combination is defined as the value which, if used in COCOMO II, would make the estimated development effort for the project equal to its actual development effort PM (P, Actual). i.e.,
 Ideal scale factor(P, Process Maturity) =

$$\frac{PM(P, Actual)}{PM(P, Process Maturity)} \quad (c)$$

Where Ideal Scale Factor (P, Process Maturity): the ideal scale factor on Process Maturity for project P.

PM (P, Actual): the actual development effort for the project P.

PM (P, Process Maturity): COCOMO II estimate excluding the Process Maturity Scale Factor.

We performed the following steps to complete the Ideal scale factor-Process maturity analysis on our datasets:

1. The first step Compute the PM (P, Scale Factor Attribute), using the following formulas:

$$PM = A \times \sum_{i=1}^{17} SIZE_i \times IEM_i \quad (d)$$

where A is a model constant, EM is a set of seventeen effort multipliers as shown in Table 1, and

$$E = B + 0.01 \times \sum_{j=1}^4 SF_But_ProMat_j \quad (e)$$

Where B is a model constant, and scale factor_But the process maturity refers to scale factors except Process Maturity, including Precededenes REC, Flexibility, Resolution, and Team.

2. Compute the ideal scale factor (P, Scale Factor Attributes) using equation 6.
3. Group Ideal Scale Factor (P, Scale Factor Attributes) by the current CMM process maturity rating (i.e., VL, L, N, H, VH).
4. Compute the mean value for each group as ideal scale factor -Process maturity value for that rating.

This step involves the computation of the mean value of ideal scale factor-process maturity for each CMM rating level.

D. The Prediction Accuracy evaluation

The purpose of this paper is on the degree to which the model's estimated effort measured in Person-Month matches the actual effort. If the model is perfect then for any project, Process maturity =Person month matches. The most common criterion for the evaluation of the cost estimation models is the Relative Error or the Magnitude of Relative Error, which are shown below :

$$\text{Relative Error} = \frac{\text{Person month matches} - \text{process maturity}}{\text{process maturity}} \quad (f)$$

$$\text{Magnitude of relative Error} = \frac{|\text{Person month Matches} - \text{Process Maturity}|}{\text{Process Maturity}} \quad (g)$$

The Relative Error and Magnitude of Relative Error values are calculated for each project whose effort is predicted. Another criterion that is commonly used is the percentage of predictions that fall within P % of the actual, denoted as Predictions (P) [13],

$$\text{Prediction (P)} = K / N \quad (h)$$

K is the number of projects where magnitude of relative error is less than or equal to P, and N is the number of projects. According to the [10], a standard method for assessing the COCOMO performance is prediction. Therefore we used this criterion to assess the COCOMO II performance as compared to the proposed model. Table 5 through Table 10 shows samples of the calculated data, that represents one project from our forty datasets.

The new set of process maturity rating values under CMMI derived by applying our methodology to the datasets in Table 11.

Table 11. The New Process Maturity Rating values.

Process maturity Description	CM MI Level 1 lower	CM MI Level 1 Upper	CMMI Level2	CM MI Level 3	CM MI Level 4	CMMI Level5
Rating level	Very low	low	Nominal	High	Very high	Extra High
New Process Maturity Values	6.44	3.45	2.34	1.34	.98	0.0

In the Figure 1, X axis represents the projects used in CMMI level 4 organization in our study and the Y axis represents the effort. Each project has three columns: the left column represents the actual effort, the middle column represents the generic COCOMO II effort estimation, and the right column represents the effort estimation for the proposed COCOMO II model with new Ideal Scale Factor - Process Maturity Values.

The figure shows that how the proposed model give an estimated effort which is closer to the actual effort than generic COCOMO II estimations due to some data anomalies, especially for low levels companies that do not have good and precise documentations for their historical projects. This case is not absolute, i.e., in some little cases like in CMMI level 1 (lower and upper) and level 2 datasets, the estimated efforts by the generic COCOMO II were relatively closer to the actual effort than the proposed model's estimation.

The proposed model here is uniformly overestimated the effort for most of the 8 projects, so it could still be a consistent model.

The black line in Figure 2 shows the current process maturity scale factor values used in COCOMO II. It shows that an increase in process maturity level corresponds with a reduction in project effort. It shows the new process maturity values derived from the ideal scale factor-process maturity analysis.

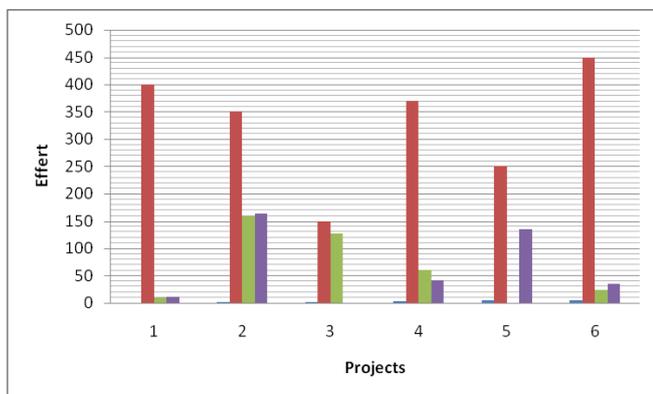

Figure 1. The Estimated and Actual effort in both generic COCOMO II and COCOMO II with Ideal Scale Factor-Process Maturity.

The few number of different Process Areas are assigned to this level, and success still depends on individual effort that is very low and low rating levels in COCOMO II's procedure maturity are categorized under CMMI level 1. Therefore, level 1 companies still need much effort to accomplish their projects, particularly for CMMI level 1 companies that rely on "heroes" to do the jobs and do not show any compliance that would satisfy subsequent levels.

The second observation is the nominal and high rating levels demonstrated a relatively obvious reduction in the procedure maturity values, which appears as a deviation first line in Figure 2. The underlying explanation behind this reduction might be due to the major additions and refinements that have occurred at CMMI maturity levels 2 and 3. As an example, going from seven key process areas in CMM level 3, to 14 process areas in CMMI level 3, and just two were dropped. These additions and refinements in maturity levels 2 and 3 reflect their significance and definitely will reduce the effort required to develop the software systems in CMMI maturity levels 2 and 3 organizations.

Ideal Scale Factor Process Maturity VS COCOMO II Process Maturity

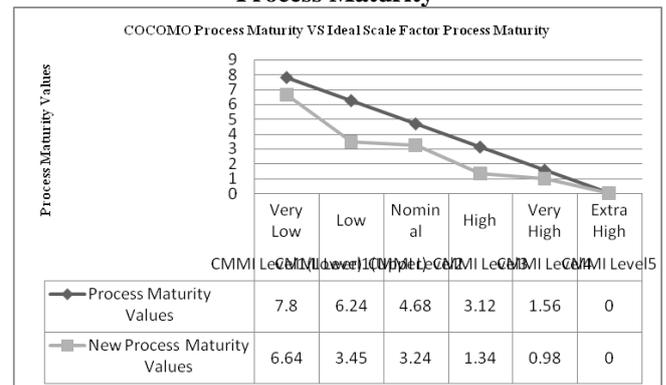

Figure 2. The Ideal scale factor -process maturity values. vs COCOMO II's process maturity values.

E. The Results of the Model Accuracy with ideal scale factor

The improvement in the model's accuracy has been realized which is shown in the below after applying the derived ideal scale factor-process maturity values back to our datasets, in the below Table 12.

Table 12. The Analysis of Accuracy Results

Level	Generic COCOMO II	COCOMO II with New Process Maturity Values	Improvement
Level 1 (Lower)	43%	55%	9%
Level 1 (Upper)	30%	43%	11%
Level 2	18%	55%	34%
Level 3	18%	58%	47%
Level 4	30%	77%	21%

The above Table shows the analysis of accuracy results that by applying the ideal scale factor procedure maturity values into our datasets which had been collected from CMMI organizations, the accuracy in all maturity levels increased by 9%, 11%, 34%, 47%, and 21% respectively as we have already mentioned and justified, that level 3 has the highest percentage of improvement, and the level 1 has lowest percentage of improvement.

V. Conclusions

The software development cost estimation is very important in all the aspects of project such as budgeting, planning and effective control of management. There are various software cost estimation models which have various inputs. The most important inputs to software cost estimation models is the process maturity. According to survey, the present values for the COCOMO II process maturity scale factor does not adequately reflect the impact of CMMI-based process maturity on development efforts. Therefore, by using the ideal scale factor method and with the aid of our datasets, we have identified the new process maturity values which better reflect the impact of CMMI based process maturity on software development effort. The new values provide an improvement in COCOMO II model accuracies 9% for CMMI level one, 11% for CMMI level one, 34% for CMMI level two, 47% for CMMI level three, and 21% for CMMI level four organizations. In future the amount of datasets allocated to each CMMI maturity level could be expanded to get a clearer picture of the impact of CMMI-based process maturity on software development effort and the locally calibrating the proposed model parameters to a particular organization, which requires collecting data from more projects belonging to the same Organization.

Abstract: With the addition of inorganic spherical nanoparticles to polymers allows the modification of the polymers physical properties in the polymer matrix. This review article covers considerations on special the aspects of TiO₂ nanoparticles composite materials in polyaniline during the polymerization. Classical nanocomposite properties, as thermo mechanical, dielectric, conductive, magnetic, as well as, mechanical properties will be summarized. Finally, typical existing and potential applications will be shown with the focus on new and innovative applications, like in energy solar systems and environment systems.

Keywords: Nanocomposites; polymer matrix; spherical nanoparticles; physical property tailoring, polymer-nanoparticles-interface

I. Introduction

The environment and energy are the biggest challenges of the 21st century. Nanomaterials, with attractive chemical and physical properties, are being explored for potential uses in energy and environmental applications. Considerable effort has been made to design, fabricate, and manipulate nanostructure materials by innovative approaches. The precise control of nanoscale structures will pave the way not only for elucidating unique size/shape dependent physicochemical properties but also for realizing new applications in science and technology. Nanotechnology offers unprecedented opportunities for improving our daily lives and the environment in which we live. The addition of inorganic spherical nanoparticles to polymers allows the modification of the polymers physical properties. The resulting thermal, mechanical, optical, magnetic or conducting properties of the nanocomposites are influenced by the filler properties as well as from the fillers surface properties. Specific interest is to develop the polymeric nanocomposite with good thermo mechanical properties, rheological characteristics and thermal stability for energy and environmental applications [1]. As global environmental and energy issues increasingly demand our attention, numerous challenges in materials science and technology will arise. Polyaniline is electro-conducting polymer containing a system of conjugated double bonds, and its properties combine semiconducting and metal physics with the molecular and solid-state chemistry. To make this polymer electrically conductive it is necessary to introduce mobile charge carriers. This can be done by oxidation or reduction reactions, commonly called "doping" and "dedoping", respectively, which can be performed by different chemical or electrochemical processing. Chemical doping-dedoping occurs when the polymer is exposed to an oxidizing or reducing agent; whereas electrochemical doping-dedoping can be obtained by anodic and cathodic polarization in suitable electrolytes [2-4]. The nanostructured metal oxides are promising new materials for blending with polymers for obtaining low weight nanocomposites with excellent mechanical, electrical, thermal, and multifunctional properties. The creation of nanocomposites based on electro-conductive polymers and

nanostructured metal oxides, i.e. incorporation of inorganic filler into polymer matrixes, can dramatically improve their processibility [5-7]. The main goal in this work is to enlarge the existing knowledge of the preparation of new advanced materials consisting of polymer matrix with nanoparticles.

II. Conductive Polymer

Conductivity or can be semiconductors. The biggest advantage of conductive polymers is their processibility, mainly by dispersion. Conductive polymers are generally not plastics, i.e. they are not thermoformable. But, like insulating polymers, they are organic materials. They can offer high electrical conductivity but do not show mechanical properties as other commercially used polymers do. The electrical properties can be fine tuned using the methods of organic synthesis (9) and by advanced dispersion techniques (10). The linear -backbone "polymer blacks" (Polyacetylene, Polypyrrole, and Polyaniline) and their copolymers are the main class of conductive polymers. Historically, these are known as melanins

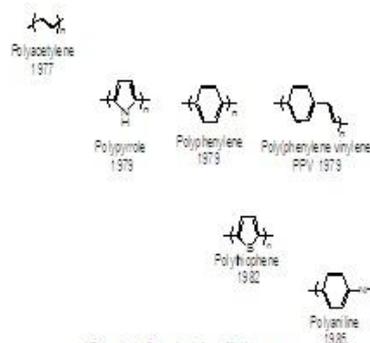

Fig. 1.1 Conducting Polymers

..Poly (p-phenylene) (PPV) and its soluble derivatives have emerged as the prototypical electroluminescent semiconducting polymers. Today, Poly (3-alkylthiophenes) is the archetypical materials for solar cells and transistors (9).

2.1 Polyaniline properties and structure:

2.1.1. Chemical properties

The name of polyaniline is a family of polymers which have the length of polymer chain, differ in oxidation state, redox properties and the value of conductivity. There are three oxidation states of polyaniline; Leucoemeraldine (LE), Emeraldine (E) and Pernigraniline (PNA).

The reduced states of polyaniline are LE and PNA in which all the nitrogen atoms are amine and the fully oxidized all the nitrogen atoms are imine forms respectively and in E the ratio amine / imine is 0.5. Standard electrochemical or chemical oxidation gives the electrically insulating LE, electrically conducting E, as for other conducting polymers [11].

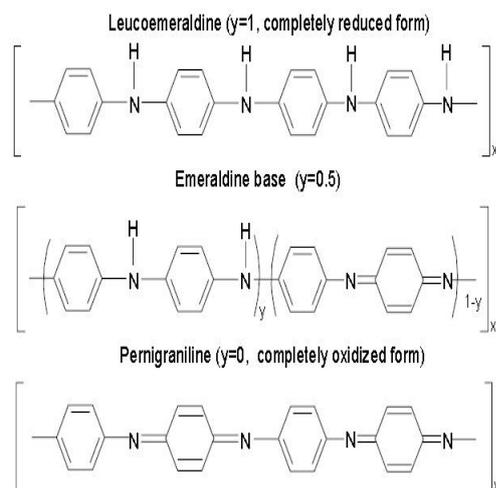

Fig 1.2 Non-conducting Polyaniline Structure

The second redox process by the oxidation gives an insulating material -PNA. Addition to this changing in behaviors of conductivity as decreases by order of ten in magnitude by the treatment of the conductivity E in neutral or alkaline medium. There is no change in the number of π electrons while protonation induces for the transition of insulator to conductor.

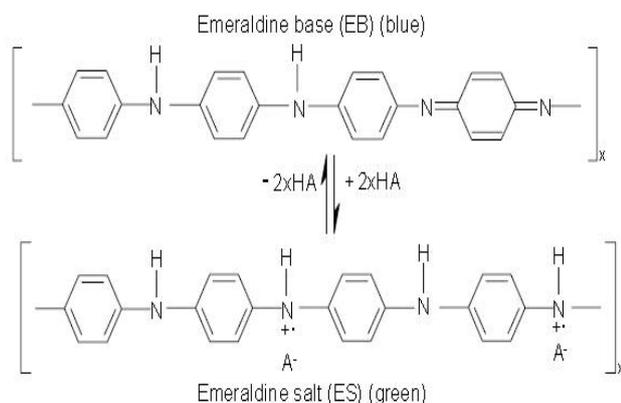

FIG 1.3 Protonated emeraldine form in transition phase from polyaniline base form. Arbitrary anion represented by A^-

Recently the structure of polyaniline was established as poly (P-phenyleneamine quinonedimine) as emeraldine base form [12]

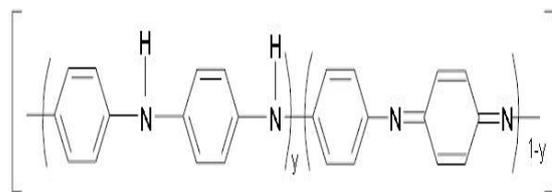

FIG 1.4 Poly (p-phenyleneamine quinonedimine) structure

The above structure of polyaniline was confirmed by the ^{13}C -NMR [13], IR and Raman spectroscopy experimental data [14, 15]. Accordance to the results, the bands C=N movement mode, C-N bending mode, for the movement of benzenoid and quinoid rings are observed. The chemical or electrochemical polyaniline oxidation gives the idea of quinoid diamine units and changing of the part of benzenoid diamine units, these results are verified by the analytical results [16] and FTIR spectroscopy [17]. The quantitative p-benzoquinone almost formed by the oxidation of Polyaniline [18]. The salts of PANI can be prepared by the protonic acids as the presence of basic amine and imine nitrogen atoms, 50% of nitrogen atoms can be protonated explained by the existence of strong effective pushing away between protons near to neighboring nitrogen atoms [18]. Aromatic amines, phenols, N, N-dimethylformamide phenols are some organic solvents and in aqueous solutions of acids, in cold 80% acetic acid, 60-88% formic acid in which polyaniline is partially soluble. The molecular weight of polyaniline base soluble in tetrahydrofuran, electrochemically obtained in aqueous solution gives the maximum value is 4300 [19] and maximum 50,000-55000, these value gives the idea of different synthesizing methods and method of treatments resulted in the molecular weight distribution shifts to the low molecular weight side [20]. The molecular weight of polyaniline effected by the temperature of synthesis, as temperature decreases of synthesis molecular weight increases [21].

2.1.2 Thermal, dielectric and mechanical properties of Polyaniline

2.1.2.1. Thermal properties

Thermal stability of Polyaniline in both conducting and insulating forms by thermo gravimetric analysis (TGA) and differential scanning calorimetry (DSC) have been studied by the researchers [22-25]. The thermogram of Polyaniline represents weight loss process in three steps.

- Due to evaporation of water or solvent molecules from the polymer between temperature ranges 65-125 °C [22].
- Loss of low molecular weight polymer and unbounded dopant ions from a Polyaniline chain between 125-350 °C [23].
- The degradation of the main polyaniline chain after the elimination of bounded dopant 350-520 °C between [24].

Thermal stability of doped polyaniline depends upon the counter anion as methane sulfonic acid (MSA) doped

polyaniline was stable up to 250 °C [26]. The first step occurring in the range of 65-125 °C is attributed to the evaporation of water or solvent molecules from the polymer [23]. The second-step weight loss occurs between 125-350 °C and is due to the loss of low molecular weight polymer and unbounded dopant ions from a PANI chain [24]. The third-step weight loss occurs between 350 and 520 °C and is due to the degradation of the main PANI chain after the elimination of bounded dopant [25]. But it should be mentioned that the thermal stability of doped PANI is dependent on the counter anion. For example, methane sulfonic acid (MSA) doped PANI was found to be stable up to 250 °C [26].

2.1.2.2. Dielectric properties

The electric field effects on polyaniline depend on the different factors temperature, electric field frequency, acid doping, and water content. The dielectric function $\epsilon(\omega)$ gives the information of transport mechanism in the system. The dielectric response is described by the complex permittivity

$$\epsilon(\omega) = \epsilon'(\omega) - i\epsilon''(\omega)$$

Where $\epsilon'(\omega)$ is storage energy in each cycle of applied electric field,

$\epsilon''(\omega)$ loss of energy in each cycle of applied electric field.

At high frequency the value of the value of $\epsilon'(\omega)$ is constant in comparisons to at low frequency and high temperature [27]. The increase of the dielectric permittivity with doping is a result of contributions from the backbone emeraldine base and the formed polaron and bipolarons to the polarization [27].

2.1.2.3. Mechanical properties

As it is known, the main disadvantages of PANI are its poor processibility and mechanical properties caused by its backbone stiffness. It was found that the mechanical property of PANI can be substantially enhanced when it was prepared from the gel and after the cross linking [28, 29]. The influence of the PANI oxidation state on the mechanical property was also established [28]. It was found that the tensile strength of EB film was improved by about 25% upon heating to 150 °C. This improvement was attributed to the interchain cross linking of PANI at high temperature and the formation of the PANI aggregates through interchain hydrogen bonding. The tensile strength of LE improved only upon its exposure to air at 200 °C, but, at the same time, the color of the film changed from yellow to blue [28]. The XPS results revealed the conversion of amine units to imines ones at this temperature [30]. Also, with the help of XPS analysis it was found that the mechanical property of the PANI film is closely related to the oxidation state of the polymer and the degree of cross linking [30]. The film orientation also was found to influence the mechanical properties. Monkman et al [30] showed that the tensile strength increases with elongation which indicates the alignment of polymer chains along the stretch direction. X-ray diffraction analysis suggested [29] a possible link of the mechanical behavior and changes in crystallinity with elongation.

2.1.3. Effect of acid-dopants on the polyaniline preparation and properties

The rate of polymerization as well as conductivity and others properties of PANI strongly depend on the used acid-dopant [31-32]. It is known that the electrical conductivity is influenced by the size and shape of the counter ion [33].

On one hand, higher the penetration of counter ions in the formed film is, the higher its conductivity is. But, on the other hand, the small molecular weight anions are more quickly removed from the polymer. That's why the choice of dopant might be a very important factor – if we need thermally stable conducting PANI we should use larger molecular weight acids, if the high value of conductivity is more important – it is better to use small protonic anions. The size of counter ion can also affect the interchain distance and, correspondingly, intermolecular interaction that can change the disorder in the polymer system [34]. Therefore, the choice of the dopant depends on the PANI application.

It should be mentioned that the rate of the aniline polymerization also changes depending on the acid in such sequence: HCl < HClO₄ < HBF₄ < HF < H₃PO₄ < H₂SO₄ [32, 35]. The acid nature at the same doping level determines also the PANI conductivity as one can see from the results in Table 1.1. Therefore, it is shown the same anion differently influences the rate of polymerization and the conductivity value of formed PANI.

In recent studies of PANI doped with various protonic acids [33, 36, 37] it was found that hydrochloric and sulphuric acids are the best dopants in terms of stability of conductivity. Kiattibutr et al [38] producing sensors for SO₂-N₂ mixtures found that at the same doping level specific conductivity of PANI-HCl is greater as compared with PANI-CSA because of two factors: a more closely packed crystalline mobility, and the ability to absorb more water molecules which induced ionic conductivity. But, in the other work [39] the opposite results can be found – the authors showed that poly (*o*-methoxyaniline) (POMA) doped with HCl is easily.

Table 1.1 Influence of the anion nature on the PANI conductivity [33]

Anion	Doping level	Conductivity, $\Omega^{-1} \cdot \text{cm}^{-1}$
CF ₃ COO ⁻	0.33	0.7
BF ₄ ⁻	0.34	0.8
ClO ₄ ⁻	0.31	2.0
Cl ⁻	0.36	1.4
NO ₃ ⁻	0.33	1.9
SO ₄ ²⁻	0.23	0.5

deprotonated in comparison to polymer doped by *p*-toluene sulphonic acid (TSA). The Cl⁻ anion is a weaker base than *p*-toluene sulphonate, thus, Cl⁻ ions are more easily removed [39]. Also, amic acids were found to be dopants for PANI [40]. PANI reacted with the selected amic acid by mixing the *N*-methyl pyrrolidone (NMP) solutions of the two materials in appropriate ratios. It was found that the conductivity in all the polymer matrices was limited by geometric limitations between the two polymers.

Phosphoric acid diesters with long alkyl substituents are also very good candidates for protonating agents which induce solution and melt processability of conducting PANI [41]. Due to their lower pH value, compared to the parent acid, they are sufficiently acidic to protonate emeraldine base. Their hydrophobic alkyl chains also induce solubility of PANI. Phosphoric acid esters are known as plasticizers for a variety of polymers. Thus, the esters can serve as plasticizers and protonating agents for PANI. Protonation of PANI was achieved by treatment with diester [bis-(2-ethylhexyl) hydrogen phosphate] (DiOHP) and diester [bis-(2-methylpropyl) hydrogen phosphate] (DiBHP) dissolved in an appropriate solvent (toluene, decaline, chlorinated hydrocarbons, *m*-cresol) or by mechanical mixing of PANI with neat diester. Phosphoric acid esters are also known to form strong intramolecular H-bonds [41].

The PANI-dopant interaction can be related to an increase in the polymer molecular weight, the polymer crystallinity and/or the molecular conformation of doped PANI that changes from a compact coil to an open coil-like structure. Not only conductivity, but also electrochromic properties depend strongly on the acid-dopant. Gazotti et al [39] established that POMA doped with TSA presents a higher optical contrast in the visible region than the same polymer doped by HCl.

Many researchers also reported that the dopant mixtures induced high conductivity and processibility [37, 42]. Dopant mixtures gave higher conductivity to PANI than a single dopant, because they could provide an effective conjugation length and a high protonated level. It should also be pointed out that not only dopant can influence the PANI properties, but also the used solvent. As it was shown, the conductivity of the PANI samples varies with dopants (TSA, CSA, and benzene sulphonic and naphthalene sulphonic (NSA) acids) in the same solvent [42]. However, using different solvents (*m*-cresol, chloroform, 2-hydroxybutanol (BeOH)) conductivity with the same dopant dramatically changes [42], which indicates that transport properties can be controlled by both dopants and solvents.

Taking into account a specificity of used systems, the observed divergences in obtained experimental results may be explained by using different polymerization methods and conditions. Significant fact may have been here also attributed to the different PANI-dopant interactions.

2.2 Synthetic methods of the polyaniline preparation

PANI is synthesized by the chemical or electrochemical oxidative polymerization of aniline [11]. There exists also a method of plasma polymerization [43], but this method is not very convenient and not easy in

application. So, we will speak only about two ways of the PANI obtaining – chemical and electrochemical polymerization.

It is possible to select such conditions under which PANI is the main reaction product. In this case the chemical and electrochemical ways of the PANI preparation produce polymers of the same composition since their electrochemical behavior is practically identical [44-46].

2.2.1. Chemical way of obtaining polyaniline

Suitable oxidants such as ammonium persulphate (APS) $(\text{NH}_4)_2\text{S}_2\text{O}_8$, sodium chlorate NaClO_3 , potassium dichromate $\text{K}_2\text{Cr}_2\text{O}_7$, Fenton reagent, hydrogen peroxide H_2O_2 , etc. [46-50] in solutions containing mineral or organic acids. As a result, dark green product is obtained, which because of its color received the name “Emeraldine”. The treatment of this product by alkaline or ammonium solution converts it into dark blue Emeraldine base (Fig. 1.2). Under these conditions Emeraldine can be received quantitatively: if oxidant is taken on the basis of 1.25 mol per one aniline molecule, so the yield reaches 97% [26]. Similar values have been found recently [31]: 1.15 ± 0.04 mol of APS per mol of aniline. These results are in good agreement with the Emeraldine formula proposed on the basis of elemental analysis and quantitative ratio [32] including quinoneimine units 1/4, brutto formula $\text{C}_6\text{H}_4.5\text{N}$

This formula is, certainly, approximate, but is close enough to reality. The aniline oxidation reaction is an exothermal reaction with an induction period [51]. It was established that the presence of PANI leads to the decrease of induction period time, i.e. the chemical oxidation as well as electrochemical one is an autocatalytic process. The properties of formed PANI are practically independent of the chosen oxidant, but only under conditions when the oxidant is not taken in excess. In the case of oxidant excess the decrease of the PANI yield is observed which is due to the PANI decomposition [31]. Moreover, the polymer formed is a little more oxidized and as a result the value of its conductivity is lower [31].

2.3 COMPOSITE MATERIAL

Ceramics and polymers, composites, especially polymer-matrix composites (PMC), allow for a physical property tailoring using different type of fillers [52, 53]. Depending on the particle size, particle shape, specific surface area and chemical nature, the following polymer matrix properties can be modified:

- Electrical and thermal conductivity
- Polymer phase behavior and thermal stability
- Mechanical properties like stiffness, Young's modulus, wear, fatigue, and others
- Flame retardancy [54]
- Density
- Physical properties such as magnetic, optic or dielectric properties.

In principle, the whole bandwidth of polymer processing technology can be used for shaping, molding or replication of the polymer-based composites enabling a low

cost fabrication of components and devices. On the one hand new potential applications can be realized using nanoparticles with small sizes, but on the other hand they complicate the realization of homogeneous and highly filled composites. Polymer matrix composites containing different kinds of nanosized fillers like clay, carbon nanotubes, and others, can be found in [54-55].

2.3.1. Features of Nanoparticles

2.3.1.1. Particle size dependent properties of inorganic nanoparticles

Ensembles of isolated nanoparticles with particle sizes below around 20 nm exhibit physical properties that may differ from their bulk counterparts. The effects are sometimes crucial, as they will strongly influence the desired or expected property of the nanocomposite. A significant influence of particle size is observed as well as on magnetic, dielectric, electronic, optical, thermodynamic, and thermo mechanical, and on structural properties. The following explanations rely on general features, found in metallic, ceramic and semiconducting nanoparticles. Size-dependent magnetic properties have been studied for around two decades. Tang *et al.* [56, 57] reported an increasing saturation magnetization in the particle size range from 7.5 nm to 25 nm. In this size regime, the authors also observed a decrease of the transition temperature. Han *et al.* described similar behavior for Co-containing ferrite nanoparticles [25]. The size dependence of saturation magnetization is depicted exemplarily in Figure 2 (left). These dependencies can be stated as general rules as nanoparticles are typically covered by a 0.5 to 1 nm thin, nonmagnetic surface layer. As the amount of surface increases with decreasing particle size, the ratio of nonmagnetic surface layer to magnetic material also increases.

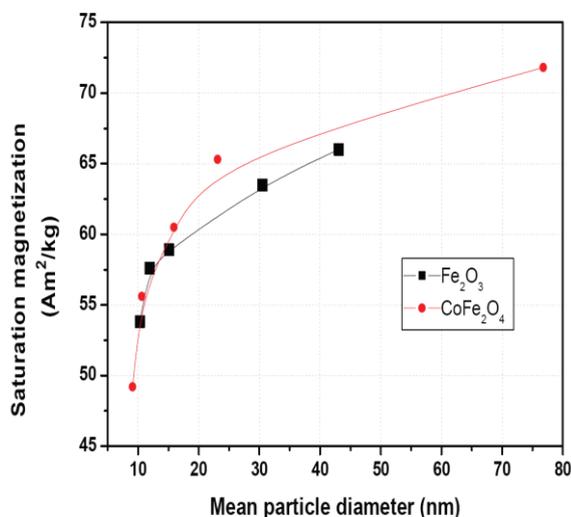

Figure 2.1 a. Examples for typical particle size-dependent physical properties. Left: Saturation magnetization as a function of particle size. Data taken from [58]. Right: Band gap energy for SnO₂ as a function of particle size. Data taken from [59]

Size-dependent refractive indices were reported for narrow band-gap semiconducting nanoparticles such as PbS by Kyprianidou-Leodidou *et al.* [60]. Above 25 nm particle

size the refractive index of PbS at different wavelengths was more or less independent of the particle size, and near the bulk values, respectively. For PbS particles with diameters below 25 nm the refractive indices decreased significantly with size. Similar observations were made from these authors featuring the absorption coefficient. In Si-nanoclusters a significant luminescence peak blue-shift was calculated for decreasing particle size. In parallel the

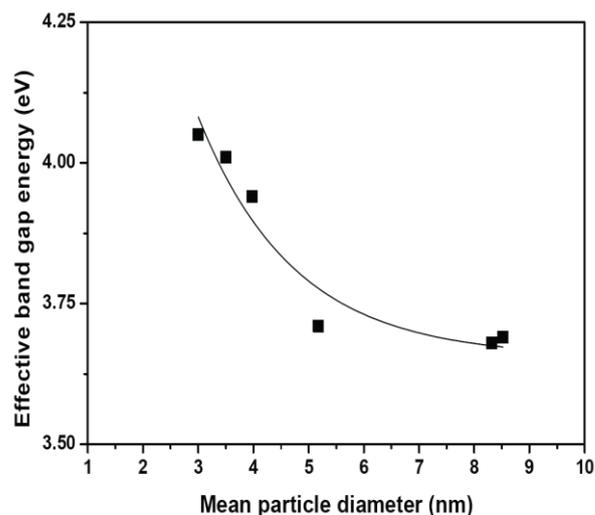

Figure 2.1 b Examples for typical particle size-dependent physical properties. Left: Saturation magnetization as a function of particle size. Data taken from [58]. Right: Band gap energy for SnO₂ as a function of particle size. Data taken from [59]

Spectra became broader with decreasing particle size. These effects were described in the size regime from 2 to 6 nm [61]. Theoretical considerations predicted size-dependent energy band gap and dielectric constants for semiconducting nanoparticles [62]. Lee *et al.* [59] studied the size dependence of band gap energies in SnO₂ quantum dots. Figure 2 (right) shows the significant increasing band gap energy with decreasing particle size. Nienhaus *et al.* [63] and Szabo *et al.* [64] observed a blue shift of the plasmon losses with decreasing particle size in SnO₂. Concerning thermodynamic properties such as phase transitions or phase stabilities, interesting observations were made for materials existing in several polymorphs. The physical properties such as optoelectronic, photochemical or catalytic properties may be influenced by phase as well as by size. This is the case for ZnO₂ and TiO₂, both existing in different phases, and very interesting as nanofillers in composites. Suresh *et al.* [65] described an inverse relationship between transformation temperature and particle size in ZnO₂, and deduced a grain size dependent phase diagram. Li *et al.* [66] made energetic considerations and calculated decreasing transition temperatures with decreasing particle sizes for nanoscaled ZnO₂. Zhang and Banfield [67] analyzed the phase stability of nanocrystalline TiO₂. They found anatase to be more stable than rutile when the particle size decreased below around 14 nm. Phase stabilities of TiO₂ and ZnO₂ were also investigated by Schlabach *et al.* [68, 69]. Both ceramics were found to occur in non-typical phases as nanoparticles compared to the bulk material and are subject to phase transformation and grain growth with increasing temperature. Coating the

nanoparticles with a different ceramic layer suppresses phase transformations and obstructs grain growth. The knowledge about which phase is stable under which conditions is in-so-far important, as TiO₂ is frequently used as filler to modify optical properties of polymers. The phases differ in their refractive indices: bulk anatase is characterized by a refractive index of 2.54 (at 550 nm) and a band gap of 3.20 eV, whereas rutile is characterized by a refractive index of 2.75 (at 550 nm) and a band gap of 3.03 eV for bulk, respectively. For amorphous thin TiO₂ films a refractive index of 2.51 (at 550 nm) and a band gap of 3.27 eV were reported [70]. Size effects regarding electrochemical properties and cycling stability were described for nanoscaled TiO₂ [71, 72]. With decreasing anatase particle size from 30 nm to 6 nm, an increase of capacity was observed, indicating an improved lithium storage capability [38]. Similar effects were observed for rutile [72]. Here the authors found a significant increase in capacity with decreasing size from 300 nm to 15 nm for rutile particles. As both phases were cycled under different conditions, the results cannot be compared directly. Deng *et al.* [73] comment that anatase - among all different TiO₂ phases - presents the most interesting potential regarding electrochemical properties.

2.3.1.2. Thermo mechanical Composite Properties

For many years, micron sized fillers have been used for the reinforcement of the polymers poor mechanical

properties. In a rough approximation, the resulting composite properties correlate with the filler volume content in the matrix. In contrast, the use of nanofillers with particle or agglomerate sizes below 100 nm and primary particles below 30 nm does not follow this simple approach in all cases, because due to size effects the following additional aspects have to be considered:

- Particle shape, agglomeration, and size distribution
- Particle specific surface area and related surface chemistry
- Particle-polymer matrix interface and interaction
- Compounding method and related shear forces.

Quite often the influence of nanoparticles on the polymer properties is not unique, but in general some trends can be observed. Jordan and coworkers collected in a very comprehensive overview the main trends of the nanofillers impact on the resulting composite mechanical behavior, considering attractive as well as repulsive interactions of the filler with an amorphous or crystalline polymer matrix [74]. Table 2.1 gives a selection of the influence trend of nanoparticles on the mechanical properties of amorphous polymers taken from [74]. Table 2.2 lists the related information for semi crystalline polymers, also taken from [74].

Table 2.1 Impact of nanoparticles on composite properties with amorphous polymer matrix.

Item	Polymer filler Interaction Impact	Item
Elastic modulus	Attractive/repulsive	Increase with volume fraction
	Attractive/repulsive	Increase with size decrease
Density/volume	Attractive	Increased volume as size decreases
	Repulsive	n.a.
Glass transition temperature	Attractive	Increase with size decrease
	Repulsive	Level until 0.5%, drops off level from 1–10%

Table 2.2 Impact of nanoparticles on composite properties with semi crystalline polymer matrix.

Item	Polymer filler Interaction	Impact Item
Elastic modulus	Attractive/repulsive	Increase with volume fraction
	Attractive/repulsive	Increase with size decrease
Density/volume	Attractive	Increased volume as size decreases
	Repulsive	n.a.
Glass transition temperature	Attractive	Decrease with addition of particles
	Repulsive	n.a.
Crystalline	Attractive/repulsive	No major effect

In the following, a few examples demonstrate the influence of nanoparticles on the phase behavior, elastic modulus, scratch resistance, hardness and elastic properties. A comprehensive review covering the impact of different nano particle types like clay, carbon nanotubes and spherical particles on the mechanical properties of polymer nanocomposites was published by Tjong in 2006 [75].

2.3.1.3 Glass transition temperature and coefficient of thermal expansion

The Rensselaer group of Siegel investigated the influence of coated and uncoated Al₂O₃ (average particle size around 39 nm) on the glass transition (TG) behavior of PMMA [76, 77]. They found, that uncoated Al₂O₃ caused, at concentrations greater than 0.5 wt %, a significant TG-drop of around 25 °C. The silanization of the Al₂O₃ enabled a constant TG even at higher Al₂O₃ load of 10 wt %. In contrast, the Hu group found that the addition of

hydrophobic nanosized SiO₂ (Aerosil®) to PMMA yielded a pronounced increase of the glass transition temperature up to 15 °C at a solid load of 4 wt % due to a strong attractive interaction of the non-polar nanoparticle with a huge specific surface area up to 200 m²/g and the non-polar polymer [78]. The decomposition temperatures of the composites were elevated remarkably even at low SiO₂ contents. Both groups used sonification in MMA as dispersing method prior to the polymerization to the final PMMA-based composite [76, 78]. The addition of two different nanosized Al₂O₃ (primary particle sizes 13 and 38 nm, solid load up to 10 wt %) to a methylmethacrylate based reactive resin caused after polymerization only a slight drop of TG [79]. The coefficient of thermal expansion (CTE) was more affected by the 13 nm Al₂O₃, which can be explained by the larger specific surface area of 107 m²/g than the 38 nm Al₂O₃ with only 34 m²/g enabling pronounced polymer chain immobility. Although a TG-increase could not be detected in PMMA/SiO₂ nanocomposites by thermal analysis (DSC), dielectric and IR-spectroscopy gave evidence for a strong attractive interaction of the nanoparticles with the polymer chains by means of reduced chain movement and longer relaxation times [80]. The direct chemical bonding of monodisperse nanosized SiO₂ to a polymer backbone, here polystyrene (PS), via grafting, caused a TG increase up to 6 °C at 2 wt %, while the simple physical mixing via sonification generated a slight TG decay [81]. Composites, consisting of nanosized Al₂O₃ and the semi crystalline high performance polymer polyetheretherketone (PEEK), fabricated by wet chemical methods followed by hot pressing, showed an elevated decomposition temperature in comparison to the neat polymer [82]. In contrast, the melting temperature was not affected by the addition of the nanosized Al₂O₃ even at very high load (30 wt %). The crystallization temperature increased slightly with load. Due to the increasing ceramic content the CTE was reduced [82]. Chen and coworkers [83] found, that small amounts (5 wt %) of the nanofiller induced a higher thermal stability, while larger Al₂O₃ concentrations (9 wt %) caused a pronounced weight loss even at low temperatures [83]. Same behavior could be found for TG. A TG increase up to Al₂O₃ filler concentrations of 5 wt % were reported by Omrani and coworkers as well [84]. Surface modified nanosized SiO₂ monospheres with an average diameter of 400 nm, dispersed in an epoxy matrix, caused an increase of TG as well as a reduction of the CTE with solid content [85]. A chemical bonding to the polymer amplified these effects. Summarizing the data the following statements can be made:

- The addition of ceramic fillers lowers the CTE.
- An increase of TG can be observed if an attractive interaction of the nanofillers with the polymer matrix by physic- or chemisorptions is given.
- A decrease of TG occurs if the nanoparticle has a repulsive interaction with the matrix.

2.3.1.4 Elastic modulus, tensile strength, flexural strength and impact performance

Hot compression molding of surface modified SiO₂ (primary particle size 12 nm) or Al₂O₃ (primary particle sizes 15 and 90 nm), mixed with micron sized PEEK powder, was used for the fabrication of test specimens for mechanical testing [86]. The authors investigated the influence of different mixing methods (direct mechanical mixing, liquid-solid mechanical dispersing, sonification, ball milling) and particle sizes on the composite properties. In agreement to results listed earlier the addition of the nanofillers to PEEK caused an increase of TG but no remarkable change of the melting behavior. The amount of crystalline domains in the polymer decreased. The authors found, that tensile and compressive strength increased with Al₂O₃ particle diameter while the flexural strength was not affected. Comparable trends could be detected for the Al₂O₃ and SiO₂ fillers load increase. Both materials showed an optimized concentration of 5 wt % for a raise of the tensile, compressive and impact strength; but a further filler concentration increase yielded a strength reduction. A nanofillers surface modification using different coupling agents did not result in a unique trend of mechanical property reinforcement or weakening. A clear influence of the dispersing method on the investigated mechanical properties was not found [86]. Surface modified nanosized Al₂O₃ (primary particle size 39 nm), dispersed in PMMA, caused an increase in strain-to-failure over 28% at a solid load of 5 wt % enabling a ductile flow in the glassy state [87]. Thin films, consisting of up to 22.8 wt % SiO₂ and polyamide 6, were investigated with respect to their mechanical properties [88]. A significant change of the viscoelastic properties (increase of storage and loss modulus) with increasing load as well as of the Young's modulus as function of solid load and temperature was reported. The mechanical properties of an *in situ* synthesized and surface modified nanosized TiO₂ using acrylates as reactive resin matrix were investigated after polymerization [89]. The sol-gel based nanoparticle synthesis and the *in situ* composite formation avoided particle agglomeration guaranteeing a homogenous particle distribution in the matrix. Increasing TiO₂ content caused an increase of hardness (from 0.030 GPa for the pure polymer and 0.198 GPa for a TiO₂ content of 10 wt %) and Young's modulus (from 2.83 GPa for the pure polymer and 4.98 GPa for a TiO₂ content of 10 wt %). The thermal stability was improved also, an increase of the refractive index in the visible range from 1.5 up to 1.8 (TiO₂ load 50 wt %) due to the high intrinsic refractive index value of TiO₂ accompanied with a good optical transmittance was measured [89]. The effect of the nanoparticle size and amount on resulting mechanical composite properties were measured by Cannillo *et al.* [90]. Fracture images showed a strong bond between the surface-modified SiO₂ and the polymer matrix. Tensile tests showed an improvement of the Young's modulus with solid load; in case of untreated, hydrophilic SiO₂ no reinforcement was observed. Hence, for a numerical description of the mechanical behavior using FEM-methods an interfacial layer between the filler and the matrix had to be assumed. Cho and coworkers found, that a pronounced dependence of the mechanical properties like Young's modulus and tensile strength is given [91]. Surface coated nanosized Fe₂O₃ with a nominal

particle size of 9 nm, dispersed in an epoxy matrix, induced an improved thermal stability of the resulting composite, a significant TG increase of 15 °C at a 10 wt % solid load as well as an improved pencil hardness [92]. The properties of nanosized SiO₂-latex composites are described by Oberdisse [93].

As a short resume the particle size, size distribution, specific surface area, particle load, degree of dispersion, and the particle morphology determine especially the composite's mechanical behavior [94]. The formation of disordered aggregates and agglomerates generating flexible micron sized clusters instead of isolated nanosized particles affect directly the mechanical properties. Hence a pronounced modulus enhancement in thermoplastic polymers is difficult.

2.3.1.5 Scratch resistance, wear and creep properties

Ng and coworkers [95] compared the influence of micron-sized and nanosized TiO₂ (10 wt %, average particle size 0.24 μm and 32 nm, respectively) on the scratch resistance of an epoxy. They found an improvement of the scratch resistance when using the nanosized in comparison to the micron-sized filled polymer and the neat polymer. Same trend was found for the strain to failure behavior; interestingly at other concentrations no impact relative to the pure polymer of the nanosized TiO₂ was found. The grafting of nanosized SiO₂ (average particle size 9 nm) with acrylamide and the dispersion in an epoxy matrix via stirring and sonification yielded composites with improved wear properties and reduced friction coefficient relative to the pure polymer and a composite with the untreated SiO₂ even at low nanofillers content (~2 vol %)[96]. A slight increase of the glass transition temperature due to an attractive filler-matrix interaction and the resulting reduced polymer chain mobility was observed also. Surprisingly no difference between the uncoated and grafted nanosilica was observed. Highly transparent composites, consisting of surface modified SiO₂ (Aerosil® 600, average primary particle size 40 nm) and Al₂O₃ (average primary particle size: 20 nm), dispersed in an acrylate-based polymer, with improved scratch resistance were synthesized by Bauer *et al.* [88, 89]. Melt mixing of polyethyleneterephthalate and nanosized Al₂O₃ yielded a composite with slightly increased friction coefficient and reduced wear rate at low filler contents up to 2 wt % [99]. In contrast, a further Al₂O₃ addition caused an increase of the wear rate to values significantly higher than the pristine polymer. This optimized filler concentration of 2 wt % correlates with a reduction of the polymers crystallinity [99]. Daseri and coworkers published quite recently a comprehensive overview covering all aspects of wear and scratch resistance in polymer-based nanocomposites [100]. Co-extrusion of nanosized TiO₂ (primary particle size 21 nm) with polyamide 6, 6 yielded composites, which were examined with respect to their creep resistance under ambient conditions and at elevated temperature (50 °C) [101]. Test specimens were fabricated by injection molding. Composites containing 1 vol % TiO₂ possesses a significant improvement of the creep resistance and a reduction of the creep strain in comparison to the unfilled polyamide.

2.4 Energy and Environment application

2.4.1 Intrinsic conductive polymer nanocomposites and organic solar cells

Organic solar cells are widely under investigation by O'Regan and Graetzel in 1991 dealing with the photocurrent generation after photon absorption by an organic dye and electron injection into the conduction band of a n-type semiconductor like TiO₂ [102]. Modern dye-sensitized organic solar cell uses polymer electrolytes quite similar to systems used in lithium-ion batteries [103]. Quite recently the positive influence of nanosized TiO₂ (13 nm, Degussa/Evonik), dispersed in PVDF, on the long term stability of the solar cell was demonstrated [104]. Intrinsic conductive polymers have gained more importance at the latest since the Noble prize for Alan J. Heeger in chemistry in 2000. These polymers, like polyaniline (PANI), polythiophene (PTP), PPy or PPV, are expected to be used in organic solar cells, display technology, photodiodes or batteries. In the last years the addition of nanosized ceramics like SiO₂, Al₂O₃, or TiO₂ for a chemical stabilization, an improvement of the physical properties as well as a better dispersibility in water or organic solvents has been investigated. Ballav and Biswas prepared composites consisting of PTP and nanosized alumina (particle size: 22–74 nm) [105]. They found a slight increase in the electrical conductivity and an improved thermal stability in contrast to the pure homopolymer. In contrast to the neat polymer, the composite showed the formation of stable suspensions in water and isopropanol. Yang and coworkers investigated the influence of nanosized SiO₂ (20 nm) and TiO₂ (20 nm) on the stability of the PPV-precursor molecule [106].

2.4.2 Sensors

Public awareness of environmental issues rises and governments make international commitments to reduce emissions, sensor arrays (electronic noses) can play a very important role in the protection of our environment [107]. Nanostructured TiO₂ films have been widely explored as sensor units for various gases. Grimes *et al.* reported that TiO₂ nanotubes prepared by anodization exhibited high sensitivity to hydrogen at temperatures as low as 180 °C [108]. It was reported by Birkefeld and co-workers that the conductivity of anatase TiO₂ varied in the presence of CO and H₂ at temperatures above 500 °C but Al-doped TiO₂ (10%) became selective to H₂ [109]. For ZnO, a variety of nanostructures such as nanowires, nanorods, nanotetrapods, and nanoparticles have been investigated for gas sensing [110-111].

III. Conclusion

The results and data discussed above allow us making a conclusion that the formation of composite materials based on PANI and common polymers opens new possibilities for production of the materials with desired conductivity, mechanical, thermal and other properties. Although a lot of such composite systems have been well known, their industrial applications are still very limited, and in the case of the important polyaniline TiO₂ / SnO₂ and polyvinyl alcohol composites are unknown. This fact can be explained by a lack of data on effects of the chemistry and physico-chemistry of the aniline polymerization process in

the presence of the matrix polymer on conductivity, thermo stability, mechanical, structural and other properties of the composite materials.

- To synthesis conductive (PANI) and polyaniline- TiO₂ / SnO₂ composite through in situ polymerization technique.s
- To make conductive films of PANI/other polymer like PVA and PANi-TiO₂/ SnO₂ other polymer like PVA by using solution casting method.
- To study the effect of TiO₂ / SnO₂ content on the conductivity behavior of the blends with varying TiO₂/aniline weight ratio.
- To study the heating effect on conductivity behavior.
- To study the effect of weight fractions of conductive components (PANI and PANI-TiO₂).

Abstract: Wireless technologies have been adopted into the field of communication in the recent past. The fast pace in the growth of advanced wireless hardware and technologies have caused the evolution and generation of five wireless communication standards within this short span of time. The fourth generation (4G) communication standard, which is the most recent of these five, is a promising area for research. 4G systems aim at implementing a global communication network by integrating all existing telecommunication standards. It modifies the main goal of wireless communication from “AlwaysConnected” to “Always Best Connected”. Major issues which are delaying the commercial release of 4G devices include network selection, vertical handoff, billing issues, jamming and spoofing, location privacy and QoS support. The main expectation about 4G is the freedom for the users to choose and switch between services provided by various service providers integrated into the 4G network.. The main purpose of this paper is to explore the various network selection schemes which have been proposed by various researchers in the area. This paper discusses the method or technique of network selection, benefits and shortcomings of each of these selection schemes. And also the paper tries to accomplish a comparative study on their effectiveness in performance. A proposal is also made to improve the network selection scheme based on QoS technique to make it suitable for emergency situations by adding a preplanner module.

KEYWORDS: 4G SYSTEMS, NETWORK SELECTION, MOBILE COMPUTING, WIRELESS COMMUNICATION, COMPARATIVE STUDY.

I. INTRODUCTION

Communication Techniques are evolving at the fastest pace ever known to mankind, with the worldwide development of new and efficient technologies in every split second. By instigating 4G, an integrated network of all networks, everything from laptops to smart phones and communication facilities from LANs to portable internet packages, grows to be a part of a common global standard. With a data rate of 100 Mbps to 1Gbps, 4G is the technology of the future. Techniques like OFDMA (Orthogonal Frequency Division Multiple Access), SDR (Software Defined Radio), MIMO (Multiple Input and Multiple Output) and so on adds to the boons of 4G wireless communication standard. This results in making computing and communication a much easily accessible and simple activity. The comparative study on various communication standards evolved in the course of the telecommunication era, shown in the figure 1, reveals further benefits of 4G standard.

	0G	1G	2G	3G	4G
TECHNOLOGY	ANALOG	DIGITAL	DIGITAL	DIGITAL	DIGITAL
PERIOD	1970s	1980s	1995+	2006+	2010+
DATA RATE	-	14.4Kbps	144-200Kbps	250Kbps-14.4 Mbps	100Mbps-1Gbps
SWITCHING	-	CIRCUIT	PACKET	PACKET	BROAD-BAND
PROTOCOLS	PSTN	NMT,AMPS ,TACS	GSM,GPRS, EDGE	DECT,HSPA ,WiMAX	OFDMA, MIMO

Figure 1. The figure shows comparative study on various communication standards.

A prominent aspect of 4G systems is the network selection scheme by which the users can choose the best connected network available for each of the services required. Suppose a user needs high security for a call, he can select the most secure call service from the available service providers. Similarly in the case where he requires a messaging service with the cheapest rate for messages he can choose the one which is cheaper among the available lot. Selection can also be made based on the values of multiple parameters as well. Thus the system always promises the best services provided by the best service providers.

To choose the suitable technology for each service at a particular place and time, assessing services provided by each of the service providers can be a tedious and complicated task. Researches on numerous schemes are going on in different parts of the world to simplify and improve the process.

Researchers around the world have accepted network selection as an NP-hard problem. The primary reason for this is the heterogeneous nature of the 4G system. In a normal mobile communication system the network utilized depends only on the signal strength from the base station. Network Selection in 4G depends on multiple criteria like bandwidth, security, cost of service, performance in heterogeneous network, user preference and so forth. Thus analysing each of these parameter values for all the networks available at each unit time for every single service turns out to be a herculean task.

Vertical handoffs, billing frauds, service theft, privacy attacks and the like may also create nuisance in efficient selection of network and its utilization. We found scores of indispensable proposals for solutions on network selection from many researchers related to the area. In this paper we discuss a few of the renowned schemes for network selection in 4G communication systems. We also try to analyze the benefits and detriments of each in performing network selection.

The rest of this paper is organized as follows. Section II provides an overview on the basic architecture of 4G. Section III to X discusses the significant schemes as analyzed by us for network selection. The comparative study on the analysis of their performance based on certain parameters is described in section XI. Section XII explains the new proposal with the preplanner module. Section XIII expounds future enhancements and section XIV the conclusion.

II. 4G : BASIC ARCHITECTURE AND FUNCTIONING

Advanced devices with imminent technologies are required for implementing 4G with its entire functional package. Various appliances developed with the aim of accomplishing this failed in executing one fragment or the other of the 4G functional plan. Although fundamental properties and functionalities were devised much earlier, the lack of suitable equipments with adaptable architecture has delayed the introduction of 4G in the communication zone. However, numerous proposals have been made by inquisitive brains around the world for developing a basic architecture for 4G systems which promise a revolution in this field.

Long Term Evolution (LTE) developed by the Third Generation Partnership Project (3GPP) is a great improvement in the Telecommunications Systems. With the use of advanced techniques like OFDM and MIMO, LTE paves the way for the integration of ubiquity into the field of wireless communication and mobile computing. Here, users are assured with Quality of Service (QoS) with the help of Evolved Packet System (EPS). It supports both Frequency Division Duplexing (FDD) and Time Division Duplexing (TDD). It gives much better performance than Code Division Multiple Access (CDMA) with bandwidths ranging from 1.4MHz to 20MHz. The actual practical implementation process of 4G is proved to be accelerated by the development of LTE. The basic LTE system architecture configuration consists of logical components like :

- User Equipment (UE) such as a smartphone for individual users
- Evolved Universal Terrestrial Radio Access Node-Bs (e-UTRAN) which act like the Base stations
- Mobility Management Entity (MME) which manages the user's mobility
- Serving Gateway(S-GW) for tunnel management and switching of UE
- Packet Data Network Gateway (PDN-GW) which is the IP point of attachment for the UE
- Policy and Charging Resource Function (PCRF) which is responsible for Policy and Charging Control (PCC) for various service providers
- IP Multimedia Subsystem (IMS) to provide services using Session Initiation Protocol (SIP)
- Home Subscription Server (HSS) which is the data repository of the subscriber's profile

By implementing the perfect architecture 4G is expected to have high performance, good interoperability, perfect networking, high bandwidth, advanced technological functions, ubiquitous coverage, convergent connectivity, better device interfaces, good scalability, high quality service and a cheaper globally connected communication system. The potential applications which are expected to be developed or improved by the effective implementation of 4G systems include virtual presence, virtual navigation, tele-medicine, tele-geoprocessing, crisis management, education, mobile banking and other emergency services. The basic functioning of 4G is based on the provision of users to select the required network for performing particular services. The following sessions describe various solutions proposed by researchers around the world for effective network selection in 4G.

III. QOS BASED NETWORK SELECTION SCHEME

Quality of Service (QoS) is the key constraint for most of the technologies in all major fields of societal life. QoS based scheme ensures the best service for maximum user satisfaction and the best approach for resource utilization.

In this scheme [21], QoS is ensured by creating the ranklist based on certain parameters evaluated during performance. Miscellaneous performance parameters to ensure QoS for the users are taken into account. Cost of the service, available bandwidth, connectivity during handover and the like are encompassed in this set of parameters. The algorithm used includes calculating the distance function based on these parameters and creating ranklists for each network as the initial step. Weighted distance function is performed on the results thus obtained and network with the highest score is selected for providing the required service.

The greatest advantage is the user has a choice in the parameters to be considered for each service selection. Also, the number of parameters considered can vary according to the required service. When considering only a single parameter, weighted distance function calculation can be skipped and network can be chosen from the rank list for that particular parameter. There is still the drawback of overhead because of repeated calculations for each and every service. In spite of this slight shortcoming, this is so far the best method for network selection as per our analysis.

IV. QOE BASED NETWORK SELECTION SCHEME

V.

Since 4G is a network of numerous existing networks and service providers, the selection based on the parameter values of individual networks may not be accurate for its proper functioning. Thus, a new scheme was anticipated where the performance of each network, in the presence of other networks, is evaluated.

Quality of Experience (QoE) in this scenario means the performance of a particular service provider or network in a heterogeneous network of networks in providing proffered services. In this scheme [14] a number of packet-switched networks are compared based on certain parameters evaluated for each network in the presence of other heterogeneous networks and the one providing highest QoE standard is chosen. The techniques of Analytical Hierarchy Process (AHP) and Grey Relational Analysis (GRA) are combined in this method. Then the available networks are ranked to discover the apt one.

This method guarantees the best performing network in a miscellaneous set of networks. But it does not consider the performance of the networks individually, which deteriorates the performance by a fraction since the number available networks can diverge in the milieu.

VI. OPEN RESOURCES BASED NETWORK SELECTION SCHEME

Resources of a network comprises of aspects like area covered, services provided, expandability, files, memory, power, external devices and so forth. For each service requested by the user, the networks with the appropriate resources to perform it need only be considered. Thus the selection process thus prunes the list of available networks and confines the list of networks to the best suited ones with the required set of resources only. So this is basically a selection process based on elimination.

In this scheme request sent by user is processed and the resources required are gathered together. Then each of the networks available is explored to confirm whether any of them comply with the request. Thus the network with maximum suitability with the request is selected and designated to provide the service to the user. If more than one network qualifies for the actual selection process, additional weights are added as per user preference before selection. If none qualifies in its entirety, the one that has the maximum match score with the resources required is selected.

Better resource utilization for the users is the foremost benefit of this method. Since no complex calculations are involved, this scheme does not generate much overhead. On the contrary, efficiency in functioning is low in comparison with the other schemes discussed earlier.

VII. USER REQUISITES BASED NETWORK SELECTION SCHEME

This is the scheme [8] which assigns utmost importance to the choice and demands of users of the system. Network selection is done based on dynamic adaptation with respect to the user's preference. Here a user agent and a network agent, its client side image, are used.

The selection algorithm is integrated into a middleware layer which hides the complexity of the system from the users. Cost functions are executed to determine service cost, power conception, network availability, bandwidth degradation and network unreliability. Each cost parameter is dynamically mapped to a weight which is dynamically calculated as per user preferences.

The scheme provides a higher dynamicity to the whole selection process. Thus it achieves a more effective criterion for selecting the access network selection. Although it has much calculation overhead and complexity in the lower layers, this is the best and user affable scheme which suits the user's preference factors.

Game theory can be used for effective modeling and resource allocation for networks. This scheme [3] models network selection problem as a game in the 4G global network. The major components included in game theory are players, strategies, payoffs and resources.

All available networks become the players of the game. These networks compete with each other in a non-cooperating manner for several rounds. Thus their pay-off values are maximized, which means the performance parameters of the services received by users have high values. Strategies are the adaptations done by the networks to provide the best service for users. Resources are the features of each network like bandwidth, power usage, coverage, security and so on.

Since this is held between access networks, users do not get tangled in the complexities of the selection process. But user participation can be ensured by collecting their preference values for the participating networks. As in every other discipline, competition improves Quality of Service among the various service provider networks involved in the 4G communication systems. Conflicts tend to occur in this scheme due to the preference factors. Also, the initial stage tends to be much tedious.

IX. RANKING BASED NETWORK SELECTION SCHEME

This scheme [5] is a collaboration technique of methods of network selection based on user preferences and open resources. It removes abnormalities due to other selection schemes and also scores high on efficiency. The critical attributes used for selection are cost per byte, total bandwidth, available bandwidth, delay, jitter, packet loss, signal strength and utilization. Terminal power consumption is also considered at times.

Initially, a list of available networks which can provide the requested service is created. Then weight matrix along with user preferences is obtained by classifying the attributes into speed, cost and quality categories. Then a ranking algorithm is executed and rounding off is done on the ranks. The network with the best rank is chosen from the results obtained.

This is a much easier method when compared to earlier techniques. Although much hectic calculations are to be performed till the rank list is obtained, choices can be made easily based on the ranks. The consistency of the algorithm paves the way for a stable ranking system.

X. UTILITY THEORY BASED NETWORK SELECTION SCHEME

Utility, in this context, implies the efficacy of a network in gratifying the user's demands. Fundamental utility theory of Von Neumann mathematically defines a set $U(w,x)$, where x is the set of user's observation on product criteria and w is the set of user preferences, both rounded off to real numbers.

The aim of this scheme [16] is to provide "Always Best Connected" (ABC) service, replacing the existing intent of providing "Always Connected" (AC) service. A new multi-criteria utility theory function has been developed in the scheme to suit the network selection process in 4G, which is expected to be consisting of dissimilar networks with contradicting attribute values. It has been created after numerical analysis on existing utility theory functions and to overcome the shortcomings of them.

Strict and effective selection is possible through this method. Also the user's preferences limits the whole lot of available networks to a few which makes the selection process much easier. However, for simple services such amount of complex mathematics ruins the objective.

XI. AGENT ACUITY BASED NETWORK SELECTION SCHEME

Agent based learning systems dynamically adapts to the environment in which they function through continuous perception. An agent is required to be adaptable to the environment its acting on for any minute changes which may happen. Cognitive networks are a group of such networks which functions on constant perception and actions based on thus acquired data. This scheme [7] provides an improved technique for the network selection by individual cognitive terminals. It also aims at improving the adaptability of the system by enhancing the resource utilization of the system.

A Q-learning algorithm is a sort of classic reinforcement learning algorithm. Constant perception is performed and actions are taken from the knowledge acquired to adapt to the system. For each state the environment is in, a particular action is adopted. Trend of performing a particular action depends on the rewards obtained on previous adaptation of the action. To determine the optimum action to be adopted an objective function is executed.

Since the system is dynamically adaptable, continuous connectivity is guaranteed throughout the service performed. Constant perception may require high memory and much complex lower level functions. Also vertical handover issues may affect the adaptation process adversely.

XII. COMPARATIVE STUDY ON THE SCHEMES

The sections above discussed the renowned schemes in performing network selection in 4G communication systems. The method adopted for network selection, benefits and shortcomings were discussed earlier. Here we make a comparative analysis on each of these methods with each other. A comparative study on these schemes based on attributes like bandwidth, user preference, dynamic adaptability, security and the like is shown in figure 2.

Network Selection Schemes Based on	Bandwidth	User preference	Dynamic Adaptability	Connectivity Maintenance	Overhead	Security	Power Requirement	Cost of Service	Heterogeneity Adaptation	Memory Requirement	Best Service
QoS	✓	✓	X	✓	✓	✓	✓	✓	✓	X	✓
QoE	✓	X	X	✓	X	✓	✓	✓	✓	X	✓
Open Resources	✓	✓	X	X	X	✓	✓	✓	X	✓	X
User Requisites	✓	✓	✓	✓	✓	X	✓	✓	✓	X	X
Network Competition	✓	✓	X	X	✓	✓	✓	✓	X	X	✓
Ranking Algorithm	✓	✓	X	✓	✓	✓	✓	✓	X	✓	✓
Utility Theory	✓	✓	X	X	✓	X	X	✓	✓	X	✓
Cognitive networks	✓	X	✓	✓	✓	✓	X	✓	✓	✓	✓

Fig. 2. The figure shows comparative study on various network selection schemes.

As per the comparative study, all the schemes provide the necessary bandwidth and consider the cost of service on network selection. Dynamic adaptation to the environment's functional situation is possible in user requisites based method and Cognitive networks utilizing Agent Acuity. However vertical handoff issues destroy this scope on practical implementation.

The best method for network selection as per the study is the QoS based method. Overhead due to calculations, which affects its performance a bit, when compared to other techniques, is much lower. Since it takes into account almost all parameters to be considered it would be easy to implement and enhance.

XIII. A NEW PROPOSAL FOR EMERGENCY SERVICES

Selection of application as per the user preference based on QoS (Quality of Service) is one of the best solution for the issue. This user-centric system works on the basis to provide best services of the network to the users. Here, a selection algorithm has been proposed which provides a better way to implement user preferences as per the features of 4G by adding a memory portion to the QoS based scheme. The steps involved in this new proposal are described in figure 3 and 4.

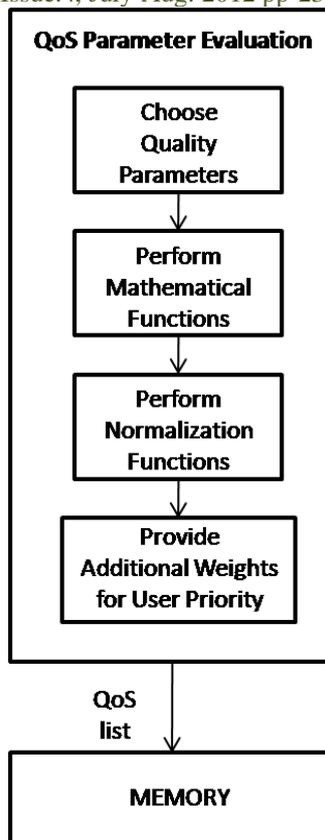

Fig. 3. The figure shows the creation of the QoS list to be stored in the memory

As in the QoS based scheme [21] for network selection, we first fix the parameters to be considered. It can be done based on the quality parameters usually considered and also with the user's demand for certain parameters if any. For example, for the deals between business empires the primary quality they prefer during communication will be secured connectivity rather than cost of communication.

Next, the values of these parameters are calculated using mathematical functions. Round off functions can be performed on the results to normalize and confine them to a scale from 0 to 10. Additional weights can be allotted to include user priorities. This list is stored in memory and is updated periodically as per the changes in each network's functionalities or policies.

The usual method based on QoS is repeated for each new service accessed by user since parameter values considered may vary in every fraction of time. This creates much overhead for emergency communication requirements. So, with the list stored in memory, a preplanner module is added to the method which enables user to plan in advance and select the networks suitable for different services so as to avoid overhead of calculations during emergencies. Plans are updated periodically to suit major changes in parameter values under consideration.

So the actual network selection process in this proposal is done as follows. Initially, the global 4G network is analyzed for available service providers in that particular area at that particular time. Then we determine the QoS score for each of the network from the QoS value list previously stored in memory.

User's requests for additional parameters are also taken care of and their values are also considered. Additional weights are added for user priorities. Again normalization is applied to obtain uniformly standardized values. Finally, the rank list is made from these scores. The best scoring network is selected for accomplishing the service.

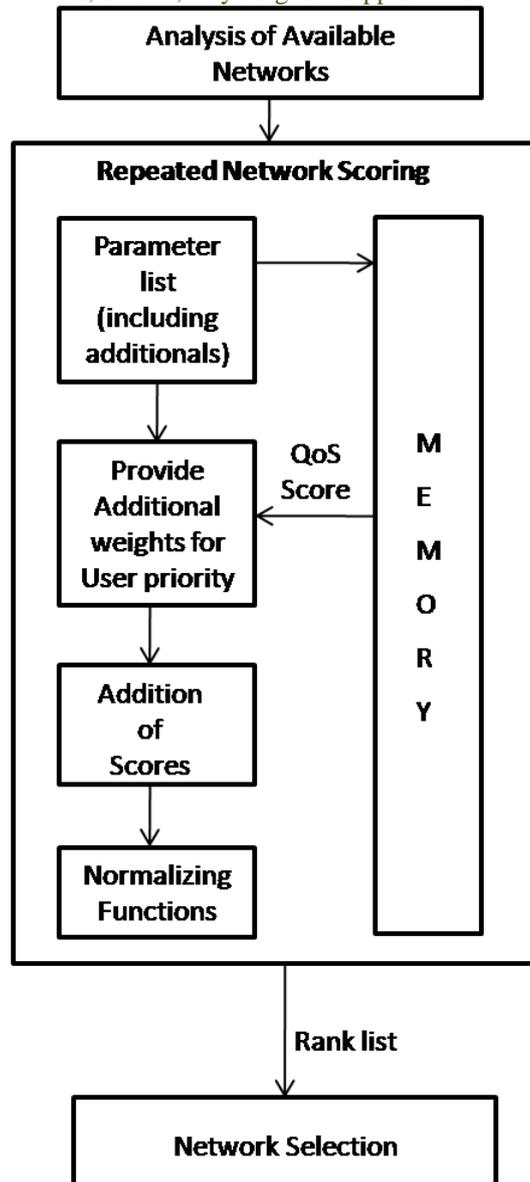

Fig. 3. The figure shows the creation of the QoS list to be stored in the memory

For emergency services, instead of repeating the whole process of calculations and selection, the network which is best from the preplanned list can be selected as suited for the required service. Thus the use of memory for storage of scores can reduce the overhead in selection in almost all normal scenarios.

For example, a user makes a call after selecting a network from the available networks.. After the call is ended he/she realizes he/she forgot to say something to the callee. When the user attempts to call again, in the normal QoS method the whole process needs to be repeated again. But with the new method, a suitable network can be selected from the preplanner module to perform the call. Of course, this is possible only if the second call is done within a particular period of time, say maximum one minute, from the first call.

XIV. FUTURE ENHANCEMENTS

Future work includes the comparison of these techniques on practical implementation factors. Of course that would take time as 4G system implementation has not yet been perfectly accomplished. Enhancing the QoS based method to reduce the overhead can make it the best method for network selection. In the case of the new solution proposed, overhead during the initial stages of the method, even though does not affect the network selection process directly, need to be reduced for effective implementation of network selection.

Emergency services require fast selection and handover processes even when services are going on. Also techniques for effectively resolving vertical handoff issues are yet to be researched on. There exists much scope on using genetic algorithmic methods for solving network selection problem in 4G.

XV. CONCLUSION

In this paper we discuss the network selection issue in 4G communication systems. A comparative study on the various technical schemes for resolving network selection issue is discussed here. Even though a bit of overhead exists in the scoring phases, the main process of network selection gets easier with lists to support the calculations involved. Numerous new proposals from many researchers are emerging day by day. 4G systems on implementation can pave the way for the ubiquitous standard of communication. This would enable “anytime anywhere” computing which is a huge leap forward in the field of global telecommunication system.

She is associated with Rajagiri School of Engineering & Technology, Cochin, India as an Assistant professor in Department of Information Technology. She has around 10 years of academic experience. Currently she is pursuing PhD at Cochin University of Science & Technology. Her research interest includes mobile computing, ad hoc networks, and Wireless Networks.

A Simulation Based Performance Analysis of AODV and DSDV Routing Protocols in MANETs

Biswaraj Sen¹, Sanku Sinha²

¹Department of Computer Sc & Engineering, Sikkim Manipal Institute of Technology, India

²Department of Computer Sc & Engineering, Sikkim Manipal Institute of Technology, India

ABSTRACT: A Mobile Ad hoc Network (MANET) is an infrastructure less, decentralized multi-hop network where the mobile nodes are free to move randomly, thus making the network topology dynamic. Various routing protocols have been designed which aims at establishment of correct and efficient routes between a pair of mobile nodes. In this work, an attempt has been made to understand the characteristics/behavior of Ad hoc On Demand Distance Vector (AODV) and Destination Sequence Distance Vector (DSDV) routing protocols when operating in more challenging environment such as frequent change in network topology and node density. The performance differentials are analyzed using throughput, average end-to-end delay and normalized routing load which shall provide an insight about the sensitivity of the protocols under consideration when exposed in more challenging environment. Simulation based analysis of the protocols have been done using NS-2.

Keywords: AODV, DSDV, MANET, NS-2.

1. Introduction

A mobile Ad hoc network is a collection of wireless mobile nodes forming a temporary network without any centralized administration or fixed infrastructure, which makes any node in the network as a potential router [1, 13]. Since the nodes are highly mobile in nature, the changes in network topology are very frequent and the nodes are dynamically connected in an arbitrary manner. Further, the limitation imposed on the transmission range of the nodes have lead to the development of routing policy where packets are allowed to traverse through multiple nodes thus making each node act as terminal as well as router. Since the topology of Ad hoc network is dynamic in nature, design of suitable routing protocol is essential to adapt the dynamic behavior of the network.

Further, it is worth mentioning that node density and pause time will have significant effect in the performance of the any routing policy due to the fact that an increase in node density will tend to increase the hop count thus changing the topology significantly. Pause time indicates the mobility of the nodes in the network. Therefore, it is imperative to state that high pause time implies a stable network topology while low pause time indicates that the topology changes frequently. This paper makes an attempt to analyze the performance of two most popular Ad hoc routing protocols, viz. AODV and DSDV where both the above discussed factors i.e. Pause Time and Node Density vary considerably. Though both protocols use sequence number to prevent routing loops and to ensure freshness of routing information, the main mechanism of routing differs drastically in AODV and DSDV in the fact

that they belong to two different routing families [3]. AODV is from reactive routing family where routes are only generated on demand, in order to reduce routing loads [5], while DSDV is from proactive routing family where routing tables are updated frequently regardless of need [2]. The rest of this paper is organized as follows: In the next section, brief overviews of both routing protocols have been discussed. Section 3 discusses the simulation environment in which both the protocols have been tested. Section 4 includes analysis of the performance of both the protocols under a varying node density environment and varying pause time with respect to performance metrics such as throughput, average end-to-end delay and packet delivery fraction. Section 5 provides conclusion, limitation and future work.

II. Overview of the Protocol

1.1 Ad hoc On Demand Distance Vector (AODV):

Ad hoc On Demand Distance Vector Routing Protocol (AODV) is a reactive routing protocol designed for Ad hoc wireless network and it is capable of both unicast as well as multicast routing [3]. The Route Discovery process in this protocol is performed using control messages RouteRequest (RREQ) and RouteReply (RREP) whenever a node wishes to send packet to destination. Traditional routing tables is used, one entry per destination [2]. During a route discovery process, the source node broadcasts a RouteRequest packet to its neighbors. This control packet includes the last known sequence number for that destination. If any of the neighbors has a route to the destination, it replies to the query with RouteReply packet; otherwise, the neighbors rebroadcast the RouteRequest packet. Finally, some of these query control packets reach the destination, or nodes that have a route to the destination. At this point, a reply packet is generated and transmitted tracing back the route traversed by the query control packet. In the event when a valid route is not found or the query or reply packets are lost, the source node rebroadcasts the query packet if no reply is received by the source after a time-out.

In order to maintain freshness node list, AODV normally requires that each node periodically transmit a HELLO message, with a default rate of one per second [9]. When a node fails to receive three consecutive HELLO messages from its neighbor, the node takes it as an indication that the link to its neighbor is down. If the destination with this neighbor as the next hop is believed not to be far away (from the invalid routing entry), local repair mechanism may be launched to rebuild the route towards the destination; otherwise, a RouteError (RERR) packet is sent to the neighbors in the precursor list

associated with the routing entry to inform them of the link failure [12].

1.2 Destination Sequenced Distance Vector (DSDV):

Destination-Sequenced Distance-Vector Routing (DSDV) [3] is a proactive routing protocol designed for Ad hoc mobile networks based on the Bellman-Ford algorithm [10]. The improvement made to the Bellman-Ford algorithm includes freedom from loops in routing tables by using sequence numbers. In mobile Ad hoc network, using of DSDV protocol assumes that each participating node as a router. Every node always maintains a routing table that consists of all the possible destinations. Each entry of the routing table contains the address identifier of a destination, the shortest known distance metric to that destination measured in hop counts and the address identifier of the node that is the first hop on the shortest path to the destination [11]. Each mobile node in the system maintains a routing table in which all the possible destinations and the number of hops to them in the network are recorded. Each route or path to the destination associated with a sequence number [4]. The route with the highest sequence number is always used and this sequence number helps to identify the stale routes from the new ones and thus it avoids the formation of loops. To minimize the traffic there are two types of packets in the system. One is known as "full dump" [5], which carries all the information about a change. However, when occasional movement occurs in the network, "incremental" [5] packet are used, which carries just the changes and this increases the overall efficiency of the system. DSDV requires a regular update of its routing tables, which uses up battery power and a small amount of bandwidth even when there is no change in the network topology. Whenever the topology of the network changes, a new sequence number is necessary before the network re-converges; thus, DSDV is not scalable in Ad hoc networks, which have limited bandwidth and whose topologies are highly dynamic [1].

III. Simulation Methodology

Simulation based study using Network Simulator NS-2 [6] has been used to compare two protocols viz. AODV and DSDV under varying node density and varying pause time, assuming that the size of network, maximum speed of nodes and transmission rate are fixed. Tables 1 and 2 summarize the parameters used in the communication and movement models for simulation.

III.2 Communication Model

The simulator assumes constant bit rate (CBR) traffic with a transmission rate of 8 packets per second. The number of nodes varies from 25 to 100 in the denomination of 25, 50, 75 and 100. given on the last line.

Table 1. Parameters of Communication Model

Parameter	Value
Traffic type	CBR
Number of nodes	25, 50, 75, 100
Transmission rate	8 packets/second

IV.2 Movement Model

In line with the realistic mobility pattern of the mobile nodes, the simulation assumes a Random Waypoint Model [7], where a node is allowed to move in any direction arbitrarily. The nodes select any random destination in the 500 X 500 space and moves to that destination at a speed distributed uniformly between 1 and nodes maximum speed (assumed to be 20 meter per second). Upon reaching the destination, the node pauses for fixed time, selects another destination, and proceeds there as discussed above. After testing all possible connection for a specific scenario, pause time changes to test the next scenario. This behavior repeats throughout the duration of the simulation (500 seconds). Meanwhile, number of nodes and pause time has been varied to compare the performance of the protocols for low as well as high density environment and for low mobility of the nodes to high mobility. Table 2 lists the movement parameters of the simulations.

Table 2. Parameters of movement model

Parameter	Value
Simulator	NS-2
Simulation time	500 seconds
Area of the network	500 m x 500 m
Number of nodes	25, 50, 100, 200
Pause time	10 seconds
Maximum speed of nodes	20 meters per second
Mobility Model	Random waypoint

V.2 Performance Metrics

Three performance metrics has been measured for the protocols:

3.3.1 Throughput: Throughput is the number of packet that is passing through the channel in a particular unit of time [8]. This performance metric shows the total number of packets that have been successfully delivered from source node to destination node. Factors that affect throughput include frequent topology changes, unreliable communication, limited bandwidth and limited energy.

$$Throughput = \frac{Received_Packet_Size}{Time_to_Send} \quad (1)$$

3.3.2 Average End-to-End Delay: A specific packet is transmitting from source to destination node and calculates the difference between send times and received times. This metric describes the packet delivery time. Delays due to route discovery, queuing, propagation and transfer time are included metric [9].

$$Avg_End_to_End_Delay = \frac{\sum_i^n (CBR_Sent_Time - CBR_Recv_Time)}{\sum_i^n CBR_Recv} \quad (2)$$

3.3.3 Normalized Routing Load: Normalized Routing Load is the ratio of total number of routing packet received and total number of data packets received [10].

$$Normalized_Routing_Load = \frac{Number_of_Routing_Pkts_Recvd}{Number_of_Data_Pkts_Recvd} \quad (3)$$

2. Simulation Result And Analysis

Figures 1, 2 and 3 represent the performance analysis in terms of throughput, average end-to-end delay and normalized routing load respectively. In all the cases the node density varies from 25 to 100 and pause time varies from 5 to 20 second.

4.1 Throughput:

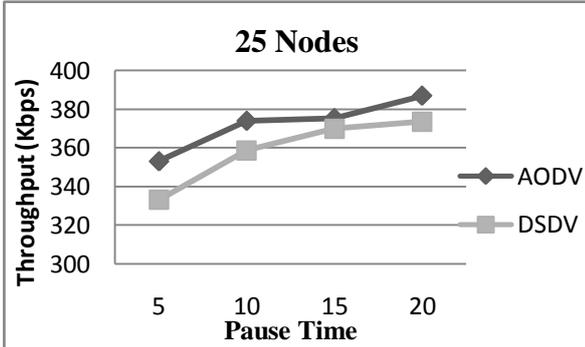

Figure 1 (a): Throughput for 25 nodes

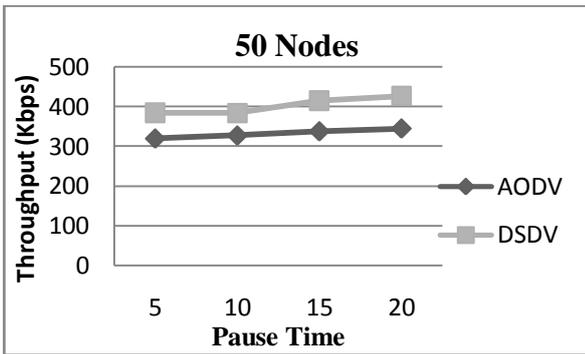

Figure 1 (b): Throughput for 50 nodes

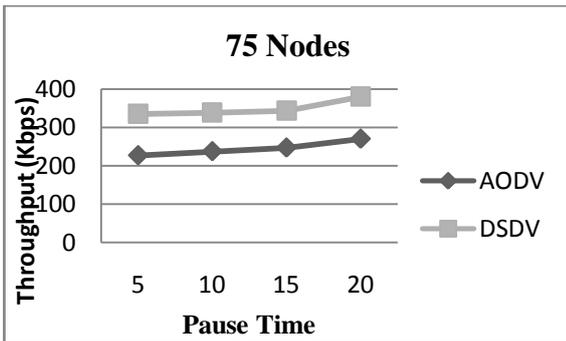

Figure 1 (c): Throughput for 75 nodes

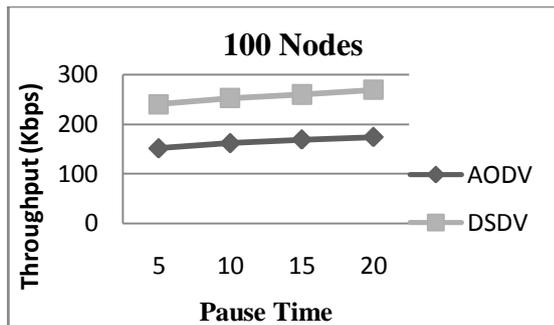

Figure 1 (d): Throughput for 100 nodes

Based on the result of simulation as indicated in Fig 1(a) it is evident that performance of AODV is better than DSDV in a low node density environment but with a rise in node density DSDV out performs AODV which is evident from Fig 1(b), 1(c) and 1(d). Another characteristic that has come to the notice is that pause time does not have significant bearing on the throughput whereas the performance is dictated only by the density of the network. The possible reason for the same is due to proactive nature of DSDV routing protocol, which causes less number of table update in a stable topology, thus producing better throughput.

4.2 Average End-to-End Delay:

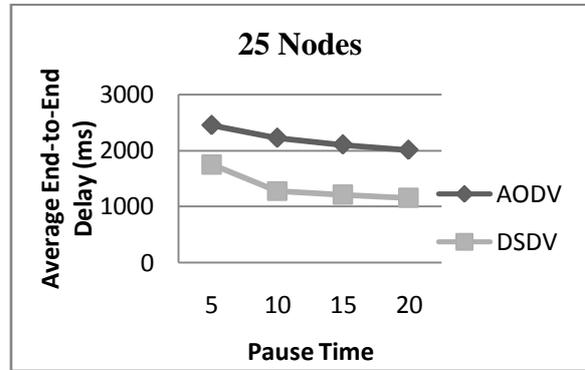

Figure 2 (a): Average End-to-End Delay for 25 nodes

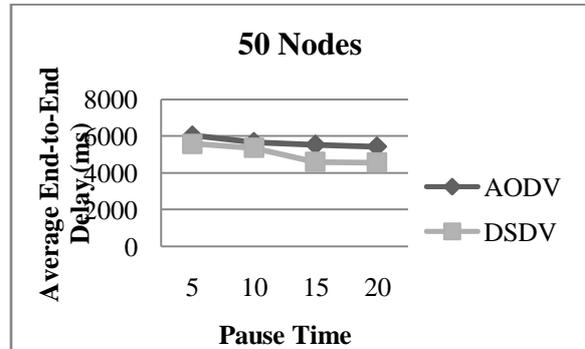

Figure 2 (b): Average End-to-End Delay for 50 nodes

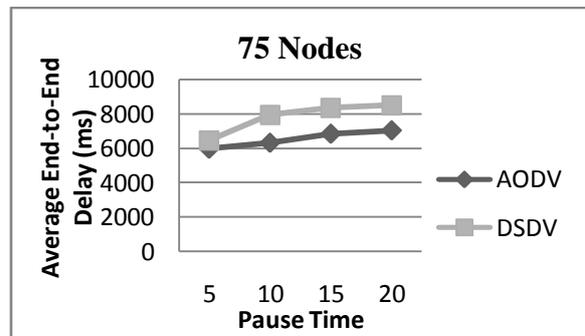

Figure 2 (c): Average End-to-End Delay for 75 nodes

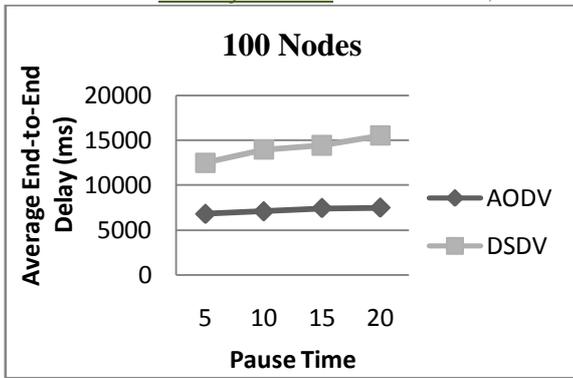

Figure 2(d): Average End-to-End Delay for 100 nodes

The simulation result as indicated in Fig 2(a) and 2 (b) shows that in case of low node density, the average end-to-end delay of AODV is higher than DSDV whereas Fig 2(c) and 2(d) indicates that with an increase in node density, AODV outperforms DSDV. It also has been observed that with an increase in pause time there is a decline in the average end-to-end for both the protocols under low node density environment (Fig 2a and 2b). However, this is not true when there is a rise in the network density. The possible reason for such behavior is the presence of more number of nodes between source and destination which effects in increase of hop count thus resulting in increased average end-to-end delay.

4.3 Normalized Routing Load:

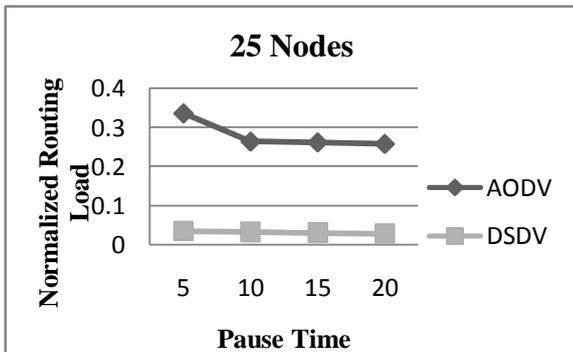

Figure 3(a): Normalized Routing Load for 25 nodes

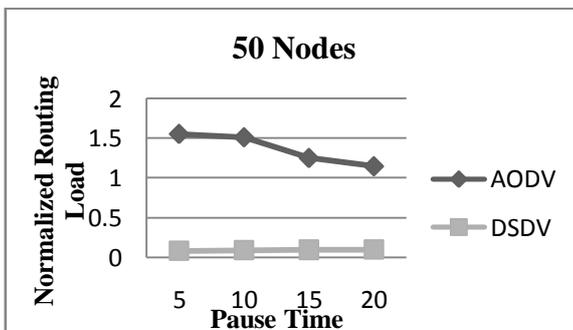

Figure 3(b): Normalized Routing Load for 50 nodes

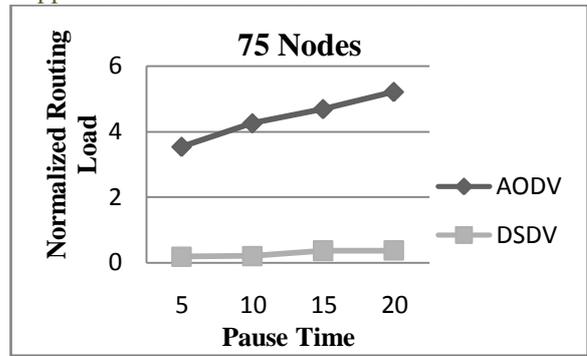

Figure 3 (c): Normalized Routing Load for 75 nodes

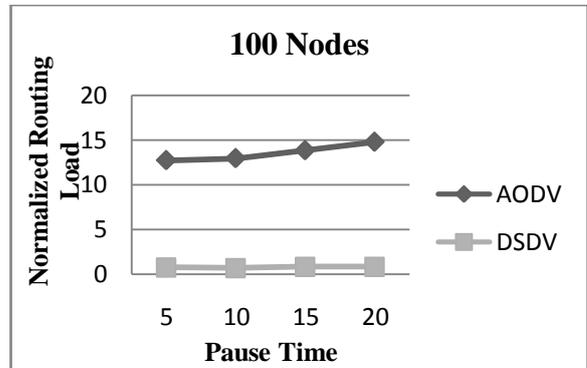

Figure 3 (d): Normalized Routing Load for 100 nodes

Fig 3(a), Fig 3(b), Fig 3(c) and Fig 3(d) indicates that normalized routing load of AODV is always higher than DSDV under any scenario. The performance of DSDV in terms of normalized routing load is not influenced in any way with respect to change in node density and pause time. The reactive nature of AODV routing protocol causes more number of control overhead than DSDV. Therefore, normalized routing load for AODV will always be higher than DSDV.

CONCLUSION

The performance evaluation of two routing protocols, AODV and DSDV, has been done with respect to metrics viz. throughput, average end-to-end delay and normalized routing load under varying node density and varying pause time. From the result analysis, it has been observed that in high node density the performance of both protocols decreases significantly. The increase of node density in the network causes more number of control packets in the network for route establishment between a pair of source and destination nodes. This is the main reason of performance degradation of the routing protocols in high node density [14]. On other hand, increase of pause time indicates more stable network. Thus the performance of both routing protocols increases with the increment of pause time. It has been observed that in low node density the performance of AODV is better than DSDV in terms of throughput, whereas the performance of DSDV is better in high node density (upto 100 nodes). Another observation has been found from the result that increment of pause time does not affect much in the performance of DSDV where the performance of AODV varies significantly with the pause time. In Current work, only three performance metrics have been considered to analyze the performance of AODV and DSDV. Inclusion of other performance metrics

will provide indepth comparison of these two protocols which may provide an insight on the realistic behavior of the protocols under more challenging environment. The current work has been limited with fixed simulation area (500x500m) with CBR traffic and node density is upto 100 nodes. From previous work [14], it has been observed that in higher node density (200 nodes) AODV performs better than DSDV. Varying simulation area and higher node density with different traffic will provide indepth performance analysis of these two protocols.

Transaction Processing In Replicated Data in the DDBMS

Ashish Srivastava¹, Udai Shankar², Sanjay Kumar Tiwari³

*(Department Deptt. of Computer Science & Engineering, Madan Mohan Malaviya Engineering College, Gorakhpur).

ABSTRACT: *The transactional Processing in Replicated Data for distributed system has been around for many years and it is considered a well-established and mature technology. The conventional transaction model, although suitable for predictable database applications such as banking and airline reservation systems, does not provide much flexibility and high performance when used for complex applications such as object oriented systems, long-lived transactions or distributed systems. In this paper we describe the transaction-processing model of distributed database includes data, Transaction, Data Manager, and Transaction Manager and their transaction process. We will study about concurrency problem of sequence of synchronization techniques for transaction with respect to distributed database. The spirit of discussion in a decomposition of the concurrency control problem into two major sub problems: read-write and write-write synchronization. We describe a sequence of synchronization techniques for solving each sub complexity.*

Keywords: *Real time system, Replication, Distributed Database, Distributed processing, Transaction, Transaction Manager, two-phase commit, Concurrency Control, Synchronization.*

I. Introduction

A real-time system is one that must process information and produce a response within a specified time, else risk severe consequences, including failure. That is, in a system with a real-time constraint it is no good to have the correct action or the correct answer after a certain deadline: it is either by the deadline or it is useless. Database replication based on group communication systems has been proposed as an efficient and flexible solution for data replication. Replicated is the key characteristic in improving the availability of data distributed systems. Replicated data is stored at multiple server sites so that it can be accessed by the user even when some of the copies are not available due to server/site failures.[1] A Major restriction to using replication is that replicated copies must behave like a single copy, i.e. mutual consistency as well internal consistency must be preserved, Synchronization techniques for replicated data in distributed database systems have been studied in order to increase the degree of consistency and to reduce the possibility of transaction rollback. [2]

In replicated database systems, copies of the data items can be stored at multiple sites. The potential of data replication for high data availability and improved read performance is crucial to RTDBS. In contrast, data replication introduces its own problems. Access to a data item is no longer control exclusively by a single site; instead, the access control is distributed across the sites each storing the copy of the data item. It is necessary to ensure that mutual consistency of the replicated data is provided

Distributed data base system is a technique that is used to solve a single problem in a heterogeneous computer network system. A major issue in building a distributed database system is the transactions atomicity. When a transaction runs across into two sites, it may happen that one site may commit and other one may fail due to an inconsistent state of transaction. Two-phase commit protocol is widely used to solve these problems. The choice of commit protocol is an important design decision for distributed database system. A commit protocol in a distributed database transaction should uniformly commit to ensure that all the participating sites agree to the final outcome and the result may be either a commit or an abort situation. Many real times database applications are distributed in nature [3] these include the aircraft control, stock trading, network management, factory automation etc.

II. DISTRIBUTED DATABASE SYSTEMS (DDBS)

A distributed database is a database that is under the control of a central database management system (DBMS) in which storage devices are not all attached to a common CPU. It may be stored in multiple computers located in the same physical location, or may be dispersed over a network of interconnected computers. Collections of data can be distributed across multiple physical locations. Distributed database system (DDBS) is system that has distributed data and replicated over several locations. Data may be replicated over a network using horizontal and vertical fragmentation similar to projection and selection operations in Structured Query Language (SQL). The database shares the problems of access control and transaction management, such as user concurrent access control and deadlock detection and resolution. On the other hand, however, DDBS must also cope with different problems. Accessing of data control and transaction management in DDBS needs different methods to monitor data access and update to distributed and replicated databases. Distributed database systems (DDBS) are systems that have their data distributed and replicated over several locations; unlike the centralized data base system (CDBS), where one copy of the data is stored. Data may be replicated over a network using horizontal and vertical fragmentation similar to projection and selection operations in Structured Query Language (SQL). Both types of database share the same problems of access control and transaction management, such as user concurrent access control and deadlock detection and resolution. On the other hand however, DDBS must also cope with different problems. Access control and transaction management in DDBS require different rules to monitor data retrieval and update to distributed and replicated databases [4, 5]. Oracle, as a leading Database Management Systems (DBMS) employs the two-phase commit technique to maintain a consistent state for the databases [6]. The objective of this paper is to

explain transaction management in DDBMS and how to implements this technique. To assist in understanding this process, an example is given in the last section. It is hoped that this understanding will encourage organizations to use and academics to discuss DDBS and to successfully capitalize on this feature of Database. The next section presents advantages, disadvantages, and failures in Distributed Database Systems. Subsequent sections provide discussions on the fundamentals of transaction management, two-phase commit, homogenous distributed database system implementation of the two-phase commit, and, finally, an example on how the two phases commit works.

2.1 Advantages of Distributed Database system (DDBS)

Since organizations tend to be geographically dispersed, a DDBS fits the organizational structure better than traditional centralized DBS. Improved Availability-A failure does not make the entire system inoperable and Improved Reliability-Data may be replicated Each location will have its local data as well as the ability to get needed data from other locations via a communication network. Moreover, the failure of one of the servers at one site won't render the distributed database system inaccessible. The affected site will be the only one directly involved with that failed server. In addition, if any data is required from a site exhibiting a failure, such data may be retrieved from other locations containing the replicated data [7]. The performance of the system will improve, since several machines take care of distributing the load of the CPU and the I/O. Also, the expansion of the distributed system is relatively easy, since adding a new location doesn't affect the existing ones.

2.2 Disadvantages of Distributed DBS

On the other hand, DDBS has several disadvantages. A distributed system usually exhibits more complexity and cost more than a centralized one. Security-network must be made secure Integrity Control More Difficult This is true because the hardware and software involved need to maintain a reliable and an efficient system. All the replication and data retrieval from all sites should be transparent to the user. The cost of maintaining the system is considerable since technicians and experts are required at every site. Another main disadvantage of distributed database systems is the issue of security. Handling security across several locations is more complicated. In addition, the communication between sites may be tapped to.

2.3 Issues in Distributed Database Design

We have to consider three key issues in distributed database design

- Data Allocation: where are data placed? Data should be stored at site with "optimal" distribution.
- Fragmentation: relation may be divided into a number of sub-relations (called fragments), which are stored in different sites.
- Replication: copy of fragment may be maintained at several sites.

III. FUNDAMENTALS OF TRANSACTION

Transaction deals with the problems of keeping the database in a consistent state even when concurrent accesses and failures occur.

3.1 What is a Transaction

A transaction consists of a series of operations performed on a database. The important issue in transaction management is that if a database was in a consistent state prior to the initiation of a transaction, then the database should return to a consistent state after the transaction is completed. This should be done irrespective of the fact that transactions were successfully executed simultaneously or there were failures during the execution,[8]. A transaction is a sequence of operations that takes the database from a consistent state to another consistent state. It represents a complete and correct computation. Two types of transactions are allowed in our environment: query transactions and update transactions. Query transactions consist only of read operations that access data objects and return their values to the user. Thus, query transactions do not modify the database state. Two transactions conflict if the read-set of one transaction intersects with the write-set of the other transaction. During the voting process, Update transactions consist of both read and write operations. Transactions have their time-stamps constructed by adding 1 to the greater of either the current time or the highest time-stamp of their base variables. Thus; a transaction is a unit of consistency and reliability. The properties of transactions will be discussed later in the properties section. Each transaction has to terminate. The outcome of the termination depends on the success or failure of the transaction. When a transaction starts executing, it may terminate with one of two possibilities:

1. The transaction aborts if a failure occurred during its execution
 2. The transaction commits if it was completed successfully.
- Example of a transaction that aborts during process 2 (P2). On the other hand, an example of a transaction that commits, since all of its processes are successfully completed [9, 10].

3.2 Properties of Transactions

A Transaction has four properties that lead to the consistency and reliability of a distributed data base. These are Atomicity, Consistency, Isolation, and Durability [6].

ACID property of transaction: The concept of a database transaction (or atomic transaction) has evolved in order to enable both a well-understood database system behavior in a faulty environment where crashes can happen any time, and recovery from a crash to a well understood database state. A database transaction is a unit of work, typically encapsulating a number of operations over a database (e.g., reading a database object, writing, acquiring lock, etc.), an abstraction supported in database and also other systems. Each transaction has well defined boundaries in terms of which program/code executions are included in that transaction (determined by the transaction's programmer via special transaction commands). Every database transaction obeys the following rules (by support in the database system; i.e., a database system is designed to guarantee them for the transactions it runs):

Atomicity: This refers to the fact that a transaction is treated as a unit of operation. Consequently, it dictates that either all the actions related to a transaction are completed or none of them is carried out. For example, in the case of a crash, the system should complete the remainder of the transaction, or it will undo all the actions pertaining to this transaction. The recovery of the transaction is split into two types corresponding to the two types of failures: Atomicity means

that users do not have to worry about the effect of incomplete transactions. Transactions can fail for several kinds of reasons:

1. Hardware failure: A disk drive fails, preventing some of the transaction's database changes from taking effect.
2. System failure: The user loses their connection to the application before providing all necessary information.
3. Database failure: E.g., the database runs out of room to hold additional data.
4. Application failure: The application attempts to post data that violates a rule that the database itself enforces such as attempting to insert a duplicate value in a column.

Consistency: Every transaction must leave the database in a consistent (correct) state, i.e., maintain the predetermined integrity rules of the database (constraints upon and among the database's objects). A transaction must transform a database from one consistent state to another consistent state (however, it is the responsibility of the transaction's programmer to make sure that the transaction itself is correct, i.e., performs correctly what it intends to perform (from the application's point of view) while the predefined integrity rules are enforced by the DBMS). Thus since a database can be normally changed only by transactions, all the database's states are consistent. An aborted transaction does not change the database state it has started from, as if it never existed (atomicity above).

Isolation: According to this property, each transaction should see a consistent database at all times. Consequently, no other transaction can read or modify data that is being modified by another transaction. If this property is not maintained, one of two things could happen to the data base.

- a. Lost Updates: this occurs when another transaction (T2) updates the same data being modified by the first transaction (T1) in such a manner that T2 reads the value prior to the writing of T1 thus creating the problem of losing this update.
- b. Cascading Aborts: this problem occurs when the first transaction (T1) aborts, then the transactions that had read or modified data that has been used by T1 will also abort.

Durability: Durability is the DBMS's guarantee that once the user has been notified of a transaction's success the transaction will not be lost, the transaction's data changes will survive system failure, and that all integrity constraints have been satisfied, so the DBMS won't need to reverse the transaction. Many DBMSs implement durability by writing transactions into a transaction log that can be reprocessed to recreate the system state right before any later failure. A transaction is deemed committed only after it is entered in the log. Durability does not imply a permanent state of the database. A subsequent transaction may modify data changed by a prior transaction without violating the durability principle. The concept of atomic transaction has been extended during the years to what has become a Business transaction, which actually implement types of Workflow and are not atomic. However also such enhanced transactions typically utilize atomic transactions as components [11, 12].

3.3 Type of distributed transaction

By structure, distributed transaction is dividing into two types. A flat transaction, FT, is an operation, performed on a database, which may consist of several simple actions. From

the client's point of view the operation must be executed indivisibly. Main disadvantage with FTs that if one action fails the whole transaction must abort. Issues related to distributed transaction: There are a number of issues or problems, which are peculiar to a distributed database and these, require novel solutions. These include the following:

3.3.1 Distributed query optimisation: In a distributed database the optimisation of queries by the DBMS itself is critical to the efficient performance of the overall system. Query optimisation must take into account the extra communication costs of moving data from site to site, but can use whatever replicated copies of data are closest, to execute a query. Thus it is a more complex operation than query optimisation in centralised databases.

3.3.2 Distributed update propagation: Update propagation in a distributed database is problematic because of the fact that there may be more than one copy of a piece of data because of replication, and data may be split up because of partitioning. Any updates to data performed by any user must be propagated to all copies throughout the database. The use of snapshots is one technique for implementing this.

3.3.3 Distributed catalog management: The distributed database catalog entries must specify site(s) at which data is being stored in addition to data in a system catalog in a centralised DBMS. Because of data partitioning and replication, this extra information is needed. There are a number of approaches to implementing a distributed database catalog. Centralized- Keep one master copy of the catalog, fully replicated. Partitioned -Partition and replicate the catalog as usage patterns demand, Centralised/partitioned- Combination of the above.

3.3.4 Distributed concurrency control: Concurrency Control in distributed databases can be done in several ways. Locking and timestamping are two techniques, which can be used, but timestamping is generally preferred. The problems of concurrency control in a distributed DBMS are more severe than in a centralised DBMS because of the fact that data may be replicated and partitioned. If a user wants unique access to a piece of data, for example to perform an update or a read, the DBMS must be able to guarantee unique access to that data, which is difficult if there are copies throughout the sites in the distributed database.

A number of problems arise while dealing with concurrency control and recovery issues in distributed databases. Some of the major problems are:

Site failure: There are situation when one or more sites in a DDBMS fail. In such situations, consistency and integrity of the database must be restored.

Network Problems: When communication network fails, causing one or more sites to be cut off from the rest of the sites in the DDBMS environment

Data Duplication: Multiple copies of the database must be monitor carefully for maintaining consistency.

Distributed Transaction: A problem arise when a transaction distributed across various sites. Some of the sites are successfully committing/rolling, while the others may not be successfully done.

Distributed Deadlocks: In DDBMS, a deadlock may occur in any one or many sites. So, careful handling is necessary.

3.3.5 Transaction Concurrency: If transactions are executed serially, i.e., sequentially with no overlap in time, no transaction concurrency⁴ exists. However, if concurrent transactions with interleaving operations are allowed in an uncontrolled manner, some unexpected, undesirable result may occur. Here

IV. Transaction Processing In Replicated Data in the DDBMS

A transaction is a logical unit of work constituted by one or more SQL statements executed by a single user. A transaction begins with the user's first executable SQL statement and ends when it is committed or rolled back by that user. A remote transaction contains only statements that access a single remote node. A distributed transaction contains statements that access more than one node. A distributed transaction is a transaction that includes one or more statements that, individually or as a group, update data on two or more distinct nodes of a distributed database. The term replication refers to the operation of copying and maintaining database objects in multiple databases belonging to a distributed system. The terms distributed database system and database replication are related, yet distinct. In a pure (that is, not replicated) distributed database, the system manages a single copy of all data and supporting database objects. Typically, distributed database applications use distributed transactions to access both local and remote data and modify the global database in real-time. While replication relies on distributed database technology, database replication offers applications benefits that are not possible within a pure distributed database environment. Most commonly, replication is used to improve local database performance and protect the availability of applications because alternate data access options exist.[13,14,16] For example, an application may normally access a local database rather than a remote server to minimize network traffic and achieve maximum performance. Furthermore, the application can continue to function if the local server experiences a failure, but other servers with replicated data remain accessible. A new component, which is a replication manager module, has been recently added to the system, in order to maintain replicated data.

4.1 Transaction-Processing Model:

A DDBMS contains four components: transactions (T), Transaction Manager (TMR), Data Manager (DMR), and data (D). Transactions communicate with TMRs, TMRs communicate with DMRs, and DMRs manage the D. TMRs supervise transactions. Each transaction executed in the DDBMS is supervised by a single TMR, meaning that the transaction issues all of its database operations to that TMR. Any distributed computation that is needed to execute the transaction is managed by the TMR. Four operations are defined at the transaction-TMR interface.

READ (A): returns the value of A (a logical data item) in the current logical database state.

WRITE (A, new-value): creates a new logical database state in which A has the specified new value.

BEGIN and **END** operations to bracket transaction executions.

DMRs manage the stored database, functioning as backend database processors. In response to commands from transactions, TMRs issue commands to DMRs specifying stored data items to be read or written.

In a centralized DBMS, private workspaces are part of the Transaction Manager (TMR) and data can freely move between a transaction and its workspace, and between a workspace and the Data Manager (DMR). Whereas in a DDBMS TMRs and DMRs may run at different sites and the movement of data between a TM and a DM can be expensive. To reduce this cost, many DDBMSs employ query optimization procedures which regulate the flow of data between sites. How a Transaction (T) reads and writes data in these workspaces is a query optimization problem and has no direct effect on concurrency control. Suppose T is updating x, y, z stored at DMR_x, DMR_y, DMR_z, and suppose T's TMR fails after issuing DMR-write(x), but before issuing the dm-writes for y and z. At this point the database is incorrect. However, in a DDBMS, other TMRs remain operational and can access the incorrect database. To avoid this problem, prewrite commands must be modified slightly. In addition to specifying data items to be copied onto secure storage, prewrites also specify which other DMRs are involved in the commitment activity. Then if the TMR fails during the second phase of two-phase commit, the DMRs whose dm-writes were not issued can recognize the situation and consult the other DMRs involved in the commitment. If any DMR received a dmr-write, the remaining ones act as if they had also received the command. In a DDBMS these are processed as follows.

BEGIN: The TMR creates a private work space for T.

READ (A): The TMR checks T's private workspace to see if a copy of A is present. If so, that copy's value is made available to T. Otherwise the TMR selects some stored copy of A, say x_i, and issues read(x_i) to the DMR at which x_i is stored. The DMR responds by retrieving the stored value of x_i from the database, placing it in the private workspace. The TMR returns this value to T.

WRITE (A, new-value): The value of A in T's private workspace is updated to newvalue, assuming the workspace contains a copy of A. Otherwise; a copy of A with the new value is created in the workspace.

END: Two-phase commit begins.

For each A updated by T, and for each stored copy x_i of A, the TMR issues a prewrite (x_i) to the DMR that stores x_i. The DMR responds by copying the value of A from T's private workspace onto secure storage internal to the DMR. After all prewrites are processed, the TMR issues dm-writes for all copies of all logical data items updated by T.

A DMR responds to dmr-write(x_i) by copying the value of x_i from secure storage into the stored database. After all dm-writes are installed, T's execution is finished.

4.2 SYNCHRONIZATION TECHNIQUES BASED ON TWO-PHASE LOCKING

Two-phase locking (2PL) synchronizes reads and writes by explicitly detecting and preventing conflicts between concurrent operations. Earlier than reading data item x, a transaction must "own" a read lock on x. Before writing into x, it must "own" a write lock on x. The ownership of locks is governed by two rules:

(1) Different transactions cannot simultaneously own conflicting locks

(2) Once a transaction surrenders ownership of a lock, it may never obtain additional locks.

The definition of conflicting lock depends on the type of synchronization being performed:

For 'rw' synchronization two locks conflict if

- (a) Both are locks on the same data item, and
- (b) One is a read lock and the other is a write lock;

for 'ww' synchronization two locks conflict if

- (a) Both are locks on the same data item, and
- (b) Both are write locks.

The second lock ownership rule causes every transaction to obtain locks in a two-phase manner. During the growing phase the transaction obtains locks without releasing any locks. By releasing a lock the transaction enters the shrinking phase. During this phase the transaction releases locks, and, by rule 2, is prohibited from obtaining additional locks. When the transaction terminates (or aborts), all remaining locks are automatically released. A common variation is to require that transactions obtain all locks before beginning their main execution. This variation is called predeclaration. Some systems also require that transactions hold all locks until termination.

4.2.1 Performance of 2PL

A performance of 2PL amounts to building a 2PL scheduler, a software module that receives lock requests and lock releases and processes them according to the 2PL specification. The basic way to implement 2PL in a distributed database is to distribute the schedulers along with the database, placing the scheduler for data item x at the DMR where x is stored. In this implementation read locks may be implicitly requested by dmr reads and write locks may be implicitly requested by prewrites. If the requested lock cannot be granted, the operation is placed on a waiting queue for the desired data item. Write locks are implicitly released by dmr-writes. However, to release readlocks, special lockrelease operations are required. When a lock is released, the operations on the waiting queue of that data item are processed first-in/first-out (FIFO) order. However, if a transaction updates A , then it must update all copies of A , and so must obtain write locks on all copies of A .

4.2.2 Primary Copy 2PL

Primary copy 2PL is a 2PL technique that pays attention to data redundancy. One copy of each logical data item is designated the primary copy; before accessing any copy of the logical data item, the appropriate lock must be obtained on the primary copy. For read locks this technique requires more communication than basic 2PL. Suppose x_1 is the primary copy of logical data item A , and suppose transaction T wishes to read some other copy, x_i , of A . To read x_i , T must communicate with two DMRs, the DMR where A is stored. But under basic 2PL, T would only communicate with x_i 's DMR. For write locks, however, primary copy 2PL does not incur extra communication.

4.2.3 Voting 2PL Method

Voting 2PL is another performance of 2PL that exploits data redundancy. Voting 2PL is derived from the majority consensus technique of Thomas and is only suitable for 'ww' synchronization. To understand voting, we must examine it in the context of two-phase commit. Suppose transaction T wants to write into A . Its TMR sends prewrites to each DMR

holding a copy of A . For the voting protocol, the DMR always responds immediately. It acknowledges receipt of the prewrite and says "lock set" or "lock blocked." After the TM receives acknowledgments from the DMRs, it counts the number of "lockset" responses: if the number constitutes a majority, then the TMR behaves as if all locks were set. Otherwise, it waits for "lockset" operations from DMRs that originally said "lock blocked." Deadlocks aside, it will eventually receive enough "lockset" operations to proceed. Since only one transaction can hold a majority of locks on A at a time, only one transaction writing into A can be in its second commit phase at any time [17, 18]. All copies of A thereby have the same sequence of writes applied to them. transaction's locked point occurs when it has obtained a majority of its write locks on each data item in its write set. When updating many data items, a transaction must obtain a majority of locks on every data item before it issues any dmr-writes. In principle, voting 2PL could be adapted for 'rw' synchronization. Before reading any copy of a transaction requests read locks on all copies of A ; when a majority of locks are set, the transaction may read any copy. This technique works but is overly strong: Correctness only requires that a single copy of A be locked—namely, the copy that is read—yet this technique requests locks on all copies. For this reason we deem voting 2PL to be inappropriate for rw synchronization.

V. Two-Phase Commit of transaction in Distributed database System

In transaction processing, databases, and computer networking, the two-phase commit protocol (2PC) is a type of atomic commitment protocol (ACP). It is a distributed algorithm that coordinates all the processes that participate in a distributed atomic transaction on whether to commit or abort (roll back) the transaction (it is a specialized type of consensus protocol). The protocol achieves its goal even in many cases of temporary system failure (involving process, network node, communication, etc. failures), and is thus widely utilized [17, 18]. However, it is not resilient to all possible failure configurations, and in rare cases user (e.g., a system's administrator) intervention is needed to remedy outcome. To accommodate recovery from failure (automatic in most cases) the protocol's participants use logging of the protocol's states. Log records, which are typically slow to generate but survive failures, are used by the protocol's recovery procedures. Many protocol variants exist that primarily differ in logging strategies and recovery mechanisms. Though usually intended to be used infrequently, recovery procedures comprise a substantial portion of the protocol, due to many possible failure scenarios to be considered and supported by the protocol. In a "normal execution" of any single distributed transaction, i.e., when no failure occurs, which is typically the most frequent situation, the protocol comprises two phases:

1. The commit-request phase (or voting phase), in which a coordinator process attempts to prepare all the transaction's participating processes (named participants, cohorts, or workers) to take the necessary steps for either committing or aborting the transaction and to vote, either "Yes": commit (if the transaction participant's local portion execution has ended properly), or "No": abort (if a problem has been detected with the local portion).

2. The commit phase, in which, based on voting of the cohorts, the coordinator decides whether to commit (only if all have voted “Yes”) or abort the transaction (otherwise), and notifies the result to all the cohorts. The cohorts then follow with the needed actions (commit or abort) with their local transactional resources (also called recoverable resources; e.g., database data) and their respective portions in the transaction’s other output (if applicable).

5.1 Commit request phase

1. The coordinator sends a query to commit message to all cohorts and waits until it has received a reply from all cohorts.
2. The cohorts execute the transaction up to the point where they will be asked to commit. They each write an entry to their undo log and an entry to their redo log.
3. Each cohort replies with an agreement message (cohort votes Yes to commit), if the cohort’s actions succeeded, or an abort message (cohort votes No, not to commit), if the cohort experiences a failure that will make it impossible to commit.

5.2 Commit phase

Success: If the coordinator received an agreement message from all cohorts during the commit-request phase:

1. The coordinator sends a commit message to all the cohorts.
2. Each cohort completes the operation, and releases all the locks and resources held during the transaction.
3. Each cohort sends an acknowledgement to the coordinator.
4. The coordinator undoes the transaction when all acknowledgements have been received

Failure:

If any cohort votes No during the commit-request phase (or the coordinator’s timeout expires):

1. The coordinator sends a rollback message to all the cohorts.
2. Each cohort undoes the transaction using the undo log, and releases the resources and locks held during the transaction.
3. Each cohort sends an acknowledgement to the coordinator.
4. The coordinator undoes the transaction when all acknowledgements have been received.

The protocol proceeds in two phases, namely the prepare and the commit phase, which explains the protocol’s name. The protocol is executed by a coordinator process, while the participating servers are called participants. When the transaction’s initiator issues a request to commit the transaction, the coordinator starts the first phase of the 2PC protocol by querying—via prepare messages—all participants whether to abort or to commit the transaction. The master initiates the first phase of the protocol by sending PREPARE (to commit) messages in parallel to all the cohorts. Each cohort that is ready to commit first force-writes a prepare log record to its local stable storage and then sends a YES vote to the master. At this stage, the cohort has entered a prepared state wherein it cannot unilaterally commit or abort the transaction but has to wait for the final decision from the master. On the other hand, each cohort that decides to abort force-writes an abort log record and sends a NO vote to the master. Since a NO vote acts like a veto, the cohort is permitted to unilaterally abort the transaction without waiting for a response from the master.

After the master receives the votes from all the cohorts, it initiates the second phase of the protocol. If all the votes are YES, it moves to a committing state by force writing a commit log record and sending COMMIT messages to all the cohorts. Each cohort after receiving a COMMIT message moves to the committing state, force-writes a commit log record, and sends an ACK message to the master. If the master receives even one NO vote, it moves to the aborting state by force-writing an abort log record and sends ABORT messages to those cohorts that are in the prepared state. These cohorts, after receiving the ABORT message, move to the aborting state, force write an abort log record and send an ACK message to the master. Finally, the master, after receiving acknowledgements from all the prepared cohorts, writes an end log record and then “forgets” the transaction. The 2PC may be carried out with one of the following methods: Centralized 2PC, Linear 2PC, and Distributed 2PC, [17, 18].

5.3 The Centralized Two-Phase Commit Protocol

In the Centralized 2PC communication is done through the coordinator’s process only, and thus no communication between subordinates is allowed. The coordinator is responsible for transmitting the PREPARE message to the subordinates, and, when the votes of all the subordinates are received and evaluated, the coordinator decides on the course of action: either abort or COMMIT. This method has two phases:

1. First Phase: In this phase, when a user wants to COMMIT a transaction, the coordinator issues a PREPARE message to all the subordinates, (Mohan et al., 1986). When a subordinate receives the PREPARE message, it writes a PREPARE log and, if that subordinate is willing to COMMIT, sends a YES VOTE, and enters the PREPARED state; or, it writes an abort record and, if that subordinate is not willing to COMMIT, sends a NO VOTE. A subordinate sending a NO VOTE doesn’t need to enter a PREPARED state since it knows that the coordinator will issue an abort. In this case, the NO VOTE acts like a veto in the sense that only one NO VOTE is needed to abort the transaction. The following two rules apply to the coordinator’s decision.

- a. If even one participant votes to abort the transaction, the coordinator has to reach a global abort decision.
- b. If all the participants vote to COMMIT, the coordinator has to reach a global COMMIT decision.

2. Second Phase: After the coordinator reaches a vote, it has to relay that vote to the subordinates. If the decision is COMMIT, then the coordinator moves into the committing state and sends a COMMIT message to all the subordinates informing them of the COMMIT. When the subordinates receive the COMMIT message, they, in turn, move to the committing state and send an acknowledge (ACK) message to the coordinator. When the coordinator receives the ACK messages, it ends the transaction. If, on the other hand, the coordinator reaches an ABORT decision, it sends an ABORT message to all the subordinates. Here, the coordinator doesn’t need to send an ABORT message to the subordinate(s) that gave a NO VOTE.

5.4 The Linear Two-Phase Commit Protocol

In the linear 2PC, subordinates can communicate with each other. The sites are labeled 1 to N, where the coordinator is numbered as site 1. Accordingly, the propagation of the PREPARE message is done serially. As such, the time

required to complete the transaction is longer than centralized or distributed methods. Finally, node N is the one that issues the Global COMMIT. The two phases are discussed below:

First Phase: The coordinator sends a PREPARE message to participant 2. If participant 2 is not willing to COMMIT, then it sends a VOTE ABORT (VA) to participant 3 and the transaction is aborted at this point. If participant 2, on the other hand, is willing to commit, it sends a VOTE COMMIT (VC) to participant 3 and enters a READY state. In turn, participant 3 sends its vote till node N is reached and issues its vote.

Second Phase: Node N issues either a GLOBAL ABORT (GA) or a GLOBAL COMMIT (GC) and sends it to node N-1. Subsequently, node N-1 will enter an ABORT or COMMIT state. In turn, node N-1 will send the GA or GC to node N-2, until the final vote to commit or abort reaches the coordinator, node

5.5 The Distributed Two-Phase Commit Protocol

In the distributed 2PC, all the nodes communicate with each other. According to this protocol, as Figure 5 shows, the second phase is not needed as in other 2PC methods. Moreover, each node must have a list of all the participating nodes in order to know that each node has sent in its vote. The distributed 2PC starts when the coordinator sends a PREPARE message to all the participating nodes. When each participant gets the PREPARE message, it sends its vote to all the other participants. As such, each node maintains a complete list of the participants in every transaction. Each participant has to wait and receive the vote from all other participants. When a node receives all the votes from all the participants, it can decide directly on COMMIT or abort. There is no need to start the second phase, since the coordinator does not have to consolidate all the votes in order to arrive at the final decision.

VI. DATABASE MANAGEMENT SYSTEM: THE TWO-PHASE COMMIT

A distributed database system is a network of two or more databases that reside on one or more machines. A distributed system that connects four databases. An application can simultaneously access or modify the data in several databases in a single distributed environment. For a client application, the location and platform of the databases are transparent. You can also create synonyms for remote objects in the distributed system so that users can access them with the same syntax as local objects. For example, if you are connected to database mfg but want to access data on database headquarters, creating a synonym on manufacturing for the remote dept table enables you to issue this query [18]. The database is a distributed database management system, which employs the two-phase commit to achieve and maintain data reliability. The DB2 database is a distributed database management system, which employs the two-phase commit to achieve and maintain data reliability. The following sections explain DB2's two-phase implementation procedures. How Session maintains between nodes in each transaction, DB2 constructs a session tree for the participating nodes. The session tree describes the relations between the nodes participating in any given transaction. Each node plays one or more of the following roles:

6.1 The Branch Tree

In each transaction, Oracle constructs a branch tree for the participating nodes. The session tree describes the relations between the nodes participating in any given transaction. Each node plays one or more of the following roles [10]:

6.1.1 Client(C): A client is a node that references data from another node.

6.1.2. Database Server (DS): A server is a node that is being referenced by another node because it has needed data. A database server is a server that supports a local database.

6.1.3. Global Coordinator (GC): The global coordinator is the node that initiated the transaction, and thus, is the root of the branch tree. The operations performed by the global coordinator are as follows:

- In its role as a global coordinator and the root of the branch tree, all the SQL statements, procedure calls, etc., are sent to the referenced nodes by the global coordinator. Instructs all the nodes, except the COMMIT point site, to PREPARE
- If all sites PREPARE successfully, then the global coordinator instructs the COMMIT point site to initiate the commit phase
- If one or more of the nodes send an abort message, then the global coordinator instructs all nodes to perform a rollback.

6.1.4. Local Coordinator: A local coordinator is a node that must reference data on another node in order to complete its part. The local coordinator carries out the following functions:

- Receiving and relaying status information among the local nodes
- Passing queries to those nodes
- Receiving queries from those nodes and passing them on to other nodes
- Returning the results of the queries to the nodes that initiated them.

6.1.5. Commit Point Site: Before a COMMIT point site can be designated, the COMMIT point strength of each node must be determined. The COMMIT point strength of each node of the distributed database system is defined when the initial connection is made between the nodes. The COMMIT point site has to be a reliable node because it has to take care of all the messages. When the global coordinator initiates a transaction, it checks the direct references to see which one is going to act as a COMMIT point site. The COMMIT point site cannot be a read-only site. If multiple nodes have the same COMMIT point strength, then the global coordinator selects one of them. In case of a rollback, the PREPARE and COMMIT phases are not needed and thus a COMMIT point site is not selected. A transaction is considered to be committed once the COMMIT point site commits locally.

6.2 Two-Phase Commit and the Database Implementation

The transaction manager of the homogenous Oracle8 database necessitates that the decision on what to do with a transaction to be unanimous by all nodes. This requires all concerned nodes to make one of two decisions: commit and complete the transaction, or abort and rollback the transaction. The Oracle engine automatically takes care of the commit

[19]. or rollback of all transactions, thus, maintaining the integrity of the database. The following will describe the two phases of the transaction manager.

6.2.1. PREPARE Phase (PP): The PP starts when a node, the initiator, asks all participants, except the commit point site, to PREPARE. In the PP, the requested nodes have to record enough information to enable them either to commit or abort the transaction. The node, after replying to the requestor that it has PREPARED, cannot unilaterally perform a COMMIT or abort. Moreover, the data that is tied with the COMMIT or abort is not available for other transactions.

Each node may reply with one of three responses to the initiator. These responses are defined below:

a. Prepared: the data has already been modified and that the node is ready to COMMIT. All resources affected by the transaction are locked.

b. Read-only: the data on the node has not been modified. With this reply, the node does not PREPARE and does not participate in the second phase.

c. Abort: the data on the node could not be modified and thus the node frees any locked resources for this transaction and sends an abort message to the node that referenced it.

6.2.2. COMMIT Phase (CP): Before the CP begins, all the referenced nodes need to have successfully PREPARED. The COMMIT phase begins by the global coordinator sending a message to all the nodes instructing them to COMMIT. Thus, the databases across all nodes are consistent.

VII. CONCLUSIONS

At the present time Transaction management is an fully grown thought in distributed data base management systems (DDBMS) for research area for research. In this paper, we have reviewed the basic concepts Transaction Processing In Replicated Data. Many associations do not implement distributed databases because of its difficulty. They simply resort to centralized databases. However, with global organizations and multi-tier network architectures, distributed implementation becomes a necessity. It is hoped that this paper to will assist organization in the implementation of distributed databases when installing homogenous DBMS, or give confidence organizations to journey from centralized to distributed DBMS. We talk about the basic concept of transaction in distributed database systems, and also discussed the advantage, property and operations transaction in distributed environments. It is really important for database to have the ACID properties to perform. We have presented the basics of distributed database technology as well as the techniques that help in distribution of database in transaction-processing model. Also, Discussion regarding the framework for the design and analysis of distributed database concurrency control algorithms. The framework has two main components are system model that provides common terminology and concepts for describing a variety of concurrency control algorithms, and a problem decomposition that decomposes concurrency control algorithms into readwrite and write-write synchronization subalgorithms. We have considered synchronization subalgorithms outside the context of specific concurrency control algorithms.

ABSTRACT: This paper deals with fuzzy goal programming approach to solve chance constrained quadratic bi-level programming problem. Chance constraints are converted into equivalent deterministic constraints by the prescribed distribution functions. In the model formulation, the quadratic membership functions are formulated by using the individual best solution of the quadratic objective functions subject to the equivalent deterministic constraints. Using first order Taylor's series, the quadratic membership functions are approximated to linear membership functions expanding about the individual best solution points. For avoiding decision deadlock, each level decision maker provides a relaxation of bounds on the decision variables controlled by him. We use two fuzzy goal programming models to reach the highest degree of membership goals by minimizing negative deviational variables. Euclidean distance function is used to identify the most compromise optimal solution. To demonstrate the proposed approach, two numerical examples are solved.

Keyword: Bi-level programming, chance constraints, fuzzy goal programming, quadratic programming problem, Taylor's series.

I. INTRODUCTION

In bi-level programming problem (BLPP), there are two types of decision makers (DMs). One is first level decision maker (FLDM) and another is second level decision maker (SLDM). The execution of decision is sequential from first level to second level and each level DM independently controls only a set of decision variables. The FLDM makes his decision first. But SLDM may not be satisfied with the decision of FLDM. Consequently, decision deadlock occurs frequently in the hierarchical decision making context.

Candler and Townsley [1] as well as Fortuny –Amart and McCarl [2] developed the formal bi-level programming problem (BLPP). In 1991, Edmund and Bard [3] studied non linear bi-level programming problems. Malhotra and Arora [4] discussed fractional bi-level programming problem using preemptive goal programming. Sakawa and Nishizaki [5, 6] studied linear fractional BLPP based on interactive fuzzy programming. Using analytical hierarchy process due to Saaty [7], Mishra [8] developed weighting method for linear fractional BLPP. Pramanik and Dey [9] presented linear fractional BLPP based on fuzzy goal programming (FGP) using first order Taylor polynomial series.

Anandalingam [10] discussed multi level programming problem (MLPP) as well as bi-level decentralized programming problem by using Stackelberg solution approach. The concept of fuzzy set theory in MLPP was first introduced by Lai [11]. Shih et al. [12] and Shih and Lee [13] extended Lai's ideas by introducing non-compensatory max min aggregation operator and compensatory fuzzy operator respectively. Fuzzy goal programming for MLPP was studied by Pramanik and Roy [14].

Quadratic bi-level programming problem (QBLPP) is a special type of non-linear bi-level programming problem. In this paper, we consider the objective function of each level DM is quadratic function and the constraints are linear functions. There are many research fields where QBLPP arise such as robust data fitting, traffic assignment problems, portfolio optimizations, transportations. In 1994, Faustino and Judice [15] developed the linear QBLPP. Vicente et al. [16] presented descent method for QBLPP. Optimality conditions and algorithm for solving QBLPP were developed by Wang et al. [17]. QBLPP for integer variables was presented by Thirwani and Arora [18]. They used linearization method and obtained integer solution for QBLPP by using Gomory cut and dual simplex method. Using Karush-Kuhn-Tucker conditions and duality theory, Calvete and Gale [19] discussed optimality conditions for the linear fractional / quadratic BLPP. Pal and Moitra [20] developed FGP approach for solving QBLPP in 2003. Recently, Pramanik and Dey [21] studied multi objective quadratic programming problem. They [22] also developed priority based FGP approach to multi objective quadratic programming problem. They [23] also extended their ideas for solving QBLPP based on FGP.

Uncertainties may occur in the decision making situations. Generally, uncertainties can be fuzzily or stochastically described. Using probability theory, Dantzig [24] introduced stochastic programming. There are two main approaches of stochastic programming, namely, chance constrained programming (CCP) and two-stage programming. Charnes and Cooper [25] developed the CCP.

In the present paper, we present QBLPP with chance constraints which is called chance constrained QBLPP. We first convert the chance constraints into equivalent deterministic constraints with prescribed distribution functions and confidence levels. We form quadratic membership function by using individual best solution. Using first order Taylor's series, the quadratic membership function are approximated into linear membership functions by expanding about the respective individual best solution

point. For avoiding decision deadlock, each decision maker prefers some bounds on the decision variables controlled by him. Two FGP models are formulated and Euclidean distance function is used to determine the most compromise solution. Two numerical examples are solved to demonstrate the efficiency of the proposed approach.

The rest of the paper is organized in the following way. In Section II, we formulate chance constrained QBLPP. In Section III, chance constraints are transformed into equivalent deterministic constraints. Quadratic membership functions are constructed in Section IV. In Section V, technique of linearization of quadratic membership function is discussed by using first order Taylor's series. In Section VI, preference bounds on the decision variables are defined. Section VII is devoted to develop two FGP models for solving chance constrained QBLPP for maximization type objective functions. Section VIII discusses FGP model formulation for solving chance constrained QBLPP for minimization type objective functions. The Euclidean distance function is described in the next Section IX. The step wise descriptions of the whole paper are summarized in the Section X. Section XI presents two numerical examples. Finally, Section XII concludes the paper with final conclusion and future work.

II. FORMULATION OF CHANCE CONSTRAINED QUADRATIC BI-LEVEL PROGRAMMING PROBLEM

The generic form of chance constrained QBLPP is

$$[FLDM] \text{Max}_{\bar{X}_1} Z_1(\bar{X}) = \bar{A}_1 \bar{X} + \frac{1}{2} \bar{X}^T \bar{B}_1 \bar{X} \tag{1}$$

$$[SLDM] \text{Max}_{\bar{X}_2} Z_2(\bar{X}) = \bar{A}_2 \bar{X} + \frac{1}{2} \bar{X}^T \bar{B}_2 \bar{X} \tag{2}$$

subject to

$$\bar{X} \in X =$$

$$\{\bar{X} \in \mathbb{R}^n : \Pr(\bar{C}\bar{X} \leq \bar{d}) > \bar{I} - \bar{m}, \bar{X} \geq \bar{0}\} \tag{3}$$

Here, the decision vector $\bar{X}_1 = (x_{11}, x_{12}, x_{13}, \dots, x_{1n_1})$ is controlled by FLDM and $\bar{X}_2 = (x_{21}, x_{22}, x_{23}, \dots, x_{2n_2})$ is controlled by SLDM. $\bar{X}_1 \cup \bar{X}_2 = \bar{X} \in \mathbb{R}^n$, $n_1 + n_2 = n$, 'T' means transposition of vector. $\bar{A}_1, \bar{B}_1, \bar{A}_2, \bar{B}_2, \bar{I}, \bar{m}$ are given vectors. The order of \bar{A}_1, \bar{A}_2 are $1 \times n$, the order of symmetric matrices \bar{B}_1, \bar{B}_2 are $n \times n$, $\bar{I}, \bar{d}, \bar{m}$ are vectors of order $p \times 1$, every elements of \bar{I} is unity. \bar{C} is the given matrix of order $p \times n$. The polyhedron X is assumed to be non-empty and bounded.

III. CONVERSION OF STOCHASTIC CONSTRAINTS INTO DETERMINISTIC CONSTRAINTS

First, we consider the chance constraints of the form:

$$\Pr(\sum_{j=1}^n c_{ij} x_j \leq d_i) \geq 1 - m_i, \quad i = 1, 2, \dots, p_1. \tag{4}$$

$$\Rightarrow \Pr\left(\frac{\sum_{j=1}^n c_{ij} x_j - E(d_i)}{\sqrt{\text{var}(d_i)}} \leq \frac{d_i - E(d_i)}{\sqrt{\text{var}(d_i)}}\right) \geq 1 - m_i, \quad i = 1, 2, \dots, p_1$$

$$\Rightarrow m_i \geq 1 - \Pr\left(\frac{\sum_{j=1}^n c_{ij} x_j - E(d_i)}{\sqrt{\text{var}(d_i)}} \leq \frac{d_i - E(d_i)}{\sqrt{\text{var}(d_i)}}\right)$$

$$\Rightarrow m_i \geq \Pr\left(\frac{\sum_{j=1}^n c_{ij} x_j - E(d_i)}{\sqrt{\text{var}(d_i)}} > \frac{d_i - E(d_i)}{\sqrt{\text{var}(d_i)}}\right)$$

$$\Rightarrow \Psi^{-1}(m_i) \geq \frac{\sum_{j=1}^n c_{ij} x_j - E(d_i)}{\sqrt{\text{var}(d_i)}}$$

$$\Rightarrow \Psi^{-1}(m_i) \sqrt{\text{var}(d_i)} \geq \sum_{j=1}^n c_{ij} x_j - E(d_i)$$

$$\Rightarrow \sum_{j=1}^n c_{ij} x_j \leq E(d_i) + \Psi^{-1}(m_i) \sqrt{\text{var}(d_i)},$$

$$i = 1, 2, \dots, p_1 \tag{5}$$

Here $\Psi(\cdot)$ and $\Psi^{-1}(\cdot)$ represent the distribution function and inverse of distribution function of standard normal variable respectively.

Considering the case when $\Pr(\sum_{j=1}^n c_{ij} x_j \geq d_i) \geq 1 - m_i$,

$$i = p_1 + 1, p_1 + 2, \dots, p. \tag{6}$$

The constraints can be rewritten as:

$$\Pr\left(\frac{\sum_{j=1}^n c_{ij} x_j - E(d_i)}{\sqrt{\text{var}(d_i)}} \geq \frac{d_i - E(d_i)}{\sqrt{\text{var}(d_i)}}\right) \geq 1 - m_i, \quad i = p_1 + 1, p_1 + 2, \dots, p.$$

$$\Rightarrow \Psi\left(\frac{\sum_{j=1}^n c_{ij} x_j - E(d_i)}{\sqrt{\text{var}(d_i)}}\right) \geq 1 - m_i$$

$$\Rightarrow 1 - \Psi\left(-\frac{\sum_{j=1}^n c_{ij} x_j - E(d_i)}{\sqrt{\text{var}(d_i)}}\right) \geq 1 - m_i$$

$$\Rightarrow \Psi^{-1}(m_i) \geq -\frac{\sum_{j=1}^n c_{ij} x_j - E(d_i)}{\sqrt{\text{var}(d_i)}}$$

$$\Rightarrow \sum_{j=1}^n c_{ij} x_j \geq E(d_i) - \Psi^{-1}(m_i) \sqrt{\text{var}(d_i)}, \tag{7}$$

$$i = p_1 + 1, p_1 + 2, \dots, p.$$

$$\bar{X} \geq \bar{0} \tag{8}$$

Let us denote the equivalent deterministic system constraints (5), (7) and (8) by X. Here, X^* and X are equivalent set of constraints.

IV. CONSTRUCTION OF MEMBERSHIP FUNCTION

In order to construct quadratic membership function subject to the equivalent deterministic system constraints, the quadratic objective functions are maximized separately.

Let $\bar{X}_i^B = (x_{i1}^B, x_{i2}^B, x_{i3}^B, \dots, x_{in_i}^B), i = 1, 2$ be the individual best solution for the objective function $Z_i(\bar{X})$.

$$\text{Let } \max_{\bar{X} \in X} Z_1(\bar{X}) = Z_1^B = Z_1(\bar{X}_1^B) \text{ and } \max_{\bar{X} \in X} Z_2(\bar{X}) = Z_2^B = Z_2(\bar{X}_2^B).$$

Considering the individual best solution as the aspiration level, the fuzzy goal appears as:

$$Z_i(\bar{X}) \underset{\sim}{\geq} Z_i^B, i = 1, 2 \tag{9}$$

We consider $\min_{\bar{X} \in X} Z_1(\bar{X}) = Z_1^W$ and $\min_{\bar{X} \in X} Z_2(\bar{X}) = Z_2^W$ as the lower tolerance limits of the fuzzy objective goals of FLDM and SLDM.

Now, the membership function for the objective function $Z_1(\bar{X})$ of FLDM can be written as:

$$\mu_1(\bar{X}) = \left\langle \begin{array}{ll} 1, & \text{if } Z_1(\bar{X}) \geq Z_1^B, \\ \frac{Z_1(\bar{X}) - Z_1^W}{Z_1^B - Z_1^W}, & \text{if } Z_1^W \leq Z_1(\bar{X}) \leq Z_1^B, \\ 0, & \text{if } Z_1(\bar{X}) \leq Z_1^W \end{array} \right\rangle \tag{10}$$

and the membership function for the objective function $Z_2(\bar{X})$ of SLDM can be formulated as:

$$\mu_2(\bar{X}) = \left\langle \begin{array}{ll} 1, & \text{if } Z_2(\bar{X}) \geq Z_2^B, \\ \frac{Z_2(\bar{X}) - Z_2^W}{Z_2^B - Z_2^W}, & \text{if } Z_2^W \leq Z_2(\bar{X}) \leq Z_2^B, \\ 0, & \text{if } Z_2(\bar{X}) \leq Z_2^W \end{array} \right\rangle \tag{11}$$

Now, the chance constrained QBLP reduces to

$$\begin{aligned} &\max \mu_1(\bar{X}), \\ &\max \mu_2(\bar{X}), \\ &\text{subject to} \\ &\bar{X} \in X. \end{aligned} \tag{12}$$

V. LINEARIZATION OF QUADRATIC MEMBERSHIP FUNCTIONS BY USING TAYLOR'S SERIES APPROXIMATION

Let $\bar{X}_i^* = (x_{i1}^*, x_{i2}^*, x_{i3}^*, \dots, x_{in_i}^*, x_{in_i+1}^*, \dots, x_{in_i}^*)$, $i = 1, 2$ be the individual best solution of $\mu_i(\bar{X})$ subject to the equivalent deterministic system constraints. Then we transform the quadratic membership function $\mu_i(\bar{X})$ into an equivalent linear membership function $\mu_i^*(\bar{X})$ at the point \bar{X}_i^* by using first order Taylor's series as follows:

$$\begin{aligned} \mu_1(\bar{X}) &\cong \mu_1(\bar{X}_1^*) + (x_1 - x_{11}^*) \frac{\partial}{\partial x_1} \mu_1(\bar{X}_1^*) + \\ &(x_2 - x_{12}^*) \frac{\partial}{\partial x_2} \mu_1(\bar{X}_1^*) + \dots + \\ &(x_{n_1} - x_{1n_1}^*) \frac{\partial}{\partial x_{n_1}} \mu_1(\bar{X}_1^*) + \\ &(x_{n_1+1} - x_{1n_1+1}^*) \frac{\partial}{\partial x_{n_1+1}} \mu_1(\bar{X}_1^*) + \dots \\ &+ (x_n - x_{1n}^*) \frac{\partial}{\partial x_n} \mu_1(\bar{X}_1^*) = \mu_1^*(\bar{X}) \end{aligned} \tag{13}$$

$$\begin{aligned} \mu_2(\bar{X}) &\cong \mu_2(\bar{X}_2^*) + (x_1 - x_{21}^*) \frac{\partial}{\partial x_1} \mu_2(\bar{X}_2^*) + (x_2 - x_{22}^*) \\ &\frac{\partial}{\partial x_2} \mu_2(\bar{X}_2^*) + \dots + (x_{n_2} - x_{2n_2}^*) \frac{\partial}{\partial x_{n_2}} \mu_2(\bar{X}_2^*) + \\ &(x_{n_2+1} - x_{2n_2+1}^*) \frac{\partial}{\partial x_{n_2+1}} \mu_2(\bar{X}_2^*) + \dots + (x_n - x_{2n}^*) \\ &\frac{\partial}{\partial x_n} \mu_2(\bar{X}_2^*) = \mu_2^*(\bar{X}) \end{aligned} \tag{14}$$

VI. CHARACTERIZATION OF PREFERENCE BOUNDS ON THE DECISION VARIABLES FOR BOTH LEVEL DECISION MAKERS

Since the objectives of level DMs are conflicting, cooperation between the level DMs is necessary in order to reach compromise optimal solution. Each DM tries to reach maximum profit with the consideration of benefit of other. Here, the relaxations on both decision variables are considered for overall benefit.

Let $(x_{1j}^* - r_{1j}^-)$ and $(x_{1j}^* + r_{1j}^+)$ ($j = 1, 2, \dots, n_1$) be the lower and upper bounds of decision variable x_{1j} ($j = 1, 2, \dots, n_1$) provided by the FLDM. Here, $\bar{X}_1^* = (x_{11}^*, x_{12}^*, \dots, x_{1n_1}^*, x_{1n_1+1}^*, \dots, x_{1n}^*)$ is the individual best solution of the quadratic membership function $\mu_1(\bar{x})$ of FDLM when calculated in isolation subject to the equivalent deterministic system constraints.

Similarly, $(x_{2j}^* - r_{2j}^-)$ and $(x_{2j}^* + r_{2j}^+)$ ($j = 1, 2, \dots, n_2$) be the lower and upper bounds of decision variables x_{2j} ($j = 1, 2, \dots, n_2$) provided by the SLDM. $\bar{X}_2^* = (x_{21}^*, x_{22}^*, \dots, x_{2n_2}^*, x_{2n_2+1}^*)$ is the individual best solution of the quadratic membership function $\mu_2(\bar{x})$ of SLDM when calculated in isolation subject to the equivalent deterministic system constraints. Therefore, preference bounds on the decision variable can presented as follows:

$$\begin{aligned} (x_{1j}^* - r_{1j}^-) &\leq x_{1j} \leq (x_{1j}^* + r_{1j}^+) \quad (j = 1, 2, \dots, n_1) \tag{15} \\ (x_{2j}^* - r_{2j}^-) &\leq x_{2j} \leq (x_{2j}^* + r_{2j}^+) \quad (j = 1, 2, \dots, n_2) \tag{16} \end{aligned}$$

Here, r_{1j}^- and r_{1j}^+ ($j = 1, 2, \dots, n_1$) and are the negative and positive tolerance values, which are not necessarily same. Similarly, r_{2j}^- and r_{2j}^+ ($j = 1, 2, \dots, n_2$) are negative and positive tolerance values that may be not be necessarily same.

VII. FORMULATION OF FUZZY GOAL PROGRAMMING MODEL OF CHANCE CONSTRAINED QUADRATIC BI-LEVEL PROGRAMMING PROBLEM

The chance constrained QBLPP reduces to the following problem

$$\text{Max } \mu_1^*(\bar{X}),$$

$$\text{Max } \mu_2^*(\bar{X})$$

subject to

$$(x_{1j}^* - r_{1j}^-) \leq x_{1j} \leq (x_{1j}^* + r_{1j}^+), (j = 1, 2, \dots, n_1)$$

$$(x_{2j}^* - r_{2j}^-) \leq x_{2j} \leq (x_{2j}^* + r_{2j}^+), (j = 1, 2, \dots, n_2)$$

$$\bar{X} \in X \tag{17}$$

According to Pramanik and Dey, it can be written [23] as:

$$\mu_i^* + d_i^- = 1, i = 1, 2. \tag{18}$$

d_1^-, d_2^- are the negative deviational variables. Now, two FGP models are formulated as follows:

Model-I

$$\text{min } \lambda \tag{19}$$

subject to

$$\mu_1^*(\bar{X}) + d_1^- = 1,$$

$$\mu_2^*(\bar{X}) + d_2^- = 1,$$

$$\lambda \geq d_1^-,$$

$$\lambda \geq d_2^-,$$

$$0 \leq d_1^- \leq 1,$$

$$0 \leq d_2^- \leq 1,$$

$$(x_{1j}^* - r_{1j}^-) \leq x_{1j} \leq (x_{1j}^* + r_{1j}^+), (j = 1, 2, \dots, n_1)$$

$$(x_{2j}^* - r_{2j}^-) \leq x_{2j} \leq (x_{2j}^* + r_{2j}^+), (j = 1, 2, \dots, n_2)$$

$$\bar{X} \in X \tag{20}$$

Model -II

$$\text{Min } \xi = \sum_{i=1}^2 d_i^-$$

subject to

$$\mu_1^*(\bar{X}) + d_1^- = 1,$$

$$\mu_2^*(\bar{X}) + d_2^- = 1,$$

$$0 \leq d_1^- \leq 1,$$

$$0 \leq d_2^- \leq 1,$$

$$(x_{1j}^* - r_{1j}^-) \leq x_{1j} \leq (x_{1j}^* + r_{1j}^+), j = 1, 2, \dots, n_1$$

$$(x_{2j}^* - r_{2j}^-) \leq x_{2j} \leq (x_{2j}^* + r_{2j}^+), j = 1, 2, \dots, n_2$$

$$\bar{X} \in X$$

VIII. MODEL FORMULATION FOR QUADRATIC BI-LEVEL PROGRAMMING PROBLEM WITH CHANCE CONSTRAINTS FOR MINIMIZATION TYPE OBJECTIVE FUNCTIONS

Let us consider the following problem of chance constrained QBLPP with minimization type objective functions.

$$[\text{FLDM}] \text{Min}_{\bar{X}} Z_1(\bar{X}) = \bar{A}_1 \bar{X} + \frac{1}{2} \bar{X}^T \bar{B}_1 \bar{X} \tag{21}$$

$$[\text{SLDM}] \text{Min}_{\bar{X}_2} Z_2(\bar{X}) = \bar{A}_2 \bar{X} + \frac{1}{2} \bar{X}^T \bar{B}_2 \bar{X} \tag{22}$$

subject to

$$\bar{X} \in X =$$

$$\{\bar{X} \in \mathbb{R}^n : \Pr\{\bar{C}\bar{X} \leq \bar{d}\} > \bar{I} - m, \bar{X} \geq \bar{0}\} \tag{23}$$

The descriptions of the coefficients, matrices, and vectors of the problem are already provided in section 2.

The chance constraints are converted into equivalent deterministic constraints as described in (5) and (7). Then, the objective functions are solved separately subject to equivalent deterministic constraints. Let \bar{X}_1^B, \bar{X}_2^B be the individual best solutions for the quadratic objective functions $Z_1(\bar{X}), Z_2(\bar{X})$ and $\min_{\bar{X} \in X} Z_1(\bar{X}) = Z_1^B = Z_1(\bar{X}_1^B)$ and $\min_{\bar{X} \in X} Z_2(\bar{X}) = Z_2^B = Z_2(\bar{X}_2^B)$.

Considering the individual best solution as the aspiration level, the fuzzy goal appears as:

$Z_i(\bar{X}) \leq Z_i^B, i = 1, 2$

$$Z_i(\bar{X}) \leq Z_i^B, i = 1, 2 \tag{24}$$

We consider $\max_{\bar{X} \in X} Z_1(\bar{X}) = Z_1^W$ and $\max_{\bar{X} \in X} Z_2(\bar{X}) = Z_2^W$ as the upper tolerance limits of the fuzzy objective goals of FLDM and SLDM.

Now, the quadratic membership functions are formulated as:

$$\mu_i(\bar{X}) = \begin{cases} 1, & \text{if } Z_i(\bar{X}) \leq Z_i^B, \\ \frac{Z_i^W - Z_i(\bar{X})}{Z_i^W - Z_i^B}, & \text{if } Z_i^W \geq Z_i(\bar{X}) \geq Z_i^B, \\ 0, & \text{if } Z_i(\bar{X}) \geq Z_i^W \end{cases} \tag{25}$$

$i = 1, 2.$

The theoretical development of chance constrained QBLPP with minimization type objective functions is remain the same as developed for chance constrained QBLPP with maximization type objective functions.

IX. DISTANCE FUNCTION FOR DETERMINATION OF COMPROMISE SOLUTION

For multi objective programming, the objectives are incommensurable and conflicting in nature. The aim of decision makers is to find out the compromise solution which is as near as possible to the ideal solution points in the decision making context. Here, we use the Euclidean distance function [26] of the type

$$S_2 = \left[\sum_{i=1}^2 (1 - \mu_i^*)^2 \right]^{1/2}$$

The solution with the minimum distance is considered as the best compromise optimal solution.

X. SUMMARIZATION OF THE PROCESS FOR SOLVING CHANCE CONSTRAINTS QUADRATIC BI-LEVEL PROGRAMMING PROBLEM

To solve chance constrained QBLPP we use the following steps.

S-1. Transform the chance constraints into equivalent deterministic constraints.

S-2. Calculate individual best solution for each quadratic objective function of the level DM subject to the equivalent deterministic constraints.

S-3. Lower and upper tolerance limits are determined for each quadratic objective function by minimizing and maximizing separately subject to the equivalent deterministic constraints.

S-4. Quadratic membership functions are formulated by using individual best solutions subject to the equivalent deterministic system constraints.

S-5. Find out the individual best solution for each of the quadratic membership functions subject to the equivalent deterministic constraints.

S-6. Using first order Taylor's series, the quadratic membership functions are approximated into linear functions at the individual best solution point.

S-7. Both level DMs express their choices for the upper and lower preference bounds on the decision variables controlled by them.

S-8. Two FGP models are formulated and solved.

S-9. Determine the Euclidean distance for two optimal compromise solutions obtained from two FGP Models.

S-10. Select the solution with the minimum Euclidean distance as the best compromise optimal solution.

XI. ILLUSTRATIVE EXAMPLES OF CHANCE CONSTRAINED QUADRATIC BI-LEVEL PROGRAMMING PROBLEM

11.1 Example 1.

To illustrate the proposed FGP approach, the following chance constrained QBLPP with maximization type objective function at each level is considered.

$$\max_{x_2} Z_1(\bar{X}) = x_1^2 - 5x_2^2 + 2x_1x_2 \tag{26}$$

$$\max_{x_1} Z_2(\bar{X}) = 3x_1 + 12x_2 - x_1x_2 + 45 \tag{27}$$

subject to

$$\Pr(x_1 + x_2 \leq d_1) \geq 1 - m_1 \tag{28}$$

$$\Pr(-2x_1 + 5x_2 \leq d_2) \geq 1 - m_2 \tag{29}$$

$$\Pr(3x_1 - 4x_2 \geq d_3) \geq 1 - m_3 \tag{30}$$

$$x_1 \geq 0, x_2 \geq 0 \tag{31}$$

The mean, variance and the confidence levels are prescribed as follows:

$$E(d_1) = 3, \text{ var}(d_1) = 2, m_1 = 0.03 \tag{32}$$

$$E(d_2) = 12, \text{ var}(d_2) = 8, m_2 = 0.01 \tag{33}$$

$$E(d_3) = 10, \text{ var}(d_3) = 18, m_3 = 0.05 \tag{34}$$

Using (5) and (7), the chance constraints defined in (28), (29) and (30) can be converted into equivalent deterministic constraints as:

$$x_1 + x_2 \leq 5.66579 \tag{35}$$

$$-2x_1 + 5x_2 \leq 18.57609 \tag{36}$$

$$3x_1 - 4x_2 \geq 3.020856 \tag{37}$$

The individual solution for each quadratic objective function of level DM subject to the equivalent deterministic constraints is obtained as $Z_1^B = 32.10118$, at $\bar{X}_1^B = (5.66579, 0)$, and $Z_2^B = 72.64119$, at $\bar{X}_2^B = (3.669145, 1.996645)$.

The fuzzy goals appear as:

$$Z_1(\bar{X}) \underset{\sim}{\geq} 32.10118, Z_2(\bar{X}) \underset{\sim}{\geq} 72.64119 \tag{38}$$

The lower tolerance limits are obtained as $Z_1^W = 1.013952$ and $Z_2^W = 48.02086$

Now, the quadratic membership function for FLDM and SLDM are constructed as follows:

$$\mu_1(\bar{X}) =$$

$$\left\langle \begin{array}{l} 1, \quad \text{if } Z_1(\bar{X}) \geq 32.10118 \\ \frac{Z_1(\bar{X}) - 1.013952}{32.10118 - 1.013952}, \text{ if } 1.013952 \leq Z_1(\bar{X}) \leq 32.10118 \\ 0, \quad \text{if } Z_1(\bar{X}) \leq 1.013952 \end{array} \right\rangle \quad (39)$$

$$\mu_2(\bar{X}) =$$

$$\left\langle \begin{array}{l} 1, \quad \text{if } Z_2(\bar{X}) \geq 72.64119, \\ \frac{Z_2(\bar{X}) - 48.02086}{72.64119 - 48.02086}, \text{ if } 48.02086 \leq Z_2(\bar{X}) \leq 72.64119, \\ 0, \quad \text{if } Z_2(\bar{X}) \leq 48.02086 \end{array} \right\rangle \quad (40)$$

The quadratic membership functions are linearized at their individual best solution point at $\bar{X}_1^B = (5.66579, 0)$, $\bar{X}_2^B = (3.669145, 1.996645)$ and we obtained equivalent linear membership functions as follows:

$$\mu_1^*(\bar{X}) = 1 + (x_1 - 5.66579) \times (2 \times 5.66579 / 31.087228) + (x_2 - 0) \times (2 \times 5.66579 / 31.087228), \quad (41)$$

$$\mu_2^*(\bar{X}) = 1 + (x_1 - 3.669145) \times ((3 - 1.996645) / 24.62033) + (x_2 - 1.996645) \times ((12 - 3.669145) / 24.62033) \quad (42)$$

Let $0 \leq x_2 \leq 2$ and $3 \leq x_1 \leq 6$ be the preference bounds provided by the level DMs.

Proposed two FGP models (see Table 1) in (19) and (20) offer the same solution at $x_1 = 3.669145$, $x_2 = 1.996645$, with $Z_1 = 8.181629$ and $Z_2 = 72.64119$.

TABLE1. COMPARISON OF DISTANCES FOR THE OPTIMAL SOLUTIONS OBTAINED FROM TWO FGP MODELS OF THE PROBLEM 11.1

MODEL NUMBER	MEMBERSHIP FUNCTION	DISTANCE FUNCTION
Model I,	$\mu_1^* = 0.2305666$	0.7694334
Model II	$\mu_2^* = 1$	

It is clear from the table that two FGP Models offer the same result.

1.2 Example 2.

To illustrate the proposed FGP approach, the following chance constrained QBLPP with minimization type objective function at each level is considered.

$$\min_{x_1} Z_1(\bar{X}) = 7x_1^2 + 6x_2^2 + 8x_1 + 11x_2 \quad (43)$$

$$\min_{x_2} Z_2(\bar{X}) = (x_1 - 1)^2 + (x_2 + 3)^2 + 7x_1x_2 + 21 \quad (44)$$

subject

$$\Pr(2x_1 + 5x_2 \geq d_1) \geq 1 - m_1 \quad (45)$$

$$\Pr(3x_1 + 6x_2 \leq d_2) \geq 1 - m_2 \quad (46)$$

The means, variances and the confidence levels are prescribed as follows:

$$E(d_1) = 6, \text{ var}(d_1) = 9, m_1 = 0.06 \quad (47)$$

$$E(d_2) = 4, \text{ var}(d_2) = 4, m_2 = 0.04 \quad (48)$$

Using (5), (7) the chance constraints defined in (45), (46) can be converted into equivalent deterministic constraints as:

$$2x_1 + 5x_2 \geq 1.335 \quad (49)$$

$$3x_1 + 6x_2 \leq 7.51 \quad (50)$$

The individual solution for each quadratic objective function subject to equivalent deterministic system constraints is obtained as: $Z_1^B = 3.364734$,

$$\text{at } \bar{X}_1^B = (0, 0.267), Z_2^B = 30, \text{ at } \bar{X}_2^B = (1, 0) \quad (51)$$

The upper tolerance limits are obtained as $Z_1^W = 63.89341$

and $Z_2^W = 40.77668$.

The fuzzy goals assume the form:

$$Z_1(\bar{X}) \leq 3.364734, Z_2(\bar{X}) \leq 30$$

Now, the quadratic membership functions for FLDM and SLDM are formulated as follows:

$$\mu_1(\bar{X}) =$$

$$\left\langle \begin{array}{l} 1, \quad \text{if } Z_1(\bar{X}) \leq 3.364734, \\ \frac{63.89341 - Z_1(\bar{X})}{63.89341 - 3.364734}, \text{ if } 3.364734 \leq Z_1(\bar{X}) \leq 63.89341, \\ 0 \quad \text{if } Z_1(\bar{X}) \geq 63.89341 \end{array} \right\rangle \quad (52)$$

$$\mu_2(\bar{X}) = \left\langle \begin{array}{l} 1, \quad \text{if } Z_2(\bar{X}) \leq 30, \\ \frac{40.77668 - Z_2(\bar{X})}{40.77668 - 30}, \text{ if } 30 \leq Z_2(\bar{X}) \leq 40.77668, \\ 0 \quad \text{if } Z_2(\bar{X}) \geq 40.77668 \end{array} \right\rangle \quad (53)$$

The quadratic membership functions are linearized at their individual best solution point at $\bar{X}_1^B = (0, 0.267)$, $\bar{X}_2^B = (1, 0)$ by using Taylor's series approximation method as follows:

$$\mu_1^*(\bar{X}) = 1 + (x_1 - 0) \times (-8 / 60.5287) + (x_2 - 0.267) \times (-12 \times 0.267 + 11) / 60.5287 \quad (54)$$

$$\mu_2^*(\bar{X}) = 1 + (x_2 - 0) \times (-13 / 10.7767) \quad (55)$$

Let $0 \leq x_1 \leq 1$, $0 \leq x_2 \leq 0.5$ be the preference bounds provided by the level DMs.

FGP model I (see Table 2) offers the optimal solution at $x_1 = 0.6184107$, $x_2 = 0.0196357$ with $Z_1 = 7.842614$ and $Z_2 = 30.34881$.

FGP Model II (See Table 2) offers the optimal solution at $x_1 = 0.6675$, $x_2 = 0$, with $Z_1 = 8.458894$ and $Z_2 = 30.11056$.

TABLE2. COMPARISON OF DISTANCES FOR THE OPTIMAL SOLUTIONS OBTAINED FROM TWO FGP MODELS OF THE PROBLEM 11.2.

MODEL NUMBER	MEMBERSHIP FUNCTION	EUCLIDEAN DISTANCE FUNCTION
Model I	$\mu_1^* = 0.92602$, $\mu_2^* = 0.96763$	0.08075066
Model II	$\mu_1^* = 0.91584$, $\mu_2^* = 0.98974$	0.08478454

It is clear from the Table 2 that the Euclidean distance is minimal for the FGP Model I which implies that Model I provides better compromise solution for this example.

Note 1. Lingo ver.11.0 is used for solution purpose.

XII. CONCLUSION

In this paper, we present chance constrained QBLPP by using FGP approach which is simple to understand and easy to apply. After transforming the chance constraints into equivalent deterministic constraints, we transform quadratic bi-level programming problem into linear bi-level programming problem by using the first order Taylor's series approximation. To avoid decision deadlock, each level DM provides preference bounds on the decision variables controlled by him. Two FGP models are proposed for solution purpose. The proposed approach can be used to deal with chance constrained multi-level quadratic programming problem. The proposed approach can further be used for solving chance constrained linear quadratic fractional programming problem.

For the future study in the hierarchical decision making context, we hope, the proposed approach can be used for chance constrained quadratic decentralized multi-level multi-objective programming problems. We hope further that the proposed approach will be useful for the real decision making problems that arise in industrial belt, supply chain, marketing, IT sector, management sciences.

Dr. Surapati Pramanik received his Ph. D. degree in Mathematics from Bengal Engineering and Science University, Shibpur. He is an Assistant Professor of Mathematics in Nandalal Ghosh B.T. College, Panpur, P.O-Narayanpur, West Bengal, India. His field of research interest includes fuzzy optimization, grey system theory, neutrosophic game theory, and mathematics education. He is the author of more than 30 international journal articles.

Ms. Durga Banerjee passed M.Sc. with Operation Research as special paper from Jadavpur University in 2005 and B.Ed. from Kalyani University in 2007. Presently, she is an assistant teacher of Mathematics at Ranaghat Yusuf Institution, Ranaghat, Nadia, West Bengal, India. Her interest of research includes fuzzy optimization, decision making in stochastic environments. Her research papers were published in four international journals. Her articles have been also published in International conference proceedings and book.

An Efficient Classification Algorithm for Real Estate domain

Geetali Banerji*, Kanak Saxena**

*(IT Department, Institute of Information Technology & Management, New Delhi, India)

** (Computer Applications Department, Samrat Ashok Technological Institute, Vidisha, India)

Abstract: Classification rule mining aims to discover a small set of rules in the database that forms an accurate classifier. In classification rule mining there is one and only one predetermined target. In this paper, we proposed an algorithm, which performs preprocessing and cleaning prior to traditional classification. Experimental results show that the classifier built this way is, in general, more accurate than that produced by the state-of-the-art classification system. In addition, this helps to solve a number of problems that exist in the current classification systems. This algorithm is especially fit to applications where it may assist domain experts in their decisions. We have taken Real estate field, which is a good example, where such applications may appear. In our dataset, there is a considerable amount of information associated with the customer (e.g. Income, personal, educational, demographic and professional details). We have applied statistical analysis and Association rules on real estate actual data and found that if we consider only customer demographic and professional details then relationship among various attributes are not that strong and it only predicts the customers who are in higher income group are willing to invest. After removing demographic details like caste, status, religion etc. we found that the relationship among remaining attributes become much stronger and it shows that customer in middle income group, house owners are also willing to invest. Further not only a person's professional details helps to identify a potential customer, in Indian context, his other responsibilities, expenditure heads also plays a crucial role. It is further proven that by taking into account the bank transaction details and buying interest of a customer, there is a drastic improvement in the results i.e. not only those customers, who are in high income group and potentially strong enough to invest but because of their other social responsibilities they are not able to do so and at the same time those who are following in middle or lower income group or having rented house with other investment are also likely to invest.

Keywords: Association Rules, Classification, DT (Decision Table), Statistical Measures, RepTree

I. INTRODUCTION

Data mining is a process, which involves the application of specific algorithms for extracting patterns (test models) from data. New knowledge may be obtained in the process while eliminating one of the largest costs, viz., data collection [2]. Real Estate data, for example, often exists in vast quantities in an unstructured format. Our proposed classification algorithm which applies statistical analysis and association rules prior to traditional classification is proved better than the traditional ones because it cleans the data and removes the noise. Experimental results show that the classifier built this way is, in general, more accurate than that produced by the state-of-the-art classification system. The traditional classifiers are faster but in many cases accuracy is not so high. Moreover many of the rules found by proposed classification algorithm cannot be discovered by traditional classification algorithm. In earlier paper [9], we have already proved that in case of statistical analysis regression is used to determine the relationship among various attributes. We have tested various regression algorithms such as linear Regression, Least Median Square Isotonic and Pace Regression. Pace regression outperforms among various regression techniques because in this method it generates a pattern which assigns weights prior to processing and it is suitable with respect to Indian context because in India, caste, religion, social status plays a prominent roles In general context, multilayer perceptron is best among various machine learning algorithms because it applies weights on different hidden layer on the basis of different input weightage during processing which is suitable for other countries where the status, caste, religion does not have any role in purchasing behavior of a customer [11].

The rest of the paper is organized as follows. The concept of Classifiers is being discussed in section II. In section III, Statistical Analysis and Association Rules are discussed, the proposed algorithm has been introduced in Section IV, Section V discusses about Empirical Evaluation and Section VI concludes the paper.

II. CLASSIFICATION

In data mining, classification is one of the most important tasks. It maps the data in to predefined targets. It is a supervised learning as targets are predefined. The aim of the classification is to build a classifier based on some cases with some attributes to describe the objects or one attribute to describe the group of the objects. Then, the classifier is used to predict the group attributes of new cases from the domain based on the values of other attributes. It is a two step process, in the first step; a classifier is built describing a predetermined set of data classes or concept. This is the learning step, (or training phase), where a classification algorithm builds the classifier by learning from a training set made up of database tuples and their associated class labels. In the second step, the test model is used for classification [3, 4].

Preparing the data for classification

The following preprocessing steps may be applied to the data to help improve the accuracy, efficiency, and scalability of the classification process [3].

Data Cleaning: This refers to reduce noise or handling missing values. This step help reduce confusion during learning.

Relevance Analysis: This refers to remove irrelevant or redundant attributes. Correlation analysis can be used to identify whether two given attributes are statistically related. For Example a strong correlation between attribute A1 and A2 would suggest that one of the two could be reduced for further analysis.

Data Transformation and Reduction: It refers to generalizing the data to higher-level concepts or normalizing the data. Normalization involves scaling all values for a given attribute so that they fall within a small specified range, such as -1.0 to 1.0.

The data mining consists of various classification methods. Different methods serve different purposes, each method offering its own advantages and disadvantages. In this paper, we are discussing Decision Table and RepTree.

Decision Table

Decision Table algorithm classifier summarizes the dataset with a 'decision table' which contains the same number of attributes as the original dataset. Then, a new data item is assigned a category by finding the line in the decision table that matches the non-class values of the data item [6, 7]. Decision Table employs the wrapper method to find a good subset of attributes for inclusion in the table. By eliminating attributes that contribute little or nothing to a test model of the dataset, the algorithm reduces the likelihood of over-fitting and creates a smaller and condensed decision table. We choose to explore decision tables because it is a simpler, less compute intensive algorithm. In this paper, we have used the Weka tools [8, 13, 14, 15], which determine which attribute or combination of attributes needs to be included for predicting the class best. The attribute space is searched greedily either top to bottom or bottom to top. A top-to-bottom search adds attributes at each stage; this is called *forward selection*. A bottom-to-top search starts with a full set of attributes and deletes attributes one at a time; this is *backward elimination*.

RepTree

Fast decision tree learner. Builds a decision/regression tree using information gain/variance and prunes it using reduced-error pruning (with back fitting). Only sorts values for numeric attributes once. Missing values are dealt with by splitting the corresponding instances into pieces (i.e. as in C4.5).

Classification rule mining and association rule mining are two important data mining techniques. They are similar except that classification involves prediction of one attribute, i.e., the class, while association rule discovery can predict any attribute in the data set [16, 17]. Classification rule mining aims to discover a small set of rules in the database to form an accurate classifier [18, 19]. Classification rule mining is indispensable to practical applications. Thus, great savings and conveniences to the user could result if the two mining techniques can somehow be integrated. [1]

III. STATISTICAL ANALYSIS AND ASSOCIATION RULES

Statistical analysis involves use of observational data together with domain knowledge to develop a model to study and understand the trend of the data for prediction and decision. The data analysis is used to refine the model or possibly to select a different model, to determine appropriate values for terms in the model, and to use the model to make inferences concerning the process. Many alternative views of the data can be examined. Many different models can be explored. Massive amount of simulated data can be used to study the model/data possibilities. Regression analysis is a statistical tool for the investigation of relationships between variables. Usually, the investigator seeks to ascertain the causal effect of one variable upon another—the effect of a price increase upon demand, for example, or the effect of changes in the money supply upon the inflation rate. To explore such issues, the investigator assembles data on the underlying variables of interest and employs regression to estimate the quantitative effect of the causal variables upon the variable that they influence. The investigator also typically assesses the “statistical significance” of the estimated relationships, that is, the degree of confidence that the true relationship is close to the estimated relationship. Regression analysis with a single explanatory variable is termed as *Simple Regression* and with multiple explanatory is termed as *Multiple Regression*. At the outset of any regression study, one formulates some hypothesis about the relationship between the variables of interest. Multiple regression allows additional factors to enter the analysis separately so that the effect of each can be estimated. It is valuable for quantifying the impact of various simultaneous influences upon a single dependent variable. Further, because of omitted variables bias with simple regression, multiple regression is often essential even when the investigator is only interested in the effects of one of the independent variables. [12]

In general, the association rule is an expression of the form $X \Rightarrow Y$, where X is antecedent and Y is consequent. Association rule shows how many times Y has occurred if X has already occurred depending on the *support* and *confidence* value.

Support: It is the probability of item or item sets in the given transactional data base:

$\text{Support}(X) = n(X)/n$ where n is the total number of transactions in the database and $n(X)$ is the number of transactions that contains the item set X .

Confidence: It is conditional probability, for an association rule $X \Rightarrow Y$ and defined as $\text{Confidence}(X \Rightarrow Y) = \text{support}(X \text{ and } Y) / \text{support}(X)$. All the traditional association rule mining algorithms were developed to find positive associations between items. Positive associations refer to associations between items existing in transactions. In addition to the positive associations, negative associations can provide valuable information. In practical there are many situations where negation of products plays a major role. For example, if I work full time in IITM then I do not work full time in any other institution. If I am a female then I am not a male.

Negative association rule is an implication of the form $X \Rightarrow \neg Y$ where X and Y are item sets and $X \cap Y = \emptyset$.

Mining association rules can be broken down into the following two sub-problems:

1. Generating all item sets that have support greater than, or equal to, the user specified minimal support. That is, generating all large item sets.
2. Generating all the rules that have minimum confidence.

We can generate the association rule with more than one number of consequent items is generated by the following method:

- I. Find the rule in which number of consequents = 1.
- II. For the given rules $p(x \rightarrow y)$ and $p(x \rightarrow z)$, the rule $p(x \rightarrow yz)$ is generated by the intersection of both the association rules and get a new rule $p(x \rightarrow yz) = p(xyz) / p(x)$.

IV. PROPOSED ALGORITHM

In this algorithm, we have tried to remove noise by applying statistical and data mining methods on actual data and cleaned the data after that the classification is done on different methods and best method is identified. The steps are as follows: [5]

1. *Preprocessing the data based on statistical measures.*
 - i. *Identify relevant attributes by applying statistical techniques on actual data with Bank Transactions of customer and in general customer purchase Interest data.*
 - ii. *Applying Association rules to identify rules on actual data with Bank Transactions of customer and in general customer purchase Interest data.*
2. *Cleaning the data*
 - i. *Removing irrelevant data from the actual data set.*
 - ii. *Applying rules to remove noise from attributes.*
3. *Application of Classification algorithm*

Classification methods are applied on cleaned dataset. In our case, we have chosen the following two methods:

 - i. *Decision Table*
 - ii. *Rep Tree*
4. *Application of Classification algorithm on three different test modes.*
 - i. *Complete dataset as a training set*
 - ii. *Cross validation with 10 fold*
 - iii. *Splitting 75% as Training data set, 25% as Test data set*
5. *Determining the best combination.*

This algorithm makes the following contributions:

➤ It proposes a new way to build accurate classifiers.

Our Experimental results show that classifiers built this way are, in general, more accurate than those produced by the state-of-the-art classification system. (Table 1, Table 2, Graph 1 & Graph 2)

➤ It helps to solve the following important problems with the existing classification systems

- Most of the traditional data mining techniques failed because of the sheer size of the data. In our algorithm this problem is solved. In case of complete data set, the number of tuples got reduced from 5821 to 3421 attributes from 43 to 41 after preprocessing & cleaning. Where as in case of selected data set tuples are reduced from 5821 to 1440 and attributes from 26 to 24. (Table 1, Table 2, Graph 1 & Graph 2)

- Most of the algorithms assume the data to be noise-free. As a result, the most time-consuming part of solving problems becomes data preprocessing. Data formatting and experiment/result management are frequently just as time-consuming and frustrating. The concept of noisy data can be understood by the example of mining logs. A real life scenario can be if one wants to mine information from web logs. A user may have gone to a web site by mistake - incorrect URL or incorrect button press. In such a case, this information is useless if we are trying to deduce a sequence in which the user accessed the web pages. The logs may contain many such data items. These data items constitute data noise. A database may constitute upto 30-40% such Noisy data and pre-processing this data may take up more time than the actual algorithm execution time. This problem is handled at the time of preprocessing.

V. EMPIRICAL EVALUATION

We have taken Real Estate data set containing 5821 tuples and 43 attributes. Firstly, we have applied statistical analysis to identify the attributes that are strongly correlated with each other, followed by applicability of Association rules to identify rules on actual data with customer Bank transactions and customer purchase Interest data. Those attributes were removed which doesn't have any relationship. In next step we applied classification algorithm on three test modes in two different environments. In first case, we have taken all the attributes (complete) and compared the patterns, results of both the methods. In second case, the same tests are performed, after discarding demographic details of customers (selected) and then compared the various results. It is found that if we are not considering demographic details of customers, we are getting very accurate results as well as the error rate is decreased. After considering the Bank Transaction details and Customer Purchase Interest, there is a drastic improvement in the results. The following paragraphs discuss the outcomes of various tests.

Comparative Analysis

Table 1 shows the results of Decision table on Actual Real Estate complete dataset and selected data sets (after removing demographic details). Each of the tests is done on three test modes. The results are generated using WEKA 3-6-2, open source software for regression analysis and data mining.

The following are the findings, as per Table 1:

- As per traditional classification, in case of complete dataset, Training test mode takes minimum time, maximum correlation, minimum error rate. In general, if we consider complete data set then training test mode is the best method. It also depicts that the customers who are in the higher income group are willing to invest.
- As per our algorithm, in case of complete dataset, minimum time is taken by splitting test mode(75% training set and 25% test set)and maximum correlation, minimum error rates are generated by training test mode. In this case, customer in higher as well as higher middle income groups are willing to invest.
- As per traditional classification, in case of selected dataset (after removing demographic details), training test mode takes minimum time, maximum correlation, minimum error rates. Here it predicts that the customers who are in higher, middle income group, House owner are willing to invest.
- As per our algorithm, in case of selected dataset(after removing demographic details), minimum time is taken by Cross validation and splitting test mode, maximum correlation, minimum error rates are generated by training test mode. In this case, the customers from higher, middle as well as lower income group with other saving, rented house are willing to invest.

From the above results it is proved that there is a drastic improvement in results after preprocessing and cleaning, the factors which are very crucial in case of Indian context are having impact on the results. It also proves that training set gives the best results. Merit of best set is also improved after preprocessing and cleaning.

Table 2 shows the results of Reptree on Actual Real Estate dataset and selected data sets (after removing demographic details). Each of the tests is done on three test modes.

The following are the findings, as per Table 2:

- As per traditional classification , in case of complete dataset, minimum time is taken by splitting test mode(75% training set and 25% test set), maximum correlation, minimum error rate is taken by Training test mode i.e. in general, if we go for complete data set then training test mode is the best test mode.
- As per our algorithm, in case of complete dataset, minimum time is taken by splitting test mode(75% training set and 25% test set)and maximum correlation, minimum error rates are generated by training test mode.
- As per traditional classification , in case of selected dataset , all the test modes takes same time maximum correlation, minimum error rates are generated by training test mode.
- As per our algorithm, in case of selected dataset (after removing demographic details), minimum time is taken by Cross validation test mode, maximum correlation, minimum error rates are generated by training test mode.

After analyzing results of both classification methods, it is very much clear that after preprocessing and cleaning the results are more efficient and accurate. It is also proved that training test mode is best among other modes because it treats each tuple equally. Decision table method is better than Reptree because it is a simple, less compute intensive algorithm that involves the manipulation of counts associated with each of the table's entries. The attribute space is searched by a best-first search because this strategy is less likely to get stuck in a local maximum. The attribute selection is evaluated using a leave-one-out cross validation.

VI. CONCLUSIONS

This paper discusses about the traditional classification algorithm, its limitations and suggests an efficient algorithm which does preprocessing using statistical techniques and association rules to remove the noise and clean the data. The effectiveness of this algorithm is that it not only considers the customer real estate data but also considers the customer's bank transactions as well as purchasing interest and gives more accurate results. The classification is done using Decision Table and RepTree. After analyzing results from both the classification methods, it is very much clear that our algorithm outperforms traditional classification algorithm. The results are more efficient, accurate and the error rates are reduced drastically. It is also proved that training test mode is best among other modes because it treats each tuple equally. Decision

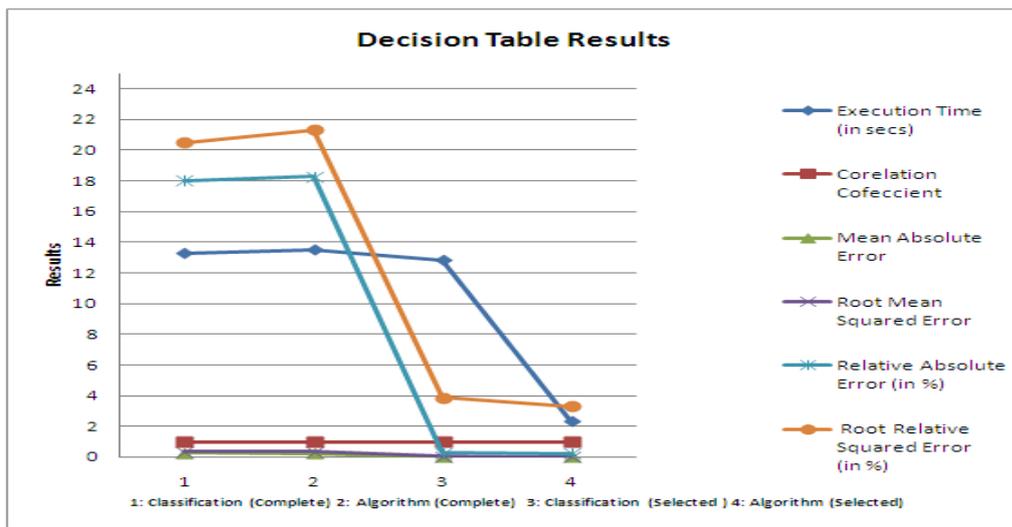

table method is better than Reptree because it is a simple, less compute intensive algorithm that involves the manipulation of counts associated with each of the table's entries. The attribute space is searched by a best-first search because this strategy is less likely to get stuck in a local maximum. The attribute selection is evaluated using a leave-one-out cross validation. It is proved that not only higher income group are willing to invest but also who in middle and higher middle group with other saving/investment with rented house or house owner are also willing to invest if, the bank transaction details and customer purchase interest are taken into account.

Moment Resisting Frame with Rubber Base Isolation for Development of Earthquake Resisting Structures

Evany Nithya S.¹, Dr. Rajesh Prasanna P.²

**(Civil engineering Department, Anna University of Technology, Tiruchirappalli, India)*

*** (Civil engineering Department, Anna University of Technology, Tiruchirappalli, India)*

ABSTRACT: Structural analysis for a base isolated four storied moment resisting frame with elastomeric seismic isolation bearing has been studied using SAP2000 software. Dynamic analysis was performed for the moment resisting frame with base isolation and the results were compared with the results obtained for moment resisting frame without base isolation. The isolating elastomer is a rubber and its total stiffness is calculated to be 3169 kN/m. The spectral displacement for the first mode suffered by the isolated building was calculated using the response spectrum curve, and found to be 0.121 m/sec². The thickness of required rubber material is calculated to be 0.121 m, assuming 100% maximum shear strain. The analysis showed that the displacement in the frame has decreased when the base isolator is added. This means that the force transferred to the building is reduced due to the presence of base isolator. The frame with base isolator produced a shear of 71.79kN – a significant shear reduction of around 88%. Thus, using rubber elastomer for base isolation, it is possible to avoid large plastic deformation of moment resisting frame and reduce shear resulting from large scale earthquake.

Keywords: Seismic Analysis, Seismic Base Shear, Base Isolation.

I. INTRODUCTION

Our intuition tells us “strengthen to resist damage”. But it is an illusion because when the foundation is rigidly fixed to the superstructure, the earthquake force will be directly transferred to the superstructure without any change in frequency resulting in heavy damage. In a base isolated structure the seismic protection is achieved by shifting its natural period away from the range of the frequencies for which the maximum amplification effect of ground motion is expected. In this way the input seismic energy introduction in to the structure is significantly reduced and consequently it is possible to avoid large plastic deformation and related damage phenomena due to non-linear response. In the base isolation strategy, at the same time it is possible to obtain a considerable reduction of large displacements attained at the base level as a consequence of the energy dissipation due to damping and hysteretic properties of isolation device. In simple words the basic concept in this approach is to uncouple a structure from the ground by interposing a flexible element/bearing between the structure and foundation. Many buildings have been constructed on some type of rubber bearings, and such structures have shown superior performance in earthquakes.

The system that has been adopted most widely in recent years is typified by the use of elastomeric bearings, the elastomer is made of either natural rubber or neoprene. In this approach, the building or structure is decoupled from the horizontal components of the earthquake ground motion by interposing a layer with low horizontal stiffness between the structure and the foundation. This layer gives the structure a fundamental frequency that is much lower than its fixed-base frequency and also much lower than the predominant frequencies of the ground motion. The first dynamic mode of the isolated structure involves deformation only in the isolation system, the structure above being to all intents and purposes rigid. The isolation system does not absorb the earthquake energy, but rather deflects it through the dynamics of the system.

II. DESIGN

The inclusion of base isolation means that a building is cushioned against the shocks of earthquakes. Instead of designing the building to resist high earthquake forces, the isolation system is designed to allow the building to stay more or less still while the ground moves underneath it in strong earthquakes. As a result the building need only be designed for much smaller forces. A seismic base isolator is a flexible support of a building, which should fulfill the following requirement:

- The material is stiff under low service loads like wind and small tremors.
- Period of vibration of the system is increased sufficiently so as to reduce the seismic force response.
- It should have the ability to with stand the large displacement and pulse-type base motions from near-fault earthquakes.
- It should have a parallel damping mechanism such that the relative deflection between the building and the ground is reduced.

To start with we have to calculate the load coming on the column. In this paper we have design the base isolation for the four storied moment resisting frame, when it is located in zone V. The frame taken for study was moment resisting frame with shear wall. Moment frames consist of beams and columns in which bending of these members provides the resistance to lateral forces. Moment-resisting frames are detailed to ensure ductile behavior of the beam-to-column joints and are normally used in zones of higher seismicity. It has 4 bay at a spacing of 5m in the X direction and 3 bay in the direction of Z at a spacing of 6m, 4.5m, 4.5, respectively. It has ground plus three stories. The height of the ground

floor is 4.5m and the heights of the rest of the three floors are 3.2m each as shown in Figure 1.

III. ELASTOMERIC RUBBER BEARING

III. I Calculation of horizontal stiffness of the rubber:

The total horizontal stiffness of the rubber isolators is computed using single degree of freedom system equation, Horizontal stiffness (K) was calculated using the below equation

$$K = 4 * \Pi * f^2 * \left[\frac{W}{g} \right]$$

From the above equation the total horizontal stiffness is calculated as 3169.01 kN/m

III. II Calculation of the thickness of the rubber:

The spectral displacement for the first mode suffered by the isolated building is calculated using the response spectrum curve for the given horizontal frequency and for the appropriate damping value and using the following expression.

Spectral displacement: S_d =Spectral displacement, S_a

$$S_d = \frac{S_a}{(2 * \Pi * f_n)^2}$$

S_a =displacement from response spectrum curve, f_n =horizontal frequency.

The Spectral displacement was found to be 0.121 m / sec². The thickness of the rubber material of the isolator is evaluated using the allowable maximum shear strain permitted for the isolator. The allowable maximum shear strain for the isolator is taken as 100%.

Thickness of rubber = S_d / γ , Where, γ =Allowable maximum shear strain. Thickness of rubber was calculated to be 0.121 m. Once the thickness and shear modulus of the rubber are know, the area of the rubber

$$K_i = \frac{G * A}{t_r}$$

material to produce the given amount of horizontal stiffness is calculated using the following expression.

Where K_i = Horizontal stiffness, G =Shear modulus of the rubber, A =Area of the rubber, t_r =Thickness of the rubber. From the above formula the area is calculated to be 0.0247 m².

From the area calculated above the diameter (180 mm) of the rubber is calculated. Thickness of individual layer of rubber are calculated as below,

$$S = D / 4 * t , \quad t = 5\text{mm.}$$

Total number of layers = total thickness / individual layer thickness = 25 numbers

The shim thickness is generally taken to be not less than 2.54mm and not greater than 3.16mm. Therefore, thickness of the shim =3mm.The end plates are usually between 19.1mm and 38.1 mm. Therefore, thickness of end plate =25mm.

IV. DISCUSSION

Dynamic analysis is performed for the moment resisting frame selected with the base isolation. The response of the structure when base isolation is added to the structure is compared with the response of the structure without base isolation. The analysis of the structure with base isolation is performed with the use of SAP2000 package. The results are compared as follows.

➤ Comparing the displacements:

The fig 3 and 4 clearly shows that there is a change in the displacement of the frame. The displacement in the frame has decreased when the base isolator is added. This decrease in the displacement show that the force transferred to the building is reduced due to the presence of base isolator. When this happens then there will be a reduction in the requirement of reinforcement in beams and columns. In this way the input seismic energy introduced in to the structure is significantly reduced and consequently it is possible to avoid large plastic deformation and will reduce the reinforcement requirement and prove to be economical and safe.

➤ Comparing the base shear:

Base shear can be put in simple words as the horizontal component of the seismic shaking. The horizontal components of shaking are the most damaging to buildings because structures are already designed to withstand the vertical force of gravity. From the analysis performed for the frame with base isolator and without base isolator in SAP2000 the base shear results are taken. The frame with fixed base has a base shear of 618kN. The frame with base isolation has a base shear of 71.79kN. There is a decrease of 88.38% in the base shear when the structure with base isolator is compared with the structure without base isolator.

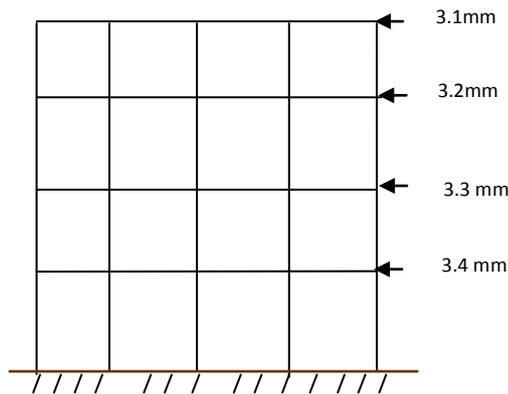

Fig. 3 Displacement of the frame with base isolation

V. CONCLUSION

Engineers realized the importance of keeping the superstructure stable while the foundation is being shaken by an earthquake. So there arises a need to design a system that puts this concept into practice. Along with many other engineers doing independent work in other countries, have produced a wealth of information about base isolators and have become common knowledge to structural engineers. By introducing base isolators the maximum expected lateral force that will occur due to seismic ground motion at the base of a structure is considerably reduced. This concept has created a breakthrough in structural design and as years go by will prove to be a life-saving innovation of historic proportions.

Nigeria's Wind Energy Potentials: the Path to a Diversified Electricity Generation-Mix

Idris N.A.¹, Lamin, H.S.², Ladan, M.J.³ and Yusuf, B.H.⁴
Energy Commission of Nigeria

ABSTRACT: For many decades, conventional energy resources have continually remained major energy sources in Nigeria. This paper therefore looks at the enormous wind energy potentials in Nigeria. Available data on wind speed for some towns in Nigeria indicates very good prospects for wind energy development. This paper advocates the inclusion of wind energy in the nation's energy supply mix. This would diversify and reverse the current acute electricity deficit experienced in the country, as well as address environmental concerns and effect of climate change.

Keywords: Electricity, Energy, Nigeria, Potentials, Wind,

I. INTRODUCTION

Nigeria is a well endowed country with abundant wind energy resources which can be used to generate electricity. However, despite the abundance of these energy resources, there is persistent electricity supply deficit, which may be attributed to under utilization of these potentials. Other major barriers to the deployment of wind energy technology in the country include high initial cost of wind power generation, systemic issues governing reliable transmission and system integration, social acceptance of technology and energy market structure. The non-proper coordination of activities in the energy sector largely because of lack of concrete policy and energy plan is also worth mentioning.

Wind energy has been widely used in Nigeria to power water supply for many decades now. In recent times efforts are largely geared towards its use for electricity generation, for example, the Federal Government of Nigeria is currently constructing 10 MW Wind Farm at Katsina and work has reached advanced stage of completion, although there are some issues with grid integration. In Nigeria, typical wind pattern occurs mostly from the east for inland areas and from the west over the coastal areas. During the harmattan period (December – March) strong winds appear covering the country especially in the northern parts where the main wind direction shifts to west / south western directions. A study on the wind energy potentials for a number of Nigerian cities shows high wind speeds in the Sokoto region, Jos, Gembu and Kano / Funtua. The stations at Maiduguri, Lagos and Enugu also indicated relatively strong wind speeds, sufficient for energy generation by wind farms. Apart from these sites, other promising regions with usable wind potentials are located at the Nigeria's shoreline [1].

The proper utilization of these wind energy potentials will ensure promotion of socio-economic development as well as quality of life of the citizenry. Expanding the use of renewable resources such as wind will reduce carbon dioxide emissions which contribute to global warming and

lower long-term overdependence on fossil fuels. Further, wind energy like other power technologies based on renewable energy resources is fast evolving globally and widely available, thereby ensuring security of supply. Prior to construction of any wind farm, a detailed verification of the specific on-site wind conditions is necessary to come up with a suitable wind map in order to identify those areas which have favorable wind regimes and can therefore be selected for the development of wind energy projects.

This paper therefore attempts to give an overview of the nation's wind energy potentials, enumerating the numerous challenges hindering its development and identify some measures that will possibly lead to inclusion of wind in the energy supply mix to satisfy our growing energy demand, diversify our supply sources to guarantee energy security and align with the new global trend of green energy growth.

II. GLOBAL TRENDS IN WIND ENERGY DEVELOPMENT

Today wind energy is one of the fastest developing renewable energy technologies in the world and mainly onshore. Wind is among the cheapest renewable sources per unit of electricity produced. Analysis indicates that a network of land-based 2.5MW wind turbines could supply over 40 times current worldwide electricity consumption [2].

Wind energy generation market is continuously growing worldwide. In 2009, 82 countries used wind to generate energy, and 49 countries increased their installed capacity [3]. Middle East and Africa also recorded a total of 230MW of newly installed capacity with almost 90% growth rate in Morocco and 170% growth in Tunisia. Although these values are small compared with wind energy producing regions like North America, Europe and Asia, the presence of wind energy in remote locations of the world simply highlights the continued rapid growth in global demand for emissions-free wind power, which can be installed virtually everywhere around the globe.

Wind energy had over 238GW of installed capacity at the end of 2011[4] and is expected to play a crucial role in mitigating future greenhouse gas emissions. The Global Wind Energy Council forecasted that global wind market will grow by over 155% to reach 240GW of total installed capacity by the end of 2012. According to recent projections, wind energy is expected to contribute some 12% of global electricity by 2050, with 57% of this energy produced by non – OECD economies. However, USD3.2 trillion will have to be invested over the next 40 years to realize this improvement [5].

Currently, Europe is the leading market for global wind power, and will probably remain so for the next decade. It

is followed by the United States and then China as world leading wind power producers. China will probably overtake the United States and OECD Pacific countries as a major producer of wind energy by 2050, with projected figure of 1660 TWh. The rest of the world, including Africa and the Middle East, provide nearly one-fifth of wind electricity in 2050 [5].

III. NIGERIA'S WIND ENERGY POTENTIALS

Wind speed in Nigeria ranges from 1.4 - 3.0m/s in the southern areas and 4.0 - 5.12m/s in the extreme north. Wind speeds are generally weak in the southern part of the country except for the coastal regions and offshore location. Initial study has shown that total exploitable wind energy reserve at 10m height may vary from 8MWh/yr in Yola to 51MWh/yr in the mountainous areas of Jos Plateau and it is as high as 97MWh/yr in Sokoto [6].

Lahmeyer International's report [1] gives potential estimates for ten (10) selected sites in the country to be between 3.6 m/s to 5.4 m/s. These results when compared with the figures obtained from calculated wind speed using Climatic Model Mainz (KLIMM) gives difference of -4.3% to 4.1% which is within the acceptable limit of error. Table 1 presents the results for these ten (10) selected sites.

Table 1: Summary of measured data of annual Wind Speeds (Ten selected sites)

Site	Land-use Type	Altitude (m a.s.l.)	Height (m)	WIND SPEED (m/s)		Difference (%)

Source: Wind energy Potential in Nigeria: (Agbetuyi et al, 2012)

IV. JUSTIFICATION FOR DEPLOYMENT

An analysis of the power generation capacity required to support the NV20:2020 economic vision shows that, Nigeria will need to generate electricity in the range of about 35,000 – 40,000MW by year 2020. To achieve this, there is need to aggressively pursue the harnessing of the nation’s wind and other renewable energy resources.

Thus, Sambo (2012) [9], gives some of Nigeria’s renewable energy resources as 14,750MW of hydro power potentials, 3.5 - 7.0 kWh/m²/day of solar radiation (485.1 million MWh/day using 0.1% Nigeria land area), (2-4) m/s at 10m height of wind speed, 72 million hectares of arable land for energy crops and agricultural production. Other conventional energy resources include 180.57 trillion SCF of natural gas, 2.734 billion tonnes of coal and lignite, 37.2 billion barrels of light crude oil, and yet to be quantified nuclear element. Despite all these renewable and non-renewable resources, Nigeria is generating electricity from only two sources (gas and hydro), which are both poorly harnessed and mismanaged.

As at 2009, the country’s total generation capacity was 8,876MW but only 3,653MW was available, which is less than 41% of the total installed capacity [10]. It is instructive for Nigeria to learn from experiences of other countries and diversify its energy supply mix to achieve energy security. Harnessing wind power offers environmental advantages in terms of reducing carbon dioxide emissions and other pollutants such as oxides of Sulphur and Nitrogen mostly

associated with burning of fossil fuels, thereby addressing global warming concerns.

V. WIND FOR ELECTRICITY GENERATION

For effective performance and maximum yield of wind power systems, project planning and siting as well as reliable prediction in terms of wind resource is a pre-requisite. Electricity is generated from wind through the use of wind turbines also known as wind energy converters (WEC). The main components of a WEC include rotor blade, generator, pitch, wind measurement system, brake, gear box, rotor hub, yaw mechanism, nacelle, transformer and tower.

The wind turbines convert the kinetic energy of wind into mechanical energy and then to electrical through the generator. The generator may be of fixed or variable speed. Due to changing wind speed and direction, the yaw mechanism is used to turn the blades of the wind turbines in line with wind direction to increase its output. The collection of wind turbines for purpose of electricity generation is called a wind farm and its planning involves series of processes.

Upon identification of the proposed site, wind data are collected for a period of at least 12 months on-site to ascertain general wind pattern for the whole year. Then, the data obtained is evaluated and analyzed with different wind turbines to determine the best for the site. The blade diameter, tower height and rated power all depends on wind data characteristics.

Other factors that need to be considered include accessibility and distance of the proposed site to the grid. Wind farm requires a considerable size of land area for its construction. In order to ensure efficiency, higher output and avoid wind theft, a minimum distance of 3D (3 times diameter of blade) between turbines and 5D to 7D in main wind direction is recommended [11].

Wind turbines are manufactured based on specification and are usually not off-shelf. Delivery may take up to a year and thus, setting up a wind farm from the scratch takes a period of at least 2 ½ years. WEC have maximum theoretical efficiency of 60% but only about 45% in practice.

Wind farms can be onshore or offshore. The offshore wind turbines need to have solid foundations and protection from corrosion. Hence, they are more expensive than onshore farms. The upside of offshore farms is the increase in yield. Load factor of onshore wind farms is usually 20-30% while that of offshore wind farms is 30-43% [5]. After about 20 years of operation wind turbines have to be decommissioned. Re-powering with a larger more efficient turbine is an economical choice.

VI. TARGET MARKETS AND COST ISSUES

Electricity from wind can be grid connected or off-grid with the latter being the most popular. Wind power is ideal for generating electricity at remote locations. Hence, clusters can be created with turbines generating electricity for remote villages or collection of thousands of households. With the low load factor of wind power plant, it can be used to boost the nation’s electricity by targeting intermediate to peak load demand taking its advantage of quick start and stop.

The cost of setting up wind farms is very high. Electricity transmission infrastructure typically accounts for around 10 – 20% of the capital costs of constructing an offshore wind farm. Wind turbines are subject to economies of scale. For example, a building-mounted turbine with 2.5kW capacity generation would cost around £10,000 and may not payback in the equipment lifetime. Whereas a large scale turbine (1MW – 2.5MW) would cost £2 – £3.3 million and the payback period could range from five years to less than one year respectively. Hence, large capacity wind farms are more economical.

The average cost of generating electricity from large scale onshore wind is now around 3 - 4 pence per kilowatt hour, competitive with new coal (2.5 – 4.5 pence) and cheaper than new nuclear (4 – 7 pence). As gas prices increase and wind turbine costs fall further as the market grows, wind energy is also likely to become competitive with gas fired power generation [12].

VII. CHALLENGES OF DEPLOYMENT

There are a series of challenges affecting wind energy deployment in the country. These include lack of financing and other fiscal incentives, lack of skilled manpower and lack of indigenous manufacturing capabilities. Others include, lack of policy and institutional framework to encourage investment and deployment of wind energy technology. Low load factor of wind farms makes it unsuitable for base load power plants.

VIII. CONCLUSION

The use of wind power to generate and supply electricity will expand Nigeria's energy base and reduced environmental pollution. Hence, sites identified with superb wind energy potentials should be adequately harnessed. Effort should be made to address issues of integration to the national grid.

All necessary policies and institutional framework should be put in place to eliminate barriers to deployment of wind energy technology in the country.

Electric Field Dependent Specific Heat of SrTiO₃, BaTiO₃ and KTaO₃ Ferroelectric Perovskites

Gaurav Kumar Aggarwal¹, Ashok Kumar², UC Naithani³

^{1, 2, 3}Department of Physics, H.N.B. Garhwal Central University, Pauri Campus,
Pauri (Garhwal), Uttarakhand., Pin – 246001, India.

Abstract: The field dependent specific heat of anharmonic ABO₃ type displacive ferroelectrics (SrTiO₃, BaTiO₃ & KTaO₃) is studied using double time Green's function technique along with Silverman-Joseph modified Hamiltonian which includes anharmonicity up to the fourth order due to the interaction of the soft mode. The soft mode contributions to specific heat are described by appropriate Einstein terms. The variation of specific heat with temperature and electric field is discussed. The specific heat in all three crystals increases non-linearly with temperature. The specific heat decreases with increase in external electric field. The effect of electric field on specific heat is more prominent in low temperature sides in all three crystals. The effect of temperature reduces in low field region and the change in specific heat arises mainly due to higher order anharmonic terms. The results are in agreement with previous experimental and theoretical results.

Keywords: anharmonicity, Cochran mode, Green's function, soft mode, Specific heat.

I. Introduction

Ferroelectricity is one of the most fascinating properties of dielectric solids. Ferroelectrics are the crystals that show spontaneous polarization which is reversible by stress or electric field. This phase transition is exhibited within the limited temperature range, called the Curie temperature T_c and is associated with a change in crystal structures and the anomalous behavior of some physical properties. All these materials are piezoelectric and have high electromechanical coupling coefficients. The ferroelectric materials have been grouped together because they have some common characteristics. There are more than a thousand ferroelectric compounds. The most commonly studied are the perovskites and the alkali dihydrogen phosphates. The perovskites have ABO₃ type structure, where A is a first, second, fourth or even fifth group ion of appropriate valency and B is a transitional metal ion such as Ti, Nb, Ta, Zr etc. For example NaTaO₃, KNbO₃, BaTiO₃, PbTiO₃, SrTiO₃, BiFeO₃ and KTaO₃ etc. are all ferroelectric perovskites.

Ferroelectrics have become a subject of considerable interest in the past few years, because of their wide potential applications in different fields. Their properties reveal many interesting applications in the ceramic industry, optoelectric devices for use in optical communication, memory display, coherent optical processing, modulators, beam reflectors, light valves and holographic storage media etc. As compared with similar magnetic devices, ferroelectric memory devices are very small in size and mass, consume less power and are not sensitive to external magnetic fields. Memory devices are constructed from ferroelectrics distinguished by a rectangular cycle of electric hysteresis, a short time needed for switching over (i.e. the time for changing the direction of spontaneous polarization).

It is now well known that several interesting temperature dependent properties of ferroelectric result from the temperature dependence of the low lying transverse optic mode of vibration [1]. One of the very interesting properties of these crystals is the electric field and temperature dependences of the low frequency transverse optic (TO) mode. The effect of electric field on the Cochran modes in SrTiO₃ and KTaO₃ was studied by Steigmeir [2], showing an upward shift in the TO-mode frequency which reduces the TO-LA interaction. All these studies reveal a remarkable effect of electric field on ferroelectric soft mode frequency. So the dynamic properties of ferroelectrics will be affected in the presence of electric field [3, 4] because of the effect of electric field on soft ferroelectric mode.

Low temperature specific heat of ferroelectric, superconducting and amorphous materials has been studied by several researchers [5,6]. These studies show that ferroelectric materials with field dependent low-lying modes will have associated field dependent specific heats at low temperatures [7]. The specific heat of all the three crystals (SrTiO₃, BaTiO₃ and KTaO₃) decreases with increase in applied electric field and this decrease is due to the hardening and splitting of the soft TO-mode frequency. There is also some published work on the specific heat of pure and mixed ferroelectric crystals [8-13]. A current review for perovskites type ferroelectric crystals is available in the literature [14-17].

The aim of the present work is to study theoretically the variation of specific heat with temperature and electric field both qualitatively and quantitatively using the method of double time temperature dependent Green's function in anharmonic ferroelectric crystals such as SrTiO₃, BaTiO₃ and KTaO₃ using a model Hamiltonian for ferroelectric crystal, augmented with anharmonicity up to fourth order. The expression for the specific heats of displacive type ferroelectric materials such as SrTiO₃, BaTiO₃ and KTaO₃ in paraelectric phase in presence of external electric field is obtained. We used double time Green's function technique to obtain thermally averaged correlation function and hence, the observable quantities with the help of Silverman-Joseph modified Hamiltonian which includes anharmonicity up to fourth order. The contribution of soft modes towards specific

heat has been taken into account. As in general, it is agreed that low temperature specific heat data can reveal the position(s) of low-lying vibrational levels in soft mode dielectric materials. The contributions from these levels are so large that specific heat data estimated from the acoustic spectrum (e.g. elastic constants) can be in error by as much as in order of magnitude. Also the soft mode contribution to the specific heat is described by appropriate Einstein terms. We make use of a unitary transformation which renders the most significant first order dipole-moment term to affect the specific heat via the applied electric field. The effect of an external electric field on the specific heat and soft mode frequency has been discussed in paraelectric phase for SrTiO₃, BaTiO₃ and KTaO₃ crystals. The properties of ferroelectric crystals are investigated both theoretically and experimentally by many workers. Calculated results have been compared with the results of other workers.

II. Theory

2.1 Green's function and the soft mode frequency

For the study of specific heat, we have used Silverman-Joseph modified Hamiltonian which includes anharmonicity up to fourth order in the potential energy similar to our previous study for zero defect case [4]. The interaction of the soft mode coordinates, resonant interactions, scattering and electric dipole moment terms are considered in the Hamiltonian.

To evaluate the expressions for various dynamic properties in presence of the electric field, we introduce the retarded double-time thermal Green's function for the optical phonon as:

$$G_0^0(t-t') = \ll A_0^0(t); A_0^0(t') \gg = -i\theta(t-t') \langle A_0^0(t); A_0^0(t') \rangle \quad \dots (1)$$

Where $\theta(t-t')$ is the usual Heaviside step function and the symbol $\langle \rangle$ denotes the statistical average. $A_0^0(t)$ and $A_0^0(t')$ are the annihilation and creation operators of the acoustic phonon of the wave vector k . While writing the equation of motion for the Green's function Eq. (1) with the help of the modified Hamiltonian, Fourier transforming and writing it in the Dyson's equation form, one obtains:

$$G_0^0(\omega + i\epsilon, E) = \frac{\omega_0^0}{\pi} [\omega^2 - \tilde{\nu}_0^0(\omega) - 2\omega_0^0 i \Gamma^0(\omega, E)] \quad \dots (2)$$

Where $\tilde{\nu}_0^{02} = \omega_0^{02} + 2\omega_0^0 \Delta^0(\omega, E)$... (3)

Here $\omega_0^{02} = \tilde{\omega}_0^{02} + \langle [F(t); A_0^0(t')] \rangle$... (4)

And $\tilde{\omega}_0^{02} = \omega_0^0 [\omega_0^0 + 2V + 12\Gamma'_1 gE + 24\Gamma'_2 g^2 E^2]$... (5)

Where the notations used are exactly similar and in the same sense as used in our previous calculations [12].

In Eqs (3) and (4), $\Delta^0(\omega, E)$ and $\Gamma^0(\omega, E)$ are the field dependent shift and width for the soft mode respectively, and are given by:

$$\begin{aligned} \Delta^0(\omega, E) = & 18\Gamma_1^2 N \left[\frac{2\Omega}{\{\omega^2 - (2\Omega)^2\}} \right] + 4\Gamma_2^2 (1 + N^2) \left[(1 + N^2) \frac{3\Omega}{\{\omega^2 - (3\Omega)^2\}} - (1 - N^2) \frac{\Omega}{\omega^2 - \Omega^2} \right] + \\ & 16 \sum |H|^2 \cdot \left[\frac{(N_k^a \pm N_k^0)(\Omega_k^a \pm \Omega_k^0)}{\omega^2 - (\Omega_k^a \pm \Omega_k^0)^2} \right] + \left[288\Gamma'_2 g^2 E^2 + 8NE^2 \times \sum |B^\lambda(k)|^2 \cdot \frac{2\Omega}{\{\omega^2 - (2\Omega)^2\}} \right] + \\ & \left[(-4|A|^2 \sum |F|^2 + 64g^2 E^2 \sum |H|^2) \frac{N\omega}{\omega^2 - \Omega^2} \right] \quad \dots (6) \end{aligned}$$

And $\Delta^0(T, E) = AT + BT^2 + CTE^2$... (7)

$$\begin{aligned} \Gamma^0(\omega, E) = & 9\pi\Gamma_1^2 N \{ \delta(\omega - 2\Omega) - \delta(\omega + 2\Omega) \} + 2\pi\Gamma_2^2 \{ (1 + 3N^2) \{ \delta(\omega - 3\Omega) + \delta(\omega + 3\Omega) \} - (1 - N^2) \{ \delta(\omega - \Omega) - \\ & \delta(\omega + \Omega) + 8\pi |H|^2 \times (Nk^a \pm Nk^0) \delta\omega - \Omega k^a - \Omega k^0 + \delta\omega + \Omega k^a + \Omega k^0 + \pi 144\Gamma'_2 g^2 E^2 + 4E^2 \times B\lambda k 2N \cdot \delta\omega - 2\Omega - \delta\omega + 2\Omega + \pi \{ [-2A2 \\ & |F|^2 + 64g^2 E^2 |H|^2] N \cdot \delta\omega - \Omega - \delta\omega + \Omega \} \} \quad \dots (8) \end{aligned}$$

And $\Gamma^0(T, E) = AT + BT^2 + CTE^2$... (9)

Where the notations used are exactly similar and in the same sense as used in our previous calculations [12].

Eqs. (7) and (9) show the temperature and field dependence of shift and width, respectively of optic phonons in frequency response.

The soft mode frequency for optic mode [Eqs (3-5)] may be written as:

$$\begin{aligned} \check{\omega}_0^{02} = & \omega_0^0 [\omega_0^0 + 2V + 12\Gamma_1' gE + 24\Gamma_2' g^2 E^2] + \langle [F(t); A_0^0(t')] \rangle > \\ & + \omega_0^0 [36\Gamma_1'^2 N \left[\frac{2\Omega}{\{\omega^2 - (2\Omega)^2\}} \right] + 8\Gamma_2'^2 \left[(1 + N^2) \frac{3\Omega}{\{\omega^2 - (3\Omega)^2\}} - (1 - N^2) \frac{\Omega}{\omega^2 - \Omega^2} \right] + 32 \sum |H|^2 \cdot \left[\frac{(N_k^0 \pm N_k^0)(\Omega_k^0 \pm \Omega_k^0)}{\omega^2 - (\Omega_k^0 \pm \Omega_k^0)^2} \right] + [576\Gamma_2' g^2 E^2 + \\ & 16NE^2 \times B\lambda k 2.2\Omega\omega^2 - 2\Omega^2 + (-8A2 |F|/2 + 128g^2 E^2 |H|/2) N\omega\omega^2 - \Omega^2 \end{aligned}$$

$$\text{Or } \check{\omega}_0^{02} = \omega_0^{02} + 2\omega_0^0 V + \gamma_1 + \gamma_2 T + \gamma_3 T^2 + \gamma_4 E + \gamma_5 E^2 \quad \dots (10)$$

Where γ_2 and γ_3 are the coefficients of T and T^2 , respectively and γ_4 and γ_5 are the coefficients of E and E^2 respectively. The square of the soft mode frequency varies as the square of the applied electric field which is in agreement with the experimental result [18]. The effect of the electric field on this mode also affects the interaction of soft mode with other modes, thus giving rise to electric field dependence of various dynamical properties.

2.2 General formulation for specific heat at constant volume (C_V)

The specific heat at constant volume (C_V) for the model of the pure crystals considered here can be obtained as follows:

$$C_V = K_B \sum_k E(Y_k) \quad \dots (11)$$

Here K_B is a Boltzmann constant and Y_k is defined as

$$Y_k = \hbar \Omega_k / (K_B T) \quad \dots (12)$$

Where Ω is the field dependent soft mode frequency of ferroelectric perovskites and $E(Y)$ is the Einstein function given by:

$$E(Y) = Y^2 \exp Y / (\exp Y - 1)^2 \quad \dots (13)$$

Substituting the value of the Einstein function $E(Y)$ for soft phonon mode ($k=0$) in Eq. (1) gives the specific heat at constant volume as

$$C_V = K_B Y^2 \exp Y / (\exp Y - 1)^2 \quad \dots (14)$$

Now substituting the value of Y (Y_k for $k=0$) from Eq. (2) into Eq. (4) it gives

$$C_V = K_B (\hbar \Omega / K_B T)^2 \exp(\hbar \Omega / K_B T) / [\exp(\hbar \Omega / K_B T) - 1]^2 \quad \dots (15)$$

For quantitative purposes, the authors consider that the Curie temperature changes with the electric field as suggested by Walter J. Merz [19], which is given by:

$$T'_c = T_c + \Delta T \text{ with } \Delta T = 1.9 \times 10^{-3} \times E$$

Where E is applied electric field in V/cm.

If the temperature is not too high, the temperature dependence of the soft mode frequency is given by:

$$\Omega_{k,T} \approx \{k(T - T_c)\}^{1/2} \quad \dots (16)$$

$$\Omega \approx \Omega_{k,E,T} \approx \Omega_{k,T} (E^2 + 1)^{1/2} (T - T'_c)^{1/2} / (T - T_c)^{1/2} \quad \dots (17)$$

Where T'_c is the changed Curie temperature in presence of electric field.

Thus the study of variation of soft mode frequency with temperature and applied electric field is necessary to study the variation of specific heat with temperature and applied electric field.

III. Results

Using Eqs (16) and (17), the soft mode frequency for all three crystals has been calculated for different temperatures in presence of external electric field. The variation of soft mode frequency with electric field at different temperatures for SrTiO₃, BaTiO₃, and KTaO₃ crystals is shown in Figs (1, 2 and 3) respectively. Soft mode frequency increases with increasing electric field and temperature. These results are in good agreement with the results of other researchers [8, 19, 20].

Specific heat at constant volume C_V of SrTiO₃, BaTiO₃ and KTaO₃ pure crystals has been calculated using Eq. (15) for different values of temperatures in presence of different electric fields. Curves of C_V against electric field for SrTiO₃, BaTiO₃ and KTaO₃ crystals at different temperatures are plotted in Figs (4, 5 and 6) respectively. It is observed from Figs (4, 5 and 6) that the specific heat increases with increase in temperature for all three crystals and for a constant temperature, the specific heat decreases with the increase in applied electric field for all three crystals.

IV. Discussion & Conclusions

Green's function technique and Dyson's equation treatment have been used to obtain an expression for the specific heat of SrTiO₃, BaTiO₃ and KTaO₃ perovskites in presence of an external electric field by using a model Hamiltonian in presence of higher order anharmonic and electric moment terms. The anharmonic coefficients and higher order electric moment terms give their contribution to various scattering processes.

It is observed from Eq (10) that the field dependence of specific heat is a clear consequence of the field dependence of the soft mode frequency. So in order to discuss the field dependence of specific heat of ferroelectric perovskite crystals, we shall first discuss the electric field dependence of the soft mode frequency. The soft modes, due to their large occupation number, should cause an appreciable scattering of other modes. It is the temperature-dependent soft mode and the process involving it, that give rise to effects peculiar to a ferroelectric material. The influence of electric field on this mode also affects the interaction

of soft modes with other modes, thus giving electric field dependence of various dynamic properties. The soft modes contribution to these properties is particularly important in the vicinity of T_C and is expected to give an anomalous behaviour. From eq. (10) it is clear that the soft mode frequency increases with the increase in applied electric field in conformity with the experimental results [18, 21]. Hence, this frequency is stabilized in the presence of electric field and anharmonicities. It is clear from Eqs (10), (11) and (12) that the presence of an applied electric field will increase the soft mode frequency and hence, will decrease the specific heat in conformity with the experimental results of Lawless [8]. Lawless [8] has described the field dependence of the soft mode using Lyddane-Sachs-Teller-Devonshire formalism [21], while we have described this electric field dependence by making use of a Hamiltonian proposed by Silverman and Joseph [22] and powerful thermal Green's function technique [12]. Also, the soft mode contribution to the specific heat is described by appropriate Einstein terms.

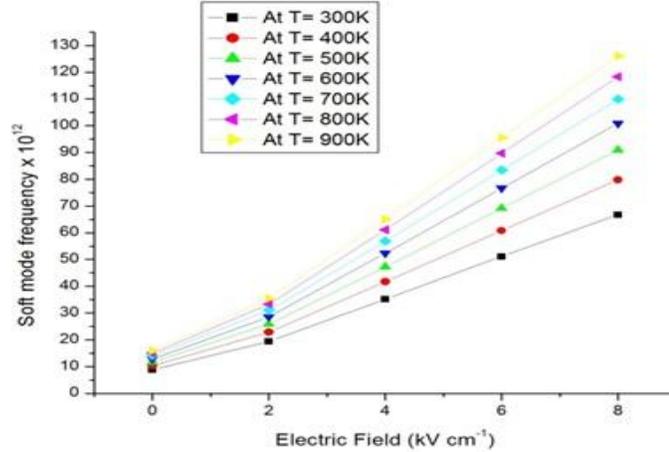

Fig. 1- Variation of soft mode frequency with electric field at different temperatures for SrTiO₃ crystal

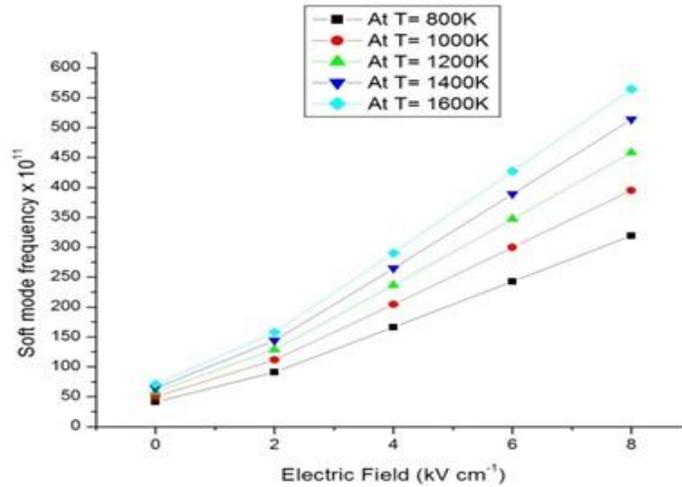

Fig. 2- Variation of soft mode frequency with electric field at different temperatures for BaTiO₃ crystal

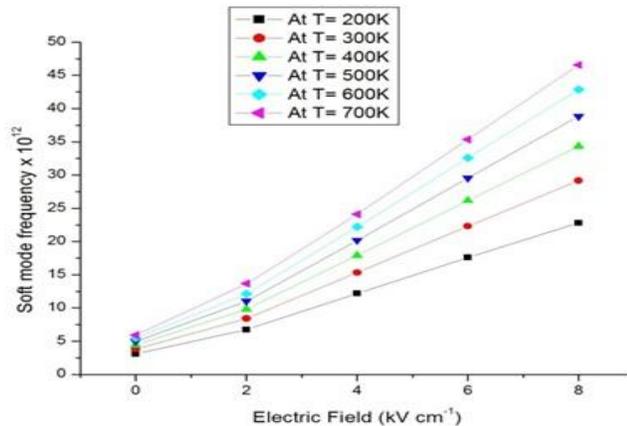

Fig. 3- Variation of soft mode frequency with electric field at different temperatures for KTaO₃ crystal

Figures (1, 2 and 3) show the variation of soft mode frequency with electric field at different temperatures for SrTiO₃, BaTiO₃ and KTaO₃ crystals respectively. The soft mode frequency increases with an increase in electric field. Taking any electric field as reference, the soft mode frequency increases with an increase in temperature. At low field's region, the temperature's effect is negligible for all the three crystals Fig. (1, 2 and 3).

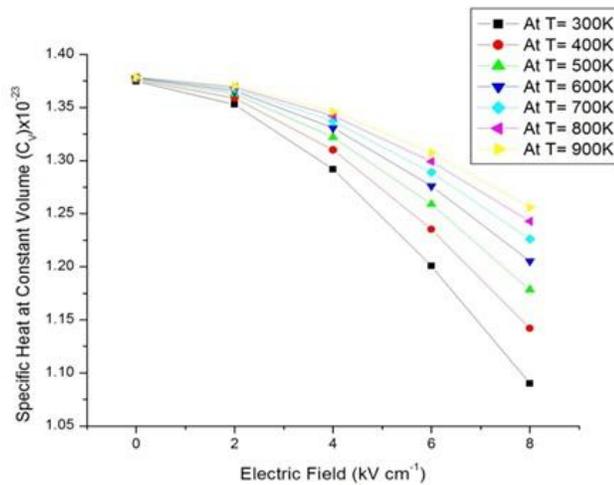

Fig. 4 – Specific heat at constant volume C_V versus electric field (in kV/cm) for SrTiO₃ at different temperatures

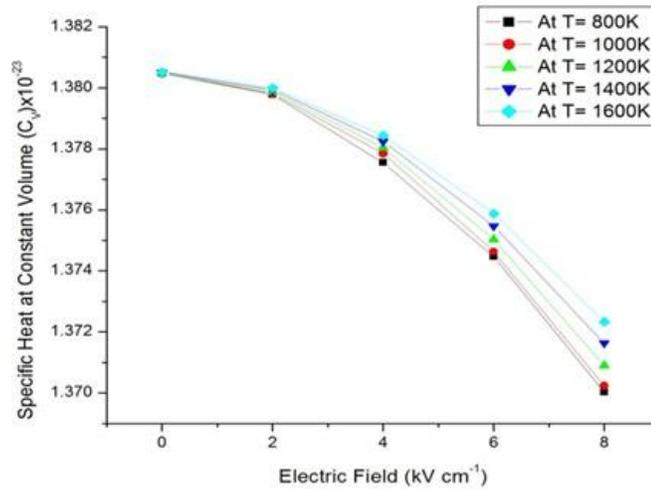

Fig. 5 – Specific heat at constant volume C_V versus electric field (in kV/cm) for BaTiO₃ at different temperatures

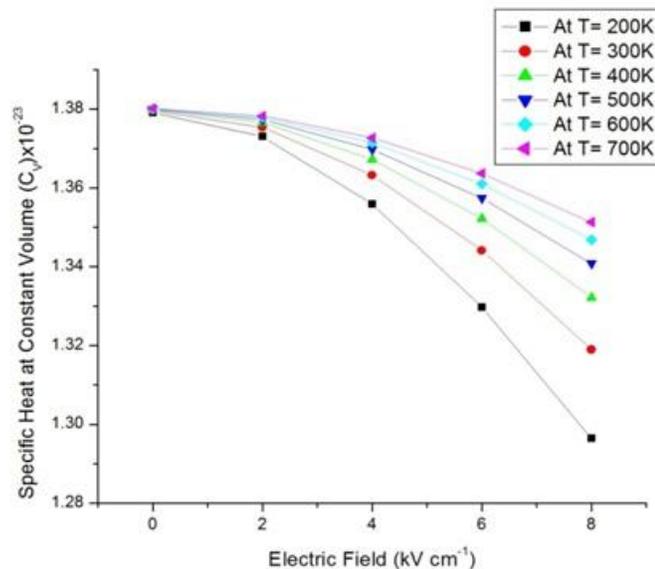

Fig. 6 - Specific heat at constant volume C_V versus electric field (in kV/cm) for KTaO₃ at different temperatures

Figures (4, 5 and 6) show the variation of specific heat with electric field at different temperatures for SrTiO₃, BaTiO₃ and KTaO₃ respectively. The specific heat at constant volume decreases with an increase in electric field. In low field region, the temperature's effect is negligible for all three crystals and the change in specific heat arises mainly due to higher anharmonic terms. Thus, our results are in good agreement with the experimental results obtained by Lawless [8] for ABO₃ type SrTiO₃ and KTaO₃ perovskites.

Strong phonon- phonon interactions due to vanishingly small frequency of the soft mode are held responsible for it. Anharmonicity is necessary in these crystals to observe these effects. Recently we have applied double time thermal Green's function technique in obtaining expression for electric field dependent inelastic scattering cross section of neutrons in BaTiO₃, SrTiO₃ and KTaO₃ displacive ferroelectric perovskites.[23]

Authors

Mr. Gaurav Kumar Aggarwal is pursuing D.Phil in Physics from H.N.B. Garhwal University, Srinagar, Uttarakhand, India. He received his M.Sc. degree in Physics from H.N.B. Garhwal University. His area of interest is Condensed Matter Physics and Electronics. He is actively involved in teaching and research. His field of research is ferroelectric materials particularly displacive ferroelectric perovskites.

Dr. Ashok Kumar obtained his PhD in Physics from H.N.B. Garhwal University, Srinagar, Uttarakhand, India. His area of interest is Condensed Matter Physics. He is actively involved in theoretical research in the field of ferroelectrics. He has published more than 30 research papers in reputed journals. His recent research is focused on designing and development of ferroelectric-perovskites.

Prof. U.C. Naithani presently holds the chair of Professor and Head, Deptt. of Physics, H.N.B. Garhwal University, Pauri Campus, Pauri, Uttarakhand, India. He did his PhD in Condensed Matter Physics. He is actively engaged in teaching and research since last 37 years. His major field of research is in the area of dielectric materials particularly ferroelectric perovskites. He has produced a dozen of PhD scholars and more than 70 research papers are to his credit in this field.

Cyclic Redundancy Check Generation Using Multiple Lookup Table Algorithms

ABSTRACT: The primary goal of this paper is to generate cyclic redundancy check (CRC) using multiple lookup table algorithms. A compact architecture of CRC algorithm (Slicing-by-N algorithm) based on multiple lookup tables (LUT) approach is proposed. This algorithm can ideally read large amounts of data at a time, while optimizing their memory requirement to meet the constraints of specific computer architectures. The focus of this paper is the comparison of two algorithms. These two algorithms are Slicing by-N-algorithm and Sarwate algorithm, in which slicing by-N-algorithm can read arbitrarily 512 bits at a time, but Sarwate algorithm, which can read only 8 bits at a time. This paper proposes the generation of CRC using slicing by 8 algorithm. In this, message bits are chunked to 8 blocks. All are processed at a time. Proposed Slicing-by-8 algorithm can read 64 bits of input data at a time and it doubles the performance of existing implementations of Sarwate algorithm.

Keywords: CRC, LUT, Slicing-by-N.

I. Introduction

Cyclic Redundancy Check (CRC) is one of the methods of detecting the errors in the information during transmission. CRC is an error-checking code that is widely used in data communication systems and other serial data transmission systems [10]. CRC are used for detecting the corruption of digital content during its production, transmission, processing or storage. CRC algorithms treat each bit stream as a binary polynomial and calculate the remainder from the division of the stream with corresponding to the remainder is transmitted together with the bit stream. At the receiver side, CRC algorithms verify that the correct remainder is has been received. Long division is performed using modulo-2 arithmetic [3].

CRC is a polynomial-based block coding method for detecting errors in blocks or frames of data. A set of check digits is computed for each frame scheduled for transmission over a medium that may introduce error and is appended to its end. The computed check digits are known as the frame check sequence (FCS). A CRC value is calculated as a remainder of the modulo-2 division of the original transmitted data with a specific CRC generator polynomial. For example, Ethernet uses the 32-bit polynomial value,

$$G(x) = 1 + x + x^2 + x^4 + x^5 + x^7 + x^8 + x^{10} + x^{11} + x^{12} + x^{16} + x^{22} + x^{23} + x^{26} + x^{32} \quad (1)$$

To find the FCS, first a number of zeroes equal to the number of FCS digits to be generated are appended to the message $M(x)$. This is equivalent to multiplying $M(x)$ by 2^n , where "n" is the number of FCS digits. This value is then divided by the generator polynomial $G(x)$ (1), which contains one more digit than the FCS. The division uses modulo-2 arithmetic, where each digit is independent of its neighbour and numbers are not carried or borrowed, thus additions and subtractions are performed via an exclusive-OR (XOR) function. The remainder $R(x)$ is appended to the end of the message before transmission. At the receiver, the message plus the FCS is divided by the same polynomial. If the remainder is zero then it can be assumed that no error has occurred [2].

To accelerate the CRC generation process, a number of algorithms have been proposed. Among these algorithms the most commonly used today is the algorithm proposed by Sarwate. The Sarwate algorithm reads 8 bits at a time from stream and calculates the CRC value by performing lookups on a table of 256 32-bit entries [4]. Looking to overcome limitations of processing 8 bits of data at a time, new algorithm have been proposed [4] and they can read arbitrarily large amount of data at a time.

Recently time is the major concern. So in order to process large amount of data at a time, Multiple Lookup based approach is more efficient. Multiple Lookup based approach contains five CRC algorithms, called Slicing by-N algorithm ($N \in 4, 8, 16, 32, 64$), which is used to read up to 512 bits at a time. So performance of the system should be increased. Here proposing Slicing by-8 algorithm to read 64 bits at a time. Here proposed an efficient design of CRC generator using Slicing by-N algorithm ($N=8$). In this algorithm, input message stream is sliced into N slices and each slice has 8 bits. So using this Slicing by-8 algorithm, it can read 64 bits at a time and it triples the performance of existing implementation of Sarwate algorithm. In this algorithm, input data stream is sliced into 8 slices. Each slice has 8 bits and these total 64 bits are processed at a time. In this design 8 Look Up tables (LUT) are used, which contain the pre-computed CRC values. These CRC values are generated by using LFSR method and 256 combinations of CRC values corresponding to 8 bit input stream are generate. In this work CRC32 standard is used. Each slice returned CRC values from each LUT and all are XORed to get the final CRC value. This algorithm can reduce the memory usage and also number of operations significantly reduces compared to Sarwate algorithm.

II. System Architecture

Cyclic Redundancy Check is an error detecting codes that are widely used due to their capability to detect the alteration of data. Different algorithms are used for generating CRC. Existing algorithms are LFSR method and Sarwate algorithm. Here proposing an algorithm, this has five algorithms, called Slicing by-N algorithm which is used to generate CRC fastly. Every CRC algorithm treat input bit stream as a binary polynomial and calculate the remainder from the division of the stream with standard generator polynomial. In this work CRC32 standard is used as a generator polynomial. The binary words corresponding to the remainder are transmitted together with input stream. In this work slicing by-8 algorithm is used to generate CRC and it can read 64 bits at a time.

The main disadvantage of existing table-driven CRC generation algorithms is their memory space requirement when reading a large number of bits at a time. To solve this problem, a new algorithm that slices the CRC value produced in every iteration as well as the data bits read into small terms. These terms are used as indexes for performing lookups on different tables in parallel. For example, Slicing-by-4 algorithm can read 32 bits of input data at a time and it doubles the performance of existing implementations of Sarwate algorithm, while Slicing-by-8 triples the performance and reads 64 bits of input data at a time. In this way, here proposed algorithm is capable of reading 64 bits at a time, as opposed to 8, while keeping its memory space requirement to 8KB.

2.1 General Block Diagram of CRC Generation

The basic block diagram of CRC generator is shown in fig.1.

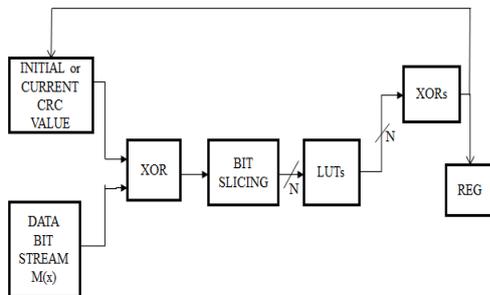

Fig.1 Block diagram of basic CRC Generator.

In this CRC generator, the data stream is firstly XORed with initial CRC value. In this work CRC32 standard is used as a generator polynomial. In the case of CRC32 standard, the initial CRC value is 0xFFFFFFFF [1] and other cases, that is, in other CRC standard initial CRC value is cleared. The output of the XOR block is then sliced into N slices and each slice has 8 bits. Each is given to each LUT for calculating the CRC value. Numbers of LUTs are same to N. Using this Slicing by-N algorithm up to 512 bits are processed at a time, that is, this Slicing by-N algorithm composed of five algorithms (N ∈ 4, 8, 16, 32, 64) in which fifth algorithm is used to read 512 bits at a time.

2.2 Block Diagram of CRC Generator Using Slicing By-8

Here proposing CRC generation using slicing by-8 algorithm which is used to read 64 bits at a time. The block diagram of Slicing by-8 algorithm is shown in fig.2 is

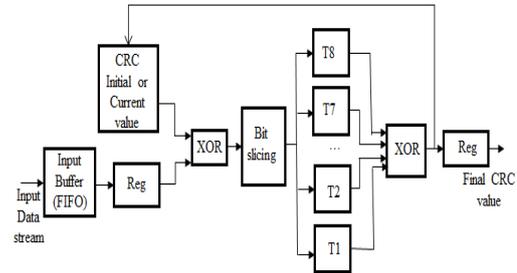

Fig.2 Block diagram of CRC Generator using Slicing by-8 Algorithm

In this, primarily the input data stream is stored in Buffer and buffer has size five and each location is 64 bit wide. Initially first 64 bit data is taken and it is XORed with initial CRC value. Here using CRC32 standard and its initial value is 0xFFFFFFFF. So the modified bit stream is got. This bit stream is sliced into 8 slices and each has 8 bit long. Each 8 bit data is given to each LUT. LUTs have the pre-computed CRC values. These LUTs have 256 entries with 32 bit wide, that is, 8 bit data has 28 (= 256) combinations of values, each has its own CRC value. The CRC value corresponding to each bit stream is getting from each LUT. Finally all CRC values are XORed to get the final CRC value.

2.2.1 Slicing-by-8 Algorithm Description

In this CRC generation process the pre computed value of CRC first stored in LUTs. The long division process is to pre-compute the current remainder that results from a group of bits and place the result in a table. Before the beginning of the long division process all possible remainders which result from groups of bits are pre-computed and placed into a Look up Table. In this way, several long division steps can be replaced by table lookup step. The benefit from slicing comes from the fact that modern processor architectures comprise large cache units. These cache units are capable of storing moderate size tables. If tables are stored in an external memory unit, the latency associated with accessing these tables may be significantly higher than when tables are stored in a cache unit. Slicing is also important because it reduces the number of operations performed for each byte of an input stream when compared to Sarwate. For each byte of an input stream the Sarwate algorithm performs the following: (i) an XOR operation between a byte read and the most significant byte of the current CRC value; (ii) a table lookup; (iii) a shift operation on the current CRC value; and (iv) an XOR operation between the shifted CRC value and the word read from the table. In contrast, for every byte of an input stream the Slicing by-8-algorithm performs only a table lookup and an XOR operation. This is the reason why the Slicing-by-8 algorithm is faster than the Sarwate algorithm.

Slicing by-N algorithm says that the current input stream is XORed with the current CRC and then the modified stream is produced. This modified stream is then sliced into N slices and each has one byte wide. Each slice

is given to the LUTs, which have the pre-computed CRC values. Output of these LUTs is then XORed to get the current CRC. Initially CRC value is 0xFFFFFFFF. Here slicing by-8 algorithm is explained. The steps of this algorithm as follows:

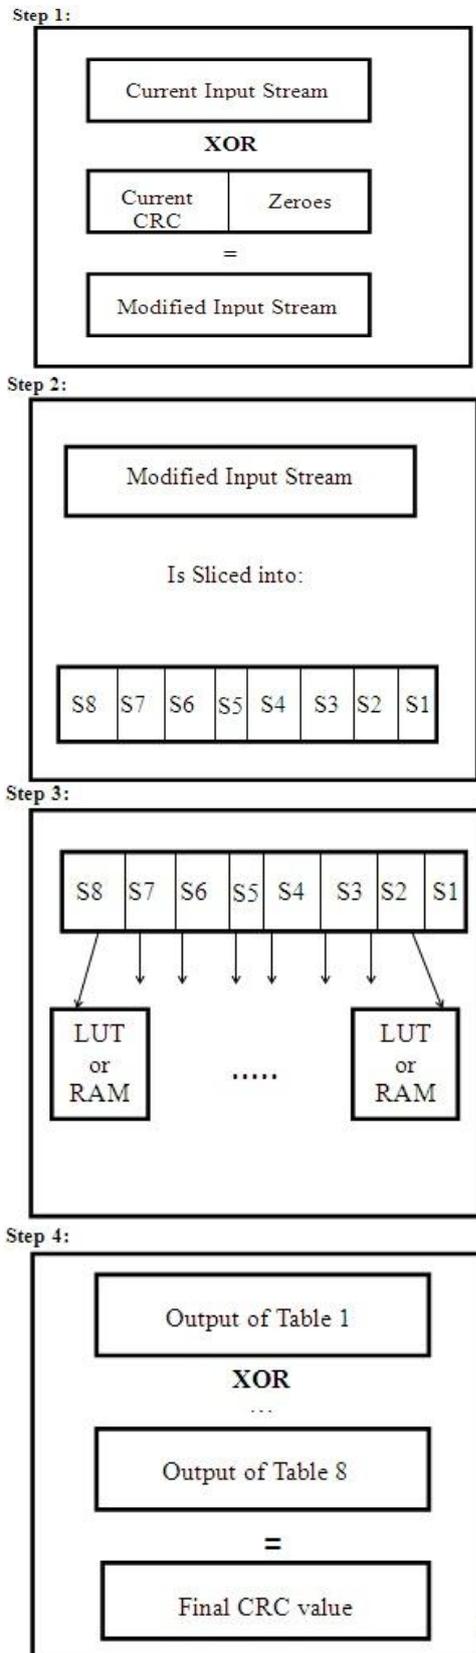

Fig.3 The Slicing by-8 Algorithm

These steps explain how this algorithm works in CRC generators. In the first step, the current input stream is XORed with the current CRC value. The input stream is 64 bit wide and CRC value is 32 bit wide. In order to perform XOR operation, 32 bit wide zeroes is appended to the current CRC value and is XORed with input stream. The modified bit is produced as output. In the second step this modified bit stream is sliced into eight slices. In the third step, each slice is given to LUTs as input and CRC value corresponding to input is produced from LUTs. In the fourth step, these outputs are XORed to get final CRC value.

2.3 Block Diagram of CRC Generator Using Sarwate Algorithm

Here explains the CRC generation using Sarwate algorithm which is used to process only 8 bit at a time. A more efficient approach to CRC computation in software was described by Sarwate [2]. This technique uses a table of pre computed effects on the shift register of 8-bit bytes, which allows the computation to run at one cycle per byte (instead of one cycle per bit) [4]. The long division process is a compute-intensive operation because it requires in the worst case one shift operation and one XOR logical operation for every bit of a bit stream. Most software-based CRC generation algorithms, however, perform the long division process quicker than the bit-by-bit marking technique. One commonly used technique for accelerating the long division process is to pre-compute the current remainder that results from a group of bits and place the result in a table. In this way, several long division steps can be replaced by a single table lookup step [3] [6].

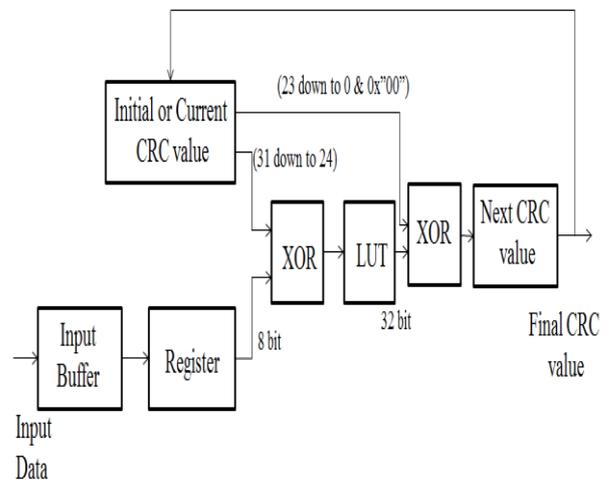

Fig.4 Block diagram of CRC Generator using Sarwate Algorithm

In both Sarwate algorithm and Slicing by 8 algorithms, Look Up Table is used for storing the 2^8 combinations of CRC values. These CRC values are computed using long division process. Long division steps are explained above. Initially the CRC value is set to 0xFFFFFFFF. The first 8 bit from the input stream is taken and is XORed with most significant 8 bits of the initial CRC value. This modified byte is given to the LUT, it produce the corresponding CRC value. It is finally XORed with the 24 least significant bits of the current CRC value, shifted by 8 bit positions to the left, which produce the next CRC value and this CRC value is used for next iteration.

2.3.1 Sarwate Algorithm Description

The most representative table-driven CRC generation algorithm used today is the algorithm proposed by Dilip.V.Sarwate. The length of the CRC value generated by the Sarwate algorithm is 32 bits. The Sarwate algorithm is more complicated than the straightforward lookup process because the amount of bits read at a time (8 bits) is smaller than the degree of the generator polynomial. Initially, the CRC value is set to a given number which depends on the standard implemented (e.g., this number is 0xFFFFFFFF for CRC32) [1]. For every byte of an input stream the algorithm performs the following steps:

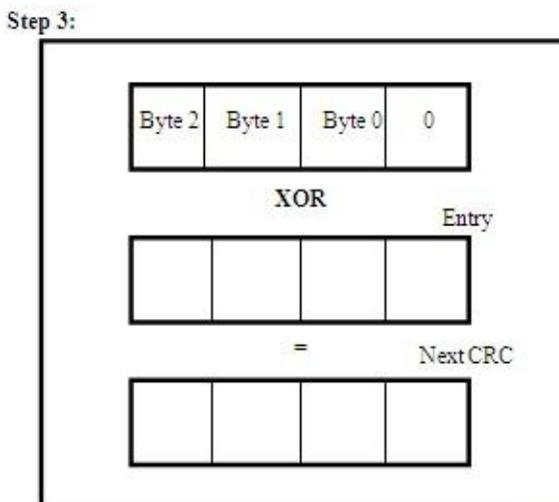

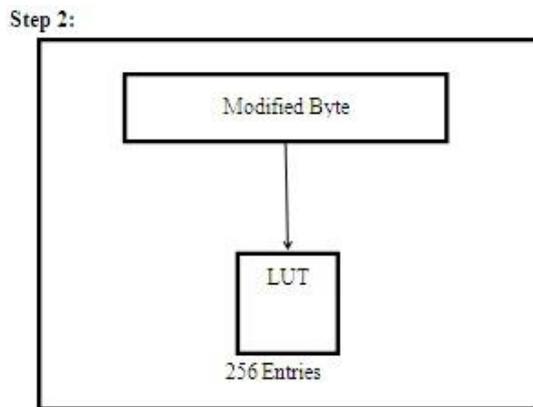

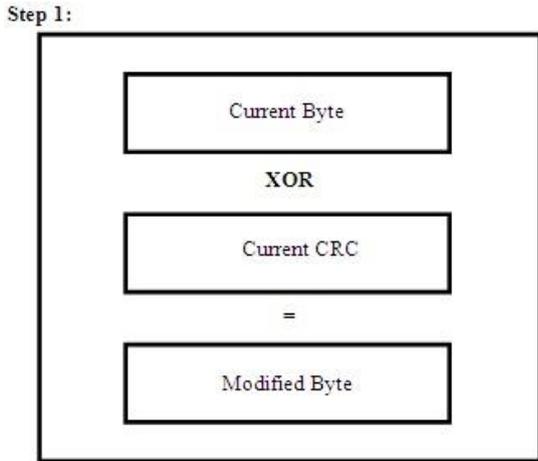

Fig.5 Sarwate Algorithm

In first step, the algorithm performs an XOR operation between the most significant byte of the current CRC value and the byte from the stream which is read. The 8-bit number which is produced by this XOR operation is used as an index for accessing a 256 entry table (Step 2). The lookup table used by the Sarwate algorithm stores the remainders from the division of all possible 8-bit numbers shifted by 32 bits to the left with the generator polynomial. The value returned from the table lookup is then XORed with the 24 least significant bits of the current CRC value, shifted by 8 bit positions to the left (Step 3). The result from this last XOR operation is the CRC value used in the next iteration of the algorithm's main loop. The iteration stops when all bits of the input stream have been taken into account.

Sarwate algorithm has been designed when computer architectures supported XOR operation with only eight bits. Today's processors support operations with 32 and 64 bits values, and if this algorithm is extended it would require lookup tables of $2^{32} = 4G$ entries for processing 32 bits of data at a time, and $2^{64} = 16G$ for 64 input data. These tables can't fit into a cache and would cause significant latency problem if in RAM.

III. 3. Simulation Results

The simulation was done using Modelsim PE 10.0c Simulator and the output waveforms is obtained as shown in fig. 6, 7,8,9,10. Slicing by-N algorithm is one of the CRC algorithms, which is used to read up to 512 bits at a time. It is Multiple Look Up based approach that is, in this N LUTs are used. In this paper, Slicing by-8 algorithm is used which it is used to read 64 at a time. Each 64 bits are sliced into 8 slices and each slice has 8 bits. In this algorithm 8 LUTs are used. Each slice is given to each LUT and these LUTs contain all 2^8 combinations of CRC values. Outputs of LUTs are CRC values corresponding to each slice and all outputs from LUTs are XORed to get final CRC value. Similarly Sarwate algorithm is used to read 8 bits at a time and in this, only one LUT is used for iteration.

3.1 Simulation waveforms

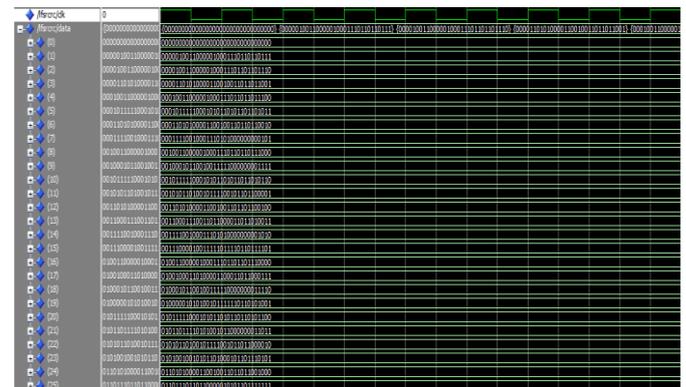

Fig.6 256 Combinations of CRC Using LFSR Method

Fig.6 shows the 256 combinations of CRC is generated using LFSR method in VHDL. In this, initially reset ('rst') is '1', all are cleared. After that, reset is '0', and calculating each CRC corresponding bits from "00000000" to "11111111". These are getting from the signal 'data'.

Fig.7 256 Combinations of CRC values using MATLAB

Fig.7 shows 256 combinations of 32-bit CRC values can be generated by MATLAB. Using MATLAB, generated these CRCs by using the ‘Deconv’ function. This function is used for polynomial division. By dividing the input stream with the standard generator polynomial, which is 33-bits, getting the remainder which is 32 bit long. These generated CRC values are stored in a text file by generating a text file using ‘file generate’ and ‘file write’ functions.

Fig.8 Comparison output for CRC values

The comparison result of CRC generation using MATLAB and LFSR method got the same. Ie, generated CRC values using LFSR method is cross verified by MATLAB. This comparison gives the result that the CRC values produced by LFSR method are correct.

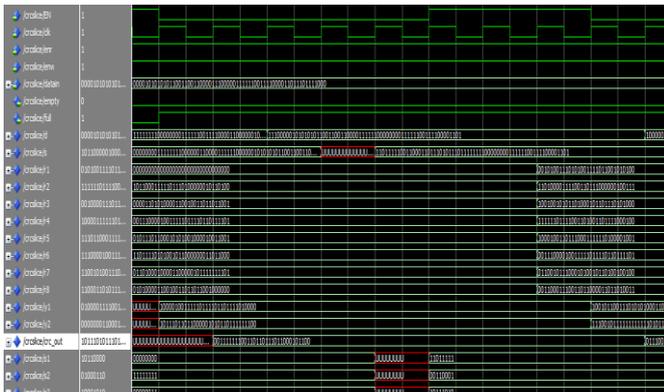

Fig.9 Output of CRC generation using Slicing by 8 Algorithm

Fig.9 shows the simulation result of CRC generation using Slicing by 8 algorithm. This result shows that the initial 64 bit from the input stream is taken and is modified with current CRC value by XORing. This output is given at the signal ‘s’. this output is slices into 8 slices, which is given at signal s1-s8. These output is given to each LUTs. This LUT produced corresponding CRC values of each byte(8 bytes), which is given at the signal ‘r1-r8’ and all are XORed to get next CRC value which is used for next iteration. This final CRC value is indicated by the signal ‘crc_out’.

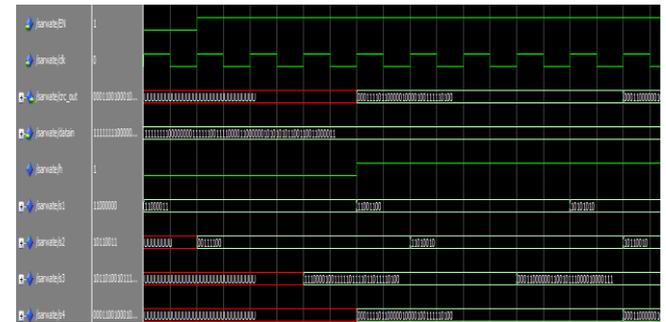

Fig.10 Output of CRC Generation Using Sarwate Algorithm

Fig.10 shows the simulation result of CRC generation using Sarwate algorithm. In this, the initial 8 bit data from the input message stream is taken (‘s1’) which is XORed with initial CRC value (0XFFFFFFF), ie, in this result if h is ‘low’ then the message bit is XORed with initial value and if h is ‘high’, then the input is XORed with MSB bit of current CRC value. This modified bit is indicated by the signal ‘s2’. This modified bit is given to LUT. In this, only one LUT is used for storing the pre computed CRC values. This LUT produce corresponding CRC value. This output is indicated by the signal ‘s3’. This output is XORed with 24 least significant bits of the current CRC value which is shifted by 8 bit positions to the left. This is the next CRC value. It is indicated by the signal ‘s4’. This CRC output is used for next iteration to get the modified bit and finally get the correct CRC value. This final CRC output is indicated by the signal ‘crc_out’.

IV. Synthesis Results

4.1 Comparison of Device Utilization

This comparison results explain how much amount of area are required for different algorithms.

4.1.1 Device Utilization Summary of Slicing by 8 and Sarwate Algorithm with 64 bit Input Stream

Device Utilization Summary (estimated values)			
Logic Utilization	Used	Available	Utilization
Number of Slices	183	4656	3%
Number of Slice Flip Flops	202	9312	2%
Number of 4 input LUTs	246	9312	2%
Number of bonded IOBs	98	232	42%
Number of BRAMs	1	20	5%
Number of GCLKs	1	24	4%

Fig.11 Device Utilization Summary of Sarwate Algorithm with 64 bit data

Device Utilization Summary (estimated values)			
Logic Utilization	Used	Available	Utilization
Number of Slices	238	4656	5%
Number of Slice Flip Flops	416	9312	4%
Number of 4 input LUTs	96	9312	1%
Number of bonded IOBs	98	232	42%
Number of BRAMs	4	20	20%
Number of GCLKs	1	24	4%

Fig.12 Device Utilization Summary of Slicing by 8 Algorithm with 64 bit data

These two summaries shows that number of slices used by Slicing by 8 algorithm is lightly greater compared to Sarwate algorithm, ie, 3% of slices are used in Sarwate algorithm and 5% of slices are used in Slicing by 8 algorithm. But the usage of 4-input LUTs are less in Slicing by 8 algorithm compared to Sarwate algorithm, ie, 2% of 4-input LUTs are used in Sarwate algorithm and 1% in Slicing by 8 algorithm. And IOB usage is same in Slicing by 8 algorithm and Sarwate algorithm, ie, 42% of IOBs are used.

4.1.2 Device Utilization Summary of Slicing by 8 and Sarwate Algorithm with 512 bit Input Stream

Device Utilization Summary (estimated values)			
Logic Utilization	Used	Available	Utilization
Number of Slices	253	4656	5%
Number of Slice Flip Flops	275	9312	2%
Number of 4 input LUTs	384	9312	4%
Number of bonded IOBs	102	232	43%
Number of BRAMs	1	20	5%
Number of GCLKs	1	24	4%

Fig.13 Device Utilization Summary of Sarwate Algorithm with 512 bit data

Device Utilization Summary (estimated values)			
Logic Utilization	Used	Available	Utilization
Number of Slices	310	4656	6%
Number of Slice Flip Flops	492	9312	5%
Number of 4 input LUTs	234	9312	2%
Number of bonded IOBs	102	232	43%
Number of BRAMs	4	20	20%
Number of GCLKs	1	24	4%

Fig.14 Device Utilization Summary of Slicing by 8 Algorithm with 512 bit data

These two summaries also gave the same comparison result with the input is 512 bits. Usage of 4-input LUTs are less and usage of slices are more in Slicing by 8 algorithm compared to Sarwate algorithm. 5% of slices are used in Sarwate algorithm and 6% in Slicing by 8 algorithm. 4% of 4-input LUTs are used in Sarwate algorithm and 2% in Slicing by 8 algorithm.

The above two comparisons, ie, for 64 bits and for 512 bits, the result shows that for 64 bits of data, number of slices used by Slicing by 8 is 2% greater compared to Sarwate algorithm and for 512 bits of data, number of slices used by slicing by 8 is only 1% greater compared to Sarwate algorithm. This result explains that by increasing the number of bits processed, number of slices used in Slicing by 8 algorithm is reduced compared to Sarwate algorithm. Also these two summaries explains that number of 4-input LUTs used by Sarwate algorithm is twice greater than Slicing by 8 algorithm.

4.2 comparison of time consumption

Fig.15 shows the comparison graph of time consumption. This graph clearly says that CRC generator with Slicing by 8 algorithm consume less time compared to Sarwate Algorithm and LFSR method. Slicing by 8 algorithm have minimum delay compared to other algorithms.

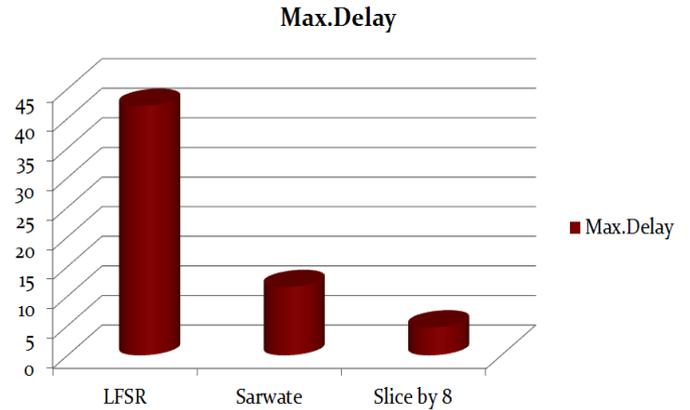

Fig.15 comparison of time delay

The below table clearly explains the comparison of different Algorithms for CRC generation purposes.

Algorithm\Data	Number of Slices	Number of 4-Input LUTs	Number of IOBs	Maximum delay
LFSR Method	1258	2301	43	42.142
Sarwate	253	384	102	11.56
Slice by 8	310	234	102	3.455

TABLE.1 Comparison of Device Utilization

4.3 Graphical Representation of Comparison Results

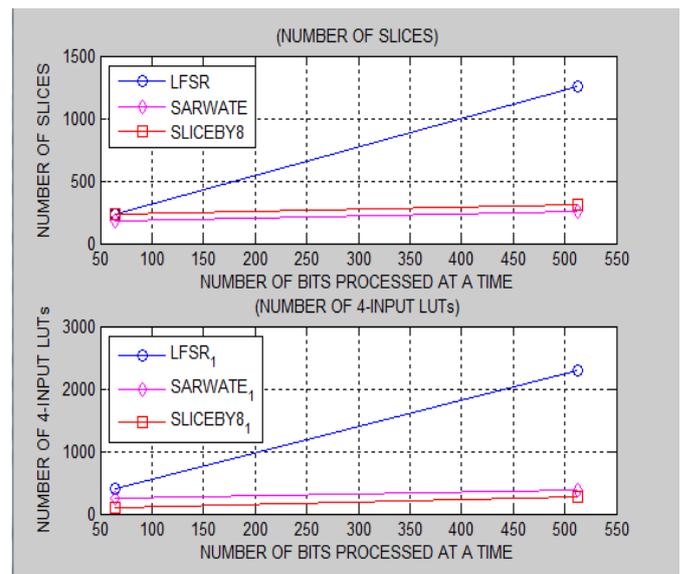

Fig.16 Graphical Representation of Comparison of Device Utilization using MATLAB

Fig.16 shows the graphical representation of comparison results of device utilization in different CRC generation methods. The first graph represents the number of slices used by LFSR, Sarwate, Slicing by 8 methods. This graph shows that slices used by LFSR are very much higher than Sarwate and Slicing by 8. The first graph represents the number of slices utilized by LFSR, Sarwate and Slicing by 8 for, 64 bits processed and also 512 bits processed. The second graph represent the number of 4-input LUTs. This graph also shows that LFSR method is high area consuming method. The second graph represents the number of 4-input LUTs are utilized by LFSR, Sarwate, Slicing by 8 in the case of both 64 bits processing and 512 bits processing.

V. Conclusion

The design of CRC generator using Multiple Look Up based approach is proposed. In this paper, slicing by-8 algorithm is designed, and compares this algorithm with the existing algorithms, that is, with Sarwate algorithm and LFSR method. In this work, first generated the CRC values using LFSR method and generated all 256 combinations of CRC using LFSR method. In this work, also generated these 256 combinations of CRC values using MATLAB. Outputs produced from MATLAB and LFSR method is cross verified. This clearly explains that these two CRC values are same. Designed Look Up Table (LUT) and stored all CRC values in the LUT. LUT contains 256 entries with 32 bit. The input stream is firstly stored in a buffer. In a buffer, five locations with each location has 64 bit wide. These 64 bit data is sliced into eight slices and each is given to each LUT. CRC values are generated from each LUTs corresponding to input stream and all are XORed and get the final CRC value. In this work CRC-32 is used for generating CRC values. So Slicing by-N algorithm can read arbitrarily large amount of data at a time that is used to reduce the time requirement. So this method is applied to CRC generator with Slicing by-N algorithm will be proposed in iSCSI (internet Small computer system interface).

Zinc Oxide Nanorods: Synthesis and Its Applications in Solar Cell

Chittaranjan Bhakat¹, Prasoon Pal Singh²

* (School of Interdisciplinary Science and Technology, International Institute of Information Technology, India)

** (School of Interdisciplinary Science and Technology, International Institute of Information Technology, India)

ABSTRACT: *Nanosized materials have been an important subject in basic and applied sciences and these metal nanoparticles have been intensively studied within the past decade. Synthesis of hexagonal shape zinc oxide nanorods is achieved by thermal decomposition process. The sample was characterized by uv-vis spectrophotometer, X-ray diffraction Scanning electron microscope. Zinc Chloride (ZnCl₂) was used as precursor with sodium hydroxide (NaOH) in 1:2 molar ratios for the preparation of zinc oxide nanoparticles by the wet chemical method. Further its application in solar cell. The results indicate that the as-prepared ZnO Nano-rods are uniform with diameters of 100–200 nm and lengths of about 1 μm*

Keywords: *Nanostructures, Chemical Synthesis, UV spectroscopy, SEM, XRD, Solar cell*

I. INTRODUCTION

Nanotechnology is an emerging, highly interdisciplinary field; it has the ability to manipulate matter at an atomic scale. Nanotechnology can be useful in diagnostic techniques, drug delivery, sunscreens, antimicrobial bandages, disinfectant, and a friendly manufacturing process that reduce waste products. Nanorods and nanowires have recently attracted considerable attention towards scientific community because of their novel properties and potential technological applications; it is widely used in the field of catalyst [1], gas sensor [2], solar cell materials [3], antimicrobial materials [4], optoelectronics devices [5,6] etc. ZnO is as wide band gap (3.37eV) compound semiconductor materials with a large exciton binding energy of 60 meV, among several oxides semiconductor ZnO nanostructures is considered to be the best, it is clearly demonstrated in many studies that nanoparticles of ZnO have significantly higher antimicrobial effects than other metal oxide nanoparticles [7]. Currently, different nanostructure of ZnO have been reported such as nanorods, nanowires, nanocombs, nanorings, nanobridge, nanobelts, nanocages [8,9], etc and these nanostructures have potential applications in fabricating functional advanced Nano electronics devices. And a wide variety of techniques have been exploited to fabricate ZnO nanostructures. ZnO nanostructures can be grown either in solution or from gaseous phase, this includes the vapour transport process [10], the catalyst-assisted vapour-liquid-solid process [11], the metal-organic vapour phase epitaxial growth [12], spray pyrolysis [13], and hydrothermal methods [14, 15, 16] which are high temperature processing methods and require costly equipment.

In this paper, we are representing a simple, low cost and low temperature method with high yields of synthesizing ZnO nanostructures. Depending on the catalyst and reaction conditions, different shapes such as nanoparticles, nanoneedles, hexagonal nanoparticles (NPs), nanoflower like structures are obtained but in this case it is hexagonal nanoparticles of ZnO. These synthesized ZnO nanostructures were characterized using X-ray diffraction (XRD), Scanning electron microscope (SEM), UV-visible absorption spectrometer.

II. MATERIALS AND METHOD

Zinc acetate dihydrate, sodium hydroxide, potassium hydroxide and other reagents used were all analytical grade without further purification. Alcoholic media such as methanol, ethanol or propanol, is mostly used for the synthesis of ZnO nanostructures because in alcoholic media growth of oxide particles is slow and controllable [17], but in this study reaction is accomplished in both alcoholic and nonalcoholic media. In a typical synthesis, of ZnO nanorods is carried out by sol gel process, at 80-90°C. Solution of zinc acetate dihydrate [Zn (O₂CCH₃)₂(H₂O)₂] was prepared by dissolving 2.195 g of zinc acetate dihydrate in 100ml distilled water/ethanol, and stirred in ambient atmosphere. Potassium hydroxide KOH 1.122g is dissolved in 10ml distilled water and was added to the above solution drop wise under continuous stirring. After few minutes solution turn into jelly form and a milky white solution was obtained, the mixture was then further heated for 3 h at 80-90°C without stirring. The resulting suspension was centrifuged to retrieve the product, and the mixture was washed with distilled water in an ultrasonic bathwater and then the powder was dried at 70° C over night and determined in terms of their structural, morphology and optical properties.

The crystalline structures of the products were characterized by X-ray diffraction (XRD) analysis using a JEOL JDX-3535 diffractometer. The absorbance spectra were recorded on a vision light UV-vis spectrophotometer. Size and morphology of the products were observed by scanning electron microscopy (SEM) which was taken on a JEOL JEM-2010 electron microscopy using an accelerating voltage of 200 kV in bright field and electron diffraction (ED) modes. A small drop of the ZnO powder re-dispersed by ethanol was dropped on a carbon film-coated copper grid. The sizes of ZnO were measured and averaged by several SEM images ($n = 100$).

III. RESULTS AND DISCUSSIONS

UV-VIS absorption spectra of the ZnO nanorods are shown in Fig. 3, it is well known that the bulk ZnO has absorption at 375 nm in the UV-visible spectrum [18]. The general

morphologies of the synthesized ZnO nanorods were studied by scanning electron microscopy (SEM). A typical SEM image of the ZnO nanorods is shown in Fig. 1. The ZnO nanorods have an average diameter of 100 nm and show perfectly flat surfaces with hexagonal symmetry. The lengths of ZnO nanorods are about 1 μ m. Figure 1 also shows the morphology of the nanostructures obtained after the completion of the reaction with zinc acetate and potassium hydroxide/ sodium hydroxide at 90 $^{\circ}$ C by sol gel process. The image reveals short rod like ZnO nanostructures with an average diameter of 100 to 200 nm and length in micrometers. We have found variation in shape size and length in the nanorods; most of the nanorods are straight with a smooth surface having hexagonal structure at the end. And in some regions we have notice that bunch of nanorods are aligned together in different direction.

XRD pattern of synthesized ZnO nanostructures by sol gel reaction at 90 $^{\circ}$ C is shown in Fig. 2. All peaks of the obtained product are corresponding to the hexagonal wurtzite structure of Zn reported in many research works [19,20]. In Fig. 2, the detected peaks are at 2 θ values of 31.7 $^{\circ}$, 34.4 $^{\circ}$, 36.2 $^{\circ}$, 47.5 $^{\circ}$, 56.6 $^{\circ}$, 62.8 $^{\circ}$ corresponding to the following lattice planes: (100), (002), (101), (102), (110), (103), respectively. The growth process of ZnO NWs can be controlled through the chemical reactions. All of these reactions are in equilibrium and can be controlled by adjusting the reaction parameters, such as precursor concentration, growth temperature, and growth time, to push the reaction equilibrium forward or backward. The size of the nanostructure can be controlled by using stabilizing agents which prevent the growth of the nanostructure, the growth mechanism of the Nanotubes is explained in many research works, and it is found that crystal size grows with increasing in reaction time at an appropriate temperature. High quality of ZnO nanopowder was obtained after completion of the reaction. In most of the sol gel synthesis process, zinc acetate and urea is used in 1:7 molar ratio at higher temperature 500-800 $^{\circ}$ C for the growth of one dimensional nanostructure there is two well explained mechanism accepted for the growth of one dimensional nanostructures, viz. the vapour-liquid-solid (VLS) and vapour-solid (VS) mechanism. The VLS mechanism is a catalyst assisted process, in which the metal catalyst particles act as a liquid forming agent, while in this process no catalyst is used.

The results indicate that ZnO nanorods have been successfully prepared by chemical reaction at low temperature.

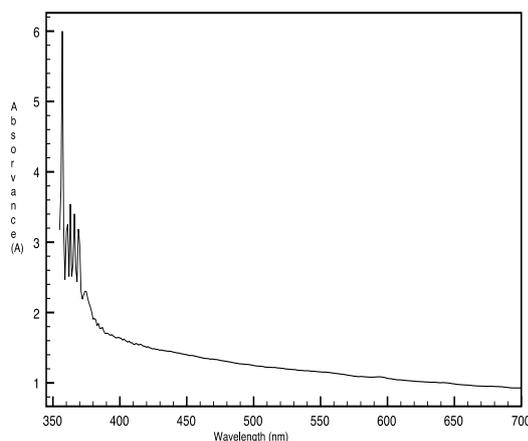

Figure 3. UV-Vis absorption spectra for ZnO nanoparticles

IV. CONCLUSION

Hexagonal ZnO nanorods were synthesized successfully without using any capping agent through sol gel process at 80-90°C. Zinc acetate dehydrate and zinc chloride was used as the zinc source. Absolute ethanol and water both are taken as a solvent, the synthesized ZnO nanorods prepared with deionized water have the diameter of 100-200nm.

Performance Analysis of RS and CC Coding Methods in OFDM WiMAX System for BPSK and QPSK Modulation Techniques

Kavita Rani¹, Ankur Sood², Nitin Arora³

(Lecturer, Chhotu Ram Rural Institute of Technology, Kanjhawala, Delhi,)

(Assistant Professor, Ideal Institute of Technology, Ghaziabad, UP)

(Assistant Professor, Haryana Institute of Technology, Bahadurgarh)

ABSTRACT: Coding techniques is used for providing reliable information through the transmission channel to the user. In coding techniques the number of symbols in the source encoded message is increased in a controlled manner in order to facilitate two basic objectives at the receiver one is Error detection and other is Error correction. The amount of error detection and correction required and its effectiveness depends on the signal to noise ratio (SNR). In digital communication, coding techniques is a broadly used term mostly referring to the forward error correction code. The WiMAX technology based on air interface standard 802-16 wireless MAN is configured in the same way as a traditional cellular network with base stations using point to multipoint architecture to drive a service over a radius up to several kilometers. The range and the Non Line of Sight (NLOS) ability of WiMAX make the system very attractive for users, but there will be slightly higher BER at low SNR. In this paper, a comparison between the performance of WiMAX using convolution code and Convolution Product Code (CPC) is made. CPC enables to reduce BER at different SNR values compared to the convolution code.

Keywords: WiMAX, BER, CPC, IEEE 802.16

I. INTRODUCTION

WiMAX is introduced by the Institute of Electrical and Electronic Engineers (IEEE) which is designated by 802.16 to provide worldwide interoperability for microwave access. There are fixed (802.16d) and mobile (802.16e) WiMAX. This technology offers a high speed, secure, sophisticate, last mile broadband service, ensuring a flexible and cheap solution to certain rural access zones[1]-[7]. In a fixed wireless communication, WiMAX can replace the telephone company's copper wire networks, the cable TV's coaxial cable infrastructure.

In comparison with Wi-Fi and Cellular technology, Wi-Fi provides a high data rate, but only on a short range of distances and with a slow movement of the user. And Cellular offers larger ranges and vehicular mobility, but it provides lower data rates, and requires high investments for its deployment. WiMAX tries to balance this situation. WiMAX fills the gap between Wi-Fi and Cellular, thus providing vehicular mobility, and high service areas and data rates. WiMAX is a standards based technology for wireless MANs conforming to parameters which enable

interoperability[1][2]. WiMAX developments have been rapidly moving forward.

The main objective of this paper is to transmit the data in WiMAX with low bit error rate in the noisy environment for that we using Forward Error Correction method which is Convolution coding. This method is useful to reduce the bit error rate (BER) and increase the efficiency.

The paper is organized as follows: Section II introduces a description for the simulation model. Description of CC and CPC scheme is presented in Section III. Simulation results are given in Section IV, and finally conclusions are reflected in Section V.

II. CONVOLUTIONAL ENCODER

The channel coding scheme, IEEE 802-16, as shown in fig 1 is based on binary non-recursive Convolutional Coding (CC) [4]. The convolutional encoder uses a constituent encoder with constraint length 7, code rate 1/2 and generator polynomials (133,171) octal. In this stage, the CPC method will be applied for coding the message and this will be shown in the following section.

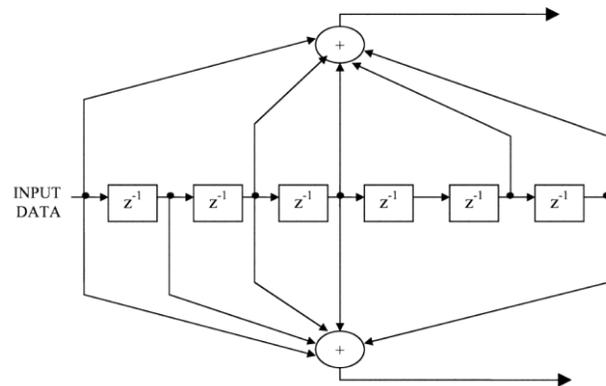

Fig: 1 Convolutional Encoder in IEEE 802.16e

A. CONVOLUTION PRODUCT CODE (CPC) METHOD

CPC is a new coding method [1], in which the information bits are placed into two dimensions (2D)

Matrix. The rows and the columns are encoded separately by using recursive systematic convolutional encoders. Each row of the matrix is encoded using a convolutional code the same recursive systematic convolutional code is used to encode each

row. Once all rows have been encoded, the matrix is sent, if desired, to an interleaver. Our original data matrix dimensions are (nxk), and the encoded data matrix dimensions will be (Znxk). The coded rows matrix is then recoded column by column using the same or different recursive systematic convolutional encoder. CPC uses a recursive systematic convolutional code with rate 1/2 and generator polynomials (1,5/7) octal to encode each row and column. Hence, the overall code rate is 1/4. The coding by CPC will be done in 2 stages. First each column will be independently coded, and then each row of the resulting matrix will be coded by the same generator polynomials.

III. REED SOLOMON CODING

The randomized data are arranged in block format before passing through the encoder [6] and a single 0X00 tail byte is appended to the end of each burst. The implemented RS encoder is derived from a systematic RS (N=255, K=239, T=8) code using GF (2⁸). The following polynomials are used for code generator and field generator.

$$G(x) = (x + \alpha^0)(x + \alpha^1) \dots (x + \alpha^{2^T-1}), \alpha = 02_{HEX}$$

$$p(x) = x^8 + x^4 + x^3 + x^2 + 1$$

IV. SIMULATION RESULTS

In this chapter the simulation results are shown and discussed.

V. CONCLUSION

In this paper, performance of WIMAX systems is studied under using CC and CPC coding method using BPSK and QPSK modulation Techniques. This lead to the reduction of BER. We investigate the performance of the OFDM WiMAX system with BPSK and QPSK modulation scheme which lead to the improvement in the BER with QPSK scheme compare to the BPSK. Spectral efficiency of WiMAX system will also improve with QPSK modulation Scheme.

VI. FUTURE SCOPE

Further scope of this paper is that performance analysis of WiMAX MC-CDMA based system using CPC coding and convolution coding method. Which may gives better result as compare to WiMAX OFDMA based system using CPC coding and convolution coding method.

Global Block-Based Redundancy Architectures For Self-Repairing Of Embedded Memories

T. Govinda Rao¹, K. V. V. Satyannarayana², J. Sathish Kumar³

ABSTRACT: In this paper, global block-based redundancy architectures are proposed for self-repairing of embedded memories. The main memory and the redundant rows/columns are divided into row blocks/column blocks. The replacement of faulty memory cells can be performed at the row/column block level instead of the traditional row/column level. Note that the redundant row/column blocks are global, i.e., they can be used to replace faulty cells anywhere in the memory array. This global characteristic is helpful for repairing cluster faults. Since the redundancy can be designed independently. It can be easily integrated with the embedded memory cores. To perform redundancy analysis, the MESP algorithm suitable for built-in implementation is also proposed. According to experimental results, the area overhead for implementing the MESP algorithm is almost negligible. Due to the efficient usage of the redundancy, the manufacturing yield, repair rates, and reliabilities can be improved significantly

Keywords: Cluster fault, embedded memory, modified essential spare pivoting (MESP) algorithm, repair rate, yield.

I. INTRODUCTION

As we migrate to the nanometer technology era, we are seeing a rapid growing density of system-on-a-chip (SOC) designs. This trend makes the manufactured chips more susceptible to sophisticated defects. Moreover, according to the Semiconductor Industry Association (SIA) and Technology Roadmap for Semiconductors (ITRS) 2007, the relative silicon area occupied by embedded memories will approach 94% by 2014 [1]. Since embedded memories also have higher density than logic cores, the overall SOC yield is dominated by these memory cores. For example, the yield of a 24 M-bit embedded memory is about 20% [2]. In order to boost the manufacturing yield of embedded memories, one promising solution is the built-in self-repair (BISR) technique. To achieve the goals of BISR, three basic functions are usually required—memory built-in self-test (BIST), built-in redundancy analysis (BIRA), and address reconfiguration (remapping) (AR).

There are many BIRA/BISR techniques proposed in the past [3]–[12]. A comprehensive exhaustive search for built-in self analysis algorithm (CRESTA) has been proposed in [8]. Although this BISR scheme can achieve optimal repair rates, the hardware overhead for implementing the CRESTA scheme is very high. Wey and Lombardi in [9] propose a branch-and-bound technique with early screening in the repair process. A bipartite graph is applied to obtain the least required number of spare

allocation, i.e., the least number of spare rows/columns to repair the faulty rows/columns in the main memory array. In our previous work [10], hybrid redundancy architectures are proposed. We have also shown that the complexity of the redundancy allocation problem is nondeterministic-polynomial-time-complete (NP-complete). From the simulation results, the manufacturing yield, repair rate (the ratio of the repaired memories to the number of defective memories), and reliability can be improved significantly.

Divided word-line (DWL) and divided bit-line (DBL) techniques are proposed in [13] and [14] to reduce the power consumption and increase the access time. This divided characteristic can also be used for fault-tolerant applications, i.e., redundant rows and columns can be divided into row blocks and column blocks. The replacement can be performed at the block level instead of the traditional row/column level. However, if the redundant rows (columns) are used locally to replace faulty row (column) blocks in the same row (column) bank, there are still some drawbacks, which should be dealt with. First, if there are many faulty cells located within a row/column bank (to be defined later), there may not be sufficient spare blocks to re-place these faulty cells. The spare blocks allocated for other banks may not be used in this case. Therefore, for some defect distribution resulting in such condition, more redundant rows (columns) should be included for successful repair of the faulty memory. The usage of spares then is inefficient. Second, if *cluster faults* are considered, this dilemma becomes more severe. This is because cluster faults usually gather within a small memory area (though there are small-area, medium-area, and large-area clusters). The local characteristic of redundancy is not suitable (or efficient) to repair such faults. Third, the local spare row (column) blocks should be implemented together with the main memory array, but then it is difficult for SOC integration.

In this paper, the *global* block-based redundancy architectures is proposed. Redundant rows/columns are still divided into row/column blocks. However, the redundant row/column blocks can be used to replace faulty row (column) blocks anywhere in the memory array. This *global* characteristic is helpful for repairing cluster faults.

Based on the proposed global redundant architectures, a heuristic modified essential spare pivoting (MESP) algorithm suitable for BISR is proposed. The area overhead for implementing the MESP algorithm is very low for easier discussion of the proposed techniques.

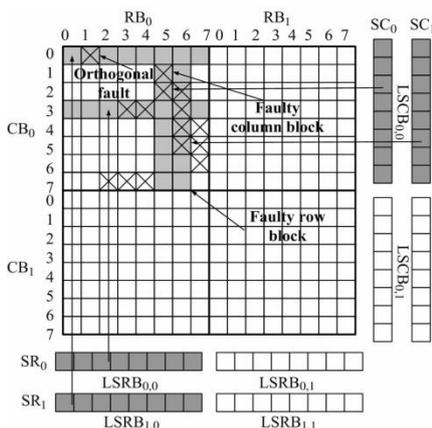

Fig. 4. Local block-level redundancy architecture.

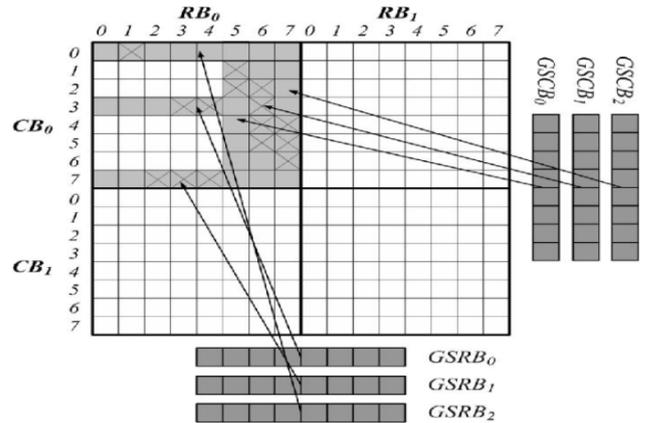

Fig. 5. Novel redundancy architecture (GBLRA).

The remainder of this paper is organized as follows. Section II reviews the DWL and DBL architectures. Section III introduces the proposed local and global block-based redundancy architecture. A heuristic built-in redundancy analysis algorithm named the MESP algorithm is described in Section IV. An example of the proposed MESP algorithm is delineated in Section V. Section VI describes the BISR circuits and the repair procedures. Experimental results are shown in Section VII. A practical 16 K × 32-bit memory chip with BISR is implemented and described in Section VIII. Finally, some conclusions are given in Section IX.

II. LOCAL AND GLOBAL BLOCK BASED REDUNDANCY ARCHITECTURES

As described above, the local block-based redundancy architectures have three major drawbacks. An example is shown in Fig. 4 where faulty memory cells are marked X's. From this figure, we can see that all faulty cells are contained in DA_{00} . Therefore, only the spare blocks in RB_0 and CB_0 can be used to replace faulty cells. An *orthogonal fault* (to be defined later) should be repaired by one spare row or column block. It is evident that the remaining faulty cells cannot be successfully repaired by using the remaining spare blocks.

The four used spare blocks are shaded, as shown in Fig. 4.

However, there are still two available spare row blocks ($LSRB_0$ and $LSRB_1$) and two spare column blocks ($LSCB_0$ and $LSCB_1$). These four spare blocks can also be used to replace the remaining faulty cells, it is evident that this faulty memory array can be repaired successfully. This scenario is more severe if cluster faults are considered. Therefore, in order to solve these drawbacks, the *global block-based redundancy architectures* are proposed in this paper. In Fig. 5, the faulty main memory array is the same as that shown in Fig. 4. However, three *global spare row blocks* (GSRBs) and three *global spare column blocks* (GSCBs) are added into the memory array. Based on this strategy, spare row blocks and column blocks are global, i.e., they can be used to replace the faulty cells anywhere in the memory array. Due to the global characteristic, we can reconfigure the memory more efficiently—the faulty memory array can be repaired successfully as indicated by the arrows shown in Fig. 5.

III. BUILT-IN REDUNDANCY ANALYSIS

The proposed MESP algorithm is based on the *essential spare pivoting (ESP) algorithm* [15]. However, we use the global block-based redundancies instead of the whole rows/columns. Before illustrating the proposed algorithm, we define some basic fault types (FTs) first.

1) Faulty row (column) block:

A row/column block that has more faulty cells than the threshold number (E_{th}) is called a *faulty row/column block*. We can use a *GSRB/GSCB* to replace the faulty row/column block. In this work, we assume that the threshold is 2.

2) **Orthogonal fault** [15]: For a faulty memory cell, if there is no other faulty cell located in the same row and column containing the faulty cell, then this faulty memory cell is

DA	LRA	LCA	FT
----	-----	-----	----

Fig. 6. Fields of the FCR.

said to have an *orthogonal fault*. For each orthogonal fault, a GSRB is required to replace it. To implement the proposed MESP algorithm, it is necessary to use the *fault collection registers (FCRs)* for fault collection. The FCRs contain $r+c$ entries, where r and c denote the numbers of GSRBs and GSCBs, respectively. During the BIST session, when a faulty cell is detected, fault information is stored into the FCR registers. There are four fields contained in each FCR, as shown in Fig. 6. The D'A field is used to store the index of the divided array containing the faulty cells. The local row (column) addresses of the faulty cells are stored in the LRA (LCA) field. The FT field identifies if the faulty memory cells are orthogonal faults (FT=0) or faulty row (FT=1)/column blocks (FT=2).

IV. BISR ARCHITECTURES AND PROCEDURES

Fig. 9 depicts the block diagram of the proposed BISR scheme that includes the BIST module, the BIRA module, and the redundant memory module containing the GSRBs and the GSCBs. The BIST module performs a specified March algorithm to detect functional faults in the redundant memory module and the main memory module. It can also locate the faulty addresses. The BIRA module performs the proposed MESP algorithm and includes two components named the *fault collection register (FCR)* and the *address remapping content-addressable memory (ARCAM)*. The FCR collects and analyzes the faulty cell information detected by the BIST module. The ARCAM is the address remapping mechanism when the memory operates in normal operation mode. After finishing the BIST session, the faulty information stored in the FCR will be shifted into the ARCAM. Fig. 10 shows the BISR procedures. In *test/repair* mode, the BIST circuit tests the spare elements first to identify fault-free spares. If a fault is detected from the spare memory, the signal is activated and the corresponding faulty flag in the ARCAM module will be set which means that the faulty spare element is unusable. After spare memory testing, the BIST circuitry

will test the main memory. If a fault is detected in the main memory, the signal will be activated. The BIST will be suspended, and the BISR performs built-in redundancy analysis (BIRA). When this procedure is completed and the memory test is not finished yet, the BIRA module will send the signal to the BIST module to resume the test procedure. After the BIST session is finished, the BIRA module shifts the *faulty information (FI)* stored in the FCRs to ARCAM. When all fault information is shifted, the ARCAM serves as an address remapping mechanism in the normal operation mode. Since the BIST controller will be suspended each time when a fault is detected. The only possible loss of fault detection capability is during the instant when the BIST controller is resumed (not at-speed testing). However, the impact of fault detection quality is very low since the number of faults existed in the memory array is usually very small.

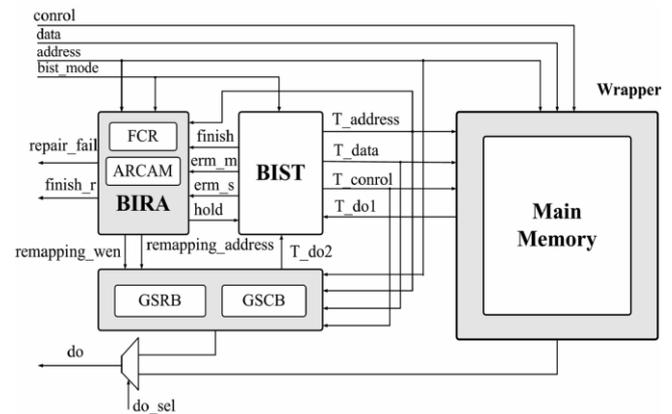

Figure 9: Block diagram of the proposed BISR scheme

The architectures of the FCR and ARCAM components are shown in Figs. 11 and 12, respectively. FCR component consists of the *FCR controller* and the *FCRs*. In *test/repair* mode, the reset signal is activated for one clock cycle to initialize all the internal registers. When a faulty cell in the spare elements is detected, the corresponding faulty flag in the ARCAM component will be set. After spare element testing, the ARCAM will send the signal to the FCRs to update the counters which count the numbers of available spare elements. If a faulty cell is detected in the main memory, this signal will force the FCR controller to send the hold signal to suspend the BIST circuit. Subsequently, the FCR controller will perform the MESP algorithm. The FCR controller is constructed with a finite-state machine with the state transition graph, as shown in Fig. 13. In this transition graph, if the BIST module does not detect faults or the fault has been repaired, it will remain in the state. Otherwise, it will enter the state. In the repair procedure state, if the detected fault is identified as a faulty row block and there are available GSRBs, the BIRA module will enter the state, which means that we can use GSRBs to repair the faulty cells. In the GSRB_repair state, the output signal will be activated. Similarly, if the incoming fault is identified as a faulty column block and there are still available GSCBs, the BIRA module will enter the state which means that we can use GSCBs to repair the faulty cells. In the GSCB_repair state, the output signal will be activated. If the incoming

fault is not identified as a faulty row block or a faulty column block and there are available GSRBs or GSCBs, the BIRA module will enter the state. The signal will be activated and the incoming faulty information will be stored into the FCRs. If the GSRBs and GSCBs are all used and there still exists some faulty cells, the *repair_fail* signal will be activated. When the BIST module finishes testing the spare memory and the main memory, the BISR procedure is finished. The signal will be activated.

V. EXPERIMENTAL RESULTS

In order to evaluate the proposed fault-tolerance techniques, the simulation model proposed in [18] is used to analyze our techniques. The number of such adjacent circuits is denoted as a . The parameter b denotes the cluster factor of the a th adjacent circuit. Similarly, the number of faults that have already occurred on the a th adjacent circuit is represented as b . Finally, the probabilities that a defect results in a faulty cell, a faulty column, a faulty row, and a cluster fault (a combination of several cell faults where the faulty cells are a cluster of any shape) are assumed to be 70%, 15%, 10%, and 5%, respectively. A simulator is implemented to simulate the proposed MESP algorithm. In our simulator, we set a as a constant. The values of b are set equal to a for simplification. The values of a and b are 0.65 and 1, respectively. We define *repair rate* as the probability of successful reconfigurations. In Fig. 14, we show the repair rates for the proposed MESP algorithm with different amounts of redundancy. The memory size is 1024 1024 bits. The average number of defects injected into a chip is assumed to be 15. From this figure we can see that if more redundancies are added, we get higher repair rates. Similarly, if the memory array is divided into more row and column banks, we will also obtain higher repair rates.

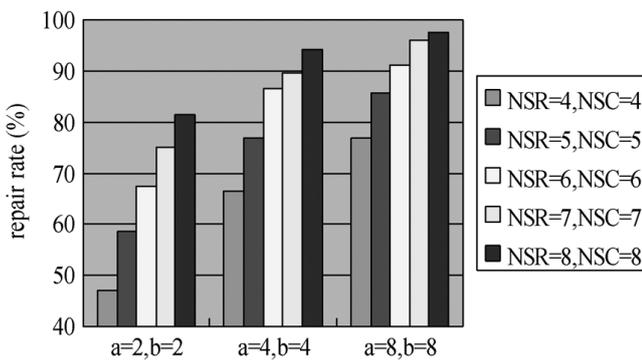

Fig. 14. Repair rates for different redundancy architectures based on the MESP algorithm.

We also compare the repair rates of the proposed MESP algorithm with those of the MESP (redundant row/column blocks are confined to their corresponding row/column banks) and ESP [15] (redundant rows/columns are not divided into row/column blocks) algorithms. The results are shown in Fig. 15. In this figure, the values of a and b are both set to 4. If the number of spare rows (columns) increases, the repair rates will also increase. From this figure we see that the MESP and MESP algorithms are much better than the ESP algorithm. It should be noted that if cluster faults are considered, the

MESP algorithm will have 10% improvement over the MESP algorithm on average. This improvement is very useful to further increase the manufacturing yield.

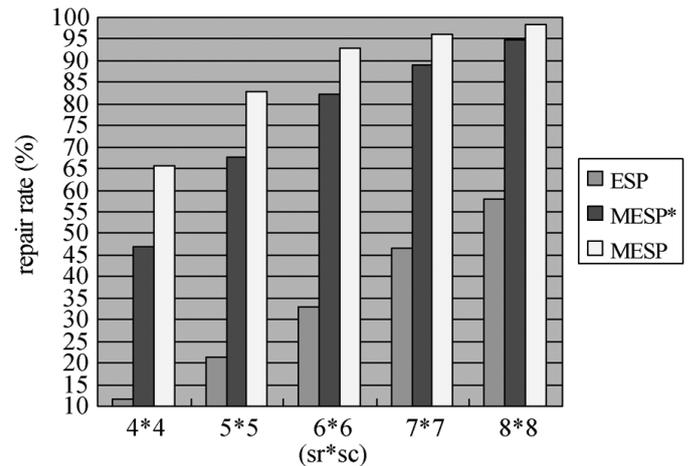

Fig. 15. Repair rates for the ESP, MESP and the MESP algorithms

If we change the values of a and b to 0.4 and 1.5, respectively, the results are, as shown in Fig. 16. The average number of defects injected into a chip is also the same. However, the injected faults are further clustered. Since the locations of defects are random and cluster faults may locate beyond the boundary of the chips or the divided arrays, the improvements of the MESP algorithm over the MESP algorithm are nearly the same as that shown in Fig. 15. From these figures, we can conclude that the proposed MESP algorithm is better than the other two algorithms. We have also tried to find the optimal solution by exhaustively searching the solution space. Therefore, massive simulations are conducted with different number of redundancies

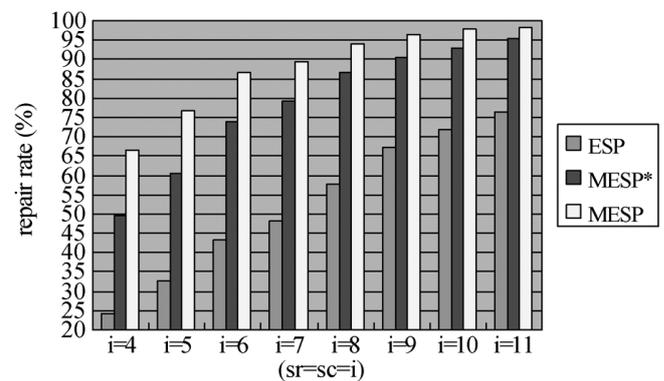

Fig. 16. Repair rates for the ESP, MESP, and the MESP algorithms

and compared the results with the optimal solution. According to our simulation results, the average repair rate is only 0.92% lower than the optimal repair rate. Therefore, by using the proposed MESP algorithm, near-optimal repair rate can be achieved.

VI. A PRACTICAL EXAMPLE

We have implemented a 16 K 32 word-oriented SRAM chip based on the TSMC 1P6M 0.18 m process. The specifications of this design are shown in Table II. The

memory blocks in this design are generated by a commercial memory compiler. We combine four 8 K 16-bit SRAMs into one 16 K 32-bit SRAM, and integrate all categories of the redundancy such as spare words, spare rows, and spare column group blocks into one 336 32-bit spare SRAM. The chip layout of the 16 K 32-bit SRAM with BISR is shown in Fig. 17. The number of I/O pins is 118. The *core size* and *chip size* is 5.0501 and 8.551 mm, respectively. According to the area of the physical layout shown in this figure, the hardware overhead of the spare elements and the BISR module is about 8.7%.

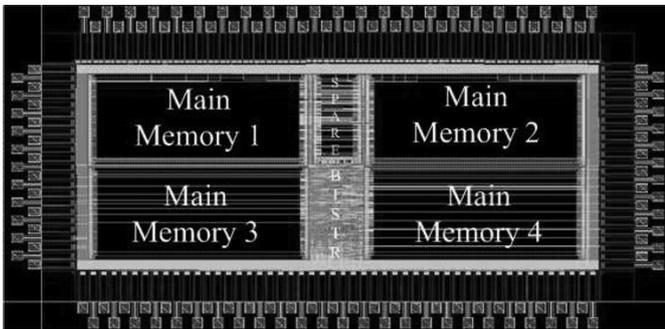

Fig. 17. Physical layout view of the 16 K x 32-bit SRAM with BISR.

VII. CONCLUSION

Instead of the traditional spare row/column redundancy architectures, *block-based* redundancy architectures are proposed in this paper. The redundant rows/columns are divided into row/column blocks. Therefore, the repair of faulty memory cells can be performed at the row/column-block level. Moreover, the redundant row/column blocks can be used to replace faulty cells anywhere in the memory array. This *global* characteristic is helpful for repairing cluster faults. The proposed redundancy architecture can be easily integrated with the embedded memory cores. Based on the proposed global redundancy architecture, a heuristic *modified essential spare pivoting (MESP)* algorithm suitable for built-in implementation is also proposed. According to experimental results, the area overhead for implementing the MESP algorithm is very low. Due to efficient usage of redundancy, the manufacturing yield, repair rate and reliability can be improved significantly.

*** (Department of Mechanical Engineering, NITTTR, India)*

ABSTRACT: *In recent decades, an interest in magnesium (Mg) alloys has progressively increased in numerous industrial fields. Magnesium alloys are characterized by favourable strength/weight ratio thus representing a valid alternative to aluminium alloys and High Strength Steels, largely adopted in those sectors where the production of lightweight parts is an important requirement (aerospace and automotive industries, electronics and sport). In order to produce Mg components with better mechanical properties, dimensional accuracy and finishing quality, sheet metal forming processes are the best manufacturing choice. Since the ductility of Mg alloys is quite poor at room temperature, the formed products of magnesium alloy is still limited. In order to find the forming method and conditions suitable for the sheet, the forming limit, i.e. the fracture initiation in sheet forming processes, has to be correctly predicted. Efforts were made to optimize process parameters by analyzing the causes of defects in order to improve the Limit Drawing Ratio of magnesium alloy work pieces. In recent years, quite a few efforts have been made to study the methods for improving the formability of wrought magnesium alloy. A great deal of research in literature confirms the effectiveness of the process parameter temperature in improving formability. A Brief overview in the field of forming operations at elevated temperatures has been reviewed to summarize the formability of magnesium alloy sheet. As, AZ31 can be more effectively formed to obtain complex geometries, which is usually measured evaluating the material formability as the locus of limit strains, more focus has been given to this alloy in the present review.*

Keywords: AZ31, Forming Limit, Limiting Drawing Ratio, Magnesium alloy, Sheet forming

I. INTRODUCTION

Magnesium alloy sheet was used in manufacturing, military, aircraft during and after the Second World War. They are used today in the automotive industry, mainly in sand and die castings; the development of light-weight vehicle is in great demand for enhancement of fuel efficiency and dynamic performance. The vehicle weight can be reduced effectively by using lightweight materials such as magnesium alloys. The low density of magnesium makes it ~35% lighter than aluminum and ~78% lighter than steel. Hence, successful implementation of magnesium in transportation industries would bring significant weight-saving benefits. Due to its lightweight and high specific strength, magnesium alloy have been considered as a promising alternative for high-strength steel and aluminum in some applications and has been widely used for structural components in the aerospace, electronics, and automobile industry to replace some existing materials[1,

2]. Because of lower density, better collision safety property and electromagnetic interference shielding capability, magnesium alloys are available for producing some structural parts such as the coverings of mobile telephones, notebook computers and portable mini-disks (MD). In the past, the demand for this alloy as a structural material was not high because of its less availability commercially as well as limited manufacturing methods. However, the use of magnesium alloys in sheet forming processes is still limited because of their low formability at room temperature and the lack of understanding of the forming process of magnesium alloys at elevated temperatures. The application of formed magnesium wrought alloys components, however, is restricted due to lack of knowledge for processing magnesium alloys, especially forming process, at elevated temperatures. However, since its alloy is a hexagonal close-packed metal and has poor formability, the formed products of magnesium alloy is still limited. In order to find the forming method and conditions suitable for the sheet, the forming limit, i.e. the fracture initiation in sheet forming processes, has to be correctly predicted. Therefore, previous studies [3–7] have been performed to summarize the formability of magnesium alloy sheet. Moreover, during the forming process, heat is generated by plastic deformation and the heat loss by conduction and by radiation and convection to the punch as well as to the environment can result in several property changes of the work piece. Therefore, this underscores the need for accurate methods to investigate a forming process of magnesium alloy not only deformation behavior but also heat transfer process, a task to which the finite element method is well suited. Finite element method (FEM) is a very effective method to simulate the forming processes with accurate prediction of the deformation behaviors. FEM can be used not only in the analysis but also in the design to estimate the optimum conditions of the forming processes. This can be done before carrying out the actual experiments for an economical and successful application of SPF to industrial components [8].

II. FORMABILITY OF MAGNESIUM ALLOYS

Magnesium possesses poor formability, difficult to be deformed at room temperature because of its hexagonal closed packed structure. It is necessary to enhance the forming temperature in order to improve formability of magnesium alloys effectively [9]. The research group has studied sheet metal forming processes of magnesium alloys in recent years [10–13] and found the mechanical properties of magnesium-alloy can be improved at elevated temperatures [14–18]. In this formability of magnesium alloy (more focus been given on AZ31 sheets) investigated by the experiment and FE analysis, various process like stamping, warm drawing, deep drawing, friction Stir

processing, Mg produced either by direct chill or twin roll continuous casting have been taken into account. Popular process used in assessment of formability of sheet metal is reviewed to determine the optimal processing parameters and explore novel forming technique [19, 20]. Fuh-Kuo Chen, Tyng-Bin Huang [21] conducted various experiments to study the formability of stamping magnesium-alloy AZ31 sheets of 1.2mm thickness at elevated temperatures. The mechanical properties of magnesium-alloy AZ31 rectangular specimens having the constant length of 140 mm, but with different widths ranging from 20 to 140mm in an increment of 20 mm, were tested at various temperatures ranging from room temperature to 400°C. A heating furnace was mounted on the MTS810 test machine and tensile tests at elevated temperatures were performed. Forming characteristics of AZ31 sheets, such as forming limit, conical cup value (CCV), spring back and minimum bending radius, were also examined by experiments. The stress-strain relations indicated that AZ31 sheets had higher yield stress and smaller elongation at room temperature, but the yield stress, the work-hardening coefficient n , dropped significantly when the sheet was heated to a temperature higher than 200°C. The experimental results showed that AZ31 sheets exhibited poor formability at room temperature, but the formability was improved significantly with greater possibility of local deformation, at elevated temperatures as in Fig.1 The sheets sustained more deformation before fracture at elevated forming temperatures. The V-bend tests revealed the spring back was reduced when AZ31 sheets were stamped at higher temperatures. In addition, the conical cup value (CCV) tests performed in the present study revealed that an optimum forming temperature, which was below 400 °C, existed, and a lower forming temperature has to be applied in the actual forming process.

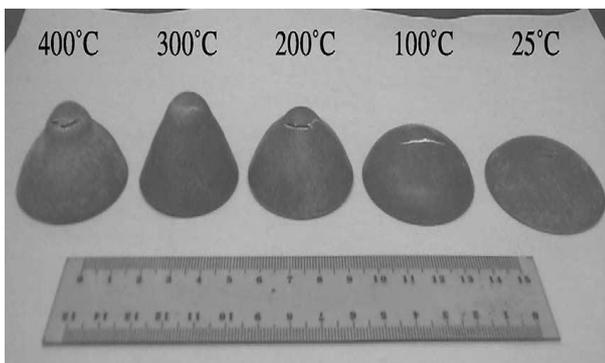

Fig.1.Fractured conical cups obtained from various temperatures.

In 2003, the square cup drawing of magnesium alloy AZ31 (aluminum 3%, zinc 1%) sheets was studied by experimental approach and the finite element analysis (The finite element software PAM STAMP). The mechanical properties of AZ31 sheets with 1.2 mm thickness according to the ASTM standards, at various forming temperatures were first obtained from the tensile tests and the forming limit tests. The test results in [22] indicated that AZ31 sheets exhibited poor formability at room temperature, but the formability could be improved significantly at elevated temperatures up to 200°C. The finite element simulations

investigated the effects of process parameters, such as punch and die corner radii, and forming temperature, on the formability of square cup drawing with AZ31 sheets. The other simulation parameters were: die clearance of 0.6 mm on each side, blank-holder force of 2.5kN, coefficient of friction of 0.1, and punch speed of 3 mm/s. In order to validate the finite element analysis, the deep drawing of square cups of AZ31 sheets at elevated temperatures was also performed. Both the tensile tests and the forming limit tests showed an inferior formability of AZ31 sheets if formed at room temperature. The formability dramatically improved when the AZ31 sheet was stamped at elevated temperatures. The punch radius (R_p) of 5 mm, die radius (R_d) of 6 mm, and corner radius (R_c) of 8 mm were the tooling dimensions used in both the finite element simulations and the experiments, both the finite element results and the experimental data revealed an optimum forming temperature of 200°C for the drawing of square cups, with 0.5 mm thick AZ31 sheets. This optimum temperature may vary with the sheet thickness and the part geometry to be formed. The finite element simulation results indicated that a larger punch radius allowed for a uniform material flow toward both of the two principal directions under the punch profile at corners delayed the occurrence of fracture and a smaller punch radius reduced the formability of square cup drawing. This strain-path pattern explained the reason why a larger punch radius leads to a better formability for the drawing of square cups. An optimum die corner radius for the drawing of square cups was also determined by both the finite element analysis and the experimental work. The investigation revealed that the formability improved as the die corner radius increased up to an optimum value, and became worse when the die corner radius was further increased. The strain path analysis indicated that the deformation of the sheet at the fracture location changed into the plane-strain mode from the stretch mode as the die corner radius was further increased from the optimum value, resulting in an early fracture since the plane-strain mode had a lower forming limit. The experimental data showed a good agreement with the simulation results, and the optimal forming temperature, punch radius and die corner radius were then determined for the square cup drawing of AZ31 sheets.

In this study [23], non-isothermal finite element (FE) simulation (DEFORM 2D and 3D, coupled thermo elastic-visco-plastic commercial FEM codes) has been conducted for forming round cups and rectangular pans from Mg alloy AZ31B sheet at elevated temperatures. The results were compared with experiments, conducted at the Technical University, Hanover. Load-stroke curve, thickness distribution and temperature distribution in the sheet obtained in experiments [24, 25] were compared with FE simulation results for various forming temperatures. The flow stress for the calculated strains, temperature and strain rate were logarithmically interpolated and extrapolated using the available input data. The friction coefficient, μ , used in the simulations was obtained from the strip draw test conducted by Droder [24] and Doege et al. [26] and it was assumed not to vary locally with interface temperature and pressure. The interface heat transfer coefficient was assumed to be uniform for the entire surface and the value was selected based on the results published in the literature [27]. The forming load predicted by simulation for round

cup and rectangular pan overestimated the experimental results. The trend predicted by simulation matched well with experiment. Higher punch force in the simulation could be due to the high frictional shear stress at interface. Coulomb friction coefficient of $\mu = 0.1$ was used in the simulation. Von Mises yield criteria was used in simulation to describe the yield surface of Mg alloy sheets. In the warm sheet forming of round cup and rectangular pan, the maximum thinning and tearing was observed at the cup wall in simulation and experiment. This was contrary to the observations in conventional stamping where the thinning occurred in the punch corner radius. This could be due to the fact that the cup walls in warm forming were at high temperature compared to punch corners, thus, the yield strength of material in cup wall was low compared to punch corner radius. A maximum thinning of 30% was observed in the simulation as compared to 10% in experiment. Excessive thinning observed in the simulation could be due to high process loads observed in simulation as compared to experiment. Simulation and experiments predicted increase in limiting draw ratio (LDR) with increase in temperature. Maximum LDR was obtained at the forming temperature of 200°C. LDR predicted by simulations for round cup for different forming temperatures were lower compared to the experimental results. Thermo-elastic-visco-plastic FEM code used in this study could successfully capture the deformation modes and the specific characteristics of the warm sheet forming process. At 300°C, the cup failed at the stroke of 32 mm. The maximum punch load obtained at all the simulated temperatures for LDR 2.3 was higher than the load obtained in experiment for corresponding temperatures. FE simulation results agreed well with experimental observations.

Tyng-Bin Huang et al. [28] studied the formability and non-isothermal deep drawing at elevated temperature of magnesium alloy AZ31B sheets by experiment and finite element analysis. The forming temperature, lubricant and sheet thickness was considered in this study. The peak punch force was increased as the diameter of blank increased. When the peak punch force was higher than the limit strength of the cup wall, the blank fractured, and the punch force decreased suddenly. The experimental results indicated that the highest limit drawing ratio (LDR) was at a forming temperature of 260°C for 0.58mm thick AZ31B sheet, and the highest LDR 2.63. The highest LDR was at a forming temperature of 200°C for 0.50mm thick AZ31B sheet, and the highest LDR 2.5 as shown in Fig.2 and Fig.3. The experimental data showed a good agreement with the simulation FEM code MSC Superform.

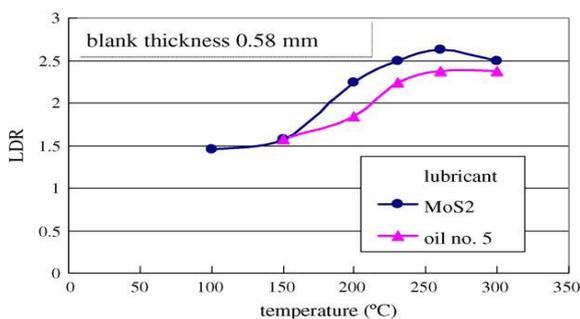

Fig.2. LDR from experiments at various forming temperature.

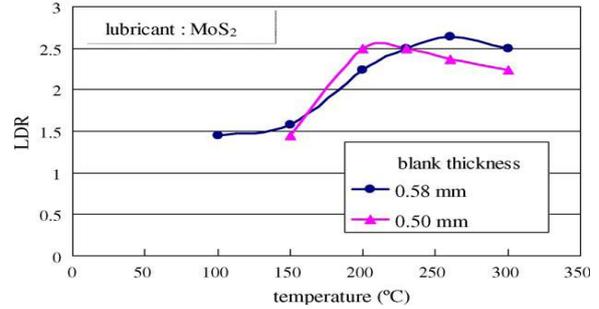

Fig.3. LDR of various sheet thickness from experiments.

In the research of [29], the forming limits on various forming process have been investigated using the experimental and FE analysis. Square cup drawing and stamping processes were used to investigate the formability of AZ31 sheet of 1.5mm thickness according to the ASTM standards. The mechanical properties of magnesium alloy AZ31 sheets at various temperatures ranging from room temperature to 400°C were obtained from experimental results and measured tensile properties were used to simulate the forming simulation by FEM commercial program, LSDyna™. The forming limit curve calculated based on the measured tensile properties could predict the fracture of formed part by FEM analysis. It showed some better formability at 400°C forming temperature. Fracture at 400°C forming temperature occurred by the diffuse necking due to the lower formability, because the work-hardening exponent was lower than that of 250 °C forming temperature. The best formability at 250 °C has been caused to the vital dynamic recrystallization as shown fig4. These experimental results well coincided with the FE analysis results predicted using the forming limit diagram (FLD) calculated by Keeler equation.

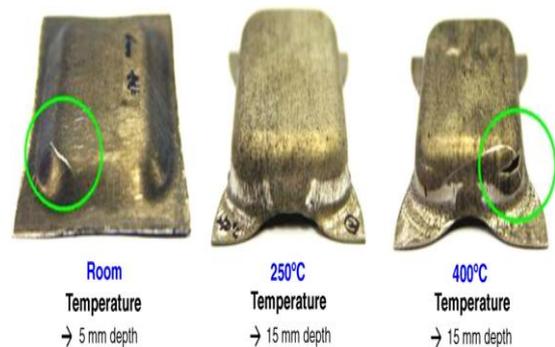

Fig.4. Square cups formed at each forming temperature.

A proper forming temperature range was determined in [30]. The effects of blank holding forces on the work piece quality were analyzed by warm deep drawing of cups from magnesium alloy sheets. Appropriate process parameters were selected to avoid forming defects effectively. In the paper, a rigid blank holder was used to adjust blank holding forces, using a 100 tonnes four-post multifunctional hydraulic press. A special liquid lubricant PTFE on the tool surfaces, punch diameter 65.6 mm/66.6 mm, punch shoulder radius 5 mm, die hole diameter 68mm and die shoulder radius 10 mm was used. The conditions of process defects, flange wrinkling and ruptures were analyzed. Experiments were carried out to verify the computer

simulation results. Efforts were made to optimize process parameters by analyzing the causes of defects in order to improve the Limit Drawing Ratio of magnesium alloy work pieces. Computer simulation with explicit finite element method was used to optimize the process parameters before carrying out the actual experiments. It was found that rolled magnesium alloy sheets had good deep drawing formability at a forming temperature range of 105–170°C with the limit drawing ratio up to 2.6. The cup of 0.4mm thickness had also been formed at this temperature. Some values greater than original thickness indicated the thickening on the flange. Formability would be reduced severely by excessive heating duration for a period of over 10 min in the preheated tools. Efforts were made to optimize process parameters by analyzing the causes of defects in order to improve the limit drawing ratio of magnesium alloy work pieces.

In the research work [31], an AZ31magnesium alloy sheet with excellent performances was fabricated by the cross-rolling and the uniform annealing treatments with annealing temperature 300°C and the holding time 1 h. The uniaxial tensile tests were conducted using a Gleeble 3500 thermal-mechanical simulator, and the mechanical properties of AZ31 magnesium alloy sheet were analyzed. Limiting drawing ratio (LDR) experiments were performed on double-acting hydraulic press. The uniaxial tensile tests showed that AZ31 magnesium alloy sheet was sensitive to the deforming temperatures and strain rates. The elongation increased from 18% to 50% with increasing temperatures from room temperatures to 200°C, and even reached 100% at 400°C. It was also found that the ductility of AZ31 magnesium alloy sheet increased sharply with the decrease of strain rates. The experiments showed that the LDR reached 2.0 at the forming temperature of 150°C and the drawing velocity of 15 mm/s. The AZ31 magnesium alloy sheet showed good formability at the temperature between 200 and 300 °C, LDR reached 3.0. The influences of drawing temperature and blank holder force on the formability are numerically investigated. A warm deep drawing process simulated by commercial explicit finite element code LS-Dyna demonstrated that variable blank holder force technology improved the LDR from 3.0 to 3.5, and decreased the wall thinning ratio from 15.21% to 12.35%.

ZE10 magnesium alloy sheets were prepared through ingot casting and the hot-rolling process. The mechanical properties, conical cup value (CCV), bore expanding performance, and limit drawing ratio (LDR) were investigated by [32] to examine the stamping formability of ZE10 alloy sheets, at temperatures ranging from 200 to 300 C. Tensile tests were carried out on SANSMT5105 testing machine. The results showed that the tensile strength decreased, whereas, plasticity, drawing-bulging performance, bore expanding properties, and deep drawing performance increased markedly at elevated temperatures. The CCV tests were performed on the universal testing machine according to the GB/T 15825.6-1995 standard. The CCV specimens could be drawn into the conical die's underside cylindrical hole from the conical cliff, without cracking, and could have the minimum CCV at 200 and 250°C. In the bore-expanding test, the bore (diameter 10mm) could be expanded to the dimension of the punch (dia. 25 mm) and the maximum bore-expanding

ratio could be achieved at above 150 C as in Fig.5. The limiting drawing ratio (LDR) of 2.85 was acquired during the deep drawing test at 230 °C as shown in Fig.6. with the punch temperature of 20 - 50 °C, the punch velocity of 50 mm * min⁻¹ and the mixture of graphite and cylinder grease as lubricant.

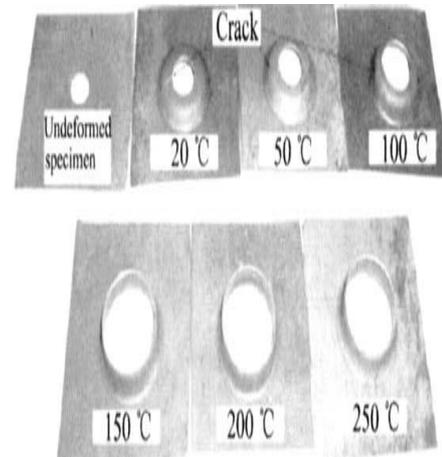

Fig.5 Specimens after bore-expanding tests at various temperatures

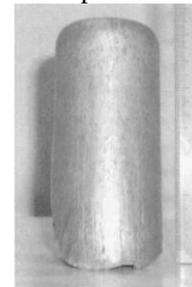

Fig. 6 LDR cup specimen at 230 C

Hai et.al [33] studied the deformation behavior of a cylindrical deep drawing of magnesium alloy sheets at elevated temperatures. Simulation was carried out by using a non-isothermal finite element based on DEFORM 3D commercial software. The experiments were conducted with a punch diameter of 40 mm, punch radius of 4 mm, die parameter of 42mm and die shoulder radius of 4 mm. The blank holder force was kept constant at 14 k N and the punch speed was 3mm/s. The tests were carried out at temperatures of tooling (die and blank holder) ranging from 423 to 523K while the temperature of punch was set at 298K. Teflon sheets were used as lubricant. In order to validate the finite element analysis, deep drawing test of cylindrical cup of AZ31 and AZ52 rolled sheets at given conditions was also performed. The LDRs of AZ31 and AZ52 increased with increasing in forming temperature and obtained the maximum values 3.2 and 2.8 at 498 K. the LDRs predicted by simulation were slightly lower compared to the experiment results. The punch force predicted by FE simulation overestimated the experiment results. This could be either due to high blank holder force and/or high shear stress caused by interface friction coefficient. The thermo-viscoplasticity FEM code, particularly Deform3D code could successfully capture the deformation behavior and specific characteristics of the warm sheet forming process. Maximum thinning of 32%

was observed in the simulation as compared to 27% in experiment. Thinning in the cup walls was greater than at the punch corner.

Forming limit diagrams were determined for a LZ61 alloy sheet with a thickness of 0.6mm by [34]. Uniaxial tension tests and press-forming tests were carried out at various temperatures. The influences of anisotropy and temperature on deformation characteristics were investigated. Formability parameters such as average plastic strain ratio, planar anisotropy, and work hardening exponent were determined by tensile test results. Tensile test results indicated that the normal anisotropy parameter value of LZ61 was not large enough to give good drawability at room temperature. The large negative value of the normal anisotropy parameter would result in serious ear formation during drawing process at room temperature. The forming limit diagrams have been experimentally evaluated at various temperatures. The LZ61 Mg alloy presented reasonable ductility at room temperature, but this alloy did not exhibit good stretchability and drawability. Anisotropic behaviors were observed in the mechanical properties at all test temperatures. The tensile properties and formability parameters were correlated with the forming limit diagrams. Some improvement of the stretchability of LZ61 alloy could be made by deforming the sheet at a higher temperature due to an increase in the normal anisotropy parameter value with temperature, though n value 0.159 dropped with increasing temperature. Increase in the normal anisotropy parameter value and decrease in the normal anisotropy parameter value with increasing temperature revealed that the drawability of LZ61 alloy could be improved by forming the sheet at elevated temperatures. Drawability improved for sheet deforming at 200°C, with the limiting fracture major strain about 25.22% and the limiting minor strain about 20.43% in tension–tension region, as shown in Fig. 7. In tension–compression region, the maximum major strain was about 43.35%, the minor strain around 24.75%.

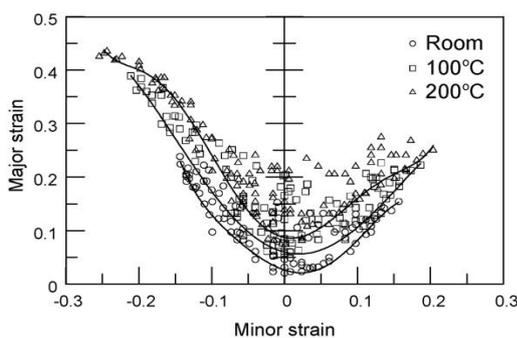

Fig. 7 Forming limit diagram of the LZ61 sheet at various temperatures.

In forming the Mg alloy AZ31-O, significant formability improvement was achieved at elevated temperatures compared to room temperature. Elevated temperature hydraulic bulge tests for Mg AZ31-O alloy sheets were conducted by [35] at the Institute for Production Engineering and Forming Machines (PtU), of Technische Universität Darmstadt using a submerged tool, designed to minimize the temperature variation in the sheet. Experiments were conducted between room temperature

and 225°C, at various approximate true strain rates. Strains upto 0.7 were obtained at 225°C and 0.025 s⁻¹. At higher temperatures and lower strain rates, thermal/work softening or stress dropped due to diffused necking. Bulge profiles at different bulge heights were measured using a CMM and the best radius values were calculated through least-square fit using several measured points. Residual plots were made to demonstrate the amount of deviation from a sphere with increasing bulge height. Twelve and 38mm bulge heights were obtained at room and elevated temperatures, respectively as shown in Fig.8. Measured and calculated bulge radius and thickness values were compared with the available analytical models and Amount of error that occurred in flow stress calculation by deploying the well-known membrane theory was investigated. Minimum thickness values were not always observed at the apex. Analytical models for thickness and radius calculations were found to be acceptable up to h_d/d_c ratios of 0.2 (h_d approx. 25 mm). At higher bulge heights ($h_d > 30$), comparisons between measured, calculated thickness and bulge radius values showed a difference of 8% and 6% from experiments, respectively.

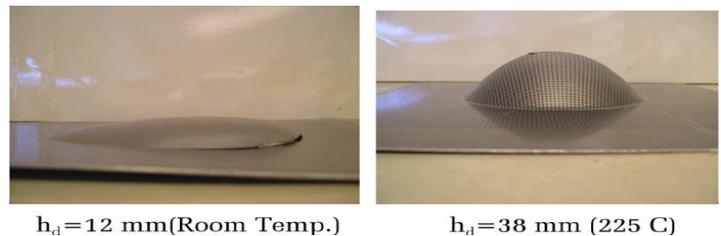

Fig.8. Variation in formability at room and elevated temperatures

In [36], warm formability of three sheet magnesium alloys AZ31, ZK10, and ZW41 was measured under isothermal conditions using the Ohio State University test (OSU) formability test adapted for testing at elevated temperatures ranging from 150 to 350°C and at a punch velocity of 1 mm/s. The punch and die were machined from D2 tool steel (ASTM A 681-08, 2007). The adapted test reliably enforced the plane strain tension over a significant fraction of the sample, thus providing an assessment of FLD(0), the minimum major strain value on a forming limit diagram. By mathematically modeling the strain as a function of punch displacement, a case was made that the punch displacement itself provided an expedient approach to ranking the relative formability of sheet metals. Combined with knowledge of the constitutive behavior of the material, the punch displacement strain relationship provided an explanation for the observed shape of the punch load versus displacement curves. Test results showed good formability at mildly elevated temperatures for the conventional magnesium alloys, AZ31 and ZK10, as well as superior formability of alloy ZW41, with an FLD(0) value of ~0.44 at 215°C (~37% improvement over the conventional). An anomalous formability decrease led to a formability minimum in all three alloys in the range of $T=250^\circ\text{C}$, due to the transition in failure mechanism from localized shear band-related plastic instability at low temperatures to more uniform necking at the highest temperatures. OSU formability test results showed that a new magnesium sheet alloy, yttrium-containing ZW41, was significantly more formable than

traditional magnesium alloys AZ31 and ZK10. The improvement was linked to a more random texture in the new alloy, which diminished the tendency for gross, catastrophic shear instability.

The authors in [37] proposed an experimental methodology based on the Marciniak stretch forming test to investigate sheet formability of the Mg alloy AZ31 in warm conditions (200°C), taking into account not only the temperature but also the strain rate effect. Specific tools to carry out such a formability test were designed and created: a flat punch of 92mm diameter (in line with Marciniak's test), embedded heating system was adopted in order to heat the central part of the specimen both rapidly and uniformly, where ruptures were forced due to the presence of a driving sheet between the specimen and the punch. A Digital Image Correlation system was also embedded in the formability equipment in order to acquire major and minor strains continuously and evaluated the moment and location of failures as in Fig.9. Finite Element simulations were run in order to define punch speed profiles (which differed according to the geometry of the specimen) that were able to keep a constant equivalent strain rate in the region where ruptures were forced. Experimental tests implementing the punch speed profiles were carried out in order to obtain temperature, load and strain data. FLCs at two different strain rate levels (0.02s⁻¹ and 0.002 s⁻¹) shifted upwards by about 35% at a temperature of 200°C. The proposed approach for FLC evaluation was effective for materials whose properties were strongly influenced by the strain rate. Such FLC data could be usefully implemented in numerical simulations of sheet metal forming processes: while tensile tests were used to determine variations in mechanical behaviour according to the strain rate, both the strain rate sensitivity index and the maximum elongation increased in line with the temperature. The punch speed profile seemed to be effective in keeping the strain rate constant for almost the whole test, reasonably near to the target strain rate value. The FLCs evaluated in this work allow us to determine the occurrence of strain path-dependent critical conditions according to the strain rate.

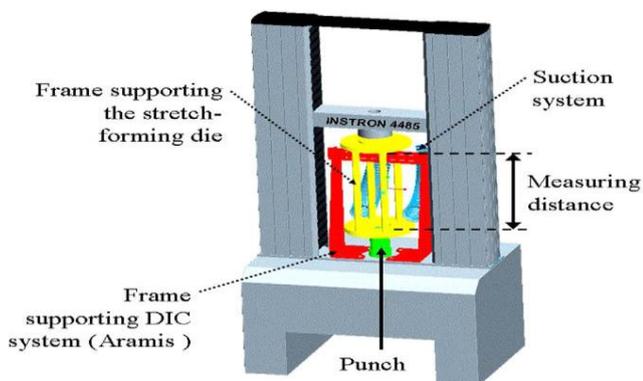

Fig. 9 Equipment for formability evaluation.

The sheet formability of AZ31 magnesium alloy has been widely investigated in [38] by means of uniaxial tensile and hemispherical punch tests, performed at different temperatures and strain rates, using samples with different fibre orientations on hydraulic testing machine by heating the samples, in the temperature range from 200 to 300°C, using a resistance furnace. Different samples keeping length

constant (100mm) and the width were varied from 12.5 to 100mm. The results of the uniaxial tensile tests were analysed in terms of flow curves, ductility and micro structural evolution. They showed that the flow stress decreased, strain rate reduced and ductility, strain rate sensitivity coefficient increased with increase in temperature whilst the strain hardening exponent increased with increasing strain rate and decreasing temperature and the ductility was independent of the fibre orientation, slightly affecting the flow stress values. The constitutive behaviour and strain rate analysed has been described using the well-known Backofen-type equation: $\sigma = A \epsilon^n \dot{\epsilon}^m$ where A, the strength coefficient, n the strain hardening exponent and m the strain rate sensitivity coefficient. Both m- and n-values were affected by the fibre orientation; The formability, described by the forming limit curves (FLCs), improved with increased temperature and decreasing strain rate with a more marked effect in the stretching side of the forming limit diagram; such behaviours were related to the micro structural evolution, that was strongly influenced by temperature and strain rate, due to the occurrence of grain boundary sliding, dynamic recrystallisation and grain growth. The formability along the rolling direction (RD) was higher than that along the transversal one (TD), even if the FLCs obtained along the TD had a larger extension in the drawing side than the ones along the RD. Such behaviours were related to the constitutive parameters and microstructure developed during deformation.

The authors in the study [39] focused on the improvement of formability of MgAZ31B alloy through friction stir processing. The friction stir processing was done on a vertical head milling machine, with the position of the tool fixed, relative to the surface of the sheet. A non-consumable taper threaded tool made of high carbon steel H13 with a shoulder diameter of 18 mm and a pin of diameter 6 mm and length 3 mm was used. Rectangular blanks of dimension 100 mm X 60 mm were used to conduct the LDH tests in plane-strain condition. Square specimens of size of 100 mm X 100 mm were blanked from the friction stir processed sheets for biaxial stretch forming. Specimens of size 140 mm long and 124 mm wide were used for Ohio State University test (OSU) test. All LDH tests were carried out in dry condition at a punch speed of 0.3 mm/s on a 50 ton hydraulic press. An optimum blank holding force in the range of 3–4 ton was applied. The processed samples were evaluated for elongation, strain hardening index, n, work hardening capacity, 1/YR and anisotropy, r. The formability of the processed samples was evaluated through two test methods namely the LDH test and Ohio State University test (OSU). The same trend of the formability behavior was found for all the samples tested irrespective of the different testing procedures followed. Further, it has been found that both rotational speed and traverse speed had significant effect on the formability. An inverse relationship existed between the yield strength and the LDH. It was found that, work hardening capacity, the inverse of yield ratio (YR), was an indicator of LDH value rather than the yield strength and uniform elongation. A statistical model has been developed to predict the formability characteristics. It was seen that, the friction stir processed material, has more FLD (0) values, and also higher than the base metal. FLD (0) was the lowest point in the FLD diagram. It was in the major

strain region and measured at plane-strain condition. The FLD of the base metal and processed metal are shown in Fig. 10. The developed model could replace the tedious formability testing procedures with a simple uniaxial tensile test, it was presumed that formability index, $FI = (e \times n \times 1/YR)/r$, FI was more for the samples with low r value, and thus, in the developed model, r was in the denominator. The results obtained from the developed model could be used as a basis for establishing the optimal friction stir process parameters, to develop the desired formability properties in Mg AZ31 alloy.

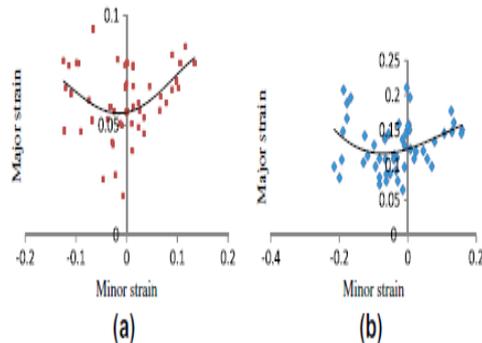

Fig.10 Forming Limits of (a) base sample (b) FSP sample

Formability of four magnesium AZ31B sheet materials, produced either by direct chill or twin roll continuous casting, was investigated by [40] at 400°C and $5 \times 10^{-3} \text{s}^{-1}$ using pneumatic stretching. Sheet specimens were deformed through a series of four elliptical die inserts, with aspect ratios ranging between 1.0 and 0.4, producing ellipsoidal domes with different biaxial strain combinations. Testing was carried out in two scenarios, i.e. with the major strains aligned either along or across the rolling direction of the material. Circle grid analysis was then used to map the planar strains of the deformed specimens; the latter were used to generate comprehensive material forming limits curves (FLCs) that bound the safe, marginal and failure deformation zones. For all four sheets, the 0° orientation showed greater formability limits than the 90° orientation. This was further confirmed through dome height measurements. Orientation effects were quantified by constructing a “composite FLD” for each of the four sheets; the diagrams collectively showed that greater formability limits were achieved along the material’s rolling direction, when the major strains accumulated along the rolling direction, and are larger than the minor strains. Detailed comparisons between the four sheets were carried out based on formability limits, deformation uniformity and maximum dome height prior to failure and fracture surface morphology and chemistry. By comparing the formability results obtained for the four sheets, it was found that the sheets produced by TRC casting outperformed the one produced by DC casting mainly due to the finer grain size of the former compared to the latter. Disparities in formability were linked to differences in grain structure and material inhomogeneities. Formability limits reduced and premature failure was due to internal material defects in the form of long oxide stringers. TRC cast sheets were more prone to this kind of defects.

III. CONCLUSION

The main objective of the present study is that of extending and improving research into the combined effect of strain rate and temperature on material formability. Formability test results showed that a new magnesium sheet alloy, yttrium-containing ZW41, was significantly more formable than traditional magnesium alloys AZ31 and ZK10. The improvement was linked to a more random texture in the new alloy, which diminished the tendency for gross, catastrophic shear instability. The formability of Magnesium alloys increased at elevated temperatures depending on the thickness and the forming process adopted. A brief review of formability of Magnesium alloys at elevated temperatures presented here would serve as platform for further development in light-weight metals and alloys and helpful in meeting the great demand for enhancement of fuel efficiency and dynamic performance of structural components in the aerospace, electronics, and automobile industry to replace some existing materials.

The Influence of Thyristor Controlled Phase Shifting Transformer on Balance Fault Analysis

Pratik Biswas

(Department of Electrical Engineering, Jalpaiguri Government Engineering College, India)

ABSTRACT: This paper analyses the method to limit fault currents and pre fault bus voltage by the use of Thyristor Controlled phase Shifting transformer (TCPST). The mathematical model of power system equipped with TCPST was systematically derived. The magnitude of the series reactance plays a very important role to limit the short circuit current, as well as TCPST inject a series voltage which reduces the pre fault bus voltage. The total fault current of the system get reduced with respect to the total fault current of the system without introducing TCPST. The effectiveness of TCPST in the proposed method is investigated in the phase fault.

Keywords: Balance Fault, FACTS, TCPST

I. INTRODUCTION

Flexible AC transmission systems (FACTS) devices are being increasingly used in a modern power system to improve both steady state and dynamic performances of the system. There are many types of FACTS devices, such as Unified Power Flow Controller (UPFC), Static Synchronous Compensator (STATCOM), Static Synchronous Series Compensator (SSSC), Thyristor Controlled Phase Shifter (TCPS), Static Var Compensator (SVC), etc. TCPST consists of a shunt transformer, a series transformer and a converter. The converter can be of ac-ac bridge type, pulse-width modulation (PWM) type, ac controller type, etc. The possibility of controlling electric power flow in a transmission system by using controllable solid state devices like TCSC and TCPST is well known. These series connected FACTS devices inject a series voltage with the line and thereby modulate the line reactance or the phase shift between the two end voltages. Recent advances in solid-state power electronics technology have made it possible to implement the above devices using power switching voltage source converters. On the other hand, short-circuit current levels increase with the addition of new lines, generators and transformers. This may surpass the short circuit current ratings of equipment, like for example circuit breakers, a frequent problem in power systems.

In today's security assessment tools the calculation of the fault level is a well established function. A fault level that exceeds the upper limit endangers the ability of circuit breakers to interrupt the short circuit current. If the fault level is beneath the lower limit, the connection of a major load results in unacceptable voltage drop.

The fault current limitation offered by modern controllers, characterized by their fast responses, may become an important assistance in the task to diminish such large currents. Since the fault clearing time is not instantaneous, depending on the operating time imposed by

protection and breaker operation delays, adequate control actions can be performed by this equipment

Although significant flexible features may be introduced in power control by those new devices, they still can be very expensive, and additional benefits like protection improvement should be investigated in order to verify the possibility of their application in the development of more secure and reliable networks

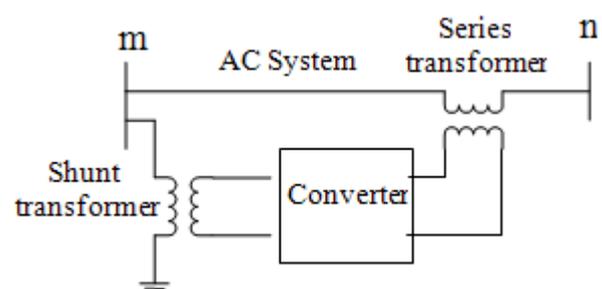

In this paper TCPST is analysis and proper modeling in a power system is discussed.

The fault limitation approach presented here explores this new technology and additional functionality offered by the series-connected FACTS controllers.

II. MODELING OF TCPST

Mathematical model: Figure 1a shows the schematic diagram of the Thyristor Controlled Phase Shifter (TCPS). The series transformer injects the voltage in series in the system. The active and reactive power injected by the series transformer is taken from the shunt transformer. For sake simplicity of analysis, the insignificant losses from transformer and converter is neglected. Thus the net complex power (real and reactive power) exchange between the TCPS and the system is zero. The injection of this complex power depends on the injection of a series voltage controlled by a converter.

Figure 1b shows the equivalent circuit of Fig. 1a. V_s and V_{sh} are represented by the synchronous voltage sources in series and shunt, respectively. X_{sh} is the leakage reactance of the shunt transformer. X'_s is the leakage reactance seen from primary side of series transformer is given by $X'_s = X_s + n^2 X_{sh}$ where n is the turn ratio number of the shunt transformer and X_s is the leakage reactance of the series transformer [2]

(a)

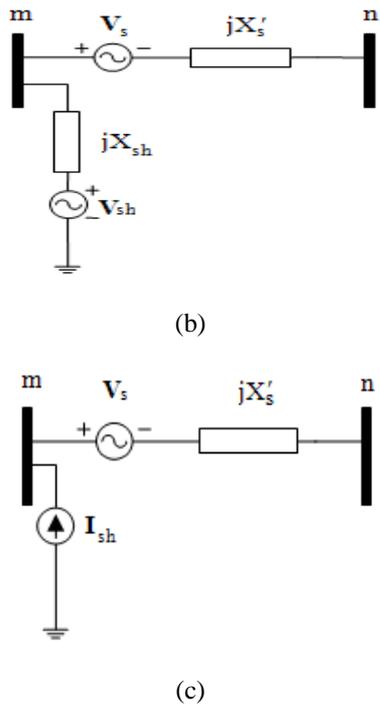

Figure 1: TCPST; (a) Schematic diagram of a TCPST; (b) a series and shunt synchronous voltage source equivalent; (c) a series injected voltage source and a shunt injected current source

The TCPST consists of two transformers; a shunt transformer or magnetizing transformer connected in parallel and a series transformer or booster transformer in series to the line (Fig.1). The current through the magnetizing transformer induces a voltage on the primary side of the booster transformer. The turn ratio of the shunt transformer is 1: n, and the turn ratio of the series transformer is 1:1. Compared to conventional phase shifting transformers, the mechanical tap changer is replaced by a thyristor controlled equivalent. The purpose of the TCPST is to control the power flow by shifting the transmission angle. In general, phase shifting is obtained by adding a perpendicular voltage vector in series with a phase. This vector is derived from the other two phases via shunt connected transformers. The perpendicular series voltage is made variable with a variety of power electronics topologies. A circuit concept that can handle voltage reversal can provide phase shift in either direction. This Controller is also referred to as Thyristor-Controlled Phase Angle Regulator (TCPAR). A phase shifter model can be represented by an equivalent circuit, which is shown in Fig 2. It consists of admittance in series with an ideal transformer having a complex turns ratio. [4]

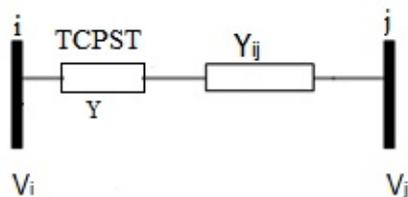

Figure 2: Admittance diagram of a system containing TCPST

The mathematical model of TCPST can be derived from Fig. 2.

$$\begin{bmatrix} I_i \\ I_j \end{bmatrix} = \begin{bmatrix} Y_{ij} + Y & -Y_{ij} \\ -Y_{ij} & Y_{ij} + Y \end{bmatrix} \begin{bmatrix} V_i \\ V_j \end{bmatrix}$$

Where Y_{ij} is the admittance of the line and Y is the admittance of the TCPST. The admittance of the TCPST is equal to the reciprocal of the reactance of the TCPST.

So, $Y = 1 / (X'_s)$. Where $X'_s = X_s + n^2 X_{sh}$. the turn ratio n is actually a complex quantity. Turn ratio equal to $n \angle \phi$.

III. FAULT VOLTAGE AND FAULT CURRENT LIMITATION

The fault current limitation is based on impedance control. Three phase faults can be controlled with limiting reactor. However, quiet small information exists on fault limitation with series voltage injection, in view of their recent introduction on networks. [1]

Since the series voltages are introduced through series coupling transformers or booster transformer, their respective leakage reactance contribute for fault current limitation, and this aspect must be considered in the analysis.

A. Fault Voltage Limitation

The most important factor that we are analyzing is the possibility of series voltage insertion, which can also be understood as an emulated reactance or capacitance inserted into the line. If a capacitive mode of compensation is in operation with voltage leading current, line fault current would be increased, and in the inductive mode of operation with voltage lagging current, the fault current could be substantially limited. The fast control action of series voltage with the introduction of power-electronics, could be significant in current limitation.

The insertion of series voltage is means of we want to reduce the voltage of the fault point. Which is in fact in agreement with the thevenin pre-fault bus voltage.

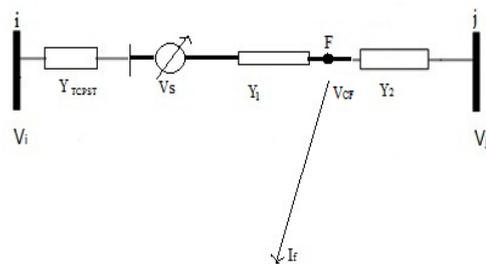

Figure 3: Fault occurring at the system containing TCPST

Now consider resistance of the line tends to zero, so $Y_{TCPST} = 1 / [X_{TCPST}]$ and $Y_1 = 1 / Z_1$.

Let's consider $X_0 = X_{TCPST} + X_1$
 So, $Y_0 = 1 / (R + jX_0) = 1 / [(1/Y_1) + (1/Y_{TCPST})]$

In the simple configuration of Fig 3, let's suppose the short circuit occurring at the point F. In the configuration it is

seen that TCPST is connected in the system. At the left of the fault the injecting source is V_s is opposition to the left equivalent source, having no effect in the line contribution.

So let's consider the fault point in Fig 3 and the admittance Y_{TCPST} added to the equivalent system admittance. The admittance to the left hand side of the fault point is considered Y_1 , and admittance right hand side of the fault point F is considered as Y_2 .

The voltage at the point F due to V_i and V_j without the presence of V_s is called uncompensated fault voltage V_F . the series voltage contribution is calculated applying the superposition theorem with the following network.

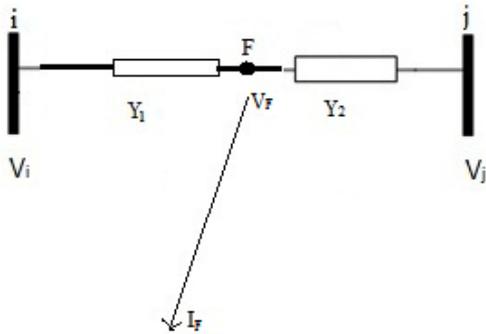

Figure 4: Uncompensated line with fault at point F.

Now applying the superposition theorem:

Consider the voltage V_{F1} at fault point when only source V_i is present, and V_{F2} when only source V_j is present.

$$V_{F1} = \frac{\frac{1}{Y_2}}{\frac{1}{Y_1} + \frac{1}{Y_2}} V_i \quad (\text{When only } V_i \text{ is present})$$

$$V_{F2} = \frac{\frac{1}{Y_1}}{\frac{1}{Y_1} + \frac{1}{Y_2}} V_j \quad (\text{When only } V_j \text{ is present})$$

So uncompensated fault voltage at point F

$$V_F = V_{F1} + V_{F2}$$

$$V_F = \frac{\frac{1}{Y_2}}{\frac{1}{Y_1} + \frac{1}{Y_2}} V_i + \frac{\frac{1}{Y_1}}{\frac{1}{Y_1} + \frac{1}{Y_2}} V_j$$

$$V_F = \frac{V_i Y_1 + V_j Y_2}{Y_1 + Y_2}$$

Now to calculate the compensated line fault voltage we have to apply superposition theorem, so consider a network where only series connected voltage source is present.

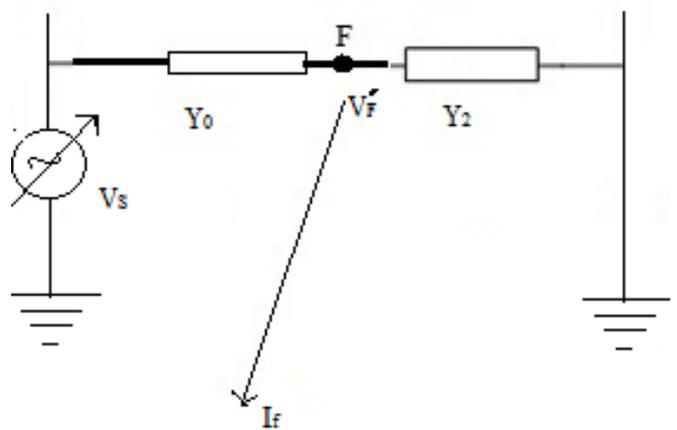

Figure 5: series voltage contribution to the fault voltage

Now the compensated fault voltage $V_{F'}$.

$$V_{F1}' = \frac{\frac{1}{Y_2}}{\frac{1}{Y_0} + \frac{1}{Y_2}} V_s$$

$$= \frac{Y_0}{Y_0 + Y_2} V_s$$

Now compensated fault voltage V_{CF}

$$V_{CF} = V_F + V_{F1}'$$

$$= \frac{V_i Y_1 + V_j Y_2}{Y_1 + Y_2} + \frac{Y_0}{Y_0 + Y_2} V_s$$

To minimize the fault voltage, the compensation term V_{F1}' has to be in opposition to V_F , with the series voltage inserted at its maximum magnitude during the fault period.

B Fault Current Limitation

The calculation of the three phase fault is well established in today's security assessment. For solving this problem the admittance matrix Y , used for power flow calculation, must be expanded to Y' by the transient reactance of generators

The impedance matrix $Z = \text{inv}(Y)$

Short Circuit current $I_f = V_{CF} * Y$

Now uncompensated fault current I_f

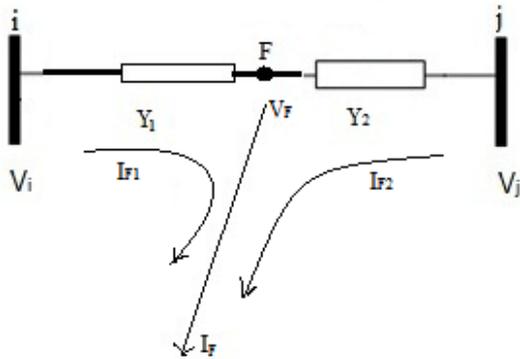

Figure 6: fault current through a network without TCPST

$$I_f = I_{F1} + I_{F2}$$

$$= V_F Y_1 + V_F Y_2$$

$$= V_F (Y_1 + Y_2)$$

After connecting TCPST in the network fault current I_{CF}

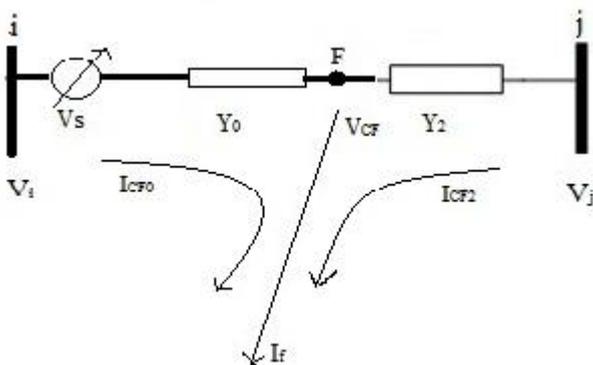

Figure 7: fault current through TCPST connected network.

Now, $I_{CF} = I_{CF0} + I_{CF2}$

$$= V_{CF} \cdot Y_0 + V_{CF} \cdot Y_2$$

Where $Y_0 = 1/X_0 = 1/[(1/Y_1) + (1/Y_{TCPST})]$

$$= 1/[X_{TCPST} + X_1]$$

X_{TCPST} is the reactance of TCPST. So after connecting the TCPST reactance will be increased, so Y_0 will be less. So I_{CF0} will be less. V_{CF} will less due to series voltage injection, so I_{CF2} will be less. Therefore the fault current I_{CF} will be limited

IV. PROBLEM FORMULATION AND SIMULATION RESULT

The above proposed method is tested in a power system network is shown in the diagram. The system tested in MATLAB platform. The power system network model is a 10 bus system. In the taken system TCPST is connected between bus no 7 and 9. The fault occurs in the line between bus no 7 and bus no 9. For simplification in calculation the fault point is considered as a bus and the no of the bus is 8. So TCPST is connected now in between bus no 7 and fault point or bus no 8.

. The transient reactance of the generators on a 100 MVA base are given below.

Table 2: Transient reactance of generators

Generator transient reactance in p.u		
Generator no.	R_a	X_d'
1	0	0.20
10	0	0.15
11	0	0.25

The line data containing the series resistance and reactance is in per unit, and one half of the total capacitance is in per unit susceptance on a 100 MVA base.

Table 1: Line data of the system are given below

Line Data				
Bus no	Bus no	R (p.u)	X (p.u)	$\frac{1}{2} B$ (p.u)
1	2	0.00	0.06	0.0000
2	3	0.08	0.30	0.0004
2	5	0.04	0.15	0.0002
2	6	0.12	0.45	0.0005
3	4	0.10	0.40	0.0005
3	6	0.04	0.40	0.0005
4	6	0.15	0.60	0.0008
4	9	0.18	0.70	0.0009
4	10	0.00	0.08	0.0000
5	7	0.05	0.43	0.0003
7	8	0.06	0.35	0.0004
7	11	0.00	0.10	0.0000
8	9	0.052	0.48	0.0000

The system diagram given below

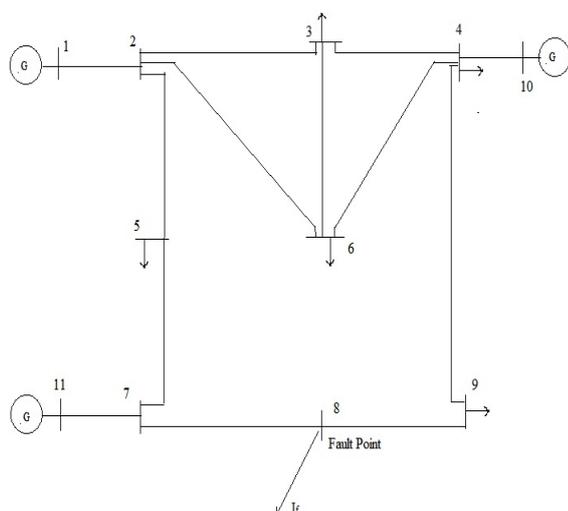

Figure 8: Single line diagram of tested system

The TCPST is connected is in 40% compensation.

Now the system is simulated in MATLAB platform. The system is tested with and without having TCPST in the system.

Without having TCPST it is seen that the pre-fault bus voltage at the fault point or bus no 8 is 1 p.u. it is seen that after connecting TCPST the pre fault voltage of the fault point is 0.81 p.u. So it is cleared that after connecting TCPST the pre fault voltage decreased by 19%.

The limitation has strong dependence on the maximum dependence on the maximum series voltage developed by the converter and the following cases the maximum value adopted is 0.4.

From the simulation result we see that line without having TCPST the total fault current is 2.3622 p.u. and the compensating total fault current is decreased to 2.0515. so fault current decreased by 0.31 p.u. As the pre-fault voltage and post fault current is limited by series compensated line having TCPST, so it is clearly observed that series compensated line having TCPST can decrease the fault level.

Figure captions appear below the figure, are flush left, and are in lower case letters. When referring to a figure in the body of the text, the abbreviation "Fig." is used. Figures should be numbered in the order they appear in the text.

Table captions appear centered above the table in upper and lower case letters. When referring to a table in the text, no abbreviation is used and "Table" is capitalized.

V. CONCLUSION

The influence of TCPST in three phase fault voltage and fault current limitation is discussed in this paper. Here TCPST insert a series connected voltage source in the line which actually opposing the bus voltage. So the pre-fault voltage of the fault point is reduced with the presence of TCPST. We have also seen that TCPST also limit the fault

current. So fault level will decrease due to decrease of pre-fault voltage and post fault current. Due to reduction in fault level the dynamic nature as well as transient stability of the system will increase. As the fault current in the system is in limit the thermal equilibrium condition will not hampered.

The future research work will be on optimal location of TCPST in a power system and control of TCPST in both balanced and unbalanced fault analysis.

Abstract: In this paper a new market Based approach for transmission expansion planning in deregulated power systems is presented. Restructuring and deregulation has exposed transmission planner to new objectives and uncertainties. Therefore, new criteria and approaches are needed for transmission planning in deregulated environments. In this paper we introduced a new method for computing the Locational Marginal Prices and new market-based criteria for transmission expansion planning in deregulated environments. The presented approach is applied to Southern Region (SR) 48-bus Indian System.

Keywords: Competitive electric market, Transmission expansion planning, Uncertainty, Scenario techniques, power transmission planning, price profile, risk analysis, uncertainty.

I. INTRODUCTION

Transmission system is one of the major components of the electric power industry. If the electric loads increases, transmission expansion planning should be increased timely and proper way to facilitate and promote competition. Restructuring and deregulation of the power industry have changed the aims of transmission expansion planning and increased the uncertainties. Due to these changes, new approaches and criteria are needed for transmission expansion planning in deregulated power systems.

Transmission expansion planning approaches can be classified into:

- Non-deterministic approaches, and
- Deterministic.

In non-deterministic approaches the expansion plan is designed for all possible cases which may occur in future with considering the occurrence probability of them.

In deterministic approaches the expansion plan is designed only for the worst cases of the system without considering the probability of occurrence (degree of occurrence) of them. Hence, Non-deterministic approaches are able to take into account the past experience and future expectations.

Non-deterministic approaches can be classified in:

- Static, and
- Dynamic approaches.

2.1 Non-deterministic Transmission Expansion Planning Approaches

Uncertainties can be classified in two categories:

- Random, and
- Non-random uncertainties.

Random uncertainties are deviation of those parameters which are repeatable and have a known probability

distribution. Hence, their statistics can be derived from the past observations. Uncertainty in load is in this category.

Non-random uncertainties are evolution of parameters which are not repeatable and hence their statistics cannot be derived from the past observations.

Non-deterministic approaches which have been used for transmission expansion planning are:

- probabilistic load flow,
- probabilistic based reliability criteria,
- scenario technique,
- decision analysis, and
- Fuzzy decision making.

Probabilistic load flow and probabilistic based reliability criteria approaches take into account random uncertainties. Scenario technique considers the non-random uncertainties. Decision analysis is a proper method for dynamic programming. Fuzzy decision making considers imprecision and vague data.

Review of the presented approaches and discussion of their advantages and drawbacks helps the procedure of presenting new approaches and criteria for transmission planning in deregulated environments. State of the art review on transmission expansion planning approaches is presented in this paper.

Transmission expansion planning approaches for:

- Regulated, and
- Deregulated power systems.

The main objective of power system planning in regulated power systems is to meet the demand of loads, while maintaining power system reliability. In this environment uncertainty is low. Transmission expansion planning is centralized and coordinated with generation expansion planning. Planners have access to the required information for planning. Therefore, planners can design the

least cost transmission plan based on the certain reliability criteria.

In deregulated power systems participants take their decisions independently. They change their strategies frequently to acquire more information from the market to maximize their benefits. Consumers adjust their loads according to the price signals. Availability of independent power producers is uncertain. Wheeling powers are time varying and affect the nodal prices of the control areas that they pass through. Transmission expansion planning is not coordinated with generation expansion planning. Hence, there is not a specified pattern for load and dispatched power in deregulated power systems. Due to these uncertainties expansion of transmission networks have been faced with great risks in deregulated environments. Therefore, the final plan must be selected after the risk assessment of all solutions. Since risk assessment is characteristically based on probabilistic and stochastic methods, probabilistic methods should be developed for transmission planning in deregulated power systems.

2.2 Transmission Expansion Planning Approaches for Deregulated Power Systems

From the viewpoint of transmission planner, there are two major differences between transmission expansion planning in regulated and deregulated environments:

- Objectives of transmission expansion planning in deregulated power systems differ from those of the regulated ones.
- Uncertainties in deregulated power systems are much more than in regulated ones.

In this section objectives of transmission expansion planning in deregulated power systems and uncertainties in deregulated power systems are discussed.

2.3 Objectives of Transmission Expansion Planning in Deregulated Power Systems

In general, the main objective of transmission expansion planning in deregulated power systems is to provide a non-discriminatory competitive environment for all stakeholders, while maintaining power system reliability. Specifically, the objective of transmission expansion planning is providing for the desires of stakeholders. The desires of stakeholders in transmission expansion are:

- Investment cost will be decreased.
- The network charges will be decreased.
- The risk of investments against all uncertainties will be reduced.
- Encouraging and facilitating competition among electric market participants.
- Providing non-discriminatory access to cheap generation for all consumers.
- Operation cost will be reduced.
- Minimizing the costs of investment and operation.
- Increasing the reliability of the network.
- The value of the system will be increased.

- The flexibility of system operation will be increased.
- The environmental impacts will be decreased. and

2.4 Uncertainties and Vagueness in Deregulated Power Systems

Development of competitive electric markets has introduced significant uncertainties and vagueness in transmission expansion planning. Since methods of modeling random uncertainties, non-random uncertainties, and vagueness are different, power system uncertainties and vagueness must be identified and classified clearly before planning. Sources of random uncertainties in deregulated power systems are:

- power and bids of independent power producers (IPPs),
- generation costs and consequently bid of generators,
- Forced outage of generators, lines and other system facilities.
- wheeling transactions and power transactions with other areas, and
- load,
- Sources of non-random uncertainties are:
- Market rules.
- Generation expansion or closure.
- Load expansion or closure.
- Installation, closure or replacement of other transmission facilities.
- transmission expansion costs, and
- There is vagueness in the following data:
- occurrence degree of possible future scenarios,
- importance degree of stakeholders in decision making , and
- Importance degree of planning desires from the viewpoint of different stakeholders.

Uncertainties in deregulated environments have increased uncertainty in required capacity for transmission expansion and consequently increased the risk of fixed cost recovery. Therefore, incentives for investing in transmission expansion have reduced and caused a delay on transmission planning.

2.5. Scenario Technique

For the planning of any system we can use the Scenario technique and decision analysis. The algorithm of transmission expansion planning using scenario techniques is shown below.

- To determine the set of probable future scenarios.
- To determine the occurrence probability or occurrence degree of future scenarios.
- To determine the set of possible solutions (expansion plans).
- To measure the goodness of expansion plans by selecting a cost function.
- To select the final plan.

The final plan can be selected by using the following methods.

1. Expected cost method: This method selects the plan that minimizes the expected cost over different scenarios i.e.:

$$\text{Min}_k E^k = \sum_l v^l f^{k,l}$$

Where E^k = expected cost of plan k, v^l = occurrence degree of scenario l, $f^{k,l}$ = cost of plan k in scenario l.

2. Minimax regret method (risk analysis): In risk analysis the best solution is determined by minimizing the regret. Regret is a measure of risk. Regret of plan k in scenario l is defined as difference between the cost of plan k in scenario l and cost of the optimal plan of scenario l, i.e.:

$$r^{k,l} = f^{k,l} - f^{op,l}$$

Where $r^{k,l}$ = regret of plan k in scenario l, $f^{op,l}$ = cost of the optimal plan of scenario l. In risk analysis the plan that minimizes the maximum weighted regret over all future scenarios is selected as the final plan, i.e.:

$$\text{Min}_k \{ \text{Max}_l (v^l r^{k,l}) \}$$

3. Laplace method: According to this method the plan that minimizes the sum of costs over all scenarios is selected as the final plan.

4. Von Neumann-Morgenstern method: In this method is extremely pessimist and believes that the most unfavorable scenario is bound to occur. According to this criterion the plan that minimizes the maximum cost over all scenarios is selected as the final plan, i.e.:

$$\text{Min}_k \{ \text{Max}_l (f^{k,l}) \}$$

Alternatively, an extremely optimist criterion can be also used for selecting the final plan, i.e.:

$$\text{Min}_k \{ \text{Min}_l (f^{k,l}) \}$$

5. Hurwitz method: the plan that minimizes a convex combination of the extremely pessimist solution and the extremely optimistic solution is selected as the final plan.

6. Pareto-optimal method: A plan is Pareto-optimum if it is not dominated by any other plan. Plan X is dominated by plan Y if its cost is more than the cost of plan Y in all scenarios. This criterion is suitable for eliminating the worst solutions.

7. Robustness method: A plan is robust in a scenario, if its regret is zero in this scenario. According to this criterion, a plan is acceptable if it is robust at least in $\eta\%$ of the scenarios.

8. β -robustness method: According to this method a plan is acceptable if its over cost with respect to the related optimal plan does not exceed $\beta\%$ in each scenario.

III. LOCATIONAL MARGINAL PRICES (NODAL PRICE)

A Locational Marginal Price (LMP) is a pricing system for selling and purchasing electric energy in deregulated power systems. In the LMP pricing system, all producers sell energy at the price of their generator bus and all consumers purchase energy at the price of their load bus. By definition locational marginal price (LMP) nodal price is equal to the "cost of supplying next MW of load at a specific location, considering generation marginal cost, cost of transmission congestion, and losses". LMPs are the Lagrange multipliers or shadow prices of DC power flow constraints. The locational marginal price (LMP) is used to determine the price at each transmission bus or node. The locational marginal price (LMP) will encourages an efficient use of transmission system by assigning prices to the buyers. By using the locational marginal price (LMP), customers can sell and buy energy at the actual price of delivering energy at their buses or nodes.

In addition to the technical criteria, market based criteria is used to achieve the objectives of transmission expansion planning in deregulated power systems. In order to calculate and define the market based criteria, we need to calculate the Probability Density Functions (PDFs) of variables which shows the performance of electric market. These variables should be affected by dynamics of both power system and electric market. For assessing the performance of electric markets, we have to calculate the PDFs of LMPs. The "probabilistic optimal power flow" or "probabilistic locational marginal prices", is used for calculating the PDFs of LMPs.

PDFs of LMPs will be affected if sellers can change their bids, sellers can change maximum or minimum of their submitted power, buyers change their bids for load curtailment, buyers can change maximum or minimum of their submitted power, transmission facilities (generator, transmission line, load,...) have forced outage, input or output power to the study area change due to new contracts with neighboring areas and wheeling transactions, or there is market power in the network. Hence, PDFs of LMPs contain more information about the power system and electric market. By analyzing the PDFs of LMPs, the performance of an electric market can be assessed.

IV. MARKET BASED CRITERIA

The main objective of transmission expansion planning in deregulated power systems is to provide a non-discriminatory competitive environment for all stakeholders, while maintaining power system reliability. To achieve this objective, it is needed to define some criteria to measure how competitive an electric market is and how much a specific expansion plan improves the competition.

In a perfect competitive market, which consists of infinity number of producers and consumers, the price is determined by interaction of all producers and consumers. In this market each customer produces or consumes only a small portion of the market production. Therefore, a producer or a consumer can not affect the price alone.

Hence, in competitive markets producers and consumers are price taker not price maker. In a competitive market there is no discrimination among producers or consumers i.e. all producers and consumers sell and buy at the same price. Moreover, in a competitive market there is no restriction for consumers to buy from any producer. To have a competitive electric market, the above conditions must be satisfied. On the other word, to have a competitive electric market all power producers and consumers must sell and buy electric energy at the same price and the power transfer restrictions must be alleviated. This means LMPs must be made equal at all buses and transmission congestion must be alleviated. Equalizing LMPs provides a nondiscriminatory market and alleviating congestion eliminates power transmission constraints.

In these section two probabilistic criteria, average congestion cost and standard deviation of mean of LMP, are proposed to measure how much a specific plan facilitates competition among customers. Average congestion cost shows how intensive transmission constraints are and consequently shows how competitive electric market is. Standard deviation of mean of LMP shows how mean of LMP spreads throughout the network. Therefore, it shows how discriminative and consequently how competitive electric market.

4.1. Average Congestion Cost

Congestion cost of a line is defined as the opportunity cost of transmitting power through it. Consider figure 4.1, line i of a network is depicted in this figure. The end buses of this line numerated with $i1$ and $i2$. $P_{l_{i1,i2}}$ MW electric power transmits from bus $i1$ to bus $i2$ through this line. LMPs of buses $i1$ and $i2$ are $lmpi1$ and $lmpi2$ in \$/MWhr. Buying 1 MW electric power from bus $i1$ costs $lmpi1$ \$/hr and buying 1 MW power from bus $i2$ costs $lmpi2$ \$/hr. Therefore, the opportunity cost of transmitting 1 MW electric power from bus $i1$ to bus $i2$ is equal to $(lmpi2 - lmpi1)$ \$/hr. Thus, congestion cost of line i or the opportunity cost of transmitting $P_{l_{i1,i2}}$ MW electric power from bus $i1$ to bus $i2$ through line i is equal to:

$$CC_i = (lmpi2 - lmpi1) P_{l_{i1,i2}} \quad i=1,2,\dots,N_l$$

Where CC_i is congestion cost of line i in \$/hr
 N_l is Number of network lines.

Total congestion cost of the network or the opportunity cost of transmitting power through the network is equal to:

$$tcc = \sum_{i=1}^{N_b} (lmpi2 - lmpi1) P_{l_{i1,i2}}$$

where tcc is total congestion cost of the network in \$/hr.

It can be proved that the total congestion cost of the network is equal to the sum of payments by loads minus sum of receives by generators, i.e.:

$$tcc = \sum_{i=1}^{N_b} P_{d_i} lmpi - \sum_{i=1}^{N_b} P_{g_i} lmpi$$

Where P_{d_i} load at bus i in MW, P_{g_i} generation power at bus i in MW, N_b number of network buses.

If there is no congestion in the network, the next MW of each load is supplied by the cheapest undispached generation (marginal generator) and then LMPs of all buses are equal.

Average of the total network congestion cost after addition of plan k is equal to:

$$\mu_{tcc}^k = \frac{1}{N_r} \sum_{i=1}^{N_r} CC_{i,j}^k$$

with μ_{tcc}^k average of total congestion cost of the network in the presence of plan k in \$/hr.

In the rest of this paper "average congestion cost" is used instead of "average of total congestion cost of the network".

4.2. Standard Deviation of Mean of Locational Marginal Price

Standard deviation of mean of LMP in the presence of plan k , where mean is taken over N_r samples and standard deviation is taken over N_b buses, is given by:

$$\sigma_{lmpi}^k = \sqrt{\frac{1}{N_b - 1} \sum_{i=1}^{N_b} (\mu_{lmpi}^k - \mu_{lmpi}^k)^2}$$

Where σ_{lmpi}^k is standard deviation of mean of LMP in the presence of plan k in \$/MWhr, μ_{lmpi}^k mean of LMP of bus i over N_r samples in the presence of plan k in \$/MWhr, μ_{lmpi}^k mean of μ_{lmpi}^k over N_b buses in \$/MWhr (average LMP of the network), μ_{lmpi}^k is equal to:

$$\mu_{lmpi}^k = \frac{1}{N_b} \sum_{i=1}^{N_b} \mu_{lmpi}^k$$

Standard deviation of mean of LMP in the presence of plan k (σ_{lmpi}^k) indicates how spread out the mean of LMP of different buses (μ_{lmpi}^k for $i=1, 2, \dots, N_b$) are from the average LMP of the network (μ_{lmpi}^k). As the standard deviation of mean of LMP decreases, differences among the mean of LMP of different buses decrease and the price profile become flatter. Flatter price profile indicates less price discrimination. As flatness of price profile increases, congestion cost decreases. Therefore, as the standard deviation of mean of LMP decreases, both transmission constraints and price discrimination decrease and hence competition is encouraged. In the same way as the standard deviation of mean of LMP increases, competition is discouraged. Therefore, standard deviation of mean of LMP is a proper criterion for measuring the competitiveness degree of electric markets.

V. MARKET BASED TRANSMISSION EXPANSION PLANNING

In this approach at first possible strategic scenarios, which may occur in planning horizon, are identified. PDFs of LMPs are computed for each scenario using probabilistic optimal load flow. Then some expansion plans (candidates) are suggested for transmission expansion by the analysis of electric market. Each of the candidates is introduced to the

network and the market based criteria are computed for each scenario. The final plan is selected by risk analysis of the solutions. The presented approach can be precised in the following steps:

1. Identifying the set of possible strategic scenarios.
2. Compute the PDFs of LMPs for the existing network in each future scenario.
3. Suggesting candidates for transmission expansion by analyzing electric market.
4. Computing the market based criteria for each plan in each scenario.
5. Selecting the final plan by risk assessment of all expansion plans.
6. Computing the capacity of selected expansion plan.

VI. CASE STUDY: SOTHEREN REGION (SR) 48-BUS INDIAN SYSTEM

In this section the proposed approach is applied to the SR 48-bus system. Figure 1. shows the single line diagram of SR 48-bus system. Characteristics of generators and loads for the peak load of planning horizon are given in Tables I and II. It is assumed that the unavailability of each transmission line is equal to 0.001.

Table II. Characteristics generators

6.1. THERE IS NOT ANY NON-RANDOM UNCERTAINTY

In this case there is only one scenario. Therefore, the minimax regret plan and the optimal plan are the same. Transmission planning is performed under the following market based criteria:

- a. $\sigma_{\mu_{lmp}}$: Standard deviation of mean of LMP (SML).
- b. $\sigma_{\mu_{lmp},w=P_g}$: Standard deviation of mean of LMP weighted with mean of generation power (WG).
- c. $\sigma_{\mu_{lmp},w=P_d}$: Standard deviation of mean of LMP weighted with mean of load (WD).
- d. $\sigma_{\mu_{lmp},w=P_g+P_d}$: Standard deviation of mean of LMP weighted with mean of sum of generation power and load (WGD).
- e. μ_{tcc} : Average congestion cost (ACC).
- f. μ_{tlp} : Average load payment (ALP).

The Values of SML, WG, WD, WGD, ACC, and ALP in different stage of planning for SR 48-bus system are shown in table III(A-F). If a new line is added to the network, standard deviation of mean of LMP reduces from \$4.039958/MWhr for the line (5-10) to \$2.07781/MWhr for the line (7-24) and Average Congestion Cost reduces from \$1608.4091/hr to \$1037.48/hr are shown in table III.(A). If a new line is added to the network, standard deviation of mean of LMP reduces from \$5.3723/MWhr for the line (32-42) to \$2.6901/MWhr for the line (2-4) are shown in table III.(B). If a new line is added to the network, standard deviation of mean of LMP reduces from \$843.51/MWhr for the line (31-43) to \$1.2140/MWhr for the line (11-15) are shown in table III.(C). If a new line is added to the network, standard deviation of mean of LMP reduces from \$9.4147/MWhr for the line (36-38) to \$2.0625/MWhr for the line (40-44) are shown in table III.(D). If a new line is added to the network, standard deviation of mean of LMP reduces from \$20.410/MWhr for the line (34-42) to \$1.2360/MWhr for the line (11-20) are shown in table III.(E). If a new line is added to the network, standard deviation of mean of LMP reduces from \$2.1315/MWhr for the line (28-36) to \$2.0638/MWhr for the line (38-42) are shown in table III.(F).

Table III.(A-F). Values of SML, WG, WD, WGD, ACC, and ALP in different stages of planning.

6.2. THERE IS NON-RANDOM UNCERTAINTY

In this case it is assumed that the following non-random uncertainties have been identified by planners:

- A generator may be added at bus 9 of the network.
- An IPP may be added at bus 16 of the network.
- Load of bus 41 may be change.

Characteristics new generator, IPP, and load are given in table IV. To take into account these non-random uncertainties in transmission expansion planning, the following scenarios are defined:

- Scenario 1: base case (scenario which is shown in tables I and II)
- Scenario 2: base case plus the new generator
- Scenario 3: base case plus the load change
- Scenario 4: base case plus the IPP
- Scenario 5: base case plus the new generator and load change
- Scenario 6: base case plus the new generator and IPP
- Scenario 7: base case plus the load change and IPP
- Scenario 8: base case plus the new generator, load change, and IPP

It is assumed that all above scenarios have the same occurrence degree. SML, WG, WD, WGD, ACC, and ALP are used as planning criterion. In other word, SML, WG, WD, WGD, ACC, and ALP are used as cost function of risk analysis.

Table IV. Characteristics new GENERATOR, IPP, and LOAD.

TYPE	BUS NO	CHANGE IN MW
GENERATOR	9	500
LOAD	16	1600
IPP	41	500

It is assumed that all above scenarios have the same occurrence degree. SML, WG, WD, WGD, ACC, and ALP are used as planning criterion. In other word, SML, WG, WD, WGD, ACC, and ALP are used as cost function of risk analysis. Table V (a-f) shows the values of SML, WG, WD, WGD, ACC, and ALP in different scenarios and different stages of planning. (a) Values of SML when different criteria are used for planning. (b) Values of WG when different criteria are used for planning. (c) Values of WD when different criteria are used for planning. (d) Values of WGD when different criteria are used for planning. (e) Values of ACC when different criteria are used for planning. (f) Values of ALP when different criteria are used for planning.

Table VI.(a-c) shows the selecting the final plan by using the minimax regret criterion at different stages of planning.

By comparing the different plans the final plan is (30-34).

VIII. CONCLUSION

In this paper, a new probabilistic tool for computing the probability density functions of nodal prices was introduced. New market-based criteria were defined for transmission planning in deregulated environments. A new approach for transmission expansion planning in deregulated environments using the above tool and criteria was presented. All random and nonrandom power system uncertainties are considered by this approach and the final plan is selected after risk assessment (minimax regret criterion) of all solutions. This approach tries to facilitate competition and provides nondiscriminatory access to cheap generation by providing a flat price profile throughout the network. It is value based and considers investment cost, operation cost, congestion cost, load curtailment cost, and cost caused by system unreliability. The presented approach was applied to Southern Region (SR) 48-Bus Indian System and the effectiveness of presented market-based criteria was demonstrated for the single and multiple scenario cases.

Abstract: When no transformer is used in a grid-connected photovoltaic (PV) system, a galvanic connection between the grid and PV array exists. In these conditions, dangerous leakage currents (common-mode currents) can appear through the stray capacitance between the PV array and the ground. In order to avoid these leakage currents, different inverter topologies that generate no varying common-mode voltages, such as the half-bridge and the bipolar pulse width modulation (PWM) full-bridge topologies, have been proposed. The bipolar PWM full bridge requires a lower input voltage but exhibits a low efficiency. This paper proposes a new high-efficiency topology that generates no varying common-mode voltage and requires the same low-input voltage as the bipolar PWM full bridge.

Index Terms: DC-AC power conversion, photovoltaic (PV) systems, transformer less inverter.

I. INTRODUCTION

Grid-connected photovoltaic (PV) systems, particularly low-power single-phase systems, are becoming more important worldwide. They are usually private systems where the owner tries to get the maximum system profitability. Issues such as reliability, high efficiency, small size and weight, and low price are of great importance to the conversion stage of the PV system. Quite often, these grid-connected PV systems include a line transformer in the power-conversion stage, which guarantees galvanic isolation between the grid and the PV system, thus providing personal protection. Furthermore, it strongly reduces the leakage currents between the PV system and the ground, ensures that no continuous current is injected into the grid, and can be used to increase the inverter output voltage level. The line transformer makes possible the use of a full-bridge inverter with unipolar pulse width modulation (PWM). The inverter is simple. It requires only four insulated gate bipolar transistors (IGBTs) and has a good trade-off between efficiency, complexity and price. Due to its low frequency, the line transformer is large, heavy and expensive.

This paper proposes a new topology that generates no varying common-mode voltage, requires the same low-input voltage as the bipolar PWM full-bridge topology, and achieves a higher efficiency and a lower current ripple in the inductor. The topology consists of six switches and two diodes and can be an advantageous power conversion stage for transformer less grid-connected PV systems.

II. COMMON-MODE CURRENTS IN TRANSFORMERLESS PV SYSTEMS

When no transformer is used, a galvanic connection between the ground of the grid and the PV array exists. As a consequence a common-mode resonant circuit appears, consisting of the stray capacity between the PV modules and the ground, the dc and ac filter elements, and the grid impedance (Fig. 1). A varying common-mode voltage can excite this resonant circuit and generate a common-mode current. Due to the large surface of the PV generator, its stray capacity with respect to the ground reaches values that can be even higher than 200 nF/kWp in damp environments or on rainy days. These high values can generate ground currents with amplitudes well above the permissible levels, such as those concerning the standards. The currents can cause severe (conducted and radiated) electromagnetic interferences, distortion in the grid current and additional losses in the system. These leakage currents can be avoided, or at least limited, by including damping passive components in the resonant circuit. Obviously, additional losses will appear in the damping elements, thus decreasing the conversion stage efficiency.

The use of conversion topologies with a constant common mode voltage is another option. The instantaneous common mode voltage V_{cm} in the full-bridge inverter of Fig. 1 can be calculated from the voltage of the two mid-points of both legs,

$$V_{AO} \text{ and } V_{BO} \text{ as}$$
$$V_{cm} = \frac{V_{AO} + V_{BO}}{2} \dots\dots\dots (1)$$

To avoid leakage currents, the common-mode voltage must be kept constant during all commutation states, that is

$$V_{cm} = V_{AO} + V_{BO}$$

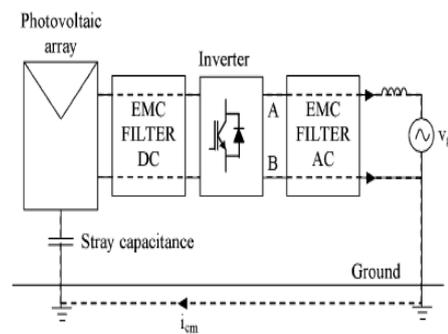

Fig.1 Common-mode currents in a transformer less conversion stage

III. MODELLING OF PV MODULE

The most commonly used model for PV-cell is one – diode equivalent circuit as shown in figure (2). Since the shunt resistance R_{sh} is large, it is normally neglected. This simplified circuit is used in this paper for modeling of a PV-cell.

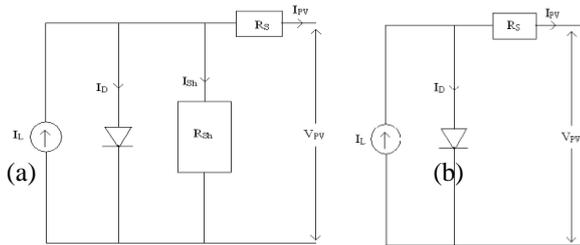

Fig.2. One-diode equivalent circuit model for a PV cell. (a) Five parameters model; (b)Simplified four parameters model

The non-linear of V_{pv} - I_{pv} and P-V curves are correspondingly drawn as shown below:

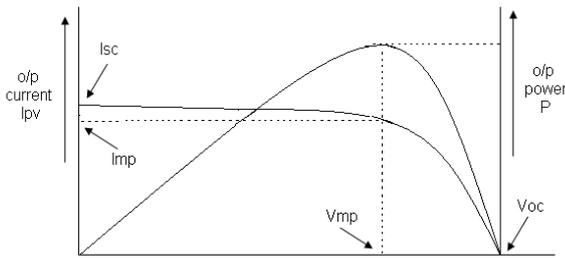

Fig.3. V_{pv} - I_{pv} & P_{pv} - V_{pv} characteristics of a PV cell
From figure (2.b) the relation between the output V_{pv} and the output current I_{pv} can be expressed as:

$$I_{PV} = I_L - I_D$$

$$I_{PV} = I_L - I_0 \left(\exp \left(\frac{V_{PV} + I_{PV} R_S}{\alpha} \right) - 1 \right) \dots (2)$$

Where I_L = Light current; I_0 = Saturation current; R_S = Series Resistance; α = Thermal voltage timing completion factor.

The above four parameters are needed to be determined to obtain the I-V characteristics of PV-module. Thus, this model can be termed as Four-parameter model. The equations for determining the four parameters are given below:

A. Light Current (I_L)

$I_L = \frac{G}{G_{ref}} (I_{Lref} + \mu_{isc} (T_C - T_{Cref})) \dots (3)$ Where G =irradiance (W/m^2); G_{ref} = reference irradiance ($1000 W/m^2$ is used in this study); I_{Lref} = light current at the reference condition ($1000W/m^2$ and $25^\circ C$); T_C = PV cell temperature ($^\circ C$); T_{ref} = reference temperature ($25^\circ C$ is used in this study);

μ_{isc} = temperature coefficient of the short-circuit current ($A/^\circ C$).

From the above equation for light current it can be observed that I_L is a function of both temperature and irradiance. Both I_{Lref} and μ_{isc} can be obtained from manufacturer data sheet.

B. Saturation Current (I_0)

$$I_0 = I_{0ref} \left(\frac{T_C + 273}{T_{Cref} + 273} \right)^3 \exp \left(\frac{e_{gap} q}{N_S \alpha_{ref}} \left(1 - \frac{T_{Cref} + 273}{T_C + 273} \right) \right) \dots (4)$$

Where I_{0ref} = saturation current at the reference condition (A); e_{gap} = band gap of the material 1.17 eV for Si materials); N_S = number of cells in series of a PV module; q = charge of an electron ($1.60217733 \times 10^{-19} C$); α_{ref} = the value of α at reference condition.

I_{0ref} can be calculated as:

$$I_{0ref} = I_{Lref} \exp \left(- \frac{V_{OCref}}{\alpha_{ref}} \right) \dots (5)$$

Where V_{ocref} = the open circuit voltage of the PV module at reference condition (V).

C. Calculation of α

$$\alpha = \frac{T_C + 273}{T_{Cref} + 273} \alpha_{ref} \dots (6)$$

The value of α_{ref} can be calculated as:

$$\alpha_{ref} = \frac{2V_{mpref} - V_{ocref}}{I_{scref} - I_{mpref} + \ln \left(1 - \frac{I_{mpref}}{I_{scref}} \right)} \dots (7)$$

Where V_{mpref} = maximum power point voltage at the reference condition (V); I_{mpref} = maximum power point current at the reference condition (A); I_{scref} = short circuit current at the reference condition (A).

D. Series Resistance (R_S)

Some manufacturers provide the value of R_S . If not provided, the following equation can be used to estimate its value:

$$R_S = \frac{\alpha_{ref} \ln \left(1 - \frac{I_{mpref}}{I_{scref}} \right) + V_{ocref} - V_{mpref}}{I_{mpref}} \dots (8)$$

R_S is taken as a constant in the model of this study.

E. Thermal Model of PV

From equations (1) to (7), it can be noted that the temperature plays an important role in the PV performance. Therefore, it is necessary to have a thermal model for a PV cell/module. In this study, a lumped thermal model is developed for the PV module. The temperature of the PV module varies with surrounding temperature, irradiance, and its output current and voltage, and can be written as:

$$C_{pv} \frac{dT_C}{dt} = K_{inpv} G - \frac{V_{pv} I_{pv}}{A} - K_{loss} (T_C - T_a) \dots (9)$$

C_{pv} = the overall heat capacity per unit area of the PV cell/module [$J/(^\circ C \cdot m^2)$]; K_{inpv} = Transmittance-absorption product of PV cells; K_{loss} = overall heat loss coefficient [$W/(^\circ C \cdot m^2)$]; T_a = ambient temperature ($^\circ C$); A = effective area of the PV cell/module (m^2).

IV. FULL-BRIDGE INVERTER

The full-bridge inverter (Fig. 3) is a single stage dc-ac conversion topology that is used quite often in PV inverters. Different PWM techniques can be applied to this topology. Depending on the shape of the output voltage waveform, they can be classified in two groups, namely unipolar and bipolar PWM. When the full bridge is part of a conversion stage with a line transformer, unipolar PWM techniques can be applied. This is in proposed topology.

Here, S_4 is on during the positive half cycle, while switches S_1 and S_2 commutate at the switching frequency. During the negative cycle, S_2 is on and S_3, S_4 commutate at the switching frequency. In this converter

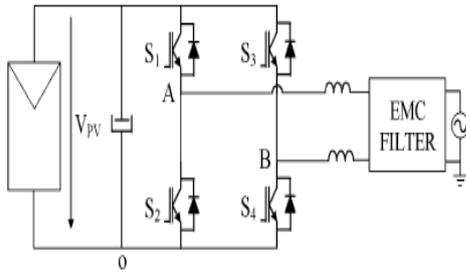

Fig 4. Full-bridge inverter

only two switches are on at the same time, and only one IGBT and one diode commutate at the switching frequency with the whole input voltage. The main drawback, that it generates a varying common-mode voltage of amplitude $V_{pv}/2$ at the switching frequency.

In the bipolar PWM, the diagonal pairs of switches $S_1 - S_4$ and $S_2 - S_3$ are switched alternatively at the switching frequency. As a consequence

$$V_{BO} = V_{PV} - V_{AO} \Rightarrow V_{cm} = V_{PV}/2 = cte$$

If the switching actions are carried out at the same time, no changes appear in the common-mode voltage and no leakage currents are generated. However, the bipolar PWM also has drawbacks. Two IGBTs and two diodes are switching at the switching frequency with the whole input voltage, therefore

doubling the switching losses. Additionally, the output voltage changes between V_{PV} and $-V_{PV}$, creating a current ripple twice that obtained in the unipolar modulation.

V. PROPOSED TOPOLOGY

The proposed topology, which consists of six switches ($S_1 - S_6$) and two diodes ($D_7 - D_8$). In this topology, diodes D_7, D_8 and the capacitive divider limit the blocking voltage of S_5 and S_6 to half of the input voltage V_{pv} . Grid-connected PV systems usually operate with unity power factor. The operational principle of the proposed converter is now analyzed for this case. The proposed topology with the modulation technique described below can operate with power factors other than unity. In these cases, the operation analysis would be similar.

In the positive half cycle, S_1 and S_4 are on. In order to modulate the input voltage, S_5 and S_6 commutate at the switching frequency with the same commutation orders. S_2 and S_3 commute at the switching frequency together and complementary to S_5 and S_6 . In this situation, when S_5 and S_6 and are on, $v_{AB} = V_{PV}$ and the inductor current, which flows through, S_5, S_1, S_4 and S_6 increases. The common-mode voltage is:

$$V_{cm} = \frac{V_{AO} + V_{BO}}{2} = \frac{V_{PV} + 0}{2} = \frac{V_{PV}}{2} \quad \dots(10)$$

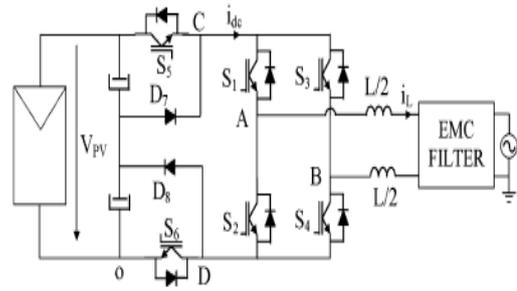

Fig 5. Proposed Topology

When S_5 and S_6 are turned off and S_2 and S_3 are turned on, the current splits into two paths: S_1 and the freewheeling diode of S_3 , and S_4 and the freewheeling diode of S_2 . Thus, S_2 and S_3 are turned on with no current and therefore no switching losses appear.

In this situation, voltages v_{AB} and v_{CD} tend to zero and diodes D_7 and D_8 fix the voltages v_{AO} and v_{Bo} to $\frac{V_{PV}}{2}$. Since V_{AB} is clamped to zero the current decreases. Now, the common-mode voltage is

$$V_{AO} = V_{Bo} = V_{PV}/2 \Rightarrow V_{cm} = V_{PV}/2 \quad \dots(11)$$

In the negative half cycle, S_2 and S_3 are on. Again, S_5 and S_6 commutate at the switching frequency in order to modulate the input voltage. S_1 and S_4 commute at the switching frequency together and complementarily to S_5 and S_6 . In this situation, when S_5 and S_6 are on, V_{AB} equals $-V_{PV}$, and the inductor current, which now flows through S_5, S_3, S_2 and S_6 , decreases.

The common-mode voltage is

$$V_{cm} = \frac{V_{AO} + V_{BO}}{2} = \frac{0 + V_{PV}}{2} = \frac{V_{PV}}{2} \quad \dots(12)$$

When S_5 and S_6 are turned off and S_1 and S_2 are turned on, the current splits into two paths. The first path consists of S_3 and the freewheeling diode of S_1 , and the second of S_2 and the freewheeling diode of S_4 . Consequently, S_1 and S_4 are turned on

with no current, so no switching losses appear. In this situation, voltages v_{AB} and v_{CD} tend to zero and diodes D_7 and D_8 fix the voltages v_{AO} and v_{Bo} to $\frac{V_{PV}}{2}$. The current decreases because v_{AB} is clamped to zero. Now, the common-mode voltage is

$$V_{AO} = V_{Bo} = V_{PV}/2 \Rightarrow V_{cm} = V_{PV}/2 \quad \dots(13)$$

From (10)–(13), it is clear that the common-mode voltage remains constant during the four commutation states of the converter. Therefore, no varying common-mode voltage is generated by the proposed topology and, hence, no leakage currents appear.

Fig. 6 shows the simulated evolution of the main electric variables during a grid period. The common-mode voltage remains constant during all commutation states. Additionally, voltage v_{AB} , and therefore the inductor current, have the same waveforms as those obtained in the unipolar PWM full bridge.

Assuming unity power factor, S_5 and S_6 commute at the switching frequency with half of the input voltage V_{pv} , and the corresponding two freewheeling diodes of the full bridge commute with V_{pv} , but with half of the current. Therefore, switching losses will be lower than those of the bipolar PWM full bridge and can be expected to be similar to those of the unipolar PWM full bridge. Since the blocking voltage of S_5 and S_6 is only half of the input voltage, switches with lower rated blocking voltage can be used and thus will exhibit lower switching losses for the same operating conditions. Therefore the switching losses of the topology will be lower than those of the unipolar PWM full bridge. The IGBT switching losses of the full bridge are neglected, since they switch at the grid frequency. When the power factor decreases, the losses of the proposed topology increase because the switching losses of the full bridge increase.

Conduction losses are expected to be greater in the proposed topology, because when S_5 and S_6 are on current flows through four switches instead of two, as in the full bridge (regardless of the PWM technique used). However, this increment is limited by the fact that S_5 and S_6 have lower saturation voltages because they have lower rated voltages.

VI. SIMULATION RESULTS

Based on the mathematical equations discussed before, a dynamic model for a PV module consisting of 153 cells in series has been developed using MATLAB/Simulink. The input quantities (solar irradiance G and the ambient temperature T_a) together with manufacturer data are used to calculate the four parameters. Then, based on equation (1), the output voltage is obtained numerically. The thermal model is used to estimate the PV cell temperature. The two output quantities (PV output voltage V_{pv} and the PV cell temperature T_c), and the load current I_{pv} , are fed back to participate in the calculations. The model parameters used in the simulation are given in Table I

Table I
THE PV MODEL PARAMETERS

$I_{SCref}(I_{Lref})$	2.664A
α_{ref}	5.472
R_s	1.324Ω
V_{OCref}	87.72V
V_{MPref}	70.731V
I_{MPref}	2.448A
G_{ref}	1000w/m ²
T_{cref}	25°C
C_{pv}	5*10 ⁴ J/(°C-m ²)
A	1.5m ²
K_{inpv}	0.9
K_{loss}	30W/(°C-m ²)

A. Model Performance

The model I_{pv} - V_{pv} characteristic curves under different irradiances are given in Figure (6) at 25°C. It is noted from the figure that the higher is the irradiance, the larger are the short-circuit current (I_{sc}) and the open-

circuit voltage (V_{oc}). And, obviously, the larger will be the maximum power (P), shown in Figure (7).

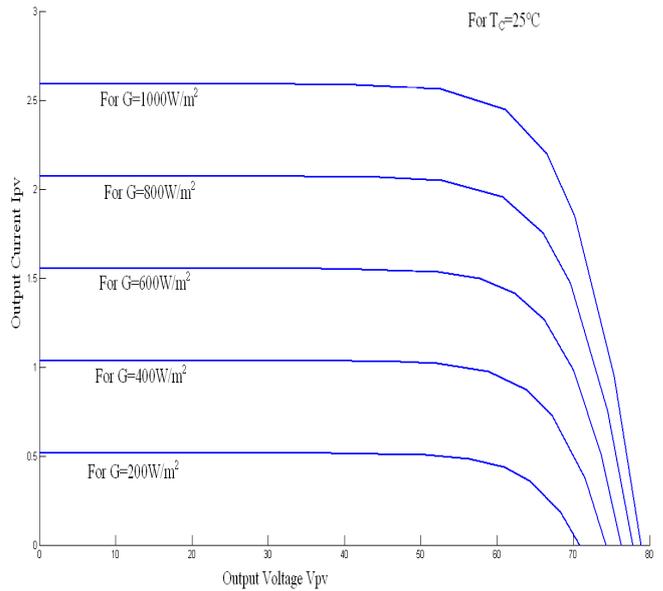

Fig.6 V_{pv} - I_{pv} characteristics for constant T_c and

Varying G

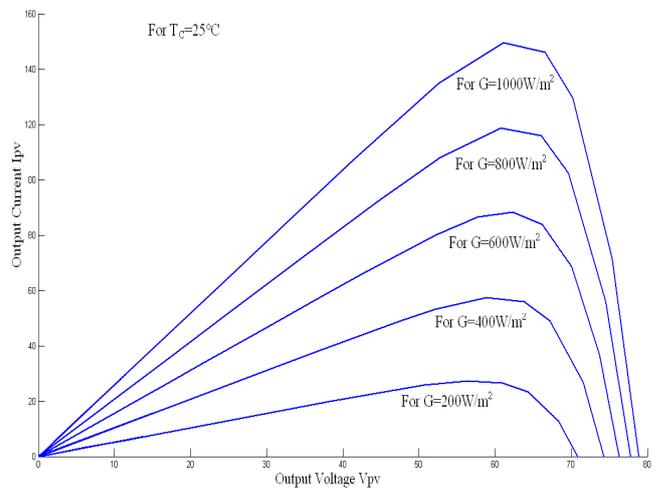

Fig.7. P - V_{pv} characteristics for constant T_c and Varying G

The simulation results of full bridge inverter and proposed topology are shown in fig 8 and fig 9

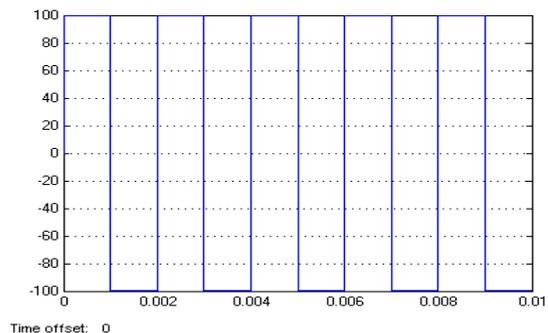

Fig 8. Voltage v_{AB} and common mode voltage in a full bridge inverter topology with bipolar PWM $F=500\text{Hz}$

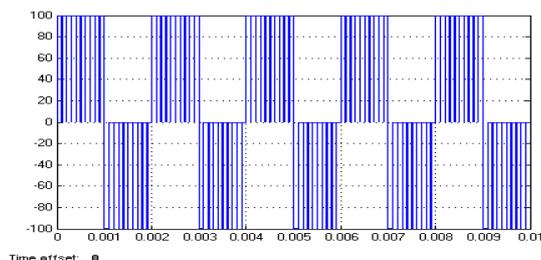

Fig.9. Voltage v_{AB} and common mode voltage in proposed topology F=500Hz

VII. CONCLUSION

This paper proposes a new transformer less, single-phase PV inverter with six switches and two diodes. The proposed topology generates no common-mode voltage, exhibits a high efficiency, and can operate with any power factor. It has been compared to other topologies and validated satisfactory results. The maximum efficiency achieved by the topology is 97.4%. As a conclusion, the proposed topology can be an advantageous power-conversion stage for transformer less, grid-connected PV systems.

Abstract: Control phase plays a critical role in the performance of time-division multiple access (TDMA)-based wireless networks. Control phase of TDMA-based medium access control (MAC) in wireless sensor networks is proposed. Wireless ad hoc networks depend upon medium access control (MAC) protocols for allocation of channel resources among mobile users. This paper studies TDMA-based timeslot allocation, convergence time and throughput parameters of TDMA using MAC protocol.

Keywords: TDMA, QoS, Medium Access Control, Wireless Ad hoc networks.

I. INTRODUCTION

Wireless ad hoc networks (WANETs) are gaining a lot of attention in research lately due to their importance in enabling mobile wireless nodes to communicate without any existing wired or predetermined infrastructures. Mobile ad hoc networks (MANETs) have rapidly gained a considerable amount of attention in research lately[5][6]. As more and more smart, small, portable, and powerful computing devices are introduced into everyday life, the need for such devices to communicate on the fly in a seamless manner and without any pre existing network wiring or infrastructure is growing. It is also natural to expect such devices to support multimedia and real time applications, which are becoming increasingly feasible due to the significant advances in CPU power, memory, speed, storage, and communication capacity of mobile devices. Such applications require the underlying network to provide certain guarantees that are manifested in the support of several important Quality of Service (QoS) parameters such as bandwidth, delay, and bit error rate. Maintaining these QoS commitments in MANETs is not an easy task. This is due to the unpredictability and variability of many factors such as bit error rates, mobility, and continuous change in the connectivity of the different nodes in the network. The design of an efficient Medium Access Control (MAC) is challenging in ad-hoc networks where users can enter, leave or move inside the network without any need for prior configuration. Ad-hoc networks require no infrastructure and nodes are free to enter, leave or move inside the network without prior configuration [3]. Fig 1 shows the example of Ad hoc network.

The main objective of this paper is to study the time division multiple access based MAC protocol behaviour in the wireless Ad hoc Networks.

The paper is organized as follows: Section I introduces a description for the TDMA based MAC protocol. Description of TDMA multiple access schemes is presented in Section II. In section III, Medium access control protocol

is explained. Simulation results are given in Section IV, and finally conclusions are reflected in Section V.

Fig: 1 Ad hoc Network

II. TIME DIVISION MULTIPLE ACCESS

In a TDMA cellular radio system, several users time-share a common carrier frequency to communicate with the base station. Each user, transmitting low bit-rate digitized speech or other digital data, is allocated one or more timeslots within a frame in the downstream (base to users) and upstream (users to base) directions, as illustrated in Fig. 2

In the downstream direction, the base station broadcasts to the active users in a Time Division Multiplex (TDM) format [1]. In the upstream direction, each active user terminal transmits to the base station only in its own assigned timeslot or slots. Inter-user interference is prevented by strict adherence to timeslot schedules, and by guard times and time-alignment procedures between upstream timeslots, in order to prevent overlaps due to different propagation times [2].

Each individual terminal's receiver and transmitter operates with a duty cycle of $1/N$ if there are N user terminals with equal bit rates sharing a common bit stream. Upstream and downstream traffic is separated either by using different carrier frequencies i.e., Frequency Division Duplex (FDD), or by alternating in time, i.e., Time Division Duplex (TDD).

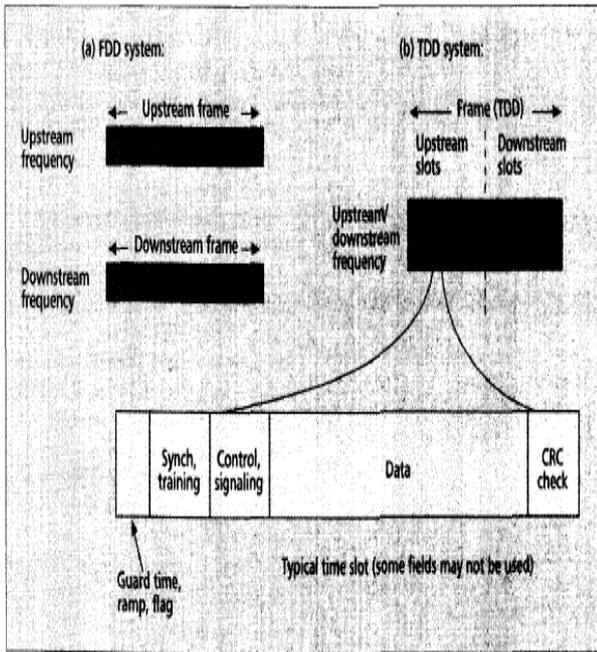

Fig: 2 TDMA frame and Time slots

III. MEDIUM ACCESS CONTROL (MAC)

MAC layer, sometimes also referred to as a sub-layer of the Data Link layer, involves the functions and procedures necessary to transfer data between two or more nodes of the network [5]. It is the responsibility of the MAC layer to perform error correction for anomalies occurring in the physical layer. The layer performs specific activities for framing, physical addressing, and flow and error controls. It is responsible for resolving conflicts among different nodes for channel access.

Since the MAC layer has a direct bearing on how reliably and efficiently data can be transmitted between two nodes along the routing path in the network, it affects the Quality of Service (QoS) of the network. The design of a MAC protocol should also address issues caused by mobility of nodes and an unreliable time varying channel [4].

In TDMA-based schemes, the transmitting node first senses the medium to check whether it is idle or busy. The node defers its own transmission to prevent a collision with the existing signal, if the medium is busy. Otherwise, the node begins to transmit its data while continuing to sense the medium. However, collisions occur at receiving nodes. Since, signal strength in the wireless medium fades in proportion to the square of distance from the transmitter, the presence of a signal at the receiver node may not be clearly detected at other sending terminals, if they are out of range. As illustrated in Fig. 3, node B is within the range of nodes A and C, but A and C are not in each other's range. Let us consider the case where A is transmitting to B. Node C, being out of A's range, cannot detect carrier and may therefore send data to B, thus causing a collision at B. This is referred to as the *hidden-terminal problem*, as nodes A and C are hidden from each other [7].

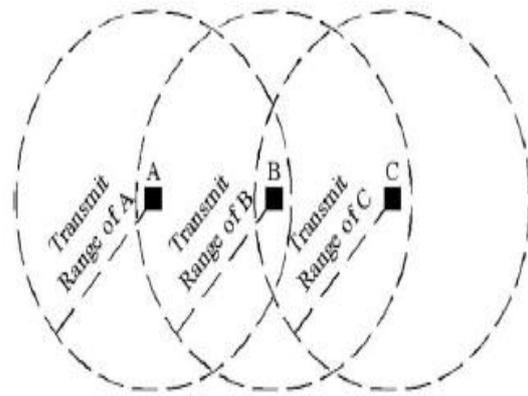

Fig: 3 hidden and exposed terminal problems

Let us now consider another case where B is transmitting to A. Since C is within B's range, it senses carrier and decides to defer its own transmission. However, this is unnecessary because there is no way C's transmission can cause any collision at receiver A. This is referred to as the *exposed-terminal problem*, since B being exposed to C caused the latter to needlessly defer its transmission [7]. MAC schemes are designed to overcome these problems.

IV. SIMULATION RESULTS

In this section the simulation results are shown and discussed. We will investigate the performance of the TDMA scheme using MAC protocol in wireless Ad hoc network. The convergence time is defined as the duration of time within which all nodes across the network collaboratively and in a distributed manner obtain conflict-free slots.

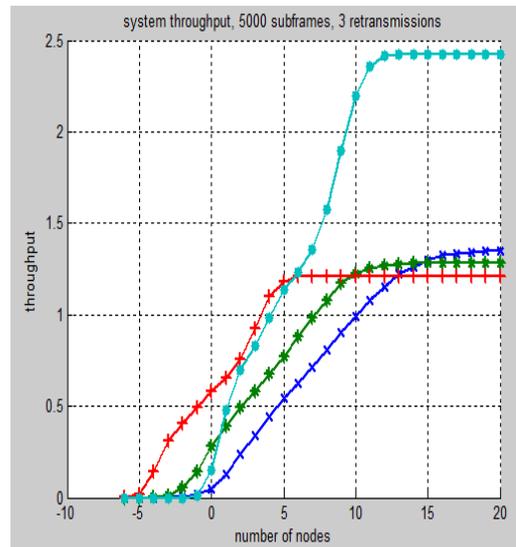

Fig: 4 Throughput of TDMA MAC with 5000 sub-frames and 3 transmissions

We have presented the Throughput for the TDMA using MAC protocol in Ad hoc Networks with 5000 sub-frames and with no HARQ. We have presented the convergence time for the TDMA using MAC protocol in Ad hoc Networks with 5000 sub-frames and with no HARQ.

V. CONCLUSION

In this paper, we presented the performance of ad hoc wireless networks with respect to MAC protocols using TDMA. Parameters, Throughput and convergence time are study to present the behaviour of the MAC protocol with TDMA.

B-Continuity in Peterson graph and power of a Cycle

S. Chandra Kumar¹, T. Nicholas²

*(Department of Mathematics, Scott Christian College, Nagercoil, Tamil Nadu, India)

***(Department of Mathematics, St. Jude's College, Thoothoor, Tamil Nadu, India)

ABSTRACT: A graph G is k -colorable if G has a proper vertex coloring with k colors. The chromatic number $\chi(G)$ is the minimum number k such that G is k -colorable. A b -coloring of a graph with k colors is a proper coloring in which each color class contains a color dominating vertex. The largest positive integer k for which G has a b -coloring with k colors is the b -chromatic number of G , denoted by $b(G)$. The b -spectrum $S_b(G)$ of G , is defined as the set of all integers k at which G is b -colorable with k colors. A graph G is b -continuous if its b -spectrum equals $[\chi(G), b(G)]$. In this paper, we prove that the Peterson graph and the power of a cycle are b -continuous. Also, we prove that the Cartesian product of two cycles $C_m \square C_n$ is b -continuous when m and n are multiples of 5. In this case, we give the color classes of b -coloring with k colors for each k with $\chi(G) \leq k \leq b(G)$.

Keywords: b -coloring, b -continuous. Peterson graph, power of a cycle.

I. INTRODUCTION

A k -vertex coloring of a graph G is an assignment of k colors $1, 2, \dots, k$, to the vertices. The coloring is proper if no two distinct adjacent vertices share the same color. A graph G is k -colorable if it has a proper k -vertex coloring [5]. The chromatic number $\chi(G)$ is the minimum number k such that G is k -colorable. Color of a vertex v is denoted by $c(v)$. A b -coloring is a coloring of the vertices of a graph such that each color class contains a vertex that has a neighbor in all other color classes. In other words, each color class contains a color dominating vertex (a vertex which has a neighbor in all the other color classes). The b -chromatic number $b(G)$ is the largest integer k such that G admits a b -coloring with k colors.

The b -spectrum $S_b(G)$ of G is defined by $S_b(G) = \{ k \in \mathbb{N} : \chi(G) \leq k \leq b(G) \text{ and } G \text{ is } b\text{-colorable with } k \text{ colors} \}$. A graph G is b -continuous if $S_b(G) = [\chi(G), b(G)]$.

El-Sahili[3] conjectured that every d -regular graph with girth at least 5 has a b -coloring with $d + 1$ colors.

Marko Jaovac and Sandi Klavzar[7] disproved this conjecture and they proved the following:

'Peterson graph is a 3-regular graph with girth 5 and b -chromatic number 3'.

In section 3, we prove this result in another way. Saeed Shaebani[9] proved that some of the Kneser graphs are b -continuous. Further, they gave some special conditions for graphs to be b -continuous.

Here we list out some of the necessary definitions. For a graph G , and for any vertex v of G , the neighborhood of v is the set $N(v) = \{ u \in V(G) : (u, v) \in E(G) \}$ and the degree of v is $\deg_G(v) = |$

$N(v)$ [4]. $\Delta(G)$ denotes the maximum degree of a vertex in G . Note that every graph G satisfies $b(G) \leq \Delta(G) + 1$.

A graph is a power of cycle, denoted C_n^k , if $V(C_n^k) = \{ v_0 (= v_n), v_1, v_2, \dots, v_{n-1} \}$ and $E(C_n^k) = E^1 \cup E^2 \cup \dots \cup E^k$, where $E^i = \{ (v_j, v_{(j+i) \pmod{n}}) : 0 \leq j \leq n-1 \}$ and $k \leq (n-1)/2$ [1]. Note that C_n^k is a $2k$ -regular graph and $k \geq 1$. We take $(v_0, v_1, v_2, \dots, v_{n-1})$ to be a cyclic order on the vertex set of G , and perform modular operations on the vertex indexes [1].

The Cartesian product $G \square H$ of two graphs G and H is the graph with vertex set $V(G \square H) = V(G) \times V(H)$ and edge set $E(G \square H) = \{ ((x_1, y_1), (x_2, y_2)) : (x_1, x_2) \in E(G) \text{ with } y_1 = y_2 \text{ or } (y_1, y_2) \in E(H) \text{ with } x_1 = x_2 \}$ [5].

A graph G_1 is called as a covering graph of G with covering projection $f : G_1 \rightarrow G$ if there is a surjection $f : V(G_1) \rightarrow V(G)$ such that $f|_{N(v_1)} : N(v_1) \rightarrow N(v)$ is a bijection for any vertex $v \in V(G)$ and $v_1 \in f^{-1}(v)$ [6].

In this paper, we prove that the Peterson graph and the power of a cycle are b -continuous. Also, we prove that the Cartesian product of two cycles $C_m \square C_n$ is b -continuous when m and n are multiples of 5. In this case, we give the color classes of b -coloring with k colors for each k with $\chi(G) \leq k \leq b(G)$.

II. B-SPECTRUM OF C_n^k AND $C_m \square C_n$

In 2001, Lee [6] obtained the following result which helps to obtain independent dominating vertex subset of big graph from small graphs under some conditions. He proved the following theorem, which we used in the next lemma.

Theorem 2.1 [6]: Let $p : G_1 \rightarrow G$ be a covering projection and let S be a perfect dominating set of G . Then $p^{-1}(S)$ is a perfect dominating set of G_1 . Moreover, if S is independent, then $p^{-1}(S)$ is independent.

In this section, we find the b -spectrum of the graphs C_n^k and $C_m \square C_n$. We prove that these two graphs are b -continuous. Further, we give a method of b -coloring the graph C_n^k with i colors for each i with $\chi(G) \leq i \leq \Delta(G) + 1$.

Lemma 2.2: Let $f : G \rightarrow H$ be a covering projection from a graph G on to another graph H . If the graph H is b -colorable with k colors, then so is G .

PROOF. Assume that H is b -colorable with k colors. Let the corresponding color classes be H_1, H_2, \dots, H_k . Define $G_i = f^{-1}(H_i)$ for $1 \leq i \leq k$. Define $c(v) = i$ if $v \in G_i$. Since H_i 's are pair wise disjoint independent vertex subsets of H , by Theorem 2.1, $\{ G_1, G_2, \dots, G_k \}$ is a vertex partition of independent subsets of G . This means that the graph G is also k -colorable with color classes G_1, G_2, \dots, G_k . It is enough to prove that each color class G_i contains a color dominating vertex.

Let $h \in H_1$ be a color dominating vertex of H with color 1 and let $g \in f^{-1}(h) \subseteq G_1$. we prove that g is a color dominating vertex with color 1 in G .

Note that $\deg_G(g) = \deg_H(h)$. Since $h \in H_1$ is colorful, and by the definition of $\{ H_1, H_2, \dots, H_k \}$, there exist vertices h_2, h_3, \dots, h_k such that $h_i \in H_i$ and $(h, h_i) \in E(H)$ for $2 \leq i \leq k$. Since $f_{N(g)} : N(g) \rightarrow N(h)$ is a bijection, there exist vertices $g_1, g_2, \dots, g_k \in V(G)$ such that $(g, g_i) \in E(G)$ and $f(g_i) = h_i$ for $2 \leq i \leq k$. Hence $g_i \in G_i$ and $c(g_i) = i$ for $2 \leq i \leq k$ and so g is a colorful vertex of G with color 1. Similarly, we can prove that there exist colorful vertices in G for all colors 2, 3, ..., k.

In [2] S. Chandra Kumar et al. proved the following Lemma.

Lemma 2.3[2]: If $k+1 \leq d \leq 2k+1$ and d divides n , then the graph $G = C_n^k$ admits b -coloring with d colors. In particular, when $d = k+1$, the fall chromatic number $\chi(G) = k+1$.

Here, we prove the above lemma more generally.

Lemma 2.4: Let $k+1 \leq d \leq 2k+1$. Then the graph $G = C_n^k$ admits b -coloring with d colors.

PROOF. Let $V(G) = \{ (v_n) v_0, v_1, \dots, v_{n-1} \}$ and $E(G) = E^1 \cup E^2 \cup \dots \cup E^k$, where $E^j = \{ (v_j, v_{(j+i) \pmod n}) : 0 \leq j \leq n-1 \}$ Let $n = id+t$ for some t with $1 \leq t \leq 2k$.

Case 1: If $1 \leq t \leq k+1$.

Let us color the vertices as follows: For each j with $0 \leq j \leq id$, color of the vertex v_j is defined by $c(v_j) = j \pmod d$. Also $c(v_{id+1}) = k+1, c(v_{id+2}) = k+2, \dots, c(v_{id+t}) = k+t$.

Case 2: If $k+2 \leq t \leq 2k+1$.

Let us color the vertices as follows: For each j with $0 \leq j \leq n-1$, color of the vertex v_j is defined by $c(v_j) = j \pmod d$.

Note that, for each g with $1 \leq g \leq k$, the vertex v_j has exactly two neighbors $v_{j \oplus g}$ and $v_{j \oplus (n-g)}$, where \oplus is the operation, addition modulo n . Hence $N(v_j) = \{ v_{j \oplus 1}, v_{j \oplus 2}, \dots, v_{j \oplus k}, v_{j \oplus (n-1)}, v_{j \oplus (n-2)}, \dots, v_{j \oplus (n-k)} \}$. Note that, two vertices v_a and v_b receive the same color only when $a \oplus b \leq k+1 \leq d$, where \oplus_d is the operation, addition modulo d . Hence the adjacent vertices will receive different colors. In cases 1 and 2, the vertices v_1, v_2, \dots, v_g are colorful vertices with colors 1, 2, ..., g respectively.

Theorem 2.5 : $S_b(C_n^k) = [\chi(C_n^k), b(C_n^k)]$.

PROOF. Since $b(G) \leq \Delta(G)+1$, we have $b(C_n^k) \leq 2k+1$. By the definition of C_n^k , it contains a set $\{ v_0, v_1, v_2, \dots, v_k \}$ of mutually pair wise adjacent vertices. Hence $\chi(C_n^k) \geq k+1$. By Lemma 2.4, it follows that $S_b(C_n^k) = [\chi(C_n^k), b(C_n^k)]$.

Remark 2.6: The graph $C_5 \square C_5$ is b -colorable with i colors for each $i = 3, 4$ and 5. The graph $C_5 \square C_5$ is given below:

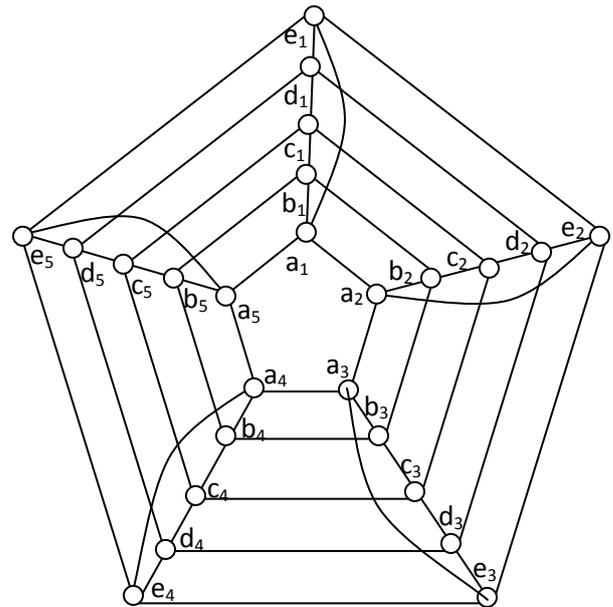

Figure 2.1: $C_5 \square C_5$

Consider the following b -coloring of $C_5 \square C_5$ with 3 colors: $c(a_1) = 1, c(a_2) = 2, c(a_3) = 1, c(a_4) = 3, c(a_5) = 2, c(b_1) = 2, c(b_2) = 3, c(b_3) = 2, c(b_4) = 1, c(b_5) = 3, c(c_1) = 1, c(c_2) = 2, c(c_3) = 1, c(c_4) = 3, c(c_5) = 2, c(d_1) = 3, c(d_2) = 1, c(d_3) = 3, c(d_4) = 2, c(d_5) = 1, c(e_1) = 2, c(e_2) = 3, c(e_3) = 2, c(e_4) = 1, c(e_5) = 3$. Note that c_1, b_1 and d_1 are colorful vertices with colors 1, 2 and 3 respectively.

Consider the following b -coloring of $C_5 \square C_5$ with 4 colors: $c(a_1) = 3, c(a_2) = 2, c(a_3) = 3, c(a_4) = 4, c(a_5) = 1, c(b_1) = 4, c(b_2) = 1, c(b_3) = 2, c(b_4) = 3, c(b_5) = 2, c(c_1) = 1, c(c_2) = 2, c(c_3) = 4, c(c_4) = 1, c(c_5) = 3, c(d_1) = 2, c(d_2) = 4, c(d_3) = 3, c(d_4) = 2, c(d_5) = 4, c(e_1) = 1, c(e_2) = 3, c(e_3) = 1, c(e_4) = 3, c(e_5) = 2$. Here a_5, b_5, c_5 and b_1 are colorful vertices with colors 1, 2, 3 and 4 respectively.

Consider the following b -coloring of $C_5 \square C_5$ with 5 colors: $c(a_1) = 4, c(a_2) = 2, c(a_3) = 5, c(a_4) = 3, c(a_5) = 1, c(b_1) = 5, c(b_2) = 3, c(b_3) = 1, c(b_4) = 4, c(b_5) = 2, c(c_1) = 1, c(c_2) = 4, c(c_3) = 2, c(c_4) = 5, c(c_5) = 3, c(d_1) = 2, c(d_2) = 5, c(d_3) = 3, c(d_4) = 1, c(d_5) = 4, c(e_1) = 3, c(e_2) = 1, c(e_3) = 4, c(e_4) = 2, c(e_5) = 5$. In this case, all the vertices are colorful vertices.

Theorem 2.7: The graph $C_m \square C_n$ is b -continuous when m and n are multiples of 5.

PROOF. Let m and n be positive integers which are multiples of 5. Since $b(G) \leq \Delta(G)+1$, we have $b(C_m \square C_n) \leq 5$.

If m and n are even numbers, then the graph is a product of two even cycles which is a bipartite graph and hence it has a b -coloring with 2 colors.

Otherwise, $C_m \square C_n$ contains an odd cycle and hence $\chi(C_m \square C_n) \geq 3$. From the above fact and from Remark 2.6, it follows that $S_b(C_5 \square C_5) = [\chi(C_5 \square C_5), b(C_5 \square C_5)]$.

As in the proof of Lemma 2.10 in [2], there exists a covering projection from $C_m \square C_n$ to $C_5 \square C_5$. Hence the result follows from Lemma 2.2.

III. B-SPECTRUM OF PETERSON GRAPH

In this section, we find the b -spectrum of Peterson graph and we prove that it is b -continues. Throughout this

section, the vertices of the Peterson graph are labeled as in the following figure. We say that the vertices a_1, a_2, a_3, a_4, a_5 are outer vertices and b_1, b_2, b_3, b_4, b_5 are inner vertices.

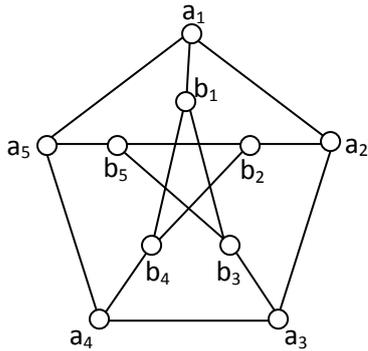

Figure 3.1: Peterson Graph

Remark 3.1: The Peterson graph P is b -colorable with 3 colors as shown in the following figure. The colorful vertices are marked by dark circles.

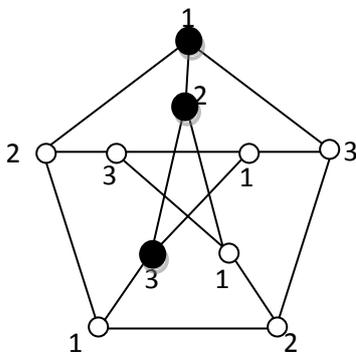

Figure 3.2

Remark 3.2: In Peterson graph, when using 4 colors, all the neighbors of a colorful vertex will receive different colors.

Lemma 3.3: The Peterson graph P is not b -colorable with 4 colors.

PROOF. Case 1: If two adjacent outer vertices of P are colorful (as shown in Fig.3.3).

Since the vertex a_2 is colorful with color 2, we should color the vertices a_3 and b_2 with colors 3 and 4.

Sub case 1.1: $c(a_3) = 4$ and $c(b_2) = 3$ (as shown in Fig.3.4). Note that the adjacent vertices b_3 and b_5 cannot be colored with colors 3 and 4.

Sub case 1.1.1: $c(b_3) = 2$ and $c(b_5) = 1$ (as shown in Fig.3.4.1). By Remark 3.2, the vertices a_3, a_4, a_5 and b_4 could not be colorful with color 4 and hence there exist no colorful vertex with color 4.

Sub case 1.1.2: $c(b_3) = 1$ and $c(b_5) = 2$ (as shown in Fig.3.4.2). In this case, by Remark 3.2, there exists no colorful vertex with color 3.

Sub case 1.2: $c(a_3) = 3$ and $c(b_2) = 4$ (as shown in Fig.3.5). Then the adjacent vertices a_4 and b_4 cannot be colored with colors 3 and 4.

Sub case 1.2.1: $c(a_4) = 1$ and $c(b_4) = 2$ (as shown in Fig.3.5.1). By Remark 3.2, the vertices a_5, b_2, b_3 and b_5 could not be colorful vertices with color 4 and hence there exist no colorful vertex with color 4.

Sub case 1.2.2: $c(a_4) = 2$ and $c(b_4) = 1$ (as shown in Fig.3.5.2). In this case, there exist no colorful vertex with color 3.

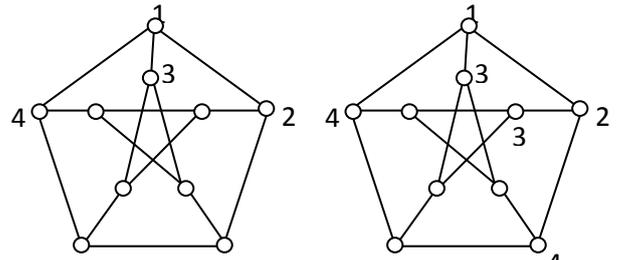

Figure 3.3

Figure 3.4

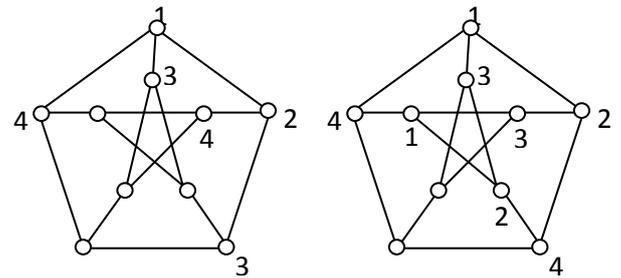

Figure 3.5

Figure 3.4.1

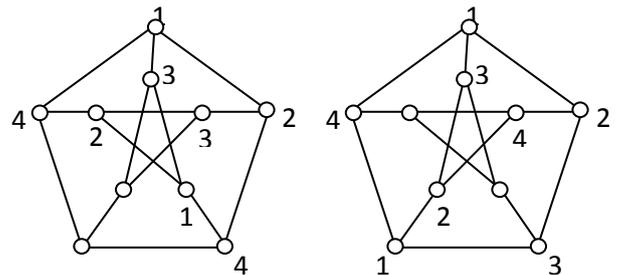

Figure 3.4.2

Figure 3.5.1

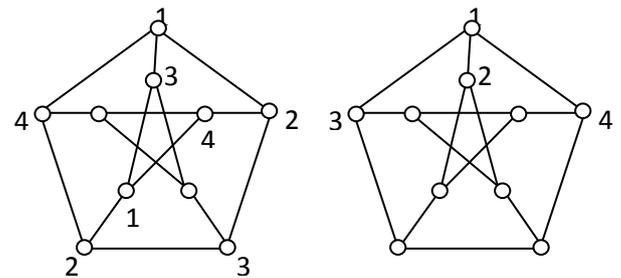

Figure 3.5.2

Figure 3.6

Similarly, it is not possible to have two adjacent colorful inner vertices.

Case 2: If two adjacent vertices of P (one is inner and another one is outer vertex) are colorful (as shown in Fig.3.6). Since the vertex b_1 is colorful with color 2, we should color the vertices b_3 and b_4 with colors 3 and 4.

Sub case 2.1: $c(b_3) = 4$ and $c(b_4) = 3$ (as shown in Fig.3.7). Here, the adjacent vertices b_2 and b_5 cannot be colored with colors 3 and 4.

Sub case 2.1.1: $c(b_2) = 1$ and $c(b_5) = 2$ (as shown in Figure 3.7.1). By Remark 3.2, the vertices a_2, a_3, a_4 and b_3 could not be colorful vertices with color 4 and hence there exist no colorful vertex with color 4.

Sub case 2.1.2: $c(b_2) = 2$ and $c(b_5) = 1$ (as shown in Figure 3.7.2). In this case, by Remark 3.2, there exist no colorful vertex with color 3.

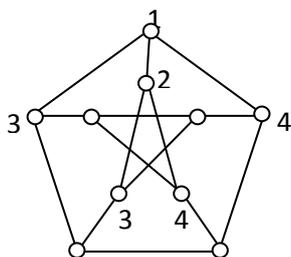

Figure 3.7

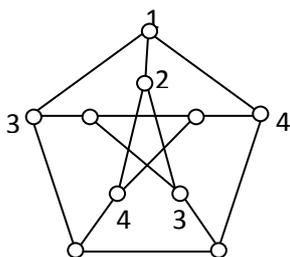

Figure 3.8

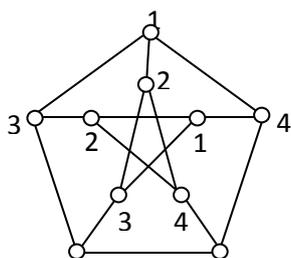

Figure 3.7.1

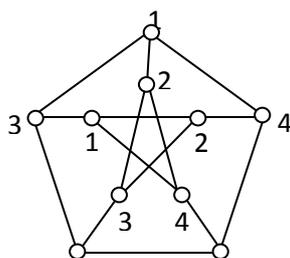

Figure 3.7.2

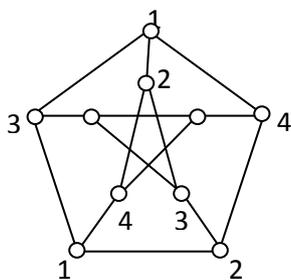

Figure 3.8.1

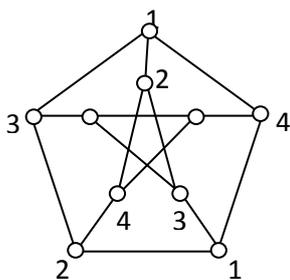

Figure 3.8.2

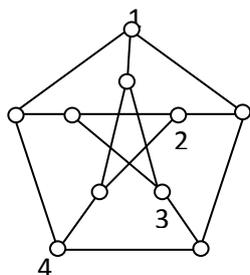

Figure 3.9

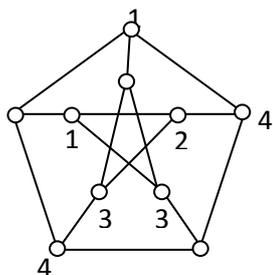

Figure 3.10

Sub case 2.2: $c(b_3) = 3$ and $c(b_4) = 4$ (as shown in Fig.3.8). Then the adjacent vertices a_3 and a_4 cannot be colored with colors 3 and 4.

Sub case 2.2.1: $c(a_4) = 1$ and $c(a_3) = 2$ (as shown in Fig.3.8.1). By Remark 3.2, the vertices a_2 , b_2 , b_4 and b_5 could not be colorful with color 4 and hence there exists no colorful vertex with color 4.

Sub case 2.2.2: $c(a_4) = 2$ and $c(a_3) = 1$ (as shown in Fig.3.8.2). In this case also, there exists no colorful vertex with color 4.

From the above two cases, it is observed that the four colorful vertices must be independent and exactly two inner(outer) vertices are colorful. This is discussed in the following case.

Case 3: The Four colorful vertices are as given in Fig.3.9. The vertex b_5 may have one of the color 1 or 4 and without

loss of generality, assume that $c(b_5) = 1$ (as shown in Fig.3.10). Then for the colorful vertex b_2 with $c(b_2) = 2$, we should have $c(b_4) = 3$ and hence $c(a_2) = 4$ (as shown in Fig.3.10). Consider the colorful vertex a_1 with $c(a_1) = 1$. Here, we should have $c(b_1) = 2$ and hence $c(a_5) = 3$ (as shown in Fig.3.11). In this case, by Remark 3.2, the vertex a_4 with color 4, is not colorful.

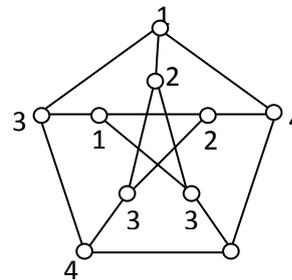

Figure 3.11

Hence, the Peterson graph is not b-colorable with 4 colors.

Since the Peterson graph is 3-regular, by Remark 3.1 and Lemma 3.3, we have the following theorem.

Theorem 3.4: The Peterson graph is b-continuous.

IV. CONCLUSION

This work may be extended in the following directions:

1. Prove that the graph $C_m \square C_n$ is b-continuous for integers m and n which are not multiples of 5.
2. Find the b-chromatic number of Cartesian product of three or more cycles.
3. Find the b-chromatic number of power of Cartesian product of two cycles and three cycles.

Effect of number of cycles on mechanical properties of Al sheets using corrugative and straightening method

Susheelkumar Vijapur, M Krishna, H N Narasimha Murthy

Research and Development, Dept. of Mech. Engg., R V College of Engineering, Bangalore-1

Abstract: The aim of the work was to study the effect of number of cycles on hardness and tensile strength of Al sheet materials processed by corrugative and straightening method. Al sheets were processed for up to 30 cycles using specially designed and developed geared corrugation and roller straightening setup. The microstructure, tensile and hardness studies were done as per standard methods. The microstructural study showed that finer grain refinement seen at 20th cycle then it grain dissolution could be seen. The experimental result showed that the hardness and tensile strength increasing with increase in number of cycles and reach maximum (105 Hv and 405 Mpa) at 21st cycle then they decreased due to grain dissolution.

Key words: Al sheets, corrugation and straightening process, microstructure, mechanical properties.

I. Introduction

The process of severe plastic deformation (SPD) is gaining great interest in material science because it is useful to refine microstructures to the sub micrometer or nanometer levels [1], which leads to improved strength with good ductility. Researchers are working on SPD different techniques namely equal- channel angular pressing (ECAP) [2-4], high pressure torsion (HPT) [5], hydrostatic extrusion (HE) [6] and repetitive corrugated and straightening (RCS) [7-8]. Many methods are limited to smaller size, heterogeneity and larger wastage of specimens. But CRCS method can work for continuous structures and reduce the wastages.

Pandey et.al [9] designed a new technique called continuous repetitive corrugation and straightening system (CRCS), which produces continuous strips without wastage of materials in a single cycle. Few researchers were working on effect of CRCS on materials such as precipitation [9], strain hardening [10], and heat treatment [11] processes. They were observed that the ductility of the samples expressed by relative elongation insignificant drop. Micro-hardness of the CRCS samples increased from about 100 to about 150 HV. The similar strength characteristics for the samples increased. However few researchers successfully worked on strengthening CRCS method but no information is available to date on the level of homogeneity achieved in processing by CRCS method. Hence the objectives of the work were to investigate number of cycles of CRCS on homogeneity mechanical properties hardness and tensile properties and which was justified with microstructure.

II. Experimental studies

In the present study the CRCS process is applied to the Al 6061 sheet the chemical composition are given in Table 1 of dimension 50 x 30 x 1 mm sheets. Al sheets brushed and clean with acetone to remove dirt and rust. The special CRCS was designed and developed using a pair of gears for corrugation and pair of rollers for straightening. The Al sheets are passed through the gears and roller continuously for strengthening, each process is one cycle. The same procedure continues for 30 cycles. Three specimens were used for every cycle that is 1 cycle- 3 specimen, 2 cycles: 3 specimens, so on. CRCS processed specimen polished with different grade SiC papers using automatic polishing machines. Then to obtain mirror finish, the specimen polished on velvete surface with diamond paste. The Keller's reagent was used as the etchant and the chemical composition is 2 ml HF, 3ml HCl and 5ml HNO₃ to obtain grain size. After surface preparation, microstructure analysis was carried out on all the specimens using optical microscope. The specimens are tested for Vickers microhardness (HV) using Micromet-5101 device, with a load of 200g for duration 20 seconds. Tensile tests were performed at room temperature with universal testing machine at cross head speed of 0.5 mm/min, having gauge length of 75mm, thickness of 12.5mm and shoulders of 30mm. three readings were taken for each cycle.

Table1. Chemical composition of Al 6061 (mass %)

Fe	Cu	Si	Zn	Mn	Mg	Cr	Ti	Al
0.16	0.19	0.71	0.04	0.02	0.94	0.08	0.03	Bal

III. Results and discussion

3.1 Microstructure

The CRCS process up to thirty cycles has been successfully performed without shape defects of specimen. Fig. 1 shows the optical microstructures observed at the transverse direction plane of the specimens produced by different cycle of CRCS process. Fig. 1(a) shows the microstructure of ascast specimen, which exhibits strong wire texture and measured average width is around 70 μm . Fig. 1(b) shows 5 cycles CRCS specimen shows less significant effect on size of the grain boundaries which can be measured around 60 μm similarly even 15 cycles CRCS specimens shown in Fig. 1(c). 20 cycle CRCS grain structure (Fig. 1(d)) is refined and microstructure of the specimen evolves into a structure with a considerable fraction of low angle of boundaries. The grain boundaries change from 70 to 30 μm . For 25 (Fig. 1(e)) and 30 cycles (Fig. 1(f)) the grain boundaries no longer change but grain boundaries dissolve within the matrix alloys.

Hence Corrugation and straightening of Al 6061 sheet metal up to 22 cycles will give a good improvement in the grain refinement and even interfaces can also be seen. After 22nd cycle the grain refinement in the Al 6061 alloy gets disolute. As the Si and Mg are flattened more the strength of the material improves.

3.2 Hardness

Fig. 2 shows the effect of number of cycles on micro-hardness of the Al alloy sheet materials. The increase in Hv continues through subsequent cycles and this is due to the well-established reduction in grain size during CRCS process. The homogeneity in the material increased with increase in number of cycles at the higher constant strain. The hardness values increased with increase in number of cycles and reach maximum at 20 cycles then it decreased. The hardness value of the specimen before CRCS processing was 42 Hv, then increase linearly up to 20th pass and the maximal hardness value was obtained at 20th cycle was 105 Hv. With the increase in number of cycles the hardness value decreased and remained constant from 27th to 30th pass.

3.3 Tensile strength

Fig. 3 shows change in mechanical properties as a function of number of CRCS cycles. Fig. 3(a) and Fig 3(b) show the ultimate tensile strength and yield strength, they are increased by 11.23% and 12.25% after processing at 20th cycle of CRCS process. Maximal strengthening was achieved at 20th cycle of the CRCS process. Further processing caused decrease in the ultimate strength and yield strength of the material. Fig. 3(c) shows initially, the ductility of the material increased reached maximum at 10th cycle then it decreased up to 20th cycle then it remains constant. This is due to work hardening in the CRCS process caused a large decrease in ductility of the material and increase in strength. The initial tensile strength of the Al 6061 before processing by CRCS was 364 Mpa and the value of tensile strength increased after processing by CRCS to 405 Mpa, at 20th cycle the maximal value of strength was obtained.

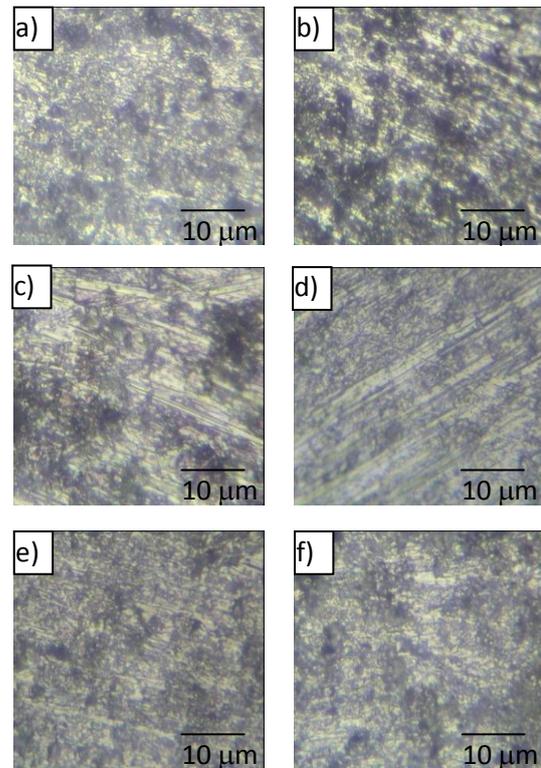

Fig. 1 Optical microstructure of CRCS processed specimens a) ascast, b) 5 cycles, c) 15 cycles, d) 20 cycles, e) 25 cycles and f) 30 cycles

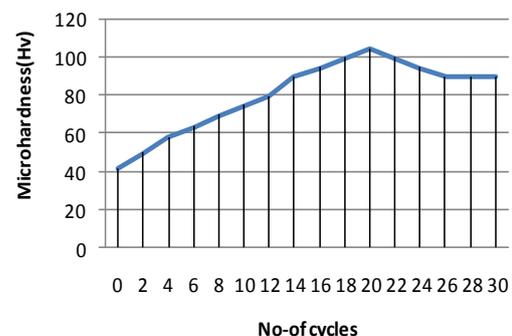

Fig. 2 Variation of microhardness of Al alloy with number of CRCS cycles

IV. Conclusions

This study was aimed to investigate mechanical properties and microstructure in Al 6061 alloy sheets processed by CRCS method. Based on the obtained results, the following conclusions can be drawn:

- The CRCS process effectively reduced the grain size of Al 6061 alloy sheets, demonstrating the CRCS as a promising new method for producing ultra fine grained metallic sheets.
- The optical microscope analysis of microstructure of Al 6061 alloy sheet after CRCS (21 passes) revealed the finer grain size.
- Micro hardness value of Al 6061 alloy sheet before processing by CRCS method was 42 Hv, it increased to about 105 Hv after processing by CRCS method.

- The strength characteristics of the investigated sheet such as yield strength and ultimate tensile strength increased after processing by CRCS method.

ABSTRACT: Sale and purchase of land are usually done by people. Most people are confuse how to find land sold in an area that people already specified. Land Sale Geographic Information System based on web and mobile web using google map is an alternative media that can mapping an area where land is sold. This base system is made by using Ruby on Rails framework and CSS responsive layout. Those platforms will facilitate developers in applying it. The Strengths of this application is user can easily see the location where they want to buy by map. The option search include; land sale by type, region, status, price. forum on the land sale information system will allow users to be able to communicate with each other. Bidding recording system is also a medium that helps to get the best between buyers and sellers selling price. and lastly, the web mobile make users able to open web from any mobile devices.

Keywords: Geographic Information System, Land Sale, Forum

I. INTRODUCTION

Land selling is an activity when the owner of some land is changing. The number of people grows rapidly not only because of the economic factor but also because of their need to find places to stay increases too. In addition, many people come from the other provinces to work and they need to find places to stay.

In some place, land selling still uses printed media and also advertising media through internet. Those media will complicate buyers to choose the land which is already decided because they have to read the articles provided one by one in order to get the information they need on the location of the land. Moreover, buyers should not only search for information in one media, but also in another media.

Seeing the issue above, the writer had an idea to develop an information system with data processing center which is integrated with Land Sale Geographic Information System, Forum Website, and Mobile. This system can help both sellers and buyers in getting the latest information easier. The system is also expected to be able to collect, save, combine, arrange, manipulate and analyze Geographic Information System related to spatial field based on Google Map API.

With the existence of Land Sale Geographic Information System, users will find it easier to find the locations of places they want. By using the system, users can also search for certain criteria such as number of home level, electricity, and building size. Users can also trade information to others in this land selling forum. This system

has a flexible ability as it can be opened using mobile.

II. LITERATURE REVIEW

Geographic Information System (GIS) is one of many information technologies that can input, store, recall, process, analyze and produce geographic or geospatial data in order to facilitate decision-making process in the planning and management of spaces, natural resources, environment, urban facilities, and other public services. GIS components are a computer system consisting of hardware and software, geospatial data, and brainware.

Spatial data are data which are related to geographic conditions, such as rivers, administrative areas, buildings, roads, etc. Spatial data are obtained from maps, aerial photos, satellite images, statistical data, and many others. Until today, common perceptions of the representation of spatial entity are raster and vector concepts. Non-spatial data, on the other hand, are data which are in the form of texts or numbers, often referred as attribute. The Figure below is an example of spatial data obtained from a map.

2.1 Google Map

Google Maps is a web mapping service application and technology provided by Google, that powers many map-based services, including the Google Maps website, Google Ride Finder, Google Transit, and maps embedded on third-party websites via the Google Maps API. It offers street maps, a route planner for traveling by foot, car, bike (beta), or public transport and an urban business locator for numerous countries around the world. Google Maps satellite images are not updated in real time; they are several months or years old[5].

Using Google Map API is not a complex that many people think. It just need HTML, CSS and javascript working together inside[1]. The map tiles are images that are loaded in the background with ajax calls and that return new images. And also the API, basically that is consist of javascript files that contain a class with methods to run the program.

2.2 Geocode

Geocoding us the process of assigning a latitude/longitude coordinate to a place[2]. Geocode also return the coordinate from sending address. Geocoding engine work with a variety of inputs, including the following:

- Address
- cros street
- city and state
- zip code

Data that return from geocode is a JSON output format. JSON that can be read from javascript.

2.3 JSON

JSON (JavaScript Object Notation) is a light data-exchange format which is easy to be written and read by human, and also easy to be translated and generated by computer[4]. JSON is only a text format that does not depend on any programming languages, as it uses a language commonly utilized by C programming family, such as C, C++, C#, Java, JavaScript, Perl, Python, etc. These characteristics make JSON ideal as a language of data exchange.

2.4 Ruby On Rails

Ruby is a script-based, object-oriented dynamic programming language. Ruby is used to combine the superiority of the existing programming languages. Ruby is written in C programming language which basic abilities similar to Perl and Python. Ruby on Rails is built around the Model-View-Controller(MVC) pattern. MVC is a design pattern used for separate an application's data model, user interface, and control logic into three separate layers with minimal dependencies.

There are three data model on RoR:

1. The controller is the component that receives the request from the browse or mobile device and performs the users-specified action.
2. The model is the data layer that is used usually from a controller to read, insert,update, and delete data stored, for example, in relational database.
3. The view is the representation of the page that the users see in their browser.

2.5 Responsive layout

Responsive layout is like an approach to web cascading style that make a flexible layout. The main objective is to build a web can detect a width and height of visitor screen size using media query.

Media queries, a feature of cascading style sheets (CSS), allow the developer to specify when a certain style takes effect. With media queries can solves a lot of design problems caused by the proliferation of new types of mobile devices. Responsive design pages use x and y coordinates on a grid for layout and mathematical percentages for images instead of fixed-width parameters. Using percentages instead of fixed-width parameters and a grid layout creates a more fluid layout that will resize itself to fit the size of the display.

This capacity means that instead of having to build a special mobile version of a website -- which often requires writing new code from scratch -- developers can simply build multiple style sheets for the same web page and perhaps even associate different images with each of the style sheets. As a result, HTML code can be repurposed instead of having to be rewritten, which saves considerable development time.

III. APPLICATION DESCRIPTION

The involved components in this geographic information system are: users, administrator, and google map.

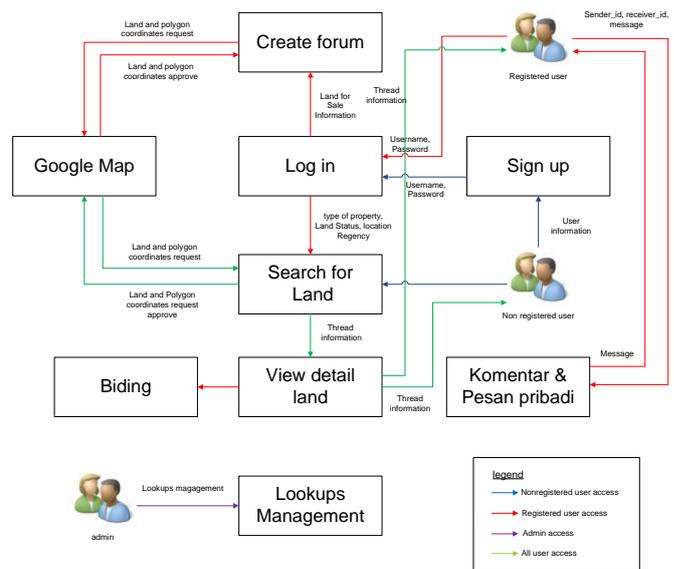

Figure 1. System Overview

Figure 1 describes the overview of Land Sale Information System. It elaborates the flow of figures and features accessible to each user. This system has three user types: guest user, registered user, and admin.

Guest user may access *land search* in the map and may also view *land details*. The search can be done by categorizing the lands based on its department (regency), sale status, prices, and type of land to be sold. The purpose is to facilitate guest user in looking for information on what other users are selling or renting out in this geographic information system.

Guest user may also register himself in the geographic information system by completing the signup process. This method enables guest users to become registered users, and could login in the system.

After logging in, registered users may create a thread to promote the land they want to sell or rent out. In creating threads, users elaborate the details of land-related information and are also able to draw their land location in a polygon shape as well as the department/regency where the land is located. As the map is clicked upon, the system will obtain latitude and longitude coordinates from Google Map to be stored as land-sale location.

Registered users may also give comments both in their own threads and in others' threads. This enables users to easily provide additional information which can be viewed and responded by other users. A private message feature is also provided to registered users, where information can be sent privately between registered users, without the knowledge of uninvited users.

Private message, only for register user. It can be made for anyone who already registered in the system.

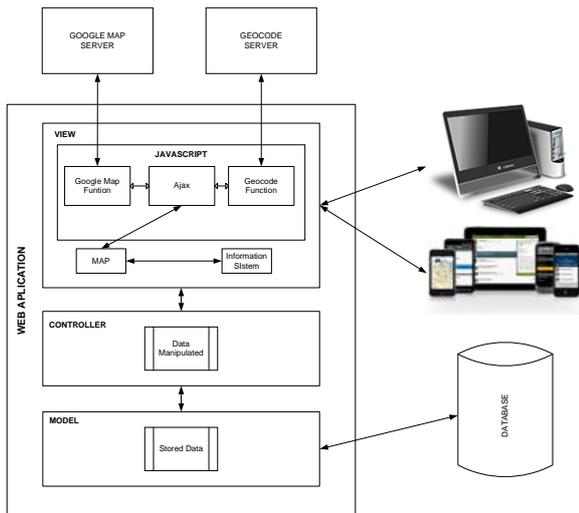

Figure 2. Flow System Description

Users may use either desktop computers or mobile devices. These devices will directly access View. In the viewing process, View would send data request to controller, where it consequently accesses to the database to obtain the data needed. The data are then sent back to View Process in a JSON format where JSON will be processed in JavaScript. Next, Ajax would send the coordinates to geocode to find out in which regency the land is located, where it would send back the information related to the regency in JSON format. Finally, Ajax sends the same coordinates to be marked in Google Map, and Google Map displays the map and its location markers.

IV. RESULTS

This geographic information system provides search feature. In this search system, users are faced with several choices: sale types, region, forum types, and price. Users may choose more than one available options. Forum Types in the map are displayed differently based on icons as can be seen in Figure3.

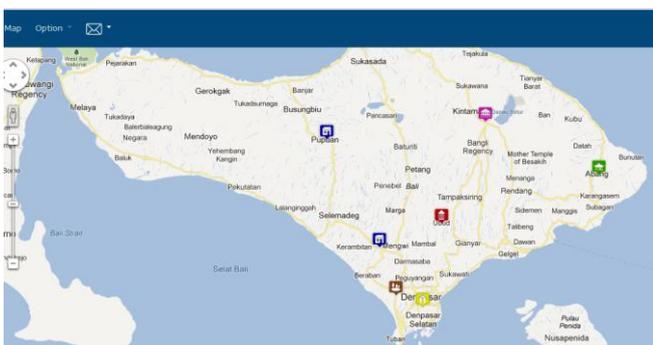

Figure 3. Search Results Based on Maps

Search results can also be seen based on the forum types. Forum displays organize information based on tables sorted by dates and prices. Figure 4 shows an example of forum-based search results.

Rumah	Treads/Post	Post Terakhir
 <p>DISEWAKAN RUMAH LT.2 Perum.Kediri Rp.15000000 Sewa Jl. By Pass Kediri No. 24</p>	Dikunjungi: 6 Post: 3 oleh:ari	2012-06-28 04:49:35 lebar jalan di depan berapa meter??
 <p>Dijual Rumah Sederhana Rumah Power Rp.2000000000 Jual Jl. Raya Pupuan no. 34</p>	Dikunjungi: 1 Post: 1 oleh:intan	2012-07-03 17:08:21 rumah kosongan apa ada isinya??
 <p>Jual rumah seputaran renon Jual Rumah Renon Rp.3000000000 Jual Jl Raya renon</p>	Dikunjungi: 0 Post: 1 oleh:boke	2012-07-02 19:37:17 Senin boleh ketemuan??

Figure 4. Search Results Based on Forum

Apart from the ability to display information based on its forum, users are also able to easily interact with each other using commentaries and private messages as seen in Figure 5.

Figure 5. Sample komentar

Another feature is the media which facilitates sellers and potential buyers to bargain and negotiate. For example, potential buyers may offer a price lower than what the seller asks, and this can be done several times. Sellers then could pick the offer they like the most to close the deal. Offers are sorted in a descending manner based on their prices. The higher the offer, the higher its position is displayed in the result.

Penawar	Harga	Waktu	Terima
ina	500000000	July 01, 2012 19:05	DEAL
dana	435000000	July 02, 2012 19:06

boke	375000000	July 01, 2012 05:31	
indra	300000000	July 02, 2012 05:30	
dana	125000000	July 03, 2012 17:16	

Figure 6. Users bidding sample

In addition, this system also has several notification features, such as:

- 1 Comment Notification**
Comment Notification informs all users commenting on a thread if there is a new reply from another user.
- 2 Private Message Notification**
Private Message Notification appears if a new message from another user is received
- 3 Negotiation Notification**
Negotiation Notification shows users if a new user is involved in a negotiation or if a new offer is made
- 4 Land Sold Notification**
Land Sold Notification informs all the users who have been involved either in a commentary thread or negotiation thread when the related land has been sold or rented out

Rating System is the last feature of this geographic information system. Users may give rating to a certain thread. The highest rating is 5 stars, while the lowest is 0. The rating score is displayed based on the average rating given by all users on certain thread.

V. STRENGTHS AND WEAKNESSES

5.1 Strengths of Land Sale Information System

Here are some advantages of this system:

- 1 The main feature, map, enables users to search for lands based on the desired location.
- 2 Its web-based characteristics let users easily access the information from any device as long as they are connected to the Internet.
- 3 This system is accessible for mobile devices which can run JavaScript such as tablet computers or smartphones. Obtaining and sharing land-related information from users' handsets would be easier.
- 4 Users may browse for land-related information in two ways: map and forum. Forum-based View provides an alternative and help users which might have difficulties in reading maps.
- 5 Registered users can give comments or ask questions in a related thread.
- 6 Registered users can send private messages to each other, in order to prevent uninvited users from viewing their conversations.

5.2 Weaknesses of Land Sale Information System

This System cannot verify whether or not the information the users have input are reliable.

VI. CONCLUSIONS

The followings are the conclusions from the research "Designing Web-Based and Mobile-Based Land Sale Geographic Information System":

1. Google Map has the capabilities of providing spatial data for exact mapping and real mapping. In addition, Google Map also has numerous features such as street mapping, satellite images, and hybrid features which can support users in map-based information search.
2. Land Sale Geographic Information System gives users easy access to search for land sales based on its location and sale status.
3. Web-Mobile version helps users to access information related to land sales, although it is not as fast and as efficient as accessing it from the computer.

Production, purification and characterization of Lipase isolated from salt water *Halobacterium sp*

V. Ramadas* and R. Lavanya Ramadoss**

(*Assistant Professor, Research Centre & P.G. Department of Zoology, R.D.Govt. Arts College, Sivagangai - 630 561, Tamil Nadu, India)

(** Former Student, Department of Biotechnology, P.S.R.Engineering College, Sivakasi, Tamil Nadu, India)

ABSTRACT: *Halobacterium* are salt loving microorganism, which thrives in the salt lake, and seawater where there is an elevated salt concentration. They have the capacity to balance the osmotic effect of the outside environment and resist against the dehydrating effects of the salts. Their novel characteristics and capacity for large scale culturing make *Halobacterium* potentially valuable for biotechnology. In the present study the *Halobacterium sp.* was isolated from seawater sample and from paddy field nearer to seashore they are characterized by morphological and biochemical characteristics. The *Halobacterium sp.* was subjected to screening for enzyme production like amylase, cellulose, lipase and protease. Lipase enzyme was produced in the laboratory scale it was purified by dialysis method and using ion exchange chromatography. The enzyme activity and concentration were determined using the standard laboratory protocols. The enzyme kinetics studies were also carried out along with the SDS-PAGE using BSA as a standard marker and it was found out that the obtained lipase enzyme was 66 KD in its molecular weight.

Keywords: Seawater - *Halobacterium*, - lipase enzyme Production and Characterization – determination of molecular weight.

I. INTRODUCTION

Halobacterium is salt – loving microorganisms that inhabit hypersaline environments [1]. These bacteria has a unique feature of possessing the purple membrane, specialized regions of the cell membrane that contain a two dimensional crystalline lattice of a chromoprotein, bacteriorhodopsin. They have the capacity to balance the osmotic pressure of the environment and resist the denaturing effects of the salts [2]. They are able to live in salty conditions by preventing dehydration of their cytoplasm. They do this by either producing large amounts of an internal organic solute or by concentrating a solute from their environment [3]. *Halobacterium* is motile spore producing aerobic microorganism found distributed all over the world in hypersaline environments, many in natural hypersaline brines in arid, coastal, even deep sea locations, as well as in artificial salterns used to mine salts from the sea. Their novel characteristics and capacity for large scale culturing make *Halobacterium* potentially valuable for biotechnology [4]. The genus *Halobacterium* consists of several species of archaea with an obligate aerobic metabolism which

require an environment with a high concentration of salt [5].

A lipase is a water-soluble enzyme that catalyzes the hydrolysis of ester bonds in water-insoluble, lipid substrates. Lipases are ubiquitous throughout living organisms, They have considerable physiological significance and industrial potential, and are being employed for the synthesis of drug intermediates and pharmaceutically important molecules. The lipases used for various purpose are usually fungal or bacterial origin [6]. They are produced as an extra-cellular product by the bacterial species and attract industrial attention. The activity of the enzymes in general appears to be stabilised by immobilisation in suitable matrices. The lipase may be immobilised in hydrogels (alginate, carrageenan, agarose etc) or in the solgels (silicate, celite etc). Many researcher have studied on various species of *Halobacterium* from salt lake [7] sea water and salt mine. Apart from these, many biomolecules synthesized by the *halobacterium* have been reported by many authors [8,9,10,11&12] Likewise, many workers have studied the proteome of *Halobacterium salinarum* using proteomics technique and also detected 14 protein molecules. Meanwhile, a very few literature available on the lipase production by *halobacterium* isolated from sea water. Hence, the present works deals with the isolation and characterisation of *Halobacterium* from the sea water. These isolated species was then subjected to the enzyme screening for the enzymes like amylase, cellulase, protease and lipase. Lipases have a large variety of applications mainly in the detergent, cosmetic, drug, leather, paper, and food industry and in several bioremediation processes. So owing to their vast and varied applications newer microbes are to be screened for production of lipases of desirable properties.

The enzyme kinetics studies like effect of temperature, pH, activator, inhibitor, and substrate concentration was also studied along with the determination of molecular weight of the lipase enzyme using SDS-PAGE.

II. MATERIAL AND METHODS:

2.1. Collection of water samples

Surface seawater (W1) samples were collected in a sterilized container from the sea at a depth of 1m and 6 km away from seashore at Tiruchendur in Southern Tamilnadu, India. Similarly, water sample (W2) was also collected from paddy field nearer to the seashore area approximately about 4 km away from the sea.

2.2. Estimation of total salt concentration and pH of the water samples

About 10 ml of each samples (W1 and W2) were taken in a two separate clean and dry test tube whose weight is determined previously and they were allowed to evaporate till there is no trace of water droplets inside the test tubes. The weight of the test tubes with the salts was measured and the difference between the weight of the test tube with salt and the empty test tube gives the weight of the salts present in the water samples. The pH of the water samples (W1 and W2) was determined using pH meter and values were recorded.

2.3. Isolation of *Halobacterium* from the samples W1 and W2

The samples W1 and W2 were serially diluted in the range of 10^{-1} , 10^{-2} , 10^{-3} , 10^{-4} , 10^{-5} , 10^{-6} , and 10^{-7} in a series of test tube. The *Halobacterium* was cultured in the nutrient medium with increased concentration of Na Cl. The pH of the medium was adjusted to 7 – 7.4, and the composition of the nutrient medium with essential ingredients were given in the Table-1. The samples were inoculated under aseptic condition in the petriplates containing nutrient agar medium using spread plate technique and are incubated at 37°C for 48 hours [13].

Table – 1. Composition of nutrient medium for bacterial growth

Sl.No.	Essential Ingredients	Concentration (g/100ml)
1.	Peptone	0.5
2.	Yeast extract	0.3
3.	NaCl	2.0
4.	Agar	2.0

2.4. Preparation of pure culture of *Halobacterium sp.*

The nutrient agar slant was prepared in test tubes and the isolated colony obtained in the petriplates were taken carefully without contamination (leaving out mixed culture colony) and streaked in the nutrient agar slant in the in a zigzag manner using the inoculation loop. Then test tubes were plugged with cotton plugs and incubated at 37°C for 48 hours.

2.5. Morphological studies of *Halobacterium* using Gram staining

The morphological studies like colony appearance, cell shape, and size on the obtained pure cultures were carried out using Gram staining method. The stained slides were observed for the morphological characteristics of the culture under the compound microscope.

2.6. Determination of respiration type of *Halobacterium*

The nutrient agar deep tube was prepared and the pure culture was inoculated deeply into the solidified medium using inoculation needle under sterile condition. After inoculation, the upper surface of the medium was covered with the molten wax with 0.5cm thickness and incubated for 48 hours at 37°C.

2.7. Biochemical characterization of *Halobacterium*

Different biochemical tests were performed to characterize and to confirm the isolated species as *Halobacterium*, such as, catalase test, indole production test, methyl red and vogas proskauer (MR – VP) test, citrate utilization test and acid production test.

2.8. Screening for enzyme production by *Halobacterium*

The pure culture of *Halobacterium* species was subjected to screening for enzyme production like, amylase, protease, cellulase and lipase. The essential ingredient for the enzyme-screening medium is given in the Table - 2.

Table – 2. Composition of enzyme screening medium

Sl.No	Essential ingredients	Concentration (g/1000ml)	
1	Amylase screening medium		
	Beef Extract	3.0	
	Peptone	5.0	
	Na Cl	7.0	
	Starch	10.0	
	Agar	20.0	
2	Lipase screening medium		
	Peptone	2.5	
	Casein	2.5	
	Yeast Extract	3.0	
	Tributyryn	10.0	
	Na Cl	7.0	
3	Protease screening medium		
	Skim Milk powder	10.0	
	Na Cl	7.0	
	Agar	20.0	
	4.	Cellulase screening medium	
		Beef Extract	3.0
Peptone		5.0	
Na Cl		7.0	
Cellulose (CMC)		10.0	
Agar		20.0	

The different types of medium used for the screening of enzyme production were sterilized using autoclave. The medium was distributed equally in the Petriplates and allowed it to get solidified, after few minutes of solidification, the pure culture was inoculated in a zigzag streak using inoculation loop and incubated at 37°C for 24 – 48 hours.

2.9. Assay of Lipase enzyme production

The lipase enzyme was produced using the *Halobacterium* isolated from the sea water in the sterilized lipase production medium. The composition of lipase production medium is indicated in the Table – 3.

Table – 3. Composition of lipase productionmedium

Sl.No.	Essential ingredients	Concentration (g/1000ml)
1.	Peptone	2.5
2.	Casein	2.5
3.	Yeast Extract	3.0
4.	Tri butyrin	10ml
5.	Na Cl	7.0

The pH of the sterilized medium was adjusted to 7.4 and isolated strains of *Halobacterium* were inoculated under aseptic condition using inoculation loop in the medium and incubated at 37°C for 48 hours in a mechanical shaker.

2.9.1. Extraction of lipase enzyme

After considerable growth of bacteria in the lipase production medium, the lipase enzyme produced as an extracellular product by the bacteria was extracted from the medium. The lipase production broth was centrifuged at 6000 rpm for 10 minutes to remove the cell debris and the supernatant was collected in the separate test tubes after centrifugation and filtered using Watt Mann Filter Paper.

The obtained filtrate was subjected for 70% saturation (for 100ml of sample about 44.2g of ammonium sulphate salt gives 70% saturation) with ammonium sulphate by adding the salt slowly in the conical flask containing the filtrate kept in the magnetic stirrer. The content was left undisturbed for one hour, and then it was centrifuged and the pellets were collected and dissolved in the 20 mM Tris buffer. About 1.5 ml of crude enzyme extract was taken in the vials and stored for the future use at 4°C.

2.9.2. Purification of lipase enzyme

The obtained crude enzyme was then purified by Dialysis method and Ion exchange chromatographic process.

2.9.3. Dialysis of crude extract of Enzyme

The obtained crude extract of enzyme was first purified by dialysis process, which is based on the principle of osmosis. About 2 litres of 50 mM Tris hydrochloride is required for the process. The cellulose acetate membrane, which can retain the molecules, whose molecular weight is greater than 10 to 12 KD is used as a dialysis membrane. The pretreatment of dialysis membrane is required to perform the dialysis process.

2.9.4. Pretreatment of Dialysis membrane

About 2 to 2.5 inches of dialysis membrane was taken and it was soaked for 10 minutes in a boiling water bath at 100°C. After 10 minutes of boiling, 2gm of

sodium carbonate was added to the boiling water containing the dialysis membrane and allowed to boil for few minutes. Then the dialysis membrane was transferred to the fresh boiling water bath at 100°C for 10 minutes.

2.9.5. Dialysis of enzyme

The pretreated dialysis membrane was taken and made into a pouch like structure with the help of thread tied at the one end of the membranes. To the pouch the crude extract of enzyme was added and it was sealed at both the ends using threads. The sealed membrane with the enzyme was then dipped into the 50 mM Tris HCl and allowed to stand for overnight undisturbed at 4°C. After incubation, the entire content was brought to room temperature and the dialysis process was repeated for 2 times with fresh Tris HCl buffer. To enhance the dialysis process the entire dialysis set up was kept in the magnetic stirrer. About 1.5 ml of dialyzed sample was taken in vials and stored at 4°C for future use.

2.9.6. Purification of lipase using Ion exchange chromatography

The dialyzed sample was further purified using ion exchange chromatography with 25 mM Tris HCl and 1 M NaCl. These ion exchange solvents with different molarities were prepared and distributed in to six different test tubes as shown in the Table – 4.

Table – 4. Ion exchange solvents with different Molarities

Test Tube No.	Tris HCl (ml)	NaCl (ml)	Distilled water (ml)
1.	0.25	0.25	9.50
2.	0.25	0.50	9.25
3.	0.25	0.75	9.00
4.	0.25	1.00	8.75
5.	0.25	1.25	8.50
6.	0.25	1.50	8.25

The enzyme, which is retained in the resin bed, was eluted by the solutions of different molarities, which are added one by one, and the filtrate was collected in the sterile test tubes.

2.9.7. Determination of activity of lipase enzyme using titrimetric method

The activity of the lipase enzyme obtained (Crude enzyme sample, Dialyzed enzyme sample, and the enzyme purified further by ion exchange chromatography sample) was determined by titrimetric method.

2.9.8. Determination of enzyme concentration by Lowry's method

The concentration of the extracted enzyme was determined by the Lowry's method.

2.10. Enzyme Kinetic studies of lipase enzyme using titrimetric method

The kinetics of enzymes like effect of temperature, pH, substrate concentration, inhibitor and activator were studied using the standard laboratory protocol.

2.10.1. Effect of temperature

A series of test tubes labeled with different incubation temperature (4°C, room temperature, 37°C, 55°C, and 100°C) including Blank. About 2.5ml of distilled water was added to each test tube along with the addition of 1.0ml of Tris HCl buffer and 0.3ml of Tributyrin (substrate). The test tubes were incubated at room temperature for 10 minutes and then about 0.1ml of enzyme was added to each test tubes except blank and incubated at 37°C for 30 minutes. About 3 ml of ethanol was added after the incubation period to the test tubes and the enzyme activity was determined.

2.10.2. Effect of pH

A series of test tubes labeled with different pH values such as 3, 5, 7, 9, and 11 along with blank. About 2.5ml of distilled water, 1ml of buffer with different pH values and 0.3 ml of Tributyrin (substrate) were added to the test tubes and incubated at room temperature for 10 minutes. Then 0.1ml of enzyme was added to all the test tubes except blank and incubated at 37°C for 30 minutes. 3.0ml of ethanol was added to the test tubes after the completion of incubation period and the enzyme activity was determined.

2.10.3. Effect of substrate concentration

A series of test tubes labeled with different substrate concentrations like 50µl, 100µl, 150µl, 200µl, 250µl, 300µl, 350µl, 400µl, 450µl, and 500µl were taken. To each test tubes about 2.5ml of distilled water, 1ml of Tris HCl buffer, and Tributyrin (substrate- with different concentration) were added. The test tubes were incubated at room temperature for 10 minutes and about 0.1ml of enzyme was added to all the test tubes except blank. After the addition of enzymes the test tubes were incubated at 37°C for 30 minutes. About 3.0ml of ethanol was added after the incubation period to the test tubes and the enzyme activity was determined.

2.10.4. Effect of activator

A series of test tubes labeled with different concentration of activator (ZnCl₂ 1mg/ml) like 0.2ml, 0.4ml, 0.6ml, 0.8ml and 1.0ml were taken and 2.5ml of distilled water, 1 ml of Tris HCl buffer and 0.3ml of Tributyrin (substrate) to each test tubes and they were incubated at room temperature for 10 minutes. After that about 0.1ml of enzyme was added to all the test tubes except blank and the activator of different concentration (Table -) again incubated at 37°C for 30 minutes. About 3.0ml of ethanol was added after the incubation to each test tubes and the enzyme activity was determined.

2.10.5. Effect of inhibitor

A series of test tubes labeled with different inhibitor (Stock solution:EDTA 1mg/ml) concentration like 0.2ml, 0.4ml, 0.6ml, 0.8ml and 1.0 ml were taken, and 2.5ml of distilled water, 1ml of Tris HCl buffer and

0.3ml of Tributyrin (substrate) were added to each test tubes.

All the experimental samples were incubated at room temperature for 10 minutes. After incubation of the content about 0.1ml of enzyme (except blank) and inhibitor of different concentration were added to each test tubes and incubated at 37°C for 30 minutes. About 3.0ml of ethanol was added after the incubation and the enzyme activity was determined.

2.11. Determination of molecular weight of lipase enzyme using SDS-PAGE

The molecular weight of the lipase enzyme obtained from *Halobacterium* species was determined by SDS-PAGE, where BSA serves as a control and the reagents used for SDS-PAGE were indicated in Table – 5.

Table – 5. Reagents used for SDS-PAGE

Sl.No	Essential ingredients	Concentration
1	Stock acrylamide solution	
	Acrylamide 30%	3g
	Bis acrylamide 0.8%	0.08g
	Water	10ml
2	Separating gel buffer pH 8.8	
	1.875M Tris HCl	2.27g
	Water	10ml
3	Stacking gel buffer pH 6.8	
	0.6m Tris HCl	0.726g
	Water	10ml
4	Electrolyte buffer pH 8.2 – 8.4	
	0.05M Tris	1.2g
	0.192M Glycine	2.88g
	0.1% SDS	0.2g
5	Ammonium persulphate solution	
	Ammonium sulphate	0.6g
	Water	10ml

About 2ml of separating gel buffer was mixed with 3.5 ml of stock acrylamide solution and to which 4.5ml of water was added. The separating gel mixture was then degassed and about 20µl of freshly prepared ammonium persulphate (APS) solution was added for the polymerization reaction to form gel. After the addition of APS the separating gel mixture was immediately poured into the tightly clamped SDS plates. The surface of the separating gel was washed with water in order to form a smooth even surface and after polymerization of separating gel, the water was removed and ensures that there is no trace of water in between the glass plates. Then the stacking gel mixture of water 3.5ml, stacking gel buffer 0.5ml and stock acrylamide solution of 1ml was vortexed and degassed, to that about 7µl of APS solution was added and poured above the separating gel

within the glass plates and the comb was inserted immediately to form the wells for loading the samples in the gel and it was left undisturbed to get solidified by the polymerization reaction. After solidification of gel the comb was removed carefully and the wells was washed with electrolyte buffer and the electrophoresis tank was filled with the electrophoresis buffer. The samples were then loaded in the wells and it was electrophoresed at 50 to 100 volts where standard BSA serves as a marker. After electrophoresis the gel was stained with staining buffer and kept for overnight. It was then destained and the presence of enzyme bands was observed.

III. RESULTS AND DISCUSSION

IV.

3.1. Estimation of total salt concentration and pH of the water samples

The sea water sample (W1) contains 4g of salts/ 100 ml of water and the water sample (W2) collected from the paddy field nearby sea shore area was found to contain 3.1g of salts / 100ml of water. The pH of the water sample W1 and W2 were recorded as 8.65 and 10.19 respectively.

3.2. Isolation of *Halobacterium*

Numerous colonies like yellow pigmented, red pigmented, white spongy, white radial, dirty white colonies were observed from the water samples. The isolated *Halobacterium sp.* from the seawater samples was found as radial white spongy gram negative bacillus colonies. Ninety five extremely halophilic species have been isolated from distinct saline regions of Turkey. Likewise, a novel species of salt water bacterial namely *Halobacterium jilantaiense* was isolated [7]

3.3. Morphological characteristics of *Halobacterium*

The isolated *Halobacterium* strains were appeared as rod like bacillus, gram-negative organism. They found as radial white spongy colonies. The results of the morphological study of the obtained colonies were indicated in the Table – 6.

All the colonies isolated both from the seawater and paddy field water was gram negative bacilli. They are motile and aerobic in nature, requires oxygen for their metabolism [14, 15, & 16].

Table – 6. Morphological characteristics of *Halobacterium*

Sl.No	Sample	Colony Appearance	Cell shape	Gram staining
1	W1	White colony	Bacilli	Gram Negative
2	W1	Dirty white colony	Bacilli	Gram Negative
3	W2	Spongy white colony	Bacilli	Gram Negative
4	W2	Milky white colony	Bacilli	Gram Negative
5	W2	Yellow pigmented colony	Bacilli posses terminal spores	Gram Negative
6	W2	White colony	Bacilli	Gram Negative

3.4. Determination of type of respiration in *Halobacterium sp.*

It was observed that the colonial growth was absent in the test tubes sealed with the waxes due to the aerobic nature of the colony which requires oxygen for its respiration [17 & 18]. Both the aerobic and anaerobic colonies were isolated from water samples W1 and W2. The results were indicated in Table – 7.

Table – 7. Determination of type of respiration in *Halobacterium sp.*

Sl.No	Sample	Colony Appearance	Respiration type
1	W1	White colony	Aerobes
2	W1	Dirty white colony	Aerobes
3	W2	Spongy white colony	Aerobes
4	W2	Milky white colony	Facultative anaerobes
5	W2	Yellow pigmented colony	Aerobes
6	W2	White colony	Facultative anaerobes

3.5. Biochemical characteristics of *Halobacterium sp.*

The isolated pure cultures were subjected to various biochemical characterization [19 & 20] and the results were indicated in Table –8. The bacterial colonies isolated from the water samples W1 & W2 were showed positive results almost for all the biochemical tests except a few carried out in the present study. The results of the morphological and biochemical characteristic studies have confirmed the *Halobacterium sp.*

Table 8. Biochemical characteristics of *Halobacterium sp.*

Name of Biochemical test	Eperimental Samples					
	W1 (1)	W1 (2)	W2 (3)	W2 (4)	W2 (5)	W2 (6)
Catalase test	+	+	+	+	+	+
Indole production test	+	+	+	+	+	+
Methyl Red test	+	+	+	-	+	+
Vogas proskauer test	-	-	-	+	-	-
Citrate utilization test	+	+	+	+	+	+
Acid Production test	+	+	+	+	+	+

3.6. Screening for enzyme production by *Halobacterium sp.*

The inoculated petri dishes were observed after 24 – 48 hours of incubation for the presence of clear zone along the colony growth and the results of the enzyme like amylase, cellulose, lipase and protease productions by the organism were tabulated in Table –9.

The inoculated colonies produce the clear zone only in the lipase and protease-screening medium and not in the amylase and cellulose production medium. This indicated that the isolated *Halobacterium* strains produce both the protease and lipase enzymes and a well distinct zone was observed in the lipase production medium than in the protease production medium indicated that the organisms have produced more amount of lipase. The lipase has been isolated from *Fusarium solani* and *Streptococcus sp.* [21, 22, 23, & 24]

Table – 9 screening of various types of enzymes produced by *Halobacterium sp.*

Sam ple No.	Colony morphol ogy	Cellulas e	Amylase	Protea se	Lipas e
1 W1	White colonies	-	-	+	+
5 W2	Yellow pigment ed colonies	-	-	+	+

3.7. Purification of lipase enzyme

The crude enzyme obtained was purified by dialysis with cellulose acetate membrane which retains

the enzyme particles with size ranged from 10 to 12 KD, and the enzyme was further purified by ion exchange chromatography and stored.

3.8. Determiation of activity of lipase using titrimetric method

The results of the activity of the crude extract of the enzyme and dialyzed sample were indicated in Table – 10 and the sample purified by ion exchange chromatography were determined by titrimetric method and the results were indicated in Tables – 11. There was no difference in the activity of crude extract and dialyzed enzyme. Whereas, in case of enzyme purified by Ion Exchange Chromatography, the enzyme activity was gradually increased with increase in the concentration of enzyme (100000 to 300000 units /ml enzyme) and after saturation level there was no increase in the activity, instead it declined [25, 26 &27].

Table – 10. Determiation of activity of lipase present in the crude extract and dialyzed sample using titrimetric method

S.No	Enzyme activity (units/ml enzyme)	
	Crude Extract	Dialyzed Enzyme
B	0	0
1W1	30000	30000
5W2	20000	20000

Table – 11. Determiation of activity of lipase enzyme purified by ion exchange chromatography by titrimetric method

Sl. No	Solvent	Tris HCl (ml)	NaCl (ml)	Dis. water (ml)	Enzyme activity (units/ml)
1	1	0.25	0.25	9.50	100000
2	2	0.25	0.50	9.25	100000
3	3	0.25	0.75	9.00	200000
4	4	0.25	1.00	8.75	300000
5	5	0.25	1.25	8.50	200000
6	6	0.25	1.50	8.25	100000

3.9. Determiation of concentration of lipase enzyme using Lowry’s method

The concentration of the lipase in crude extract, sample after dialysis and purified using ion exchange chromatography was determined by Lowry’s method [28] and results were indicated in Table – 12. The concentrations of enzyme in the crude extract, dialyzed enzyme and purified by ion exchange chromatography were determined spectrophotometrically and recorded as 0.12µg/ml, 0.18µg/ml and 0.10µg/ml respectively.

Table – 12 Determination of concentration of lipase enzyme present in crude extract, dialyzed sample and purified sample by ion exchange chromatography

Effect of temperature on lipase activity		Effect of pH on lipase activity	
Temp range °C	Enzyme activity (units/ml enzyme)	pH	Enzyme activity (units/ml enzyme)
B	0	B	0
4	200000	3	200000
RT	300000	5	300000
37	300000	7	800000
55	400000	9	600000
100	200000	11	100000
Effect of substrate concentration on lipase activity			
Substrate concentration (µl)		Enzyme activity (units/ml enzyme)	
B		0	
50		200000	
100		300000	
150		500000	
200		500000	
250		900000	
300		1100000	
350		1200000

4	1800000	4	700000
5	2200000	5	400000

using Lowry's method

3.9. Enzyme kinetics of lipase enzyme obtained from *Halobacterium*

The enzyme kinetic studies were carried out to determine maximum activity of enzyme at optimum conditions. Especially the effect of temperature (Fig.1), pH (Fig.2), substrate concentration (Fig.3), inhibitor (Fig.4), and activator (Fig.5) on lipase activity have been indicated in Table - 13.

Table – 13. Effect of Temperature, pH, substrate concentration, activator and inhibitor on lipase enzyme obtained from *Halobacterium*

Sl.No	Vol. of std BSA (ml)	OD Values at 600 nm		
		Crude Extract	Dialyzed Sample	Purified sample by IEC
B	0	0	0	0
1	0.2	0.108	0.012	0.012
2	0.4	0.148	0.020	0.020
3	0.6	0.258	0.050	0.050
4	0.8	0.324	0.056	0.056
5	1.0	0.368	0.086	0.086
T	0.1	0.172	0.084	0.044

The optimum temperature and optimum pH at which the maximum activity of the enzyme was predicted for the lipase enzyme as 55°C, and 7 respectively. Whereas, in case of substrate concentration, the enzyme activity increases steadily with increase in the concentration of substrate up to 300µl and the activity of enzyme remains constant further increase in the substrate concentration.

Fig .1 Effect of temperature on lipase isolated from *Halobacterium sp.*

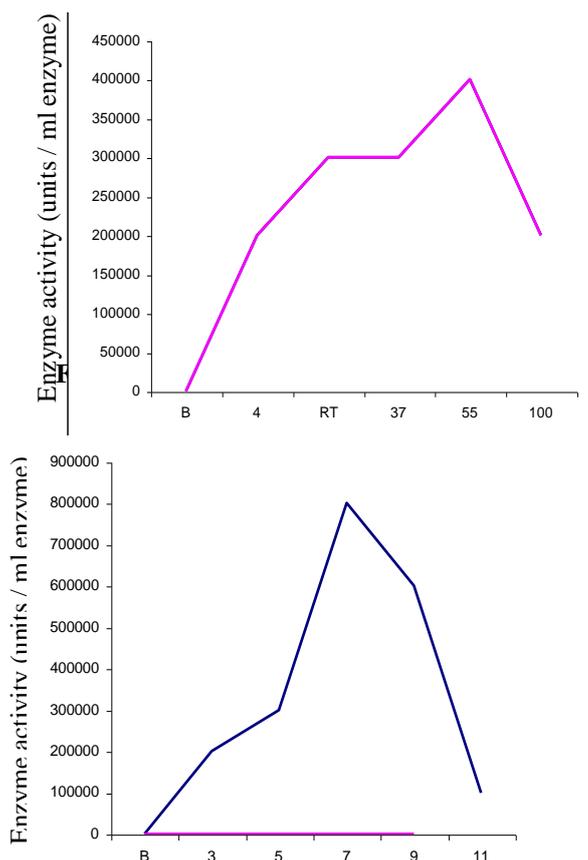

Fig. 3. Effect of substrate concentration on lipase isolated from *Halobacterium*

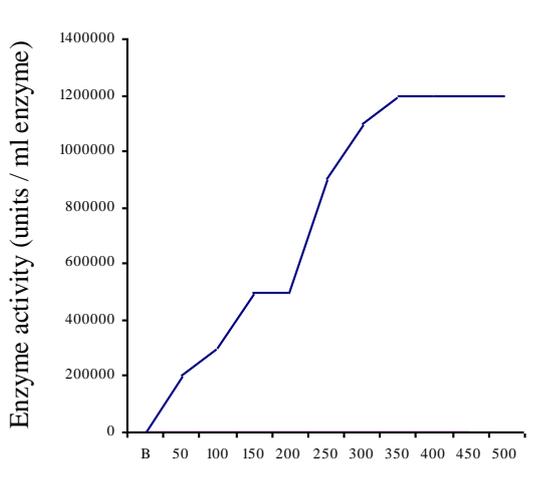

Fig.4. Effect of activator on lipase isolated from *Halobacterium sp.*

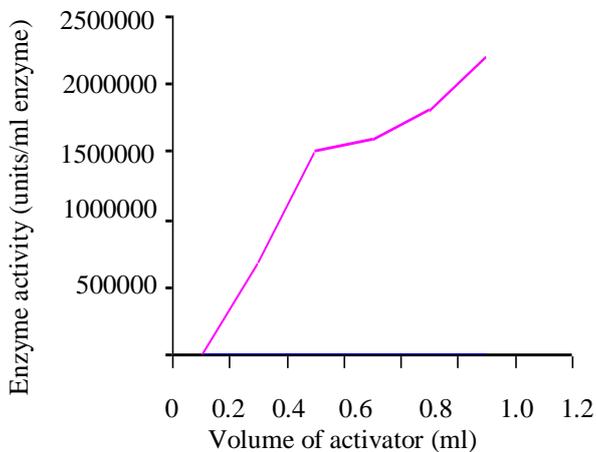

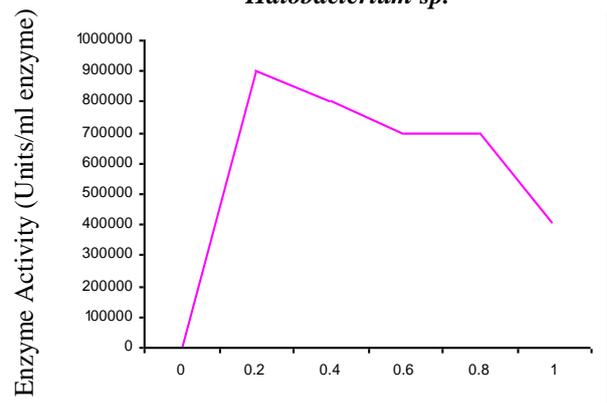

Fig .5. Effect of inhibitor on lipase isolated from *Halobacterium sp.*

The inhibitor (EDTA) inhibits the activity of the enzyme whereby the enzyme activity gradually decreases with increase in the concentration of inhibitor. Similarly, a gradual and steady enhancement in the enzyme activity was observed with increase in the concentration of the activator ($ZnCl_2$) in the present investigation. Similar studies have been carried out in *Streptococcus sp.*, and it was reported that, the optimum temperature and range of pH value for maximum activity of lipase as $37^\circ C$ and 8 – 8.4 respectively.

3.10. Determination of molecular weight of lipase using SDS-PAGE

The molecular weight of the lipase isolated from *Halobacterium sp.* was found to be 66 KD, which was determined using standard BSA as a marker in the SDS polyacrylamide gel electrophoresis. Similarly, the molecular weight of lipase isolated from *Streptococcus sp.* was reported as 44.7 KD [6].

ARM Based Solar Tracking System

K. Sreenivasa Rao¹, M. Mahesh²

*(Department of Electronics and Communication Engineering, AITS, India)

** (Department of Electronics and Communication Engineering, AITS, India)

ABSTRACT: Solar energy systems have emerged as a viable source of renewable energy over the past two or three decades, and are now widely used for a variety of industrial and domestic applications. Such systems are based on a solar collector, designed to collect the sun's energy and to convert it into either electrical power or thermal energy. In general, the power developed in such applications depends fundamentally upon the amount of solar energy captured by the collector, and thus the problem of developing tracking schemes capable of following the trajectory of the sun throughout the course of the day on a year. This project is designed with ARM7TDMI processor. The ARM7TDMI processor does the job of fetching the input from the sensor and gives command to the motor to run in order to tackle the change in the position of the sun.

Keywords: Solar collector, Light Dependent Resistor (LDR), ARM7TDMI processor.

I. INTRODUCTION

Solar energy is the energy extracted from the rays issued from the sun in the form of heat and electricity. This energy is essential for all life on Earth. It is a renewable resource that is clean, economical, and less pollution compared to other resources and energy. Therefore, solar energy is rapidly gaining notoriety as an important means of expanding renewable energy resources. As such, it is vital that those in engineering fields understand the technologies associated with this area. Our paper includes the design and implementation of a microcontroller-based solar tracking system. Solar tracking allows more energy to be produced because the solar panel is tracking the maximum power point of the sun's position.

To get an efficient solar tracker system, a small solar panel is used instead of a large one to obtain a graphical position data of the sun when it is detected and send this data to the large panels. This system can be installed anywhere in the world without knowing the sun directions and seasons.

II. SOLAR SYSTEM TRACKER

A solar tracker is an electro-mechanical system used on behalf of orienting a solar photovoltaic panel in the direction of the sun. It is used in many applications such as the transportation signaling, lighthouses, emergency phones installed in the highways, etc... Its main objective is to find the maximum sun radiations in order to get maximum charge for the batteries.

Electricity can be generated from the sun in several ways. Photovoltaic's (PV) has been mainly developed for small and medium-sized applications, from the calculator powered by a single solar cell to the PV power plant. For large -scale generation, concentrating solar thermal power plants have been more common, however new multi-megawatt PV plants have been built

recently. A photovoltaic cell (PV cell) is a specialized semiconductor that converts visible light into direct current (DC). Some PV cells can produce DC electricity from infrared (IR) or ultraviolet (UV) radiation. Photovoltaic cells are an integral part of solar-electric energy systems, which are becoming increasingly important as alternative sources of power utility.

Solar cells generate DC electricity from light, which in turn can be used in many applications such as: charging batteries, powering equipment, etc. They produce currents as long as light shines, as shown in Fig.1.

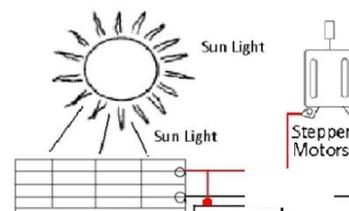

Figure 1. block diagram of the solar energy system

The detection of the position of the sun undergoes several steps as shown in Fig.2. A digital system (LPC2148) is used to calculate the maximum sun radiation. It is connected to a stepper motor and to light dependent resistors to redirect the panel to the sun. It sends the received data (position of the sun) to the stepper motors in order to position it toward the sun. The position angles are stored in the processor registers and can be displayed on an LCD or can be transmitted to a remote system.

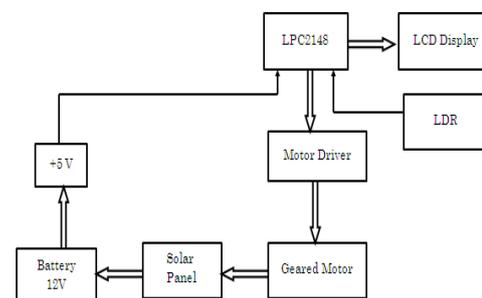

Figure2. block diagram of the solar tracker

2.1 Solar Tracker

A solar tracker is an electro-mechanical device for orienting a solar photovoltaic panel toward the sun trackers, especially in solar cell applications require a high degree of accuracy to ensure that the concentrated sunlight is directed precisely to the powered device.

Solar trackers can be active or passive and may

be single axis or dual axis. Single axis trackers normally use a polar mount for maximum solar efficiency and employ manual elevation (axis tilt) adjustment on a second axis, which can be adjusted regularly during the year.

Trackers can be relatively inexpensive for photovoltaics. This makes them especially effective for photovoltaic systems using high-efficiency panels. Solar trackers usually need inspection and lubrication on a regular basis.

Active trackers, which use motors and gear trains, are controlled by an electronic circuit responding to the solar direction.

2.2 Applications

In this paper a solar tracker is realized to capture maximum power from sunlight. The position of maximum capture of power is stored in memory. The stored data can be applicable for many applications such as Large photo voltaic panels can track the sun all the day light and by that it give above 65% efficiency in generating electricity. Solar heaters will also track the sun all the day light and by that less panels are required at the initial cost while in the home automation systems, this system is also needed in turning light ON and Off and also for opening and closing the curtains.

III. HARDWARE IMPLEMENTATION

3.1 Solar Panel

A photovoltaic module or photovoltaic panel is a packaged interconnected assembly of photovoltaic cells, also known as solar cells. A typical silicon PV cell is composed of a thin wafer consisting of an ultra-thin layer of phosphorus-doped (N-type) silicon on top of a thicker layer of boron-doped (P type) silicon. Regardless of size, a typical silicon PV cell produces about 0.5 – 0.6 volt DC under open-circuit and no-load conditions. The current (and power) output of a PV cell depends on its efficiency and size (surface area), and is Proportional to the intensity of sunlight striking the surface of the cell. The photovoltaic module, known more commonly as the solar panel, uses light energy (photons) from the sun to generate electricity through the photovoltaic effect. The majority of modules use wafer-based crystalline silicon cells or a thin-film cell based on cadmium telluride or silicon.

Crystalline silicon, which is commonly used in the wafer form in photovoltaic (PV) modules, is derived from silicon, a commonly used semi-conductor. The solar panel used in the proposed system is of 4W power rating as shown in Fig.3.

Figure3. 4W Solar Panel

3.2 Stand Assembly

The frame for the solar panel is made up of L shaped steel rod. The length is 0.95m and width is 0.38m. A square plate of dimensions 28x30 cm is made out of iron plate is fixed to the main structure at the height of 90cm from the base. The main frame is also made up of L shaped iron rod. Fig.4 illustrates stand assembly.

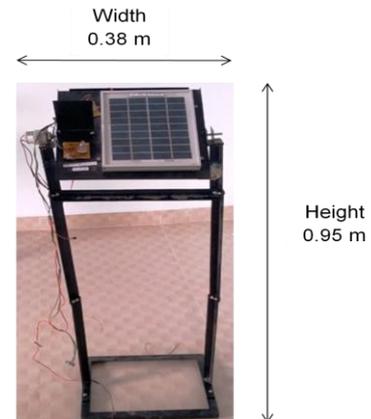

Figure4. Stand Assembly

3.3 Sensors

Sensor can be defined as a device which receives a signal and converts it into electrical form which can be further used for electronic devices. The light dependent resistors (LDR) are used in the circuit to sense the change in the sun's position. A photo resistor or light dependent resistor or cadmium sulphide (CdS) cell is a resistor whose resistance decreases with increasing incident light intensity. A photo resistor requires a power source because it does not generate Photocurrent a photo effect is manifested in the change in the material's electrical Resistance. Fig.5 shows a photo resistive cell.

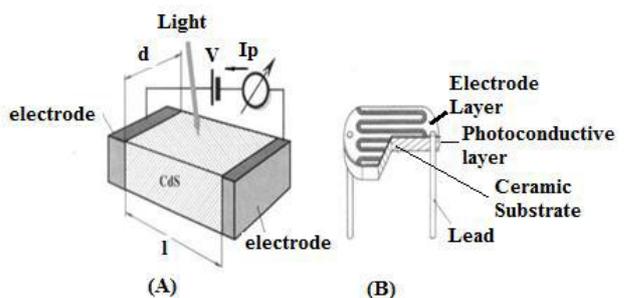

Figure5. (A) Structure of a photo resistor and (B) a plastic-coated photo resistor having a serpentine shape

3.4 ARM Processor:

LPC 2148 is a microcontroller with an internal ARM processor. In this project it gets signals from the light dependent resistors and is used to drive a geared motor to get maximum intensity of light. For this, the microcontroller uses PWMTCR, PWMTC, PWMPR, PWMPC, PWMMR0, PWMMCR, and PWMPCR register to control the direction of the solar panel using pulse width modulation. Fig.6 shows LPC2148 mother board.

Figure.6. LPC2148 Mother Board

3.5 Geard motor:

The motor chosen for the proposed system is 12V motor with 60rpm, coupled with a worm gear. The gear ratio is 25:1. The main reason for the selection of the geared motor is that it will consume very less power for a very small span of time. Also the torque required to rotate heavy PV arrays is sufficient enough. Fig.7 shows a 12V dc geared motor of 60RPM.

Figure.7. 12V geared motor

IV. CONTROL ALGORITHM AND PRIMARY RESULTS

4.1 Control Algorithm

In order to demonstrate the efficiency of the proposed system, a control algorithm is generated as shown in TABLE I, which is illustrated in Fig.8.

TABLE I. CONTROL ALGORITHM

Step #	Action
1	Install the small PV
2	Put PV in initial position (0,0)
3	Find the maximum sun light, using the photo resistors, and save the position of the PV
4	Measure the current (I)
5	If $I <$ threshold value (minimum current) wait for 30 minutes and go to step 3, otherwise go to step 6
6	Turn PV left for 3.5° , measure the current if it is greater than the previous current continue turning left until finding the maximum Current in x and y axis.
7	Send the coordinates (x,y) of the solar panel to the processor.
8	Go to step 3

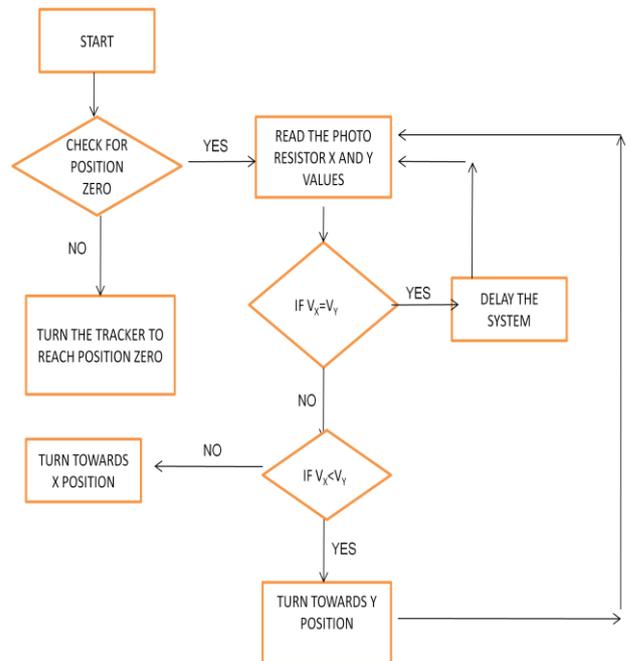

Figure.8. control algorithm

4.2 Preliminary Results

In order to assess the efficiency of the proposed system, some measurements were taken during a sunny summer day. TABLE II shows the comparison between the maximum current using a fixed Photovoltaic panel (PV) and using the proposed system at different times.

TABLE II. COMPARISON OF THE CURRENT BETWEEN FIXED PV AND USING THE PROPOSED SYSTEM

Time	Current using a fixed PV(mA)	Current using the Proposed system (mA)
08:00 AM	0.42	0.85
09:00 AM	0.55	0.90
10:00 AM	0.75	0.92
11:00 AM	0.81	0.95
12:00 PM	0.92	0.99
01:00 PM	0.95	0.99
02:00 PM	0.88	0.99
03:00 PM	0.76	0.98
04:00 PM	0.42	0.95
05:00 PM	0.23	0.95
06:00 PM	0.08	0.72
Total	6.84	10.39

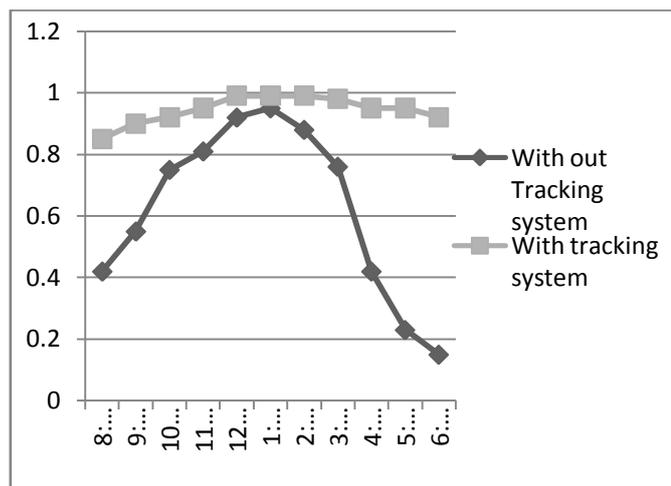

Figure.9. Efficiency of the Solar Tracking system

The Fig.9 shows the efficiency of the tracking system. It seems that the efficiency of the proposed system can be increased around 64% on a summer sunny day. In addition, the proposed system consumes little power to turn the PV panel using a stepper motor instead of using large panel which consumes high power. Moreover, this system can power itself from the PV panel using a 12V battery.

V. CONCLUSION

This project reports a "LPC2148 Based Improved Structure of Solar Tracker". The Monitoring controller based on the closed loop algorithm is designed and implemented with ARM7 TDMI processor based LPC2148 controller in embedded system domain. Experimental work has been carried out carefully. By using this project maximum current can be obtained from solar panel. Solar trackers are devices used to orient photovoltaic panels, reflectors, lenses or other optical devices towards the sun. Since the sun's position in the sky changes with the seasons and the time of day, trackers are used to align the collection system to maximize energy production.

ABSTRACT : *In this paper, we propose a new method for discovering frequent itemsets in a transactional data stream under the sliding window model. Based on a theory of Chernoff Bound, the proposed method approximates the counts of itemsets from certain recorded summary information without scanning the input stream for each itemset. Together with an innovative technique called dynamically approximating to select parameter-values properly for different itemsets to be approximated, our method is adaptive to streams with different distributions. Our experiments show that our algorithm performs much better in optimizing memory usage and mining only the most recent patterns in very less time performance with pretty accurate mining result.*

Keywords: Chernoff Bound, DataStream, Frequent Itemsets

I. INTRODUCTION

The most significant tasks in data mining are the process of mining frequent itemsets over data streams. It should support the flexible trade-off between processing time and mining accuracy. Mining frequent itemsets in data stream applications is beneficial for a number of purposes such as knowledge discovery, trend learning, fraud detection, transaction prediction and estimation [1]. However, the characteristics of stream data – unbounded, continuous, fast arriving, and time- changing – make this a challenging task.

In data streams, new data are continuously coming as time advances. It is costly even impossible to store all streaming data received so far due to the memory constraint. It is assumed that the stream can only be scanned once and hence if an item is passed, it can not be revisited, unless it is stored in main memory. Storing large parts of the stream, however, is not possible because the amount of data passing by is typically huge. In this paper, we study the problem of finding frequent items in a continuous stream of items. Many real-world applications data are more appropriately handled by the data stream model than by traditional static databases. Such applications can be: stock tickers, network traffic measurements, transaction flows in retail chains, click streams, sensor networks and telecommunications call records. In the same way, as the data distribution are usually changing with time, very often end- users are much more interested in the most recent patterns [3]. For example, in network monitoring, changes in the past several minutes of the frequent patterns are useful to detect network intrusions [4].

Many methods focusing on frequent itemset mining over a stream have been proposed. [13] proposed *FPSStream* to mine frequent itemsets, which was

efficient when the average transaction length was small; used lossy counting to mine frequent itemsets; [7],[8], and [9] focused on mining the recent itemsets, which used a regression parameter to adjust and reflect the importance of recent transactions; [27] presented the *FTP-DS* method to compress each frequent itemset; [10] and [1] separately focused on multiple-level frequent itemset mining and semi-structure stream mining; [12] proposed a group testing technique, and [15] proposed a hash technique to improve frequent itemset mining; [16] proposed an in-core mining algorithm to speed up the runtime when distinct items are huge or minimum support is low; [15] presented two methods separately based on the average time stamps and frequency-changing points of patterns to estimate the approximate support of frequent itemsets; [5] focused on mining a stream over a flexible sliding window; [11] was a block-based stream mining algorithm with *DSTree* structure; [12] used a verification technique to mine frequent itemsets over a stream when the sliding window is large; [11] reviewed the main techniques of frequent itemset mining algorithm over data streams and classified them into categories to be separately addressed.

The above methods are mostly based on the (ϵ, δ) approximation scheme, and depend on error parameter ϵ to control the memory consumption and the running time. While a dilemma between mining precision and memory consumption will be caused by the error parameter ϵ . A little decrease of ϵ may make memory consumption large, and a little increase of ϵ may degrade output precision. Since uncertain streams are highly time-sensitive, most data items are more likely to be changed as time goes by, besides people are generally more interested in the recent data items than those in the past.

Thus this needs an efficient model to deal with the time-sensitive items on uncertain streams. Sliding-window model is the most comprehensive approach to coping with the most recent items in many practical applications. So we introduce a Chernoff bound with Markov's inequality to deal with this problem.

The remainder of this paper is organized as follows. In Section 2, we give an overview of the related work and present our motivation for a new approach. Section 3 goes deeper into presenting the problems and gives an extensive statement of our problem. Section 4 presents our solution. Experiments are reported in Section 5, and Section 6 concludes the paper with the features of our work.

II. RELATED WORK

Many previous studies contributed to the efficient mining of frequent itemsets (FI) in streaming data [4, 5]. According to the stream processing model [20], the research of mining frequent itemsets in data streams can be divided into three categories: landmark windows [15,

12, 19, 11, 13], sliding windows [5, 6, 14, 16, 17, 18], and damped windows [7, 4], as described briefly as follows. In the landmark window model, knowledge discovery is performed based on the values between a specific timestamp called landmark and the present. In the sliding window model, knowledge discovery is performed over a fixed number of recently generated data elements which is the target of data mining.

According to the existential uncertain stream model, an uncertain stream US is a continuous and unbounded sequence of some transactions, $\{T_1 T_2 \dots T_n \dots\}$. Each transaction T_i in US consists of a number of items, and each item x in T_i is associated with a positive probability $PT_i(x)$, which stands for the possibility (or likelihood) that x exists in the transaction T_i . For a given uncertain stream, there are many possible instances called worlds that are carried by the stream. The possible worlds semantics has been widely used

in [8, 9], which can be adopted in this paper to illustrate uncertain streams clearly. Each probability $PT_i(x)$ associated with an item x deduces two possible worlds, pw_1 and pw_2 . In possible world pw_1 , item x exists in the transaction T_i , and in possible world pw_2 , item x does not exist in T_i . Each possible world pw_i is annotated with an existence probability, denoted as $P(pw_i)$ that the possible world pw_i happens. By this semantics, we can get $P(pw_1)=PT_i(x)$ and $P(pw_2)=1-PT_i(x)$. In fact, a transaction often contains several items.

We introduce a new approach which combines the mathematical model Chernoff bound for this problem. The main attempts were to keep some advantages of the previous approach and resolve some of its drawbacks, and consequently to improve run time and memory consumption. We also revise the Markov's inequality, which avoids multiple scans of the entire data sets, optimizing memory usage, and mining only the most recent patterns. In this paper, we propose a remarkable approximating method for discovering frequent itemsets in a transactional data stream under the sliding window model. Based on a theory of Combinatorial Mathematics, the proposed method approximates the counts of itemsets from certain recorded summary information without scanning the input stream for each itemset.

III. PROBLEM DESCRIPTION

The problem of mining frequent itemsets was previously defined by [1]: Let $I = \{i_1, i_2, \dots, i_m\}$ be a set of literals, called items. Let database DB be a set of transactions, where each transaction T is a set of items such that $T \subseteq I$. Associated with each transaction is a unique identifier, called its TID. A set $X \subseteq I$ is also called an itemset, where items within are kept in lexicographic order. A k -itemset is represented by (x_1, x_2, \dots, x_k) where $x_1 < x_2 < \dots < x_n$. The support of an itemset X , denoted $support(X)$, is the number of transactions in which that itemset occurs as a subset. An itemset is called a frequent itemset if $support(X) \geq \sigma \times |DB|$ where $\sigma \in (0, 1)$ is a user-specified minimum support threshold and $|DB|$ stands for the size of the database.

The problem of mining frequent itemsets is to mine all itemsets whose support is greater or equal than

$\sigma \times |DB|$ in DB. The previous definitions consider that the database is static. Let us now assume that data arrives sequentially in the form of continuous rapid streams. Let data stream

$DS = B^{b_1}, B^{b_1+1}, \dots, B^{b_n}$ be an infinite sequence of batches $, a_i \quad a_{i+1} \quad a_n$

where each batch is associated with a time period $[a_k, b_k]$, i.e.

B^{b_k} , and let a_n be the most recent batch

Each batch B_k consists of a set of transactions; that is, Each batch $B_k = [T_1, T_2, T_3, \dots, T_k]$. We also assume that batches do not have necessarily the same size. Hence, the length

The support of an itemset X at a specific time interval $[a_i, b_i]$ is now denoted by the ratio of the number of customers having X in the current time window to the total number of customers. Therefore, given a user-defined minimum support, the problem of mining itemsets on a data stream is thus to find all frequent itemsets X over an arbitrary time period $[a_i, b_i]$, i.e. verifying:

$$support_t(X) \geq \sigma \times |B^{b_i}|, t = a_i$$

of the streaming data using as little main memory as possible. Given a transaction sets X , we are interested in finding strong bounds

$$\text{Low End: } \Pr[X < a]$$

$$\text{High End: } \Pr[X \geq a]$$

Lemma 1.1 (Markov's Inequality) Let X be a non-negative random variable (transaction sets) with finite expectation μ . Then for any $\alpha > 0$: $\Pr[X \geq \alpha] \leq \mu/\alpha$.

Lemma 1.2 (Chebyshev's Inequality) Let X be a random variable (transaction sets) with finite expectation μ and standard deviation σ . Then for any $\alpha > 0$: $\Pr[|X - \mu| \geq \alpha \sigma] \leq 1/\alpha^2$.

Chebyshev's inequality follows from Markov's inequality for the variable $Y = (X - \mu)^2$ (so $E[Y] = \text{Var}[X]$) and the fact that $x \rightarrow x^2$ is a strictly monotonic function on R_0 .

$$\Pr[|X - \mu| \geq \alpha \sigma] = \Pr[(X - \mu)^2 \geq \alpha^2 \sigma^2]$$

$$\leq \frac{E[(X - \mu)^2]}{\alpha^2 \sigma^2} = 1/\alpha^2$$

This makes it tempting to use even higher moments to get better bounds. One way to do this nicely is by considering an exponential of the basic form of e^x .

Proof. Lemma 1.3 (Simplified Chernoff Bounds)

Low End:

$$\Pr[X < (1 - \delta)\mu] < e^{-\mu\delta^2/2} \quad 0 < \delta \leq 1$$

High End:

$$\Pr[X \geq (1 + \delta)\mu] < e^{-\mu\delta^2/3} \quad 0 < \delta \leq 1$$

$$\Pr[X \geq (1 + \delta)] < e^{-(1+\delta)\mu} 2e - 1 < \delta$$

Proof.

For the LowEnd let $D = (1 - \delta)^{1-\delta}$. By Taylor expansion we get

$$\begin{aligned} \ln D &= (1 - \delta) \ln(1 - \delta) \\ &= (1 - \delta)(-\delta - \delta^2/2 - \delta^3/3 - \dots) \\ &= -\delta + \delta^2/2 + \delta^3/6 + \dots \\ &> -\delta + \delta^2/2 \end{aligned}$$

By Applying this simplified method in the series we can get the following equation for low end windows.

$$\text{Hence } \left(\frac{e^{-\delta}}{(1 - \delta)^{1-\delta}} \right) = e^{-\mu\delta/2}$$

IV. CBMFI ALGORITHM

CBMFI (Chernoff Bound Based Mining Frequent Itemsets) algorithm relies on a verifier function and it is an exact and efficient algorithm for mining frequent itemsets sliding windows over data streams. The performance of CBMFI improves when small delays are allowed in reporting new frequent itemsets, however this delay can be set to 0 with a small performance overhead.

The following algorithm shows how it combines with CB for Mining frequent itemsets.

CBMFI

Initialization

For all u pick a route $rt(u)$.

Place all M_u such that $D(u) = \mu u$ into C_e where e is the first window on $rt(u)$.

Main Loop $r = 0$

while(there is a packet not at its destination)

in parallel, for all window ends $e = (x, y)$

do

if C_e is not empty,

pick the highest priority itemsets in C_e

$y = \text{itemsets}(T)$

if (a moved itemset is not at its destination)

$C_e = \text{next end transaction}$

$r = r + 1$

We would like to use a Chernoff bound, so we need to find some independent Poisson trials somewhere. This requires a bit of thought, lots of random variables associated with this algorithm are not independent;

The expected length of a route is $k/2$, so the total number of edges on all routes is expected to be $nk/2$. The total number of edges in a hypercube is nk , so we have $E[R(e)] = 1/2$. It follows that $E[H] \leq k/2$. Now apply the simplified Chernoff bound where $\delta > 2e - 1$:

$$\Pr[H \geq 6k] < 2 - 6k$$

This is allowed since $6k = (\delta + 1)\mu$ implies $\delta > 11$. By applying this in the CBMFI algorithm we can get the efficient result.

V. EXPERIMENTAL RESULTS

All experiments were implemented with C#, compiled with Visual Studio 2005 in Windows Server 2003 and executed on a Xeon 2.0GHz PC with 4GB RAM. We used 1 synthetic datasets and 1 real-life datasets, which are well-known benchmarks for frequent itemset mining. The T40I10D100K dataset is generated with the IBM synthetic data generator.

We firstly compared the average runtime of these two algorithms under different data sizes when the minimum support was fixed. As shown in all of the images in Fig.5.1, the running time cost of MFI and CBMFI increase following the data size; these results verify that both algorithms are sensitive to data size, which is due to the using of unchanged absolute minimum support

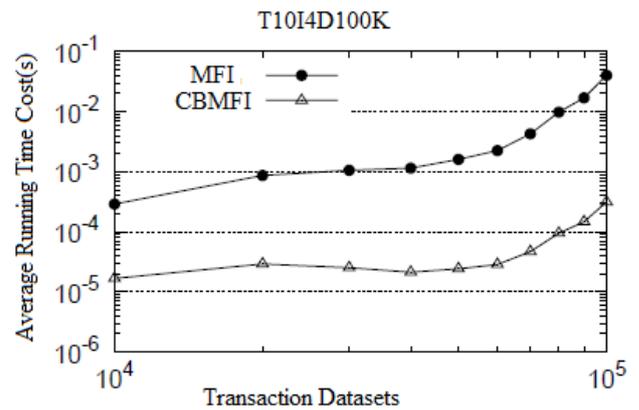

Fig: 5.1 Runtime vs number of Records

Memory Cost Evaluation

To evaluate the memory cost of our algorithm, we compared the count of generated items in MFI and CBMFI. As shown in Fig.5.2 and Fig.5.3, when we fix the minimum support and increase the data size, the generated items of both algorithms become more, but the overall item count of CBMFI is less than that of MFI since CBMFI uses a simplified method for itemsets.

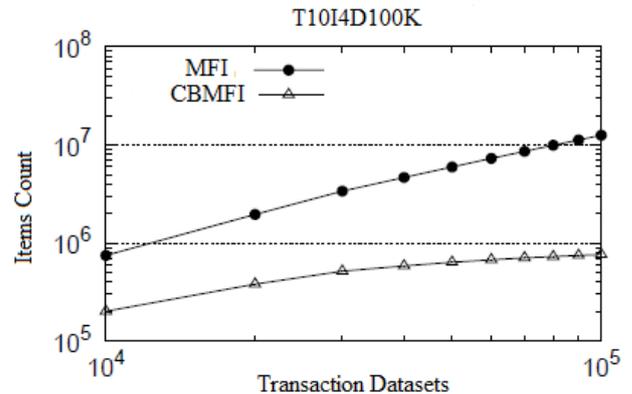

Fig: 5.2 Itemset Count cost vs Transaction Set

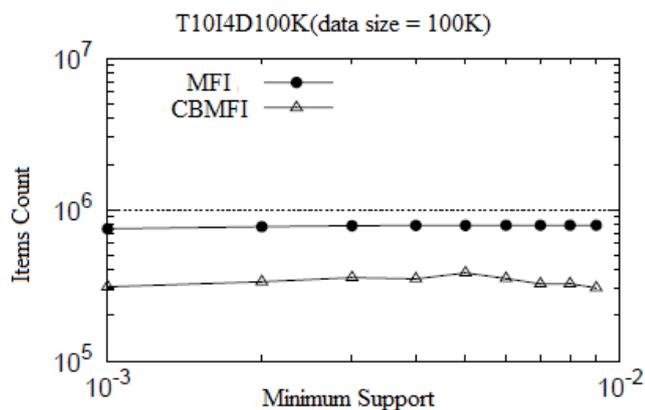

Fig: 5.3 Itemssets Count cost vs. Minimum Support

Furthermore, when the minimum support increases, the incremental scope of *CBMFI* is much reduced than that of *MFI*, that is because more redundant items when the overall items count is fixed but the itemsets count increases.

VI. CONCLUSION

In this paper we considered a problem that how to mine frequent itemset over stream sliding window using Chernoff Bound. We compared two algorithms *MFI* and *CBMFI* and introduce a compact data structure, which can compress the itemset storage and optimize itemset computation, based on combinatorial mathematical. Our experimental studies showed that our algorithm is effective and efficient.

Analysis of Load Constant in Manual Material Handling Task by Taguchi Technique & Mathematical Regression Modeling

Ganesh Pal Singh Jadon, Manish Kumar Sagar

¹ME (Material Handling) Madhav Institute of Technology & Science, Gwalior.

²Assistant Professor, Mechanical Engineering, Madhav Institute of Technology & Science, Gwalior.

Abstract: Now a day, the working in the industries is not as comfortable as they were in the earlier time. The man power is decreasing day by day and new recruitments are not in the same ratio as the person leaving industries. This in turn increases the work load on the present employees. It has been seen that the workers are not assigned to the appropriate machine according to their physical aspects and strength. This causes an uneven distribution of work in the industries, which in turn causes severe physical problems to the employees and also decreases the productivity of industry. The purpose of this paper is to efficiently determine the optimum combination of three parameters (Worker age, Worker weight and strength) for mitigate the load constant of the worker, the researcher have used the Taguchi parameter optimization methodology, and finally the Modeling of input parameters (Worker age, worker weight and strength) and output parameter (Load constant) is done using regression modeling and MATLAB Software R2011b. With the help of mathematical modeling one can select the appropriate person for a particular load for a particular work to minimize the fatigue of worker in the industry.

Keywords: Manual Material Handling, Load Constant, Regression Modeling, Taguchi Techniques.

I. Introduction

Manual Material Handling (MMH) including lifting, lowering, pushing, pulling, twisting, carrying and holding is a regular task that almost everyone performs every day. There are kinds of injuries and disabilities associated with MMH tasks, among which Low back disorders (LBDs) are the most common of all musculoskeletal disorders and are a major health and socioeconomic problem in the western world (Woolf and Pfleger, 2003). According to Punnett et al (2005) about 37% of all LBDs are directly attributable to occupational risk factors (RFs). Thus identifying and preventing risk of LBD is the most significant problem complained by workers and it is still a hard topic for researchers (Kuiper et al., 1999). Many researchers have developed tools and techniques for identify jobs which are associated with risk of LBD (Ciriello & Snook, 1999; Marras, 2000; Marras, Fine, Ferguson, & Waters, 1999; Zurada, Karwowski, & Marras, 1997). Chaffin and Park (1973) developed a lifting strength ratio (LSR) and demonstrated its relationship to LBD. LSR was defined as the ratio of the maximum load lifted on the job and lifting strength in the same load position for a large/strong man. Snook (1978) defined MMH limits for lifting, lowering, pushing, pulling and carrying activities based on psychophysical criteria. In 1981 the National Institute for occupational Safety and Health (NIOSH), a US federal agency recognized the problems related to lower back injuries and published the Work Practices Guide for manual lifting. This contained a summary lifting related literature before 1981, and guidelines are also given for lifting (Ayoub, Selan, Jiang, 1983).

In this MMH area load that lifted by the person is play important role LBD problem. Load is also known as load constant it is load that is lifted by worker without any musculoskeletal problem. NIOSH (1991) is set the value of load constant, which is 23 kg., but researcher are going to find that it may change with age, weight and strength of worker. In this paper researchers derive a formula for

calculating load constant for the worker which is assign for the lifting work.

For calculating the load constant researcher applied the Taguchi Optimization Technique and calculates the load constant according to worker's age, worker's weight and strength of worker. Taguchi methodology is described in next chapter.

II. Taguchi Methodology

Taguchi method is a powerful methodology/ technique for the design of high quality systems (Taguchi, 1990) and has been widely used in engineering design (Ross, 1988). Taguchi design provides a simple, efficient and systematic approach to optimize design for performance, quality and cost over a verity of conditions. Taguchi steps are shown in figure 1 for present research work.

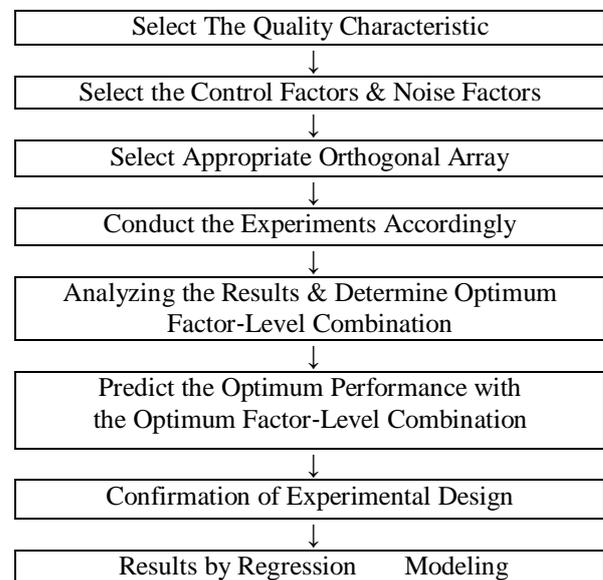

Figure 1: Steps of Taguchi Method

2.1 Design of Experiment

The experimental design was done according to L9 orthogonal array based on the Taguchi method. The use of Taguchi orthogonal array would evidently reduce the number of experiments. The L9 orthogonal array had three columns and nine rows, so it had six degrees of freedom to manipulate three parameters with three levels as indicated in Table 1. Thus, in this investigation three parameters with three levels were indicated in Table 2.

Table 1: Orthogonal L9 Array of Taguchi

Experiment S.No.	Parameters		
	1	2	3
1	1	1	1
2	1	2	2
3	1	3	3
4	2	1	3

III. Taguchi Parametric Optimization technique

The collected data are arranged according to L9 array. As per the Taguchi Technique the Quality characteristic utilized in the research is larger the Better. Researchers have calculated Load Constant, Mean Slandered Deviation (MSD) of Load Constant and Signal to Noise Ratio (S/N) for analysis of the data. Following formula is used for calculation of larger the better. Data analysis is shown in table 4.

$$MSD = (1/Y1^2 + 1/Y2^2 + 1/Yn^2 \dots\dots) / N$$

$$S/N = - 10 \log_{10} (MSD)$$

Table 4: Data Analysis

S. No.	Worker age	Worker Weight	Strength (Newton)	LC	MSD	S/N ratio
1.	L	L	L	28	1.275×10^{-3}	28.94
2.	L	M	M	34	8.650×10^{-4}	30.62
3.	L	H	H	50	4×10^{-4}	33.97
4.	M	L	H	44	5.165×10^{-4}	32.86
5.	M	M	L	29	1.189×10^{-3}	29.24
6.	M	H	M	36	7.716×10^{-4}	31.12
7.	H	L	M	39	6.574×10^{-4}	31.82
8.	H	M	H	41	5.948×10^{-4}	32.25
9.	H	H	L	23	1.890×10^{-3}	27.23

3.1 Load Constant (LC)

The analysis of each controllable parameter is done and the effects of each parameter at individual level (i.e. at 1, 2, 3 levels) is shown in Table 5. This analysis is shows that at the lower age, man having the higher strength and vice-versa.

(a) **Case 1:** The main effect of the worker age on Load Constant at various level is calculated as follows:

For lower level:

$$(28 + 34 + 50) / 3 = A_1 = 37.33$$

For medium level

$$(44 + 29 + 36) / 3 = A_2 = 36.33$$

For higher level

$$(39 + 41 + 23) / 3 = A_3 = 34.33$$

(b) **Case 2:** The main effect of worker's weight at various levels are calculated as:

For lower level

$$(28 + 44 + 39) / 3 = B1 = 37$$

For medium level

$$(34 + 29 + 41) / 3 = B2 = 34.67$$

For higher level

$$(50 + 36 + 23) / 3 = B3 = 36.33$$

(c) **Case 3:** The main effect of the Strength at various levels are calculated as:

For lower level

$$(28 + 29 + 23) / 3 = C_1 = 26.67$$

For medium level

$$(34 + 36 + 39) / 3 = C_2 = 36.33$$

For higher level
 $(50 + 44 + 41) / 3 = C3 = 45$

Table 5: Factors Effect Table for Load constant

Symbol	Controllable Factors	Level 1 Lower	Level 2 Medium	Level 3 Higher
A	Worker's Age	37.33 (A1)	36.33 (A2)	34.33 (A3)
B	Worker's Weight	37 (B1)	34.67 (B2)	36.33 (B3)
C	Strength	26.67 (C1)	36.33 (C2)	45 (C3)

The values in bold in table 5 show the Larger the better criteria as proposed by Taguchi method. The value obtained from table 5 are plotted to visualize the effect of the three parameters at three levels on mean response graph which is shown in figure 2.

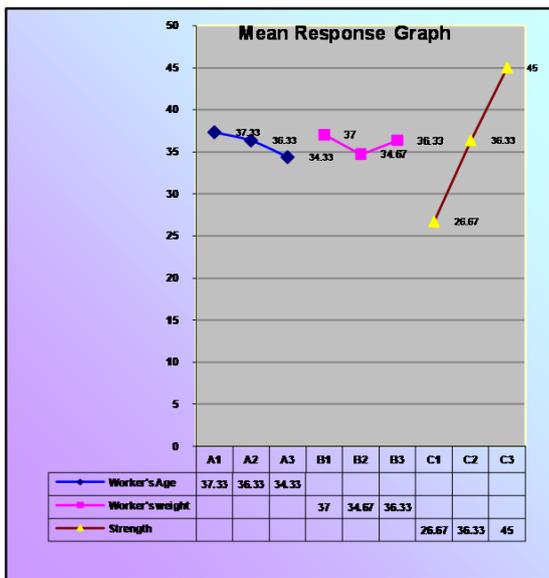

Figure 2: Mean Response Graph

3.2 Analysis of Signal to Noise (S/N) Ratio

According to the Taguchi approach, the term signal represents the desired value (mean) for the output characteristics and term noise represent the undesirable value (standard deviation) for the output characteristics. Therefore S/N ratio is the ratio of mean to the standard deviation. Taguchi uses the S/N ratio to measure the quality characteristics deriving from desired value. The S/N ratio is defined as given equation.

For Higher the better

It is when the occurrences of some undesirable product characteristics are to be maximized. It is given by $S/N = -10 \log ((\Sigma y1/ y2)/N).....$

All the three level of every factor are equally represented in the nine experiments. S/N ratio and Load Constant for each parameter at each level and Load Constant for each of the Parameters at each level is calculated. These also called as main effects.

Table 6: Effect of S/N, corresponding to chosen parameters

Symbol	Controllable Factors	Level 1 Lower	Level 2 Medium	Level 3 Higher
A	Worker's Age	31.17	31.07	30.43
B	Worker's Weight	31.20	30.70	30.77
C	Strength	28.25	31.18	33.02

The values in bold in table 6 show the Larger the better criteria as proposed by Taguchi method. The value obtained from table 6 are plotted to visual seize the effect of the three parameters at three levels on mean response graph which shown in figure 3.

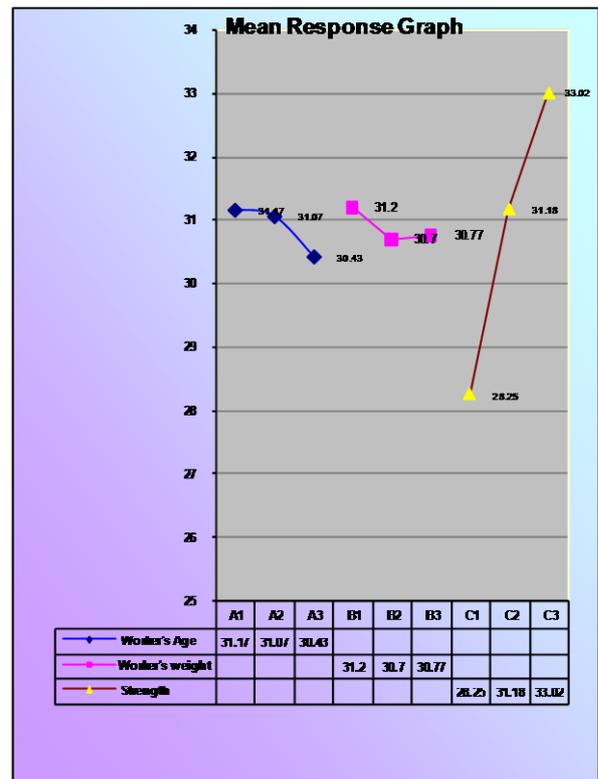

Figure 3: Mean Response Graph for S/N Ratio

IV. Mathematical Regression Modeling

Defining the formula of load constant, researchers use the regression modeling techniques. Previously, Load constant is tabulated as per combination of parameters. Empirical formula has going to be drawn in following steps.

4.1 Modeling of Parameters

To generalize the results, the Modeling of input parameters (Age of Worker, Weight of Worker and strength) and Load constant is done using Regression modeling with MATLAB software R2011b.

The parameters under consideration are

1. Age of worker.
2. Weight of Worker
3. Strength of worker

The regression analysis has been adopted. Load constant(LC) has been taken as single output parameter (Y) whereas Age of worker (X₁) and Weight of Worker (X₂) and strength (X₃) has been taken as input parameter X = [X₁, X₂, X₃]. The Load Constant is a function of Worker Age, Worker weight and Strength.

LC \propto Worker Age * Component weight * Strength

$$LC = (\text{Worker Age})^{C_1} * (\text{Worker weight})^{C_2} * (\text{Strength})^{C_3}$$

$$L_n(LC) = C_1 l_n(\text{Worker age}) + C_2 l_n(\text{Worker weight}) + C_3 l_n(\text{Strength})$$

Where, C₁, C₂, C₃ are constants which are to be determined by Regression Modeling and using MATLAB software R2011b. The following results were obtained.

$$C_1 = 0.1563; C_2 = 0.5149; C_3 = 0.7840$$

Putting these values the equation becomes.

$$LC = (W_a)^{0.1563} * (W_w)^{0.5149} * (\text{Strength})^{0.7840}$$

Here W_a is Age of Worker,
 W_w is Weight of Worker.
 LC is load constant.

V. Summary

Finally a formula is obtained for load constant by the application of Taguchi Methodology and Mathematical Regression Modeling the researchers have find out a way to calculate the correct load constant of the correct person. By using this formula problem of LBD is minimized in all kinds of industry where manual material handling is done.

ANFIS Modeling and Experimental Study of Standalone Photovoltaic Battery Charging System

A. Durgadevi¹, S. Arulsevi²

Department of Electronics and Instrumentation Engineering
Annamalai University, Chidambaram, Tamil Nadu, India.

Abstract: Due to scarcity of fossil fuel and increasing demand of power supply, we are forced to utilize the renewable energy resources. Considering easy availability and vast potential, world has turned to solar photovoltaic energy to meet out its ever increasing energy demand. The mathematical modelling and simulation of the photovoltaic system is implemented in the MATLAB/Simulink environment and the same thing is tested and validated using Artificial Intelligent (AI) like ANFIS. This paper presents a scheme for transferring power from photovoltaic (PV) module to a battery using solar charge controller based on buck DC/DC converter. The converter is configured in open loop mode and the same thing is implemented in hardware. The results reveals that the implemented hardware results matches closely with the simulated software results. Due to high initial investment on PV systems and non linearity of PV cell output characteristics counteract its wide commercialization. The PV array has an optimum operating point to generate maximum power at some particular point called maximum power point (MPP). To track this maximum power point and to draw maximum power from PV arrays, MPPT controller is required in a stand-alone PV system. Due to the nonlinearity in the output characteristics of PV array, it is very much essential to track the MPPT of the PV array for varying maximum power point due to the insolation variation. In order to track the MPPT conventional controller like PI controller with Incremental conductance algorithm is proposed and simulated. The output of the controller, pulse generated from PWM can switch MOSFET to change the duty cycle of buck DC-DC converter. The result reveals that the maximum power point is tracked satisfactorily for varying insolation condition.

Key words: Photovoltaic, Pulse Width Modulation, Proportional Integral Controller.

I. INTRODUCTION

Today photovoltaic (PV) systems are becoming more and more popular with increase of energy demand and there is also a great environmental pollution around the world due to fossils and oxides. Solar energy which is free and abundant in most parts of world has proven to be economical source of energy in many applications [1]. The energy that the earth receives from the sun is so enormous and so lasting that the total energy consumed annually by the entire world is supplied in as short a time as half an hour. The sun is a clean and renewable energy source, which produces neither green house effect gas nor toxic waste through its utilization. It can withstand severe

weather conditions, including cloudy weather. The watt peak price is decreased since the

seventies, this leads to large scale promising areas. It does not have any moving parts and no materials consumed or emitted. Unfortunately, this system has two major disadvantages, which the low conversion efficiency of electric power generation (9 to 16%), especially under low irradiation conditions and the amount of electric power generated by solar array changes continuously with the weather conditions like irradiation and temperature. To overcome this problem, maximum power point tracking (MPPT) technique will be used.

In order to regulate the converter due to non linearity conventional controller like PI controller with Incremental conductance algorithm is proposed and simulated. The tracking algorithm integrated with a solar PV system has been simulated with buck DC-DC converter for the application of battery charging in stand - alone PV system. The proposed PV system with buck DC-DC converter is shown in Fig.1.

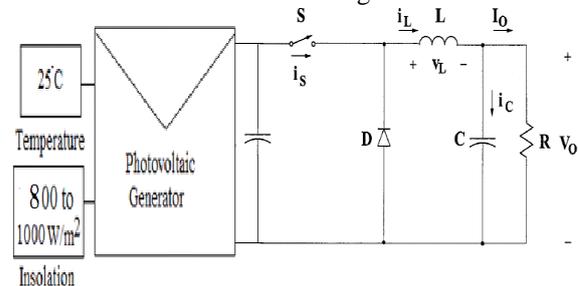

Fig.1. Photovoltaic module with DC-DC buck converter.

II. MATHEMATICAL MODELING OF PHOTOVOLTAIC CELL

The proposed MPPT is based on the behavior of the photovoltaic array by means of temperature and irradiation variation [2]. The mathematical model of PV array is implemented in the form of current source controlled by voltage, sensible to two impact parameters, that is, temperature ($^{\circ}\text{C}$) and solar irradiation power (w/m^2).

An equivalent simplified electric circuit of a photovoltaic cell presented in Fig.2.

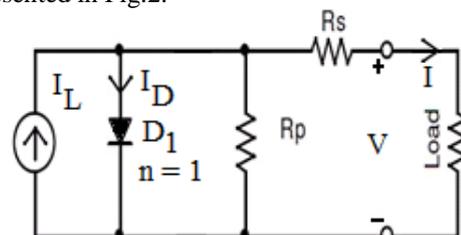

Fig.2. Equivalent circuit of photovoltaic cell.

The expressions obtained from fig.2. are given below.

The load current I_L is obtained is given in equation (1) as,

$$I = I_L - I_o [\exp\left(\frac{q(V+IR_s)}{\gamma k T_c}\right) - 1] \quad (1)$$

I_L is the photo electric current related to the given irradiation condition given by equation (2),

$$I_L = \left(\frac{G}{G_{REF}}\right) [I_{L,REF} + \mu_{ISC} (T_c - T_{c,REF})] \quad (2)$$

The diode saturation current (I_o) is given by the equation (3),

$$I_o = I_{o,REF} \left(\frac{T_c}{T_{c,REF}}\right)^3 \exp\left[\left(\frac{qE_g}{k\gamma}\right)\left(\frac{1}{T_{c,REF}} - \frac{1}{T_c}\right)\right] \quad (3)$$

where I_D is the diode current; I_L is the photoelectric current related to a given condition of irradiation and temperature; V is the output voltage [V]; I_o is the saturation diode current [A]; γ is the form factor which represents an index of the cell failing; R_s is the series resistance of the cell [Ω]; q is the electric charge ($1.602 \times 10^{-19} C$); k is the Boltzmann's constant ($1.381 \times 10^{-23} K$); T_c is the module temperature [K]. E_g is the energy gap of the material with which the cell is made (for the silicon it is 1.12 eV); G is the radiation [W/m^2]; G_{REF} is the irradiation under standard conditions [W/m^2]; $I_{L,REF}$ is the photoelectric current under standard conditions [A]; $T_{c,REF}$ is the module temperature under standard conditions [K]; μ_{ISC} is the temperature coefficient of the short circuit current [A/K], given by the manufacturer according to CEI EN 60891 standard [3-4].

Figure 3 shows the simulated P-V characteristics for varying irradiation and temperature in MATLAB/SIMULINK environment. It can be observed from simulated results as shown in Fig. 3(a), the photo current is directly proportional to irradiation. It is noted from Fig. 3(b) that the terminal voltage increases with decreasing temperature.

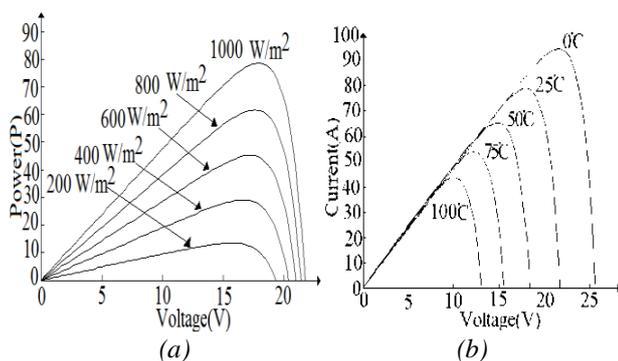

Fig.3. Simulated waveforms showing the effect of (a) radiation and (b) temperature on P-V characteristics.

The manufacturers data at standard conditions are given as $P_{max} = 80W$, $I_{max} = 4.515 A$ and $V_{max} = 21.6V$. The simulation results obtained were: $P_{max} = 78.51W$, $I_{max} = 4.35 A$ and $V_{max} = 18.2 V$. It is seen that the simulation model showed excellent correspondence to manufacturer's data and therefore this model was considered sufficient for the purpose of further study [4-8].

Simulated I-V, P-V characteristics for the maximum power point tracking (MPPT) is shown in figure.4. At this Maximum Power Point (MPP), the solar array is matched to its load and when operated at this point the array will yield the maximum power output. From Fig. 4 (a) & (b), it is observed that the power output has an almost linear relationship with array voltage unit, hence the MPP is attained. Any further increase in voltage results in power reduction [5].

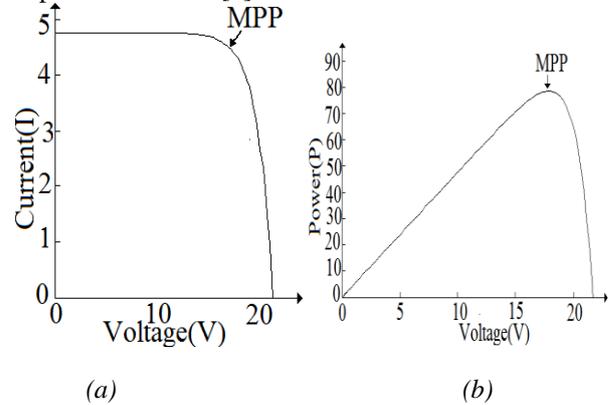

Fig.4. PV array simulated curves (a) I-V curve (25°C) and (b) P-V curve (1000w/m²).

III. ANFIS MODELING

The main objective of this work is to investigate the suitability of artificial intelligent systems (neural network and fuzzy logic) for validating the proposed PV system under variable climatic condition. Neural network models are data based where as fuzzy logic models are based on expert knowledge; in a situation in which both data and knowledge of underlying system are available, a neuro fuzzy approach is able to exploit both sources.

a. Stand – Alone Photovoltaic System

Fig.5 shows the overall simple configuration of the stand alone Photovoltaic power supply system.

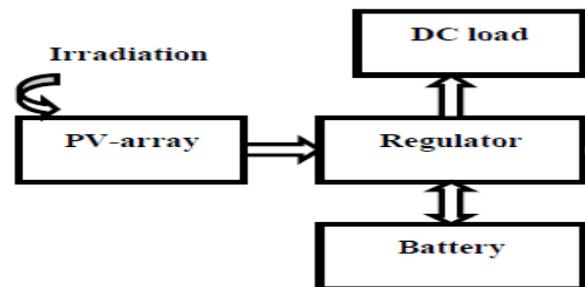

Fig.5. schematic of the Stand-Alone Photovoltaic Power supply system.

b. ANFIS Modeling of photovoltaic system

The Neuro-Fuzzy system used here is the adaptive network based fuzzy inference system (ANFIS). Fig.6 shows the developed ANFIS model. In order to obtain the modeled, predicted and optimized PVPS system due to its non linearity this is influenced by variable climatic conditions like solar irradiation and ambient temperature. Artificial Intelligent technique like ANFIS is proposed and simulated. The ANFIS was validated with several test data by minimizing mean square error.

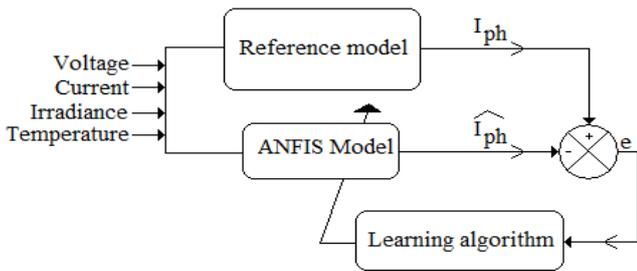

Fig.6. Developed ANFIS model.

Fig.7 shows the architecture of an ANFIS equivalent to a first-order sugeno fuzzy model with two inputs and two rules consisting of five different layers.

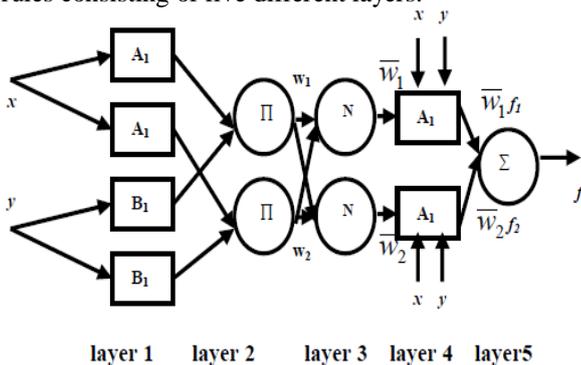

Fig.7. Architecture of an ANFIS equivalent to a first-order sugeno fuzzy model with two inputs and two rules.

The detailed description of the each layer is given as below:

Layer 1:

Generates the membership grades based upon premise signals using any appropriate parameterization membership function such as the generalized bell function given in equation (4):

$$O_{1,i} = \mu_{A_i}(x) = \frac{1}{1 + \left| \frac{x - c_i}{a} \right|^{2b_i}} \quad (4)$$

Layer 2:

Generates the firing strength of each rules using designated Π which is given by equation (5):

$$O_{2,i} = w_i = \mu_{A_i}(x) \mu_{B_i}(y) \quad i=1,2 \quad (5)$$

Layer 3:

Generates the normalized firing strength which is given by equation (6)

$$O_{3,i} = \bar{w}_i = \frac{w_i}{w_1 + w_2} \quad (6)$$

Layer 4:

Calculates the rule outputs based upon consequent parameters using the function (7):

$$O_{4,i} = \bar{w}_i f_i = \bar{w}_i (p_i x + q_i y + r_i) \quad (7)$$

Layer 5:

Gives the overall ANFIS output by equation (8).

$$O_{4,i} = \sum_i \bar{w}_i f_i = \frac{\sum_i w_i f_i}{\sum_i w_i} \quad (8)$$

Where: A_i, B_i are the linguistic labels (“small”, “large,” etc.); $\{a_i, b_i, c_i\}$ is the premise parameter; w_i is the weight factor; (p_i, q_i, r_i) is the consequent parameter; O is the output function and Π is the firing strength of each rule.

Fig.8 shows the simulated result of a photovoltaic power supply system using an adaptive Neuro-Fuzzy Inference System (ANFIS) under standard test condition of irradiation 1000w/m^2 and temperature of 25°C .

The result reveals that the correlation coefficient between measure values and those estimated by the ANFIS gave good prediction accuracy. The satisfactory performance of ANFIS proves that it can be used for the prediction of the optimal configuration of the PV system.

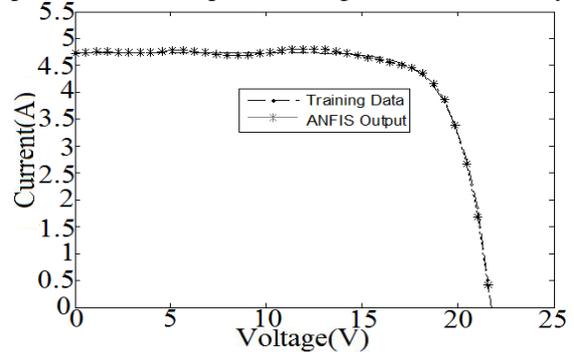

Fig.8. ANFIS modelling of the photovoltaic system for irradiation of 1000w/m^2 and temperature 25°C .

IV. DESIGNING OF BUCK CONVERTER

a. Circuit diagram of buck converter.

Fig.9 shows the schematic diagram of buck converter with varying irradiation, which consists of DC supply voltage V_s , as PV generator controlled switch S , diode D , buck inductor L , filter capacitor C and load resistance R . The current and voltage waveforms of the converter in CCM are presented in fig.10.

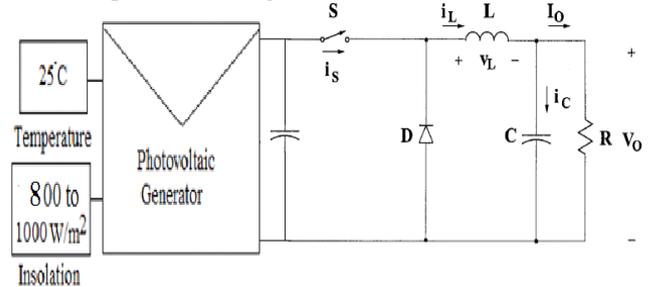

Fig.8. Circuit diagram of buck converter with PV module.

It can be seen from the circuit that when the switch S is commanded to the on state, the Diode D is reverse biased. When the switch S is off, the diode conducts to support an uninterrupted current in the inductor through the output RC circuit using faradays law for the buck inductor as given in (9)

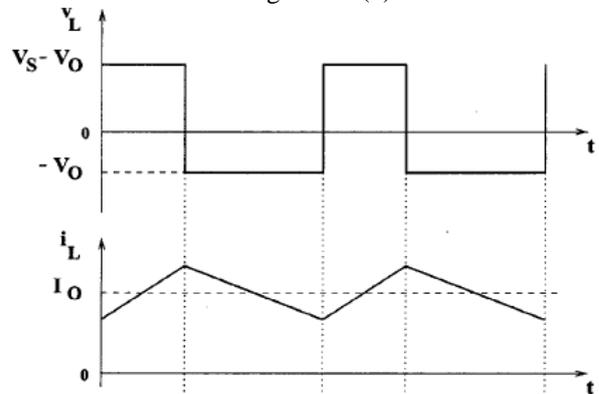

Fig.10. Theoretical voltage and current waveforms of buck converter.

$$(V_s - V_o)DT = (-V_o)(1 - D)T \quad (9)$$

The DC voltage transfer function turns out to be,

$$M_v = \frac{V_o}{V_s} = D \tag{10}$$

The buck converter operates in the CCM for $L > L_b$. The calculated value of inductance $L = 20\mu H$. To limit the ripples in the output side, larger filter capacitor is required. The filter capacitor must provide the output dc current to the load when diode D is off. The minimum value of filter capacitance calculated that results in the voltage ripple V_r is given by $C_{min} = 472.5\mu F$.

Thus the buck converter is designed in the open loop for the supply voltage of 21.7V DC, which is generated by the Photovoltaic panel for $1000w/m^2$ and $25^\circ C$. Fig.11 shows the simulated voltage and current waveforms of buck converter. It is seen that these waveforms are agreed closely with theoretical waveforms as shown in fig.10 [9-11].

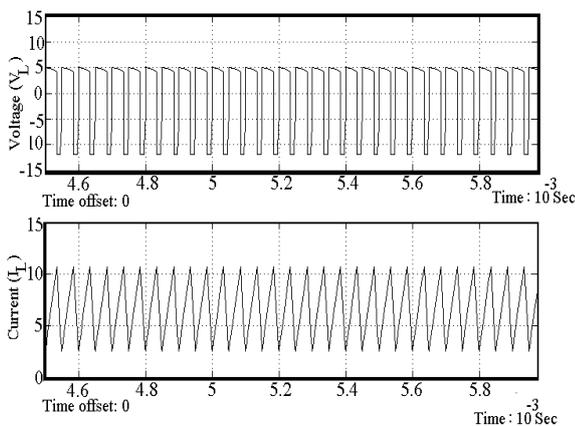

Fig.11. Simulated waveforms showing the voltage and current of buck converter.

V. CLOSED LOOP SIMULATION OF BUCK CONVERTER WITH INCREMENTAL CONDUCTANCE MPPT ALGORITHM

The block diagram of closed loop simulation with MPPT algorithm is shown in fig.12. To regulate the output voltage V_o , the switching frequency of the PWM pulses are varied depends on error.

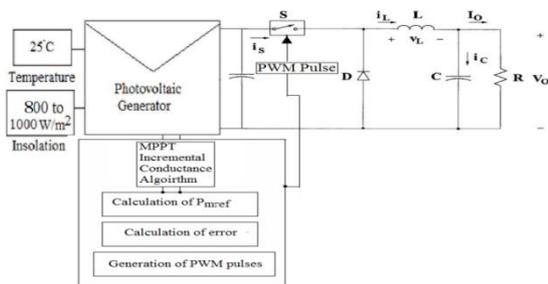

Fig.12. Block diagram of the proposed Incremental Conductance based MPPT scheme.

a. MPPT with incremental conductance algorithm

To track and extract maximum power from the PV arrays for a varying insolation level and at a given cell temperature, a conventional controller like proportional integral controller is proposed with incremental conductance algorithm as tracking method [11-16]. The Flow chart of the proposed Incremental Conductance algorithm is shown in Fig.13. This algorithm has the

advantage of fast response to the rapidly varying illumination condition. The conventional PI controller parameters are obtained by Z-N open loop method [9] as proportional gain $K_c = 1e-5$ and integral gain $K_i = 0.01$.

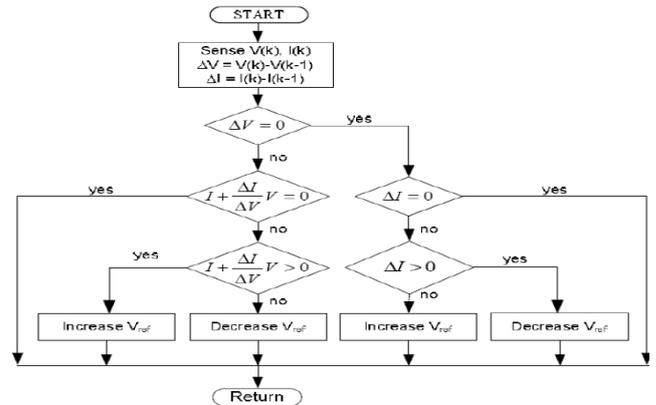

Fig.13. Flow chart of the proposed Incremental Conductance algorithm.

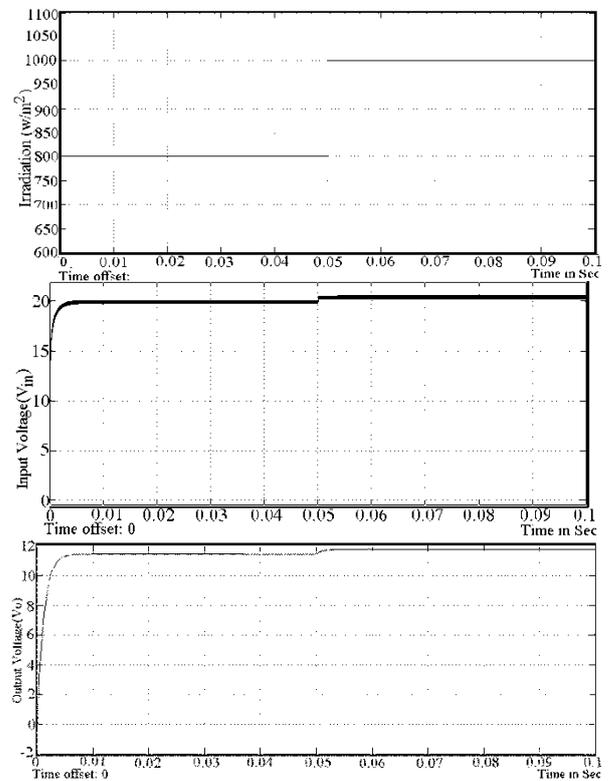

Fig.14. Simulation results depicting the change of insolation from 800 to

1000w/m², input voltage (V_{in}) and output voltage (V_o).

The simulated closed loop output for the insolation variation from $800 w/m^2$ to $1000 w/m^2$ with input voltage (V_{in}) and output voltage (V_o) are shown in Fig.14.

VI. OPEN LOOP EXPERIMENTAL SET UP

The electrical characteristics of the proposed panel are given in table I.

TABLE I
STANDARD TEST CONDITION DATA
ELECTRICAL CHARACTERISTICS

Cell	Poly-crystalline silicon
------	--------------------------

No of cells and connections	36 in series
Open circuit Voltage (V_{oc})	21.75 V
Short – circuit current (I_{sc})	4.85A
Maximum Power Voltage at $P_{max}, (V_{pm})$	18.25 V
Maximum Power Current (I_{pm})	4.315 A
Maximum Power (P_{max})	78.24 W (+10%/-5%)
Module Efficiency (η_m)	13%
Series Fuse Rating	10 A
Type of output terminal	Junction Box
Temperature coefficient of I_{sc}	$0.65e-3 \pm 0.015\%/^{\circ}C$
Temperature coefficient of V_{oc}	$-160 \pm 20mV\%/^{\circ}C$
Temperature coefficient of Power	$-0.5 \pm 0.05\%/^{\circ}C$

a. Battery

The lead-acid battery of 13.3V (± 1) with 7.5Ah is used for the solar photovoltaic charging application.

Fig.15. shows the input voltage to the buck converter from photovoltaic panel.

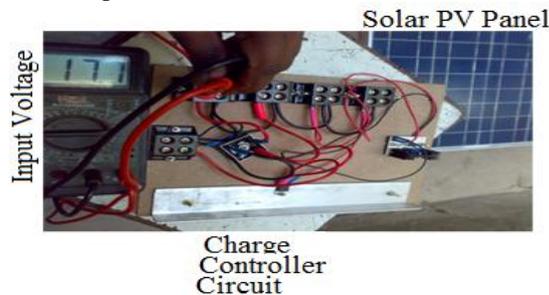

Fig.15. Photocopy of the Experimental setup showing input voltage (V_{in})

of 17.1 V from the photovoltaic panel under $1000w/m^2$ irradiation.

Fig.16. output voltage (V_o) from the charge controller which charges the battery without MPPT algorithm.

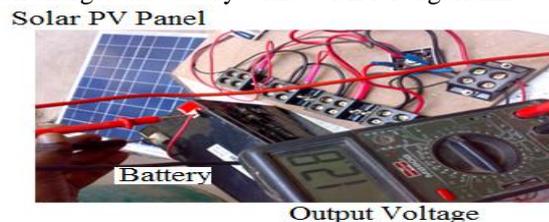

Fig.16. Photocopy of the Experimental setup showing output voltage (V_o) of 12.8 V from the charge controller which charges the battery under $1000w/m^2$ irradiation.

VII. SCOPE FOR FUTURE WORK

The scope for future work is the hardware implementation of the above said stand alone process with MPPT algorithm in closed loop using PIC16F87X microcontroller for varying illumination.

VIII. CONCLUSION

Conventional PI Controller method for MPPT of Photovoltaic array is presented in this paper on the basis of Incremental Conductance algorithm. The simulation results show that the Incremental Conductance algorithm has the merits such as simplicity fast response, low over-tuning, high control, precision and easy implementation. The hardware results are in line with simulated results.

²(Asst.Professor, Dept of C.S.E Madanaplle Institute of Technology & Science, Madanaplle, Andhra Pradesh, India)

Abstract: Software systems nowadays are composed from prefabricated commercial components and connectors that offer complex functionality and hold in complex interactions. Unfortunately, because of the diverse assumptions made by developers of these products, fruitfully integrating them into a software system can be difficult often causing budget and plan overruns. A number of integration risks can often be determined by selecting the 'right' set of COTS mechanism and connectors that can be integrated with minimal effort. In this paper we illustrate a framework for selecting COTS software components and connectors ensuring their interoperability in software thorough systems. Our framework is built upon average definitions of both COTS mechanism and connectors and is intended for use by architect and developers through the design phase of a software system. We highlight the function of our framework using a difficult example from the data-intensive systems domain. Our groundwork experience in using the framework indicates an increase in interoperability assessment productivity by 50% and accuracy by 20%.

I. Introduction

The mounting complexity of software systems attached with the decreasing costs of causal hardware has ushered forth the realization of Brook's celebrated "buy versus build" meeting [1]. In the past a production organization spent over a million dollars to build up a customized payroll system over 3 years and another 2 million dollars to preserve and grow it forth rest of its prepared life-cycle. Nowadays still, a business organization cannot afford to spend so much on a customized system that will take over 3 years to realize and a fortune to maintain and evolve. Instead they often opt to purchase a commercial off-the-shelf (COTS) software system (or component) that can accomplish the same desired capabilities. Such COTS systems and components persistently have diminished up-front cost, development time, maintenance, and development costs. These economic considerations often entice organizations to piece together COTS components into a working software system that meets dealing organization's requirements, and the system's functional rations, even at the expense of altering the organization's existing business processes! unluckily over the past ten years numerous studies [2-6] have shown that piecing together available open source and COTS components is quite contradictory from custom development.

Instead of the traditional requirements-design-develop-test-deploy process, COTS-based progress involves activities such as assessment-selection-composition-integration-test-deploy [7-11]. overriding to the success of the entire process, are the assessment and selection of the "right set" of COTS components and connectors. Careful and precise execution of these behavior often ensures the development of a system on time, on resources and in line with the objectives of the project. There are two major mechanism within the assessment and selection process: (1) assessment of COTS functional and non-functional requirements; and(2) assessment of interoperability to ensure that the selected COTS components will suitably interact with each other. While the former has been addressed formerly [7-11] an efficient

solution to the latter has eluded researchers. The first example of such an interoperability issue was accepted by Garlan et al. in [5] when attempting to construct a suite of software architectural modeling tools using a base set of 4 reusable components. Garlan et al. termed this problem architectural divergence and found that it occurs due to (specific) assumptions that a COTS section makes about the structure of the application in which it is to appear that ultimately do not hold true.

The best-known solution to identifying architectural mismatches is prototyping COTS communications, as they would occur in the conceived system. Such a move toward is extremely time-and effort-intensive. The approach compels developers (in the interest of limited resources) to either neglect the interoperability issue overall and hope that it will not create problems during the work and integration phases or it compels them to neglect interoperability until the number of COTS combinations available for selection are cut down to a manageable number (based on functional and quality of service requirements). Both these options add considerable risk to the project. When developers absolutely neglect interoperability measurement they often will be essential to write enormous amounts of glue-code, causing cost and schedule overruns. Otherwise, they risk losing a COTS product arrangement which is easy to integrate, but just "isn't right" because of some low-priority functionality it did not possess. Neither of the above scenario is appealing to development teams.

In addition to the above stated COTS component integration issues, there are issues of utilizing available COTS connectors that occur as well. The study of software architecture [12] tells us that software connectors are the embodiment of the relations and associations between software components. Therefore, ideally, when trying to construct the architecture of a software system, we need to be able to deal not only with the gathering of software components, but additionally the assembly of software connectors. This is exacerbated by the current lack of

considerate in many software system domains (e.g., data-intensive systems [13]) of how to select between dissimilar available COTS connectors. The research literature [14, 15] contains many other studies that describe the enormous difficulty in assembling software connectors by themselves, let alone with COTS software components.

In this paper, we propose an attribute-driven framework that addresses selection of (C)OTS components and connectors to make sure that they can be integrated within project possessions and schedule. One of the key contributions of our work is the classification of connectors to (1) “bridge the gap” between COTS components and ensure interoperability, and (2) satisfy systems quality of service (QoS) supplies. Our proposed construction identifies COTS component incompatibilities and recommends resolution strategies comparatively by using specific connectors and glue-code to integrate these components. Where component exchanges require fulfilling of QoS supplies the framework will propose proper connectors. Such incompatibility in sequence can be used to estimate the effort taken in COTS integration [16], which can then be used as a criterion when selecting COTS products. The framework is non-intrusive, interactive, and tailor able. The quantity conducted by the framework can be approved out as early as the commencement phase, as soon as the development team has known possible architectures and a set of COTS components and connectors. We have tested this framework in a classroom setting and in various example studies, including a challenging real world example from the data-intensive systems domain. Our early experience from using the framework indicates that our come near is feasible, and worthy of active pursuit.

1.1 Definitions

We adopt the SEI COTS-Based System Initiative’s definition [7] of a COTS product: a product that is

- sold, leased, or licensed to the general public;
- offered by a vendor trying to profit from it;
- supported and evolved by the vendor, who retains the logical property rights;
- available in multiple identical copies;
- used without source code modification.

For the purpose of this work we include open-source products as part of the COTS domain except where the source code is personalized by the user (and not redistributed as a fix or a version upgrade). In this paper, we define a component generally as a unit of computation or data store [14]. Components may be as small as a single process or as large as an entire application. Connectors are architectural building blocks used to representation interactions among components and rules that govern those interactions [14]. The rest of this paper is organized as follows. In Section 2, we describe a motivating real-world COTS assessment and selection problem in the data-intensive systems domain. In Section 3 we describe the assessment framework in detail, including the attribute metadata that it captures and how it applies to our example.

In Section 4 we present observed evidence and data taken from a graduate software engineering course at USC that evaluated our framework. Section 5 identifies related works to our own approach and section 6 rounds out the paper with a view of some expectations work.

II. Assessment and Selection Framework

The framework is modeled using three key components, these are: COTS interoperability surveyor, COTS representation attributes, and mixing rules. Inputs to the framework are various COTS component definitions and a high-level system architecture. The output of the framework is an interoperability assessment report which includes three major analyses:

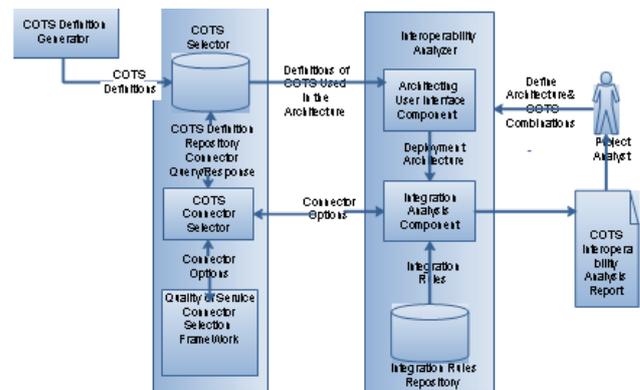

Figure 2. COTS Interoperability evaluation framework

1. Internal postulation mismatches, which are caused due to assumptions made by interacting COTS’ systems about all other’s internal structure [4].
2. Interface (or packaging) mismatches, which occur because of incompatible communication interfaces between two components.
3. Dependency analysis, which ensure that services required by COTS packages used in the system are being provisioned (e.g. Java-based CRM solution requires Java Runtime Engine).

In the remainder of this section we will describe each of the framework components in details.

1.2 COTS interoperability evaluator

To develop the COTS interoperability evaluator we needed to address two considerable challenges:

1. Ensure that the effort spent in COTS interoperability assessment is much less than the effort spent performing the assessment manually.
2. Ensure that the framework is extensible, i.e. so that it can be updated based on popular COTS characteristics.

We tackle these challenges by developing a framework that is modular, automated, and where COTS definitions and assessment criteria can be updated on-the-fly. Our framework allows for an organization to continue a reusable and frequently updated portion (COTS selector) remotely, and a segment which is minimally updated (interoperability analyzer) at client-side. This allows for a dedicated team to maintain definitions for COTS being assessed by the organization. The internal architecture of

the COTS interoperability surveyor component is shown in Figure 2. The architecture consists of the following sub-components. COTS Definition Generator is software utility that allows users as well as COTS vendor to define the COTS components in a generally accepted standard format. Currently we have implemented an XML-based format; however, the implementation format is independent of the primary metadata (e.g., the COTS definition can still be represented using other representation formats, so long as suitable parsers exist). For brevity, we omit its full description of our existing XML format and we point the reader to [17] for a complete description.

COTS Definition Repository is an online storage of assorted COTS definitions indexed and categorized by their roles and functionality they provide (database systems, graphic toolkits etc.). The repository is queried by different sub-components of the interoperability surveyor. In practice, this component would be collective across the organization to enable COTS definitions reuse. Alternately, such a repository could be maintained and updated by a third-party vendor and its access can be licensed out to various organizations.

Architecting User Interface Component provide a graphical user interface for the developers to create the system deployment diagram. The component queries the COTS definition storehouse to obtain the definitions of COTS products being used in the conceived system. Integration Rules storage area specifies various integration rules that will drive the analysis results and interoperability assessment. The rules repository can be maintained

classify internal assumption mismatches, interface (or packaging) mismatches and dependency analysis. When the integration analysis element encounters an interface variance the component queries the COTS connectors elector component to identify if there is an existing bridge connector which could be used for integration of the components, if not it will recommend in the interoperability analysis report that a wrapper of the suitable type (either communication, or coordination or conversion) be utilized. The integration analysis component then provides some simple textual information (in human readable format) as to the functionality of the wrapping required to enable interaction between the two components. In addition the combination analysis component identifies mismatches caused due to internal assumption made by COTS components, and also identifies COTS component dependency not satisfied by the architecture. For cases where the COTS component definition has misplaced information the integration analysis component will include both an cheerful and a pessimistic outcome. These identifications are both included in the interoperability analysis report. COTS Connector Selector is a query interface used by combination analysis component to identify abridging connector in the event of interface incompatibility, or a QoS specific connector. **Quality of Service Connector Selection Framework** is inextensible component built for identifying quality of service specific connectors. One such extension discussed in this paper aids in the selection of highly distributed and voluminous data connectors. Other quality of service extensions may include connectors for mobile-computing environments that require low memory footprint, or connectors for highly reliable, fault-tolerant systems. To create a quality of service extension, a developer first identifies needed COTS attribute information and ensures the information is captured in the COTS definition repository. This information will typically describe the scenario requirements for COTS connector selection for the particular level of service, e.g., for data intensive systems, it may include the Total Volume, Number of Delivery Intervals and possibly the Number of Users present in the data transfer. The developer then can construct a simple web-based service that accepts the COTS connector definition information, and any other needed data, and then returns the appropriate COTS connectors to select to satisfy the desired level of service scenario. **COTS Interoperability Analysis Report** is output by the selector and contains the result of the analysis in three major sections: (1) internal assumptions mismatch analysis, (2) interface (packaging) mismatch analysis, and (3) dependency analysis. This is the ultimate product of the interoperability framework.

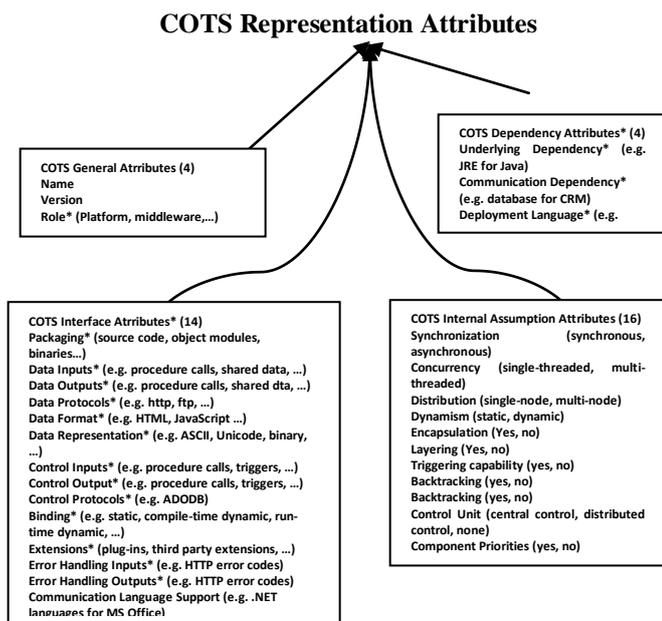

Figure 3. COTS Representation Attributes

remotely; however it will be required to download the complete repository at the client-side (interoperability analyzer) before performing interoperability measurement. This reduces the number of remote queries required when assessing COTS architectures. **Integration Analysis Component** contains the actual algorithm for analyzing the system. It uses the rules specified in the combination rules depository along with the architecture specification to

1.3 COTS Representation Attributes

The COTS Representation Attributes are a set of 38 attributes that define COTS produce interoperability characteristics. COTS interoperability characteristics defined using these attributes are utilized by the integration analysis component along with incorporation assessment rules (described in the next section) to carry out interoperability analysis. These attributes have been consequent from the literature, as well as our clarification in various software integration projects.

The two major criteria used for selecting these attributes were:

1. attributes should be able to capture sufficient details on the major sources of COTS product mismatches (interface, internal assumption and dependency mismatches) identified - internal postulation mismatches,
2. attributes should be defined at advanced so that COTS vendors are able to provide feature definitions without revealing confidential product information

To date, we have surveyed about 40 COTS products of which 30 were open source. For the non open source COTS we could identify at least 34 of the 38 attributes from the publicly available information itself. We neglected to include many attributes such as data topology, control structure, and control flow because they were either : too detailed and required accepting of internal designs of COTS products for defining them, or could alternately be represented at a higher level by an already included attribute, or did not provide significant mismatches to warrant us including them. We have classified the attributes that we selected into four groups shown in Figure 3. Attributes (or attribute sets) marked with an asterisk indicate that there may be multiple values for a given attribute (or set) for the given COTS product.

The remainder of this section summarize attribute classifications. The full metaphors of all the attributes can be accessed at [17]. **COTS general attributes (4)** aid in the identification and querying of COTS products. The attribute include name, version, role and type. **COTS interface attributes (14)** define the communications supported by the COTS product. An interaction is defined by the exchange of data or control amongst machinery. COTS products may have multiple interface, in which case it will have multiple interface definition. For example: the Apache Web Server will have one complete interface definition for the web-interface (interaction via HTTP), and another complete definition for server interface (interaction via procedure call). These attributes include packaging (source code modules, object modules, dynamic libraries, etc.), data and control inputs, outputs, protocols etc. When developing the COTS product the developer makes certain assumption about the internal operations of the COTS products. The **COTS internal assumption attributes (16)** confine such internal assumption For example developers of the Apache Web Server assume that the software will contain a central control unit which will regulate the performance of the system. COTS internal statement attributes include synchronization, concurrency, distribution and others. **COTS dependency attributes (4)** define the conveniences required by a COTS product i.e. software the COTS product requires for successful execution. For example any Java-based system requires the Java Runtime Environment (JRE) as a platform. COTS dependency attributes include primary and communication dependencies, deployment language support, and execution language support. An example COTS definition using the attributes specified in Figure 3 is shown in Table 1.

1.4 Integration Assessment Rules

The Integration review Rules are a set of rules used to perform the interoperability analysis. Every rule has a set of pre-conditions, which if true for the given planning and components, identifies an architectural mismatch. For example consider one of the architectural mismatches found by Gacek in [4]:“Data connectors connecting components that are not always active”. For the given mismatch the precondition are: 2 components connected via a data connector (only) and one of the components does not have a central control unit. There are similar rules for performing arts interface, dependency, and internal assumption analysis. Interface analysis discovers if there are commonly shared interfaces between two communicating COTS components, if not it includes recommendation on the type of “glue ware” (or “glue code”) required to integrate the components.

enslavement analysis rules verify if the architecture satisfies all the dependencies that a COTS product require. Finally, for internal assumption we leverage upon the mismatches identified in [4] and add new mismatches based on newly added attributes. Currently, our framework is still underdevelopment and we are in the process of evaluating these rules for behavior such as completeness, correctness, tractability and scalability. We have perform an initial appraisal along two of these evaluation target (correctness and completeness) and our ongoing work involves solidifying means of measuring and evaluating our work.

1.5 Framework Application to Motivating Example

To answer the two questions posed in the motivating example section we apply our framework to analyze the system architecture and COTS combinations. In our example there are 2 major considerations when assessing COTS products and implementation technologies to identify interoperability conflicts:

1. Interoperability conflicts when integrate the digital asset management system with the database.
2. Selection of languages to develop the custom components so as to minimize the development effort by leveraging upon existing support provided by COTS products.

Table 1 Definition of Apache 2.0 using COTS Representation Attributes

COTS General Attributes (4)		
Name	Apache	
Version	2.0	
Role	Platform	
Type	Third-party component	
Interface Attributes (14)	Background Interface	Web Interface

Underlying Dependencies	Linux, Windows, (OR)	Unix, Solaris
Communication Dependency	None	
Deployment Language	Binary	
Execution Language Support	CGI	

The project analyst should provide the following information for every interaction in the proposed architecture:

- data and/or control interaction,
- Unidirectional of bidirectional interaction, and which component initiates the interaction,

For the interactions where the large volume data transfer connectors (C1, C2, and C3) are required, the analyst will define attributes specific for that QoS (described further in this section). Assume a scenario where D Space is being assessed as the digital asset management system, and MySQL as the database server. The architecting component user interface will automatically retrieve the definitions for D Space and MySQL and pass the architecture, interaction and definition information to the integration analysis component for assessment. The integration analysis component will apply the rules (from integration rules repository) using COTS attributes and based on the deployment architecture definition to identify:

- Common interfaces supported by MySQL and D Space, bridging connectors and the type of glue code (communication, conversion, synchronization or a combination thereof) required [15].
- Internal assumption mismatches between MySQL and D Space
- Verification that the COTS dependencies have been satisfied in the given architecture.
- Recommended languages for the query manager and data recovery component that will simplify developing glue-code between COTS and custom components.

In the event that the two interacting components (D Space and MySQL) do not share common interfaces, it will recognize (using the COTS connectors selector) a connector that can enable announcement between the two components (JDBC-MySQL driver) and output the fallout in the report. The project analyst can use these findings to estimate the effort required to test (for internal assumption mismatches) and integrate the COTS and custom apparatus [16]. Development

teams can run such evaluation on all their COTS and custom combinations; and use the exertion results as an input to their COTS evaluation table [10] to facilitate the COTS component collection decision. External users, when selecting COTS products and implementation technologies to develop application can run our framework by keeping COTS and technologies selected by JPL and ESA constant and varying their choices of COTS harvest to identify the set which will require minimal integration effort.

To deal with the range of connectors to support large-volume data transfer between JPL and ESA (as shown in Figure 1), and the external users, we employ a specific level of service extension that we have constructed for large-scale, data-intensive systems. The extension was particularly motivated by our experience developing such systems at JPL. A careful, detailed description of this level of service extension is beyond the scope of this paper: for more information on its internal architecture, motivation and objectives the reader is directed to [13]. However for

the purposes of our COTS assessment and selection framework, we will explain the data-intensive level of service extension's high level architecture focusing on two of its critical phases: connector classification, and selection. The inputs to the data-intensive level of service extension are called Distribution Connector Profiles, or DCPs. DCPs capture metadata describing connector Data Access, Distribution and Streaming information abstracted from Mehta et al.'s [15] connector taxonomy.

The profiles also contain information critical to data distribution including Delivery Intervals, Number of Users and Total Volume (in total, there are eight core dimensions of data distributions we are focusing on). To generate DCPs, an architect can manually classify a set of COTS distribution connectors: or the DCPs can be generated using some automated process. For our motivating example, we assume that the production of DCPs has already been performed offline, and we assume the presence of a knowledge base of DCPs resultant from the arrangement. The connectors profiled for the knowledge base take account of connectors C1, C2, and C3 shown in Figure 1. Connector selection starts after the system architecture has been arrived upon and after data allocation scenarios (e.g., constraints on the DCP metadata) have been identified by the user(s) of the system. In our example, there are three distinct distribution scenarios to consider (represented below in human readable form and then following in constraint query format):

- S1. Distribution of data from JPL scientists to ESA scientists
- S2. Distribution of data from ESA scientists to JPL scientists
- S3. Distribution of JPL and ESA data to the outside community

The three scenarios can be expressed as the following constraint queries against the DCP metadata:

```
(Total Volume > 100 GB) ^ (Number Of Users = 2) ^
(S1)
(Num Delivery Intervals = 4) ^ (Volume Per Interval = 25
GB)
^ (Num User Types = 1) ^ (Geographic Distribution =
WAN)
(Total Volume = 1GB) ^ (Number Of Users = 4)
```

For instance, S1 represent the user preference of the

ESA scientists who would like to receive their JPL colleagues' data. S1 describe a allotment scenario in which the producer of data (the JPL scientists) are conveyance over 100 GB of data using a wide-area network (WAN) to 2 regulars of data (the ESA scientists), using 4 escape intervals where each interval consists of 25 GB of data. In S1, from the perspective of the producer of data (JPL scientists), there is a single user type, the ESA scientists. Queries S2 and S3 are formulated similarly. Using S1-S3 as selection criteria, "candidate" connectors are chosen based on their DCP metadata at hand in the DCP knowledge base using a conventional database attribute matching

approaches. After candidate connector filtering, the distribution connectors are assessed for architectural mismatches that may result from their combined use in support of the given circulation scenario.

This appraisal is conducted using an conservatory to Gacek's [4] simple pair-wise mismatch algorithm that compares two architectural elements (in this case, distribution connectors) along the metadata values provided by the DCP. For every value, our algorithm detects potential mismatch areas and decides whether the (set of) mismatches identified are severe enough to avoid connector combination, otherwise, selects suitable connectors that could be used together. For example there may be a divergence in the Number of Users dimension of two of the freedom connectors from the JPL and ESA system, C1 and C2. If C2 supports fewer users than connector C1, then C2 may become the restricted access in the distribution. The detected mismatches are labeled using a simple, but adaptable set of divergence levels, such as severe, or allowable. A severe mismatch may prevent combination of two otherwise matched connectors, while an allowable label may still allow their combination.

The levels are tailor able and meant to be profiled to suit each respective user of our framework. Relating back to our motivating example, the algorithm may decide based on the DCP metadata, that connectors C1 and C2 should be combined, and to combine the Grid FTP [18] connector with an HTTP based custom COTS data connector. Additionally, the level of service extension may conclude that connector C3 can be implemented using an available OTS peer to-peer distribution connector, such as Bit torrent.

III. Empirical Results

In bounce semester of 2006 we conducted an conduct experiment in a graduate software engineering course at USC using our assessment framework. The course focus on software classification development [19] requested by a real-world client. Over the last few years the course has twisted systems for e-services, explore (medicine and software), as well as commercial selling domains. Graduate students enrolled in the track form teams of about 5 members to design and implement a software system within a 24-week time period. During this period the project progresses through inception, elaboration, manufacture and transition phases. Our experiment was conducted close to the end of the elaboration phase, when the team propose a system architecture that would meet the system requirements. We asked 6 teams, whose architectures included at least 3 or more COTS components to use our framework on their personal projects and measured results in four areas:

1. Accuracy of interface incompatibilities notorious by the framework considered as $1 - (\text{number of interface incompatibilities missed by the team} / \text{total number of interface incompatibilities})$. Interface measurement results produced by our framework were verified later through a survey when the teams actually integrated the COTS products. Results in this area price the completeness and correctness of our interface assessment rules.
2. Accuracy of dependency identified by the framework calculated as $1 - (\text{number of dependencies missed by the})$

team / total number of dependencies). Addition assessment results produced by our framework were also later verified through a survey after the project was implemented. These results evaluate the completeness and correctness of our interface dependency rules.

3. Effort spent in assessing the architectures using the framework contrasting to the effort spent in assessing the architectures manually by an comparable team. These results demonstrate the competence of using our framework to perform interoperability assessment as opposed to performing a manual assessment.

4. Effort spent in performing arts the actual integration after using the framework as opposed to effort spent by an equivalent team.

Results here validate the overall utility of our framework Equivalent teams were chosen from past CSCI 577 projects such that they had analogous COTS products, similar architectures, and whose team-members had similar years of experience in project enlargement.

Upon performing autonomous T-test [20] for the metrics above we recorded the results shown in Table2. Our results indicate that the framework increases dependency assessment accuracy and interface assessment accuracy by more than 20% and reduces both assessment effort and integration effort by approximately 50%. These results are significant at the alpha = 5% level.

Table 2. Empirical assessment of our framework

Groups	Mean	Std-Dev.	P-Value
Interface Assessment Accuracy			
Before using the framework	76.9%	14.4	0.0029
After using the framework	100%	0	
Dependency Assessment Accuracy			
Before using the framework	79.3%	17.9	0.017
After using the framework	100%	0	
Effort spent in performing architecture assessment			
Projects using the framework	1.53	1.71	0.053
Equivalent projects	5 hrs	3.46	
Effort spent when integrating the COTS products			
Projects using the framework	9.5	2.17	0.0003
Equivalent projects	18.2	3.37	

IV. Conclusion and Future Work

This paper presents a construction that enables evaluation and selection of COTS workings and connectors early in the software development lifecycle. The skeleton does not eliminate detailed testing and prototyping for evaluating COTS interoperability, however it does provide an analysis of interface compatibilities and dependency. The framework recommends connectors to be used or glue code required and early indications of probable incompatibilities during system integration. Moreover, since the framework is automated it enables evaluation of large number of architectures and COTS combinations, increasing the trade-off space for COTS component and connector selection. Currently we have completed a tool prototype to enable such examination and are in the process of developing a fully functional tool suite. We are also planning experiment to gather empirical data to further test the utility of the framework across a larger sample size and in different development environments. It is also important to note that attribute for frameworks such as ours must be periodically updated based on prevailing COTS characteristics.

ABSTRACT: *In these modern research areas the Non-linear Dynamics is a very popular topic, the researchers study the nonlinear behaviour of every system which can be an industrial machine/instrument or a theoretical aspect. Prior researchers already studied the nonlinear dynamics of Current Controlled DC-DC Boost Converter. But the Power Factor Corrected Boost Converter is a circuit which is used in very practical purpose where the input is AC, the AC is rectified to DC by diode bridge rectifier and the rectified DC is to feed the boost converter i.e. conventional pure DC supply is replaced by the rectifier DC. In this converter the circuit is designed specially as input power factor can maintain unity so it is called Power Factor Corrected (PFC) Boost Converter. This paper aims to develop a circuit for PFC boost converter to observe Phase-Portrait diagrams and also discuss the control of chaos.*

Keywords: *AC-DC PFC Boost Regulator, State Equations, Phase-Portrait Diagrams, Control of Chaos.*

I. INTRODUCTION

Power factor correction converter (PFC) is an important area of study and research in power electronics motivated by practical applications [1]. This AC-DC converter provides DC voltage at the output with high input power factor. In fact, a low power factor reduces the power available from the utility grid, while a high harmonic distortion of the line current causes EMI problems and cross interferences through the line impedance between different systems connected to the same grid. It is usually assumed that the output ripple can be neglected by using a huge output capacitor, which is not acceptable in design due to its high cost and size. Thus many efforts are being done to develop interference systems, therefore to ensure a minimum distortion and a power-factor close to the unity. One of the most common circuits used to achieve unity power factor is the boost Power Factor Correction circuit.

In last decade, studies of complex behaviour in switching power converters have gained increasingly more attention from both the academic community and the industry. Various kinds of nonlinear phenomena, such as bifurcation and chaos have been revealed [2][3]. Chaos could be described as noise like, bounded oscillations with an infinite period found in nonlinear, deterministic systems [4]. These complex behaviours implying instability can be observed by changing circuit parameters, or enclosing the accessional control method when the circuit parameters are fixed. The occurrence of bifurcation and chaos in power

electronics was first reported in the literature in the late 1980 [5][6]. In [7] the chaotic behaviour in a buck converter with certain parameter range was verified theoretically and experimentally.

Deane [8] first discussed the route to chaos in a current controlled boost converter. Chan and Tse [9], S. Banarjee and K. Chakrabarty [10] studied various types of routes to chaos and their dependence upon the choice of bifurcation parameters.

Recently some nonlinear behaviours in the PFC boost converter have been reported [11].

The possibility of controlling nonlinear chaotic dynamical systems has been subjected to extensive investigation. The prior researchers focused on control of Chaos by means of small, time-dependent parameter or input perturbations [12,13]. Many different strategies to control chaotic dynamics in nonlinear systems have been proposed in recent surveys of some of the available methods for control of chaos can be found in [14], [15], [16] and [17]. *Time-Delayed Auto Synchronization (TDAS)* was proposed by Pyragas in [18]. *Extended Time-Delayed Auto Synchronization (ETDAS)* was proposed by Socolar et al. [19]. Partial differential equations, initial conditions and the domain of control of a given system have been described in [20], [21], [22]. Mostly developed in the area of control engineering which makes use of *State Feedback Controllers (STC)*, *Adaptive Control Schemes* [23] to solve the problem of controlling chaos.

In this thesis, in order to better understand the dynamics of PFC boost regulator, model of CCM is considered to analyze its behaviours. The modelling and simulation aspects of current-mode controlled PFC boost regulator are operating in chaotic regime are addressed. Firstly, the numerical simulation of chaotic and discontinuous system is presented, so that the results reflect the true behaviour, as an extremely challenging task for any simulation tool. Secondly, MATLAB/Simulink is used to compare the results obtained by numerical simulation.

II. DESIGN CONCEPT OF AC-DC PFC BOOST REGULATOR

DC power supplies are extensively used inside most of electrical and electronic appliances such as in computers, monitors, televisions, audio sets and others. The high power non linear loads (such as static power converter, arc furnace, adjustable speed drives etc) and low power loads (such as fax machine, computer, etc) produce voltage fluctuations, harmonic currents and an imbalance in network system which results into low power factor operation of the power system. There is a need of improved power factor and reduced harmonics content in input line

$$v_s = 220 \sin \omega t, L = 40 \text{ mH}, C = 100 \mu\text{F}, R = 44 \Omega, K_1 = 400$$

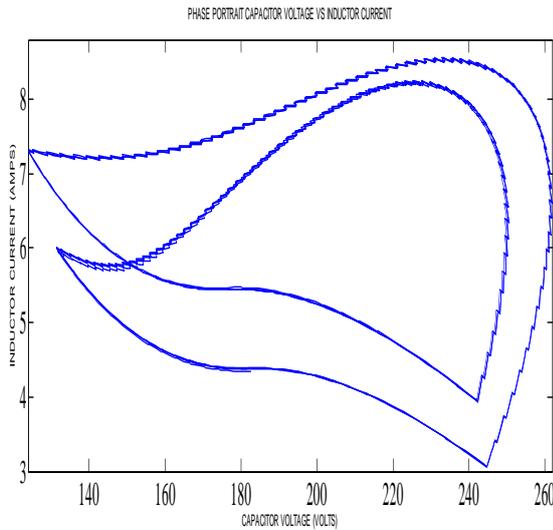

Fig. 4: Phase Plane Trajectory (Case II) Capacitor Voltage vs. Inductor Current (Period II operation)

Case III(Period V Operation)

$$v_s = 220 \sin \omega t, L = 40 \text{ mH}, C = 100 \mu\text{F}, R = 38 \Omega, K_1 = 400$$

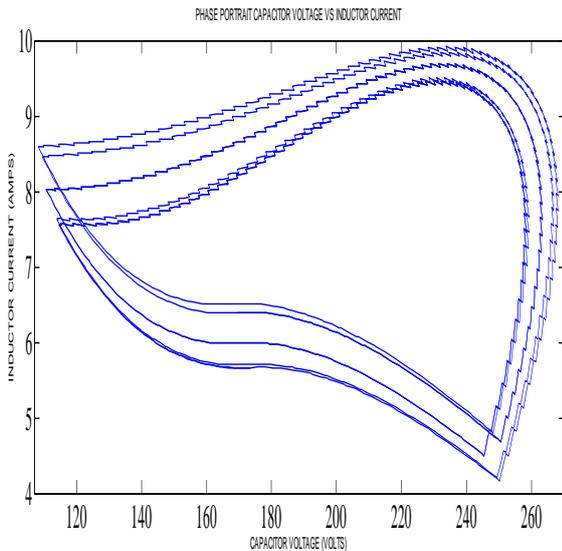

Fig. 5: Phase Plane Trajectory (Case III) Capacitor Voltage vs. Inductor Current (Period V operation)

Case IV(Chaotic Mode Operation)

$$v_s = 220 \sin \omega t, L = 40 \text{ mH}, C = 100 \mu\text{F}, R = 65 \Omega, K_1 = 400$$

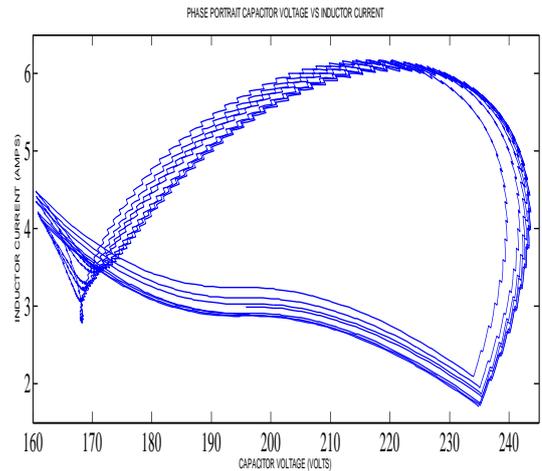

Fig. 6: Phase Plane Trajectory (Case IV) Capacitor Voltage vs. Inductor Current (Chaotic Mode Operation)

The time domain diagram of state variables i.e. inductor current and output capacitor voltage repeats after "n" times of cycles, so it is a "Chaotic mode operation". Chaos is largely unpredictable long-term evolution occurring in deterministic, nonlinear dynamical system because of sensitivity to initial conditions. The Phase Plane Trajectory of "Chaotic mode operation" is shown in Fig. 6.

VI. CONTROL OF CHAOS

There are several kinds of methods to controlling chaos (previous discussion), here the TDS method is picked up. Our strategy to stabilize the UPO of the current-mode-controlled boost converter will consist of modifying the reference current with a term proportional to the difference between a linear combination of the present and past states of the system. Precisely, instead of compare it to $I_{ref} + \eta(\alpha(v(t) - v(t - 1))) + \beta(i(t) - i(t - 1))$

Where η is an overall feedback gain and α and β are relative weights. Notice again that, for a period - I solution the feedback signal vanishes. One must bear in mind that, although the mathematical computations to find out the range of parameters that stabilize the orbit can be quite imposing, once those value are known, the actual implementation requires only the knowledge of the period of target orbit in order to form the feedback signal. For the system like PWM - controlled converters the period of any orbit is a multiple of period of the clock used to generate the pulses. More detailed information about the target unstable orbits can be obtained experimentally using, for instance, the techniques exposed in [17], and this can be used to numerically compute the parameter range mentioned above.

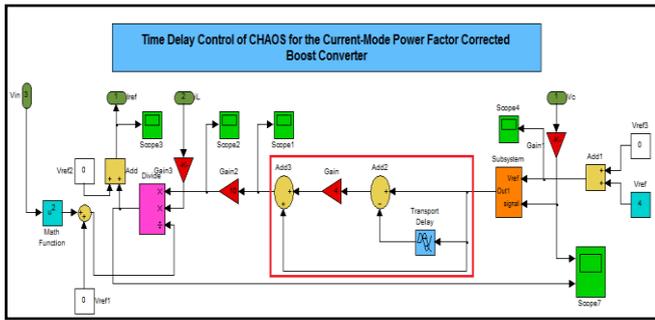

Fig. 7: MATLAB Model of Time – Delay Feedback Control of Chaos of PFC Boost Converter BEFORE CONTROLLING CHAOS

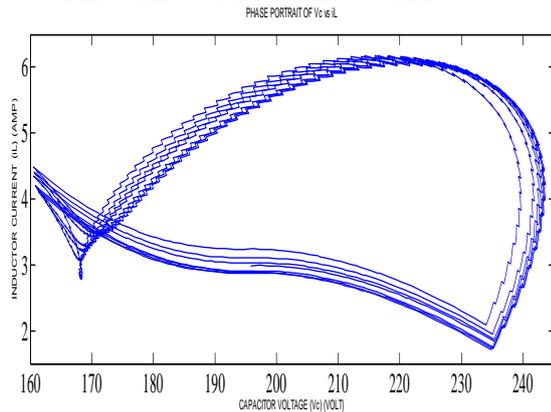

Fig. 8: Phase Portrait of Capacitor Voltage vs. Inductor Current in Chaotic Mode AFTER CONTROLLING CHAOS

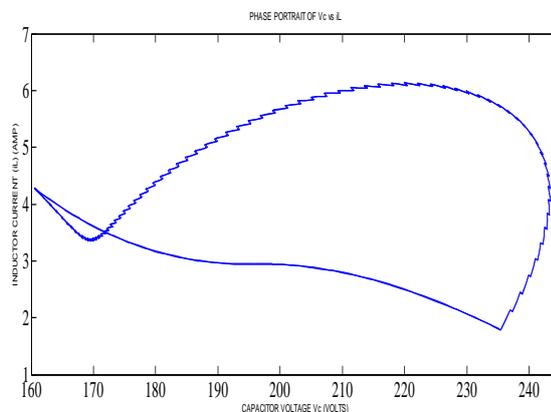

Fig. 9: Phase Portrait of Capacitor Voltage vs. Inductor Current after Controlling Chaos

The Chaotic mode phase portrait is shown in Fig. 8, the Time Delay Feedback System is used (Fig. 7) for controlling the chaos. Fig. 9 is shown after controlling the chaos.

VII. CONCLUSION

The Power Factor Corrected (PFC) AC-DC Boost Regulator with current-mode control has been investigated depending on the nonlinear model. Results highlight that the proposed model of practical PFC regulator, simulation results and phase-portrait diagrams. The phase-plane-trajectory curves are observed by varying value of resistance (R). The value of load resistance (R) is increased or decreased; the phase-portrait of output capacitor voltage (v_c) and inductor current (i_L) is going to period I to period II to chaotic-mode. Chaos phenomena are

shown by multiple loops on phase-plane diagram. The most important point of all the case studies, if the entire system is operated in chaotic-mode the output capacitor voltage ripples has been minimized by increasing the chaotic-region. The chaos control are also done by time delay feedback system (TDS). We can control entire system in our desired region according to our demand. In a DC-DC converter system, the input voltage is constant and therefore the dynamical behaviour is periodic with the switching frequency. On the other hand, the input voltage of the boost AC-DC PFC regulator system is periodic with the line frequency. The results highlight that the dynamical behaviour is periodic with the line frequency not with the switching frequency and simulation results are also agree with our statements.

Stroke-Database Design for Online Handwriting Recognition in Bangla

K. Roy

West Bengal State University, Barasat, Kolkata, India

Abstract: *Handwriting recognition is a difficult task because of the variability involved in the writing styles of different individuals. This gets more complicated in Asian script for its large character set and presence of modified and compound characters. This paper presents a scheme for the online handwriting recognition of one of the major Indic script, Bangla. Online handwriting recognition refers to the problem of interpretation of handwriting input captured as a stream of pen positions using a digitizer or other pen position sensor. Strokes are extracted from the characters. The sequential and dynamical information obtained from the pen movements on the writing pads are used as features in the proposed scheme. These features computed from the strokes, and fed to the MLP classifier for recognition. The characters are identified from its constituent strokes. The system was tested on 21372 Bangla character data and obtained 92.92% accuracy with top 3 choices.*

I. Introduction

Data entry using pen-based devices is gaining popularity in recent times. This is so because machines are getting smaller in size and keyboards are becoming more difficult to use. Also, data entry for Indian scripts having large alphabet size is difficult using keyboard. Moreover, there is an attempt to mimic the pen and paper metaphor by automatic processing of online characters. Work on online character recognition started gaining momentum about forty years ago. Numerous approaches have been proposed in the literature [1] - [9].

Many techniques are available for on-line recognition of English, Arabic, Japanese and Chinese [1] - [9] characters but there are only a few pieces of work [10] - [15], [19] available towards Indian characters although India is a multi-lingual and multi-script country. Connell et al. [11] presented a preliminary study on online Devnagari character recognition. They considered only the main characters that occur in the core-strip neglecting the ascending and the descending parts of the characters. Connell et al. [13] also proposed a work on Devnagari on-line character recognition. Joshi et al. [14] proposed an elastic matching based scheme for on-line recognition of Tamil character recognition. Although there are some work towards on-line recognition of Devnagari and Tamil scripts but the on-line recognition work towards other Indian languages is very few. In this paper we propose a system for the on-line recognition of Bangla handwritten characters. Recognition of Indian characters is very difficult with compare to English because of its shape variability of the characters.

There are twelve scripts in India and in most of these scripts the number of alphabets (basic and compound characters) is more than 250, which makes keyboard design and subsequent data entry a difficult job. Hence, online recognition of such scripts has a commercial demand. Although a number of studies [16] have been done for offline recognition of a few printed Indian scripts like Devnagari, Bangla, Gurumukhi, Oriya, etc. with commercial level accuracy, but to the best of knowledge no system is commercially available for online recognition of any Indian script. There is a proliferation of on-line recognizers developed as compared to off-line recognizers. There are two main reasons for this disparity. First, on-line recognizers are easier to build [3], because the order of the pen-strokes is known, as well as timing information and also direction information of writing may be extract. Secondly, handwriting recognition can easily be used for input in handheld or PDA-style computers, where there is no room for a keyboard. Since a recognizer in this use is very visible, this visibility spurs on development.

In this work a new algorithm is proposed for online Bangla handwritten character recognition from stroke. A database of strokes is generated based on the database of characters collected for the experiment. After recognition of the strokes a tree based approach is used for construction of valid character from its constituting strokes. This algorithm is robust against stroke number and order-variations.

The organization of the paper is as follows. In Section 2 the property of Bangla script as well as the pre-processing is described. Section 3 deals with detailed property of stokes in Bangla character and their extraction strategy. The feature extraction technique is described in Section 4 and the classifier is in Section 5. Finally in Section 6 the result and their analysis is given.

II. BANGLA SCRIPT & PREPROCESSING

Bangla, the second most popular language in India and the fifth most popular language in the world, is an ancient Indo-Aryans language. About 200 million people in the eastern part of Indian subcontinent speak in this language. Bangla script alphabets are used in texts of Bangla, Assamese and Manipuri languages. Also, Bangla is the national language of Bangladesh.

The alphabet of the modern Bangla script consists of 11 vowels and 40 consonants [16]. These characters are called as basic characters. Writing style in Bangla is from left to right and the concept of upper/lower case is absent in this script. It can be seen that most of the characters of Bangla have a horizontal line (Matra) at the upper part. From a statistical analysis on printed document it was noticed that the probability that a Bangla word will have horizontal line is 0.994 [16].

In Bangla script a vowel following a consonant takes a modified shape. Depending on the vowel, its modified shape is placed at the left, right, both left and right, or bottom of the consonant. These modified shapes are called modified characters. A consonant or a vowel following a consonant sometimes takes a compound orthographic shape, which is called as compound character. Compound characters can be combinations of two consonants as well as a consonant and a vowel. Compounding of three or four characters also exists in Bangla. There are about 280 compound characters in Bangla [16]. In this work the recognition of Bangla basic characters are considered.

To get an idea of Bangla basic characters and their variability in handwriting, a set of handwritten Bangla basic characters are shown in Figure 1. This is the form which is also used for collection of isolated characters.

Fig. 1. Examples of Bangla handwritten characters.

A. Pre-processing

$$P_{i=1}^M \in R^2 \times \{0,1\}$$

The digitizer output is represented in the format of $P_{i=1}^M \in R^2 \times \{0,1\}$, where p_i is the pen position having x-coordinate (x_i) and y-coordinate (y_i) and M is the total number of sample point. For writing Bangla characters, M varies from 14 to 189 for a character. If p_i and p_j are two consecutive pen points, i^{th} point (p_i), is retained with respect to j^{th} point (p_j), if the following condition is satisfied:

$$x^2 + y^2 > m^2 \tag{1}$$

Where $x = x_i - x_j$ and $y = y_i - y_j$. The parameter m is empirically chosen. M is set to 0; in equation (1) to removes all repeated points.

Analyzing a total of 22,000 Bangla character it was found that, for writing Bangla characters, the number of points varies from 14 (ঔ) to 189 (ঐ) points. The average number of points in a Bangla character is 72. It was also noted that the character (ঐ) uses the maximum number of points in average and its value is 115. It is closely followed by ‘উ’ (108), ‘ঋ’ (105), & ‘আ’ (104). The minimum number of points in an average is used by the character ‘ঢ’ (47) and is closely followed by ‘ব’ (49) ‘দ’ (51).

Smoothing: To remove jitter from the handwritten data, every point $(x(t), y(t))$ are replaced in the trajectory by the mean value of its neighbors:

$$x'_i = \frac{x_{i-N} + \dots + x_{i-1} + \alpha x_i + x_{i+1} + \dots + x_{i+N}}{2N + \alpha}$$

$$y'_i = \frac{y_{i-N} + \dots + y_{i-1} + \alpha y_i + y_{i+1} + \dots + y_{i+N}}{2N + \alpha}$$

The parameter ‘ α ’ is based on the angle subtended by the preceding and succeeding curve segment of $(x(t), y(t))$ and is empirically optimized. This help to avoid smoothing of sharp edges. Here the value for N is taken as 2.

III. STROKE DATA BASE GENERATION

Analyzing of Bangla characters it was found that Bangla characters are formed by combination of one or more basic strokes. The recognition of Bangla script is more difficult compare to roman script due to its large size of character set and compound characters. It gets tougher due to presence of multiple strokes while writing Bangla character. By stroke I mean collection of pen points that are collected between one pen down and pen up (with lifting in between).

The problem of online Bangla handwriting recognition gets more complex due to stroke order variation and variation in number of strokes used to write a character. For example let us consider the character ‘আ’. Again it may be seen that 2-6 of the 7 strokes are used for writing the same (as found from statistical analysis of the database). For example see figure 2. So with possible 6 strokes (out of 7) and their order variation makes the recognition process more complicated. Some ways of writing the character ‘আ’ is shown in figure 3.

The problem is more complex due to stroke order variation. If only 4 strokes are considered to write the character ‘আ’, they may be again in different order. For example see figure 4.

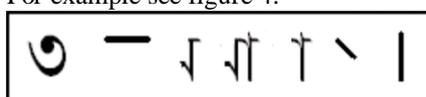

Fig.2. Examples of strokes use to write আ

$\langle ৩, ৭ \rangle = আ$	Total no of stroke = 2
$\langle ৩, ৭, ৭ \rangle = আ$	Total no of stroke = 3
$\langle ৩, ৭, \cdot, \rangle = আ$	Total no of stroke = 4
$\langle ৩, ৭, \bar{\quad} \rangle = আ$	Total no of stroke = 3
$\langle ৩, ৭, ৭, \bar{\quad} \rangle = আ$	Total no of stroke = 4
$\langle ৩, ৭, \cdot, , \bar{\quad} \rangle = আ$	Total no of stroke = 5
$\langle ৩, \cdot, , \cdot, , \bar{\quad} \rangle = আ$	Total no of stroke = 6

Fig 3: Some of the ways of writing ‘আ’ using some of the possible strokes in some combinations.

৩	ত	অ	আ
৩	অ	অ	আ
৩	অ	আ	আ

Fig. 4: Example of part of the different stroke-order for a character having four strokes.

A Bangla character may be written with single stroke like ‘৩’ and minimum of two strokes for the character having two disjoint parts like ‘৳’. From statistical analysis on the dataset it is found that the minimum number of stroke used to write a Bangla character is 1 and maximum number is 6. It is also seen that ‘ঐ’, ‘ঔ’ & ‘ঝ’ have almost written by single stroke where as ‘ঊ’ has an average of 4 strokes followed by ‘আ’ and rest all characters has average stroke number less than 3. It also found that almost always ‘ঐ’, ‘ঔ’, ‘ত’, ‘ন’, ‘৳’, ‘ঐ’ and ‘ঊ’ are written by 2 strokes. The average number of stroke per character is 2.2. In the database there are 61 basic characters in Bangla character set, so the total number of stroke in the Bangla Script should have been 135 (app). But from statistical analysis on the present stroke data base it is found that only 59 strokes are enough to represent all basic Bangla Characters. All these basic strokes are shown in figure 5. This is because some of the strokes are common to various characters. For example see table 1. For example the stroke ‘𑄣’ is common in the characters ‘ঋ’, ‘ক’, ‘ঋ’, ‘ধ’, ‘ব’, ‘৳’. From statistical analysis it is found that 40 out of the 61 characters generally bear Matra (𑄣). This stroke comprises 24.03% of the stroke database. The second most used stroke is ০ and is used by 8 basic characters and it comprises 8.45% of the stroke database. The top 10 frequent strokes with their percentage of occurrence in the database and the characters in which they occur are detailed in table 1. It is found from the analysis that top 10 frequent strokes comprises 59.76% of the stroke data base and least 20 frequent strokes comprises only 10.24% of the total stroke database. So the character having some of its constituent strokes are common (inter character similarity) are look similar (sometime even the strokes only vary in relative position only) and some time the same character is written with different strokes (intra character variability) makes the recognition process more complicated.

Table 1: Most frequent strokes (with percentage) and the characters in which they occur.

Stroke	Occurrence in Database	No of Character having this stroke (Characters)
—	24.01%	40
০	08.45%	8 (‘৳’, ‘ড’, ‘ঢ’, ‘ঝ’, ‘০’, ‘ঐ’, ‘ঔ’, ‘ঝ’)
১	05.64%	8 (‘ই’, ‘ঐ’, ‘উ’, ‘ঊ’, ‘ঐ’, ‘ঔ’, ‘ট’, ‘ঠ’)
৬	04.99%	6 (‘ঊ’, ‘ঊ’, ‘জ’, ‘ড’, ‘ড’, ‘ড’)
৭	03.09%	6 (‘ঋ’, ‘ক’, ‘ঋ’, ‘ধ’, ‘ব’, ‘৳’)

৩	02.79%	4 ('অ', 'আ', 'ত', 'ও')
এ	02.72%	3 ('এ', 'ঐ', 'ঋ')
া	02.71%	5 ('অ', 'আ', 'ঈ', 'ঐ', 'স')
ঋ	02.67%	4 ('ঋ', 'ঌ', 'ফ', 'ষ')
২	02.56%	3 ('ই', 'হ', '২')

A data collection form was prepared for isolated character collection but stroke can't be collected similarly. This is because normal human are not acquainted with writing strokes individually and secondly if strokes are written individually then the stroke variation (shape, size and number) may not reflect properly. So here the strokes are extracted from their parent characters. To extract the strokes properly from characters for training of the proposed system, the strokes are classified in the following categories:

Major Stroke: A stroke is called Major stroke if it occupies major part of the character. For the character 'অ' the major stroke is '৩'.

Minor Stroke: A stroke is called Minor stroke if it occupies minor part of the character. For the character 'অ' the minor stroke is 'া'.

Upper Stroke: A stroke is called Upper stroke if it occurs at the upper part of the character. For the character 'ই' the upper stroke is 'ই'.

Lower Stroke: A stroke is called Lower stroke if it occurs at the lower part of the character. For the character '০' the lower stroke is '০'.

Left Stroke: A stroke is called Left stroke if it occurs at the left part of the character. For the character 'ধ' the left stroke is 'ধ'.

Right Stroke: A stroke is called Right stroke if it occurs at the right part of the character. For the character 'অ' the right stroke is '৩'.

Matra: A stroke is called Matra if it is a horizontal straight line occurred at the upper part of the character. For the character 'অ' the major stroke is 'া'.

Depending on the positional information all stroke of a character are classified into above classes. This classification has two important roles in this recognition. As this is a stroke based approach, so training is done on all individual stroke. But this stroke are not collected separately rather they extracted, identified and classified from the character data. Second important role played by the stroke in time of matching of identified stroke in to characters. This time to overcome the problem of different sequence of stroke order even in case of same character, Major stroke and Matra are find out and they are placed at first and last position respectively in stroke sequence. This minimizes the permutation in tree structure and it gives a greater freedom to consider different confidence value of non major character.

IV. FEATURE EXTRACTION

Any online feature is very much sensitive to writing stroke sequence and size variation. A total of 105 features (90+15) are used for recognition. The features used are (i) Structural features (15) and (ii) Point based feature (90).

4.1 Structural features

Gradient (t_{N+1}):

$$t_{N+1} = n \begin{matrix} \text{৩} & \text{ধ} & \text{ধ} & \text{ধ} & \text{ধ} \\ \text{৩} & \text{ধ} & \text{ধ} & \text{ধ} & \text{ধ} \end{matrix} x_i y_i \quad x^2 - \begin{matrix} \text{৩} & \text{ধ} \\ \text{৩} & \text{ধ} \end{matrix} x \quad \begin{matrix} \text{৩} \\ \text{ধ} \end{matrix}$$

$$t_{N+2} = \begin{matrix} \text{৩} & \text{ধ} & \text{ধ} & \text{ধ} & \text{ধ} \\ \text{৩} & \text{ধ} & \text{ধ} & \text{ধ} & \text{ধ} \end{matrix} y_i \quad x^2 \quad \begin{matrix} \text{৩} & \text{ধ} & \text{ধ} & \text{ধ} & \text{ধ} \\ \text{৩} & \text{ধ} & \text{ধ} & \text{ধ} & \text{ধ} \end{matrix} x_i y_i \quad x_i^2 - \begin{matrix} \text{৩} & \text{ধ} \\ \text{৩} & \text{ধ} \end{matrix} x_i \quad \begin{matrix} \text{৩} \\ \text{ধ} \end{matrix}$$

Here t_{N+1} and t_{N+2} are the gradient and the intercept in the y-axis of the straight line, constituting by the consecutive 3-points respectively.

Length by Width ratio (t_{N+3}): $t_{N+3} = (\max(x_i) - \min(x_i)) / (\max(y_i) - \min(y_i)) \quad \forall \quad i = 0, 1, \dots, N$ By using this feature the ratio of the length and width of the corresponding stroke is calculated.

Standard Deviation (t_{N+4}): The standard deviation measures the spread of the data about the mean value. It is useful in comparing sets of data which may have the same mean but a different range. Here the deviation of each co-ordinate is calculated with respect to its mean value.

Normalized Start Co-ordinates and End Co-ordinates (t_{N+4}): In this feature only the first and last co-ordinates in the strokes of a character considered. Taking the first and last co-ordinates normalized them and stored them as feature.

Crossing of the lines: Here the co-ordinate position of the crossing of the stroke is stored with itself as shown in figure 6. In this system only first two crossing are considered.

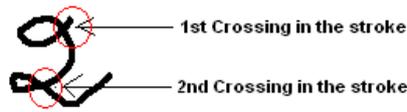

Fig. 6: Crossing points of a stroke.

4.2 Point based feature

The strokes are first normalized in to 30 points. The normalization is done in two stages. First the points are re-sampled to fixed number points and then they are converted from equal time sample to equal distant points. For example see Figure 7. The processed character is transformed into a sequence $t = [t_1, \dots, t_N]$ of feature vectors $t_i = (t_{i1}, t_{i2}, t_{i3})^T$ [4]. The following features were calculated:

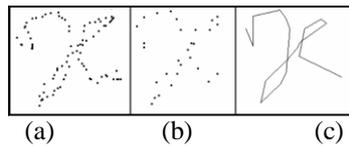

Fig. 7. Feature extraction from a sample stroke is shown. (a) Original stroke, (b) its normalized 30 points used as feature, (c) the normalized stroke.

Normalized horizontal (t_{i1}) and vertical (t_{i2}) co-ordinates: $t_{i1} = \frac{(x_i - \mu_x)}{\sigma_x}$ and $t_{i2} = \frac{(y_i - \mu_y)}{\sigma_y}$ are the pen co-ordinates normalized by the sample mean $\mu = \frac{1}{N} \sum_{i=1}^N P$ and standard deviation, $\sigma = \sqrt{\frac{1}{N} \sum_{i=1}^N P^2}$ of the character's sample points.

Tangent slope angle (t_{i3}): $t_{i3} = \arg((x_{i+1} - x_{i-1}) + j*(y_{i+1} - y_{i-1}))$, with $j^2 = -1$ and "arg" the phase of the complex number above, is an approximation of the tangent slope angle at point i .

Thus finally, a feature vector sequence is defined as $t = [t_1 \dots t_N t_{N+1} \dots t_{N+15}]$, each vector of it as $t_i = (t_{i1}, t_{i2}, t_{i3})^T$ is obtained. Here the number of points in which the character is normalized is (N) 30. So a total of 105 (30 X 3 [3 for each point] + 15 [15 local features based on Stroke]) features are used.

V. RECOGNITION

In this work, the recognition module has been divided into two parts: (i) Recognition of input strokes and (ii) Construction of valid character from recognized strokes.

5.1 Recognition of input strokes:

Based on the above-normalized features, a Multilayer Perceptron Neural Network based scheme was used for recognition of the strokes [18]. The Multi Layer Perceptron Network (MLP) is, in general, a layered feed-forward network, pictorially represented with a directed acyclic graph. Each node in the graph stands for an artificial neuron of the MLP, and the labels in each directed arc denote the strength of synaptic connection between two neurons and the direction of the signal flow in the MLP. For pattern classification, the number of neurons in the input layer of an MLP is determined by the number of features selected for representing the relevant patterns in the feature space and output layer by the number of classes in which the input data belongs. The neurons in hidden and output layers compute the sigmoidal function on the sum of the products of input values and weight values of the corresponding connections to each neuron.

Training process of an MLP involves tuning the strengths of its synaptic connections so that it can respond appropriately to every input taken from the training set. The number of hidden layers and the number of neurons in a hidden layer required to design an MLP are also determined during its training. Training process incorporates learning ability in an MLP. Generalization ability of an MLP is tested by checking its responses to input patterns which do not belong to the training set.

Back propagation algorithm, which uses patterns of known classes to constitute the training set, represents a supervised learning method. After supplying each training pattern to the MLP, it computes the sum of the squared errors at the output layer and adjusts the weight values of the synaptic connections to minimize the error sum. Weight values are adjusted by propagating the error sum from the output layer to the input layer.

The present work selects a 2-layer perceptron for the handwritten numeral recognition. The number of neurons in input and output layers of the perceptron is set to 105 and 59; respectively since the number features is 105 and the number of possible classes in hand written stroke considered for the present case is 59. The number of hidden units was set to 90, back propagation learning rate and acceleration factor is set to suitable values, based on trial runs. A network of 105-90-59 is thus finally designed.

5.2 Construction of valid character from recognized strokes:

Each character will be constructed with the help of its recognized strokes. To do so, all the probable sequences of strokes are stored in a tree structure that makes a valid character into a database. To build this a database report is generated from the raw data (characters), from which the sequences of strokes of the characters are gotten, that are generally used by people.

5.3 Construction of the Rule base:

The database has been designed using a tree structure to store the possible sequences of strokes of the characters. To store the sequences a stroke is considered as a root.

Figure 8 represent the stroke sequences of ‘ছ’. According to above tree structure, there exist two probable sequences of ‘ছ’. The first sequence is {b, -, 7} and second is {b, 7, -}.

The classifier returns a set of the recognized strokes with their corresponding confidence values. Here it is plain s to consider only the top three choices; number of choices can be extended in future as the system requirement. With these recognized strokes it will be tried to match those sequences with the stored sequence of strokes in the database. When a match will be found then the character recognized as a valid character and all the other combinations will be discarded.

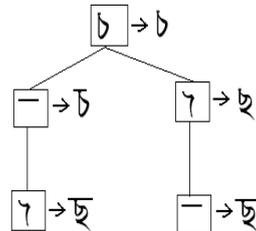

Fig. 8: Sample tree structure.

VI. RESULTS AND DISCUSSION

The experimental evaluation of the above techniques was carried out using isolated Bangla strokes. The data was collected from people of different background. A total of 21372 characters are collected for the experiment. Out of them strokes were extracted and total size of the stroke database used for the training was 30,000. One fourth of the strokes were used for the training of the classifier for the present work and rest will be used for the testing purpose.

6.1 Recognition result on isolated Stroke

The recognition rate of the isolated strokes was found to be 96.85% on the test set.

6.2 Recognition results on Bangla Character.

From the experiment it was found that the overall accuracy of the proposed scheme was 88.23% without rejection. The accuracy improved to 92.9%, if we consider first three top choices of the recognition results. The detail recognition results are given in Table 2.

Maximum error occurred between ‘ম’ and ‘স’ and it is noted that about 1.067% cases they miss-recognized one as the other. Here the difference between the above two characters is that there is a small loop in left bottom side of one of the character. Some times during handwriting people do not give this loop and hence miss-recognition occurs. The next erroneous character is ‘ষ’. It is misclassified with ‘খ’ and some time with ‘ম’, because difference between ‘ষ’ with ‘খ’ and ‘ম’ is that ‘খ’ have a small loop at upper left and ম have the loop at lower left other wise they are similar. Sometime writer do not give this small loop and neglect all other very small difference. ‘ষ’ is miss-recognized as ‘খ’ in 5 cases and miss-recognized as ‘ম’ in 8 cases. For details see Table 3.

Table 2: Top three recognition accuracy are shown.

Choices from top	Recognition rate
1	88.23%
2	91.57%
3	92.93%

Table 3: Maximum confusion pair arte shown.

Character	Miss-Recognized	
ষ	খ(8%)	ম(13%)
ম	ষ(1%)	স(1%)
ঢ	ঢ(1%)	
ন	ন(11%)	

This work describes a novel system of Online Bangla Handwriting Recognition. This work is on a preliminary stage and it is hoped that the result will improve when more and combinations of stroke will be added to the rule base. After completion of the first stage of isolated character recognition the system will be modified for unconstrained Bangla online text recognition. I think this work will be helpful for research in Bangla online handwriting recognition. However it not only help the development of Bangla script but also other Indic script which have a lot of similarity with Bangla script with adequate modification.

ABSTRACT: The push-to-talk technology provides a walkie-talkie like service for group communication. In this paper, we propose an efficient outbound voice traffic reduction scheme in the push-to-talk environment when network congestion happens. The Open Mobile Alliance push-to-talk over cellular (OMA PoC) architecture, the standard for this kind of group communication, is used as a base network in this paper. The PoC server plays an important role in copying and forwarding of received RTP media packets and the outbound voice traffic of this PoC Server tends to be affected by other traffic when network congestion happens. We extend the functionality of the Controlling PoC Server to accommodate the location information of PoC Clients by co-operating the location management server, which also communicates with the location reporting and packet forwarding agent node. By minimizing the outbound voice traffic of the PoC server, we improve the overall performance in terms of the end-to-end quality which is derived from the E-model. Simulation results show that the proposed scheme outperforms the existing PoC scheme when network congestion happens.

Keywords: Push-to-talk, group communication, OMA PoC architecture, voice traffic, network congestion

I. INTRODUCTION

Recently many Internet applications have been used widely in our lives for the proliferation of smart phones. Especially the concept of the VoIP has been used in many applications such as Skype, Viber, Voxer, TiKL *etc.*, which have potentials to replace the traditional voice communication through the public switched telephone network. There are many terms such as mVoIP, VoWLAN, and VoLTE that show the proliferation of this kind of packetized voice communication. Among applications which support VoIP, there are several VoIP applications such as Voxer, and TiKL which support the group communication as well as one-to-one communication, which is also known as the push-to-talk (PTT or P2T) [1, 2, 3]. This push-to-talk technology supports the half duplex communication among end-to-end users like the trunked radio system (TRS). Nextel communications was the first company to provide the push-to-talk service commercially using iDEN.

The Open Mobile Alliance (OMA) has standardized the technology for the push-to-talk over cellular (PoC) to support group communication among mobile subscribers through wireless networks since 2005. The OMA PoC architecture defines functional entities for the network configuration with the SIP/IP core including several SIP proxies and SIP registrars to support the push-to-talk service [1]. The control plane protocol is used as a signaling protocol which extends some of SIP procedures

for the group communication [4] and the user plane protocol is used to support media packet transmission and control the talk right [5].

The well-known problem in VoIP applications including PTT or OMA PoC is that the VoIP capacity is limited in wireless networks due to the small periodic voice data. Several researches on the VoIP system capacity in the IEEE 802.11 wireless LAN (WLAN) have shown that it has a very small threshold compared to the link bandwidth due to its medium access control (MAC) protocol [6, 7]. In addition, we observed that the outbound traffic of a PTT/PoC server, which receives a talker's voice data as an inbound traffic and transmits its copy to other group members, is seriously influenced by the other network traffic when network congestion happens. We will show the performance degradation of media packet flows through the simulation study.

In this paper, we propose an efficient scheme which reduces the outbound traffic of a PoC server, by which it decreases the packet delay and the packet loss caused by the network congestion. An efficient mechanism is provided in this paper to detect PoC Clients' registration and exchange control messages to manage the location information of PoC Clients. Also the PoC Server functionality is extended to use this location information of PoC Clients to reduce the outbound voice traffic. Simulation results show the performance improvement by the reduction of the outbound traffic. The simulation was performed using *ns-3* [8]. The mean opinion score is used as the main performance metric to measure the end-to-end quality, which can be derived from the E-model.

In Section 2, we describe the OMA PoC standard related to this paper. In Section 3 and Section 4, we present the proposed scheme to reduce the outbound voice traffic in the OMA PoC environment and show the performance improvement through the simulation study, respectively. Finally, we give a conclusion in Section 5.

II. OMA PoC

In this section, we describe the OMA PoC standard related to the proposed scheme. The OMA PoC standard is mainly divided into the control plane protocol [4] which is a signaling protocol similar the SIP [9] and the user plane protocol [5] which carries user's voice traffic based on RTP [10].

2.1 SESSION ESTABLISHMENT

Now we describe some of the control plane protocol related to the proposed scheme. Fig.1 shows the brief OMA PoC architecture which includes functional entities only related to the proposed scheme. The service logic for SIP sessions are implemented in the application server using SIP/UDP/IP. The application server functionality is implemented by the PoC server when the SIP/IP Core for

the PoC service is according to 3GPP/3GPP2 IP Multimedia Subsystem (IMS) [4]. Thus the SIP/IP Core and PoC Server functionalities may be in one physical entity. Media packets carrying users' voice data and the talk/media burst control for managing the talk right are transferred between PoC Clients and a PoC Server using RTP/UDP/IP [5].

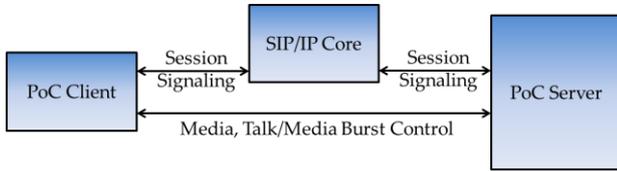

Figure 1. A brief OMA PoC architecture

The PoC Server performs either the Controlling PoC Function or the Participating PoC Function. In this paper, we call the PoC Server with the Controlling PoC Function and the Participating PoC Function as the Controlling PoC Server and the Participating PoC Server in short. The Controlling PoC Server mainly performs the management of PoC sessions such as the session establishment and the media burst control [4]. The Participating PoC Server performs relays the Talk Burst and Media Burst Control messages between the PoC Client and the Controlling PoC Server and may relay RTP media packets from the Controlling PoC Server.

Each PoC Client should register to their Participating PoC Server prior to participating in the PoC session according to rules and procedures of RFC 3261 [9] with extended headers including PoC feature tags [4]. Fig.2 shows the registration procedure of the PoC Client. In the SIP REGISTER request of the PoC Client, information such as the SIP URI and IP address of the PoC Client can be found. This information is used in the proposed scheme to keep the location information of PoC Clients.

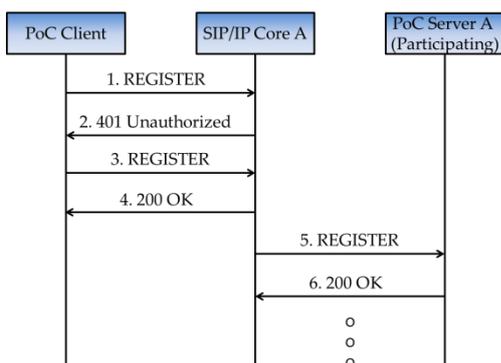

Figure 2. Registration procedure

PoC Session establishment is also made according to rules and procedures of RFC 3261 with extended headers including PoC feature tags as shown in Fig. 3 [4]. For simplicity, messages from/to the SIP Core are excluded from Fig.3 and only messages from/to OMA PoC entities are shown in the figure. Dotted arrows represent MBCP (media burst control protocol) messages,

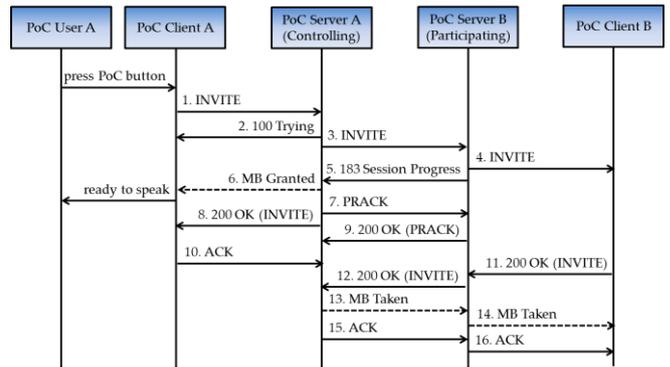

Figure 3. Ad hoc PoC Session establishment on-demand Session

which manages the talk right of PoC Clients [5]. There are four kinds of PoC Sessions: 1-1, ad-hoc, pre-arranged, and chat [4, 11]. In this paper, we are interested in the ad-hoc PoC Session and the pre-arranged PoC Session. In the ad-hoc PoC Session, the group information can be found from the recipient list in the SIP INVITE request. In the pre-arranged PoC Session, the group information is maintained by the Controlling PoC Server. Thus, we can find the group information when the SIP INVITE request is arrived at the PoC Server. A PoC Session can also be classified into the on-demand session and the pre-established session according to the time of the session establishment. The on-demand session is started when a user initiates the PoC Session with his/her recipient list [4]. The pre-established PoC Session is another method for the session establishment, which first makes a parameter negotiation to establish a PoC Session and RTP packet transmission is performed if required [4].

The determination of the PoC Server role of either Controlling PoC Function or Participating PoC Function takes place during the PoC Session setup and lasts for the duration of the whole PoC Session. In ad hoc PoC group sessions, the controlling PoC server is the PoC server of the inviting user. In pre-arranged PoC sessions, the controlling PoC server is the PoC server hosting the pre-arranged PoC group. That is, the Controlling PoC server is the PoC server of the domain that owns the URI that identifies the pre-arranged PoC group.

2.2 MEDIA TRANSFER

After either the ad hoc or the pre-arranged PoC Session is established, media packets including voice data are transferred between the PoC Server and PoC Clients. These media packets are transported by RTP/UDP/IP [5]. The PoC Server forwards received RTP Media packets towards all other PoC Clients that are not on hold [5], that is, the received packet is copied and forwarded to other PoC Clients in a group. The basic RTP header of media packets is described in RFC 3550 [10] and additional RTP payload formats for various audio/video codecs such as G.729A, GSM, EVRC and AMR are described in several RFC documents [12, 13, 14]. From the SSRC field of the RTP header, the PoC Server and PoC Clients can find who sends the RTP packet.

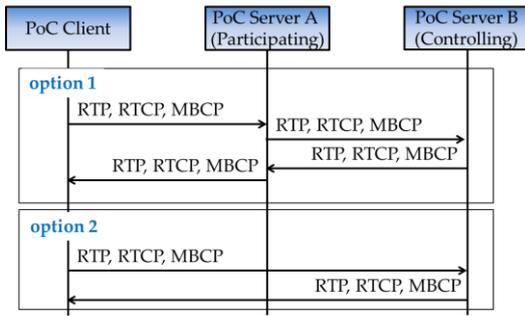

Figure 4. Media transfer options

Fig.4 shows two options that transfer voice data between PoC clients. In Option 1, the Participating PoC Server is in charge of transferring voice packets and also provides the filtering function and the transcoding function among different codecs. However the performance may be degraded due to the increased packet delay compared to Option 2 in which voice packets and other related packets are transmitted directly through the Controlling PoC Server. In this paper, we only consider Option 2 to support group communication. The incoming traffic and the outgoing traffic of a PoC Server are unbalanced because of its one-to-many communication pattern. Thus problems such as the traffic handling at a PoC Server and packet transmission to recipient PoC Clients occur especially when network congestion happens.

III. VOICE TRAFFIC REDUCTION SCHEME

In this section, we describe the basic concept and the algorithms used for the proposed scheme.

3.1 BASIC CONCEPT

Fig.5 shows the basic concept of the proposed scheme. We consider the situation of network congestion like Fig.5(a) which can make the transmission problem. For group communication, the Controlling PoC Server copies received RTP media packets from a PoC Client which has the media burst right and forwards those copies to all other PoC Clients in a group. Those RTP media packets are forwarded through the Internet with other packets generated by network applications such as FTP, email, web, etc. The nature of the Internet is basically the best-effort network due to the characteristics of the layer 3 protocol, IP. Thus this small amount of periodic RTP media packets can be easily damaged by other packets travelling the Internet, which will be shown in Section 4 through the simulation study. Dotted arrows in Fig.5 (a) indicate the possible packet loss while forwarding RTP media packets from the Controlling PoC Server to other PoC Clients.

The concept of the proposed scheme is shown in Fig.5 (b). Two functional entities have an important role in implementing the proposed scheme. The first one is the Controlling PoC Server, which exists in the OMA PoC standard. Its functionality will be extended by including a function to manage the location information of PoC Clients with the collaboration of a location management server which is newly introduced for the proposed voice traffic reduction scheme. The other one is the location reporting and packet forwarding (LRPF) agent

functionality, which supports to find OMA PoC Clients in the same network and manages received RTP media packets. The LRPF agent functionality can be easily implemented in routers, gateways or wireless access points in order to reduce the outbound voice traffic from the Controlling PoC Server. For example, a gateway and an access point are used in Fig.5 (b). Both the gateway and the access point are assumed that they are located in one-hop distance far from PoC Clients so that it is possible to forwarding media packets efficiently, which still has the voice capacity problem if it is a wireless network [6, 7].By reducing the outbound voice traffic from the Controlling PoC Server as small as possible, the interference from other traffic sources can be avoided significantly.

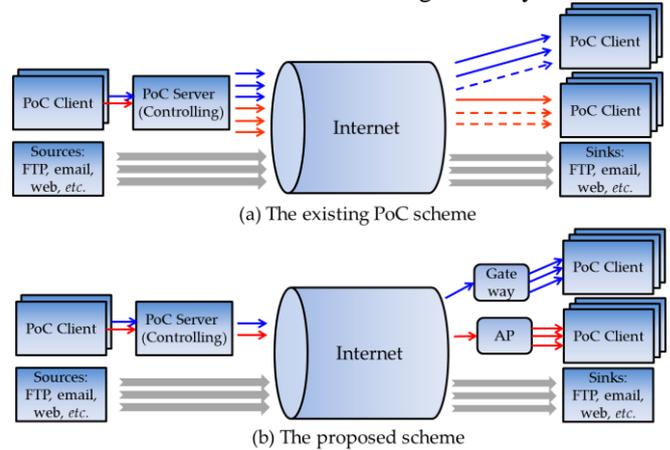

Figure 5. The basic concept of the proposed scheme

3.2 ALGORITHMS

First we define the notation used for the operations used in the proposed scheme.

- G : the set of groups, $G = \{G_i \mid 0 \leq i < k\}$
- G_i : the set of group members in the i -th group, $G_i = \{m_j^i \mid 0 \leq j < n\}$ for $n \geq 0$
- m_j^i : the j -th member of the i -th group
- V : the set of LRPF agent nodes, $V = \{v_i \mid 0 \leq i < l\}$
- $M_{v_i}^{G_x}$: the set of active group members of LRPF agent node v_i for the given group G_x
- C_{v_i} : the set of PoC Clients which are located with LRPF agent node v_i
- F_{sid} : the forwarding set of the current session, sid , for received RTP media packets
- M_{sid} : the set of active group member sets for v_i 's of the current session sid

Now we explain the operations for the LRPF agent functionality in Fig.6, which can be divided into three operations for PoC Client management, session establishment and RTP packet management. These operations are related to those operations in the location management server, which maintains the location information of PoC Clients and the group information. In

Operation I, the LRPF agent collects the information of PoC Clients in the same network by packet sniffing SIP REGISTER requests to Participating PoC Servers and then sends the information to the location management server. Operation II will be performed while the PoC Session is established. The Controlling PoC Server will send the information of a forwarding set for the new PoC session, which will be used for RTP packet forwarding in Operation III. We call the node which performs the LRPF agent functionality the LRPF agent node.

Operation I. PoC Client Management

1. do {
2. get a packet copy from every upward packets;
3. if the packet type is the SIP REGISTER request with the PoC feature tag {
4. send the tuple (v_i, m_k^j) to the location management server;
5. }
6. } while (true);

Operation II. Session Establishment

1. do {
2. wait the tuple message $(sid, M_{v_i}^{G_x})$ from the Controlling PoC Server;
3. make a forwarding set
 $F_{sid} = \{m_k^x \mid m_k^x \in M_{v_i}^{G_x}\};$
4. } while (true);

Operation III. RTP Packet Management

1. do {
2. wait a RTP packet;
3. get the session information, sid , from the RTP packet;
4. for every PoC Client $m_k^x \in F_{sid}$ {
5. make a copy of the received RTP packet;
6. send the copy to the PoC Clients m_k^x ;
7. }
8. } while (true);

Figure 6. Operations for the LRPF agent functionality

Operation I. LRPF Agent Node Management

1. do {
2. wait a tuple message (v_i, m_k^j) from any LRPF agent node;
3. add the PoC Client m_k^j to the PoC Client set of v_i , i.e., $C_{v_i} \leftarrow C_{v_i} \cup \{m_k^j\}$
4. } while (true);

Operation II. Session Establishment

1. do {
2. wait an INFO request from the Controlling PoC Server;
3. get the set of group members $G_x = \{m_k^x\}$ from the request;
4. prepare a forwarding set $F_{sid} = \{v_i \mid m_k^x \in C_{v_i}\}$ for every $m_k^x \in G_x$;
5. prepare the set of active group member sets for v_i 's of the current session
 $M_{sid} = \{(v_i, M_{v_i}^{G_x})\}$, where

$$M_{v_i}^{G_x} = \{m_k^x \mid m_k^x \in G_x \bigwedge m_k^x \in C_{v_i}\}$$

for every $v_i \in F_{sid}$;

6. send an INFO response with the tuple (G_x, F_{sid}, M_{sid}) to the Controlling PoC Server;
7. } while (true);

Figure 7. Operations for the location management server

Fig.7 shows the operations for the location management server (LMS), of which the functionality is introduced to manage the relationship between LRPF agent nodes and PoC Clients. In Operation I, LMS maintains the information of PoC Clients for each LRPF agent node while it receives a message from a certain LRPF agent node. In Operation II, LMS computes the forwarding set, F_{sid} , and the set of active group member sets, M_{sid} , for LRPF agent nodes for a given set of group members G_x whenever it receives an INFO request from the Controlling PoC Server. This information will be sent to the Controlling PoC Server and then sent to LRPF agent nodes from the Controlling PoC Server for RTP packet forwarding. This LMS functionality should be introduced since we cannot determine which PoC Server performs the Controlling PoC Function until the session establishment by the SIP INVITE request is started. One of PoC Servers in the system may perform this LMS functionality. Two messages of type INFO request and INFO response are introduced in the proposed scheme to exchange the required information between the Controlling PoC Server and LMS.

Operations for the Controlling PoC Server are described in Fig.8. Operation I is for the session establishment. We assume that the on-demand signaling is used for the session establishment, which enables the session initiation by looking up the SIP INVITE request. Whenever the Controlling PoC Server receives an SIP INVITE request, it retrieves the forwarding set, F_{sid} , and the set of active group member sets, M_{sid} , for LRPF agent nodes from LMS, which will be done by exchanging the INFO request and the INFO response. The information in the INFO response will be sent to all the necessary LRPF agent nodes for RTP packet transmission. Operation II is involved in the RTP packet management. When the Controlling PoC Server receives a RTP packet from a PoC Client, it forwards its copies to LRPF agent nodes in the forwarding set, F_{sid} , not to all PoC Clients. This makes the main difference between the existing PoC scheme and the proposed scheme. The outbound voice traffic is reduced to the amount of difference between the number of LRPF agent nodes and the number of PoC Clients. In general, the number of PoC Clients may be larger than the number of LRPF agent nodes because LRPF agent nodes are either gateways or access points and PoC Clients belong to one of them. Thus we can find easily that the outbound voice traffic will be reduced significantly if most PoC Clients are under the management of a few LRPF agent nodes.

Operation I. Session Establishment

1. do {
2. wait an SIP INVITE request with the PoC feature tag;
3. get the set of group members $G_x = \{m_k^x\}$ in the SIP INVITE request;

4. set the session id, sid , for the SIP INVITE request;
5. send an INFO request to the LMS with the group information G_x ;
6. receive an INFO response to get a tuple message (G_x, F_{sid}, M_{sid}) from the LMS;
7. send the tuple $(sid, M_{v_i}^{G_x})$ to the corresponding LRPF agent node v_i for every $(v_i, M_{v_i}^{G_x}) \in M_{sid}$;
8. } while (true);

Operation II. RTP Packet Management

1. do {
2. wait a RTP packet;
3. get the session information, sid , from the RTP packet;
4. for every LRPF agent node $v_i \in F_{sid}$ {
5. make a copy of the received RTP;
6. send the copy to the LRPF agent node v_i ;
7. }
8. } while (true);

Figure 8. Operations for the Controlling PoC Server

Fig.9 shows an example of the proposed scheme. For simplicity, we assume that two groups exist: $G_0 = \{m_0^0, m_1^0, m_2^0, m_3^0\}$ and $G_1 = \{m_1^1, m_2^1, m_3^1\}$. We also assume that PoC Clients m_i^j are located as shown in Fig.9 and thus they can be accessed through LRPF agent nodes v_0, v_1 , and v_3 . While PoC Clients register to their PoC Server, LRPF agent nodes collect and send the information to LMS, which is shown as dotted lines in Fig.9. Thus LMS has the information for PoC Clients and this information is used for processing the INFO request of the Controlling PoC Server. The information in the INFO response is used in Operation I and II of the Controlling PoC Server. The set of active group members of an LRPF agent node is sent to each LRPF agent node involved in the new PoC Session, which is used as forwarding set in an LRPF agent node to guarantee that invited PoC Clients will receive RTP media packets correctly.

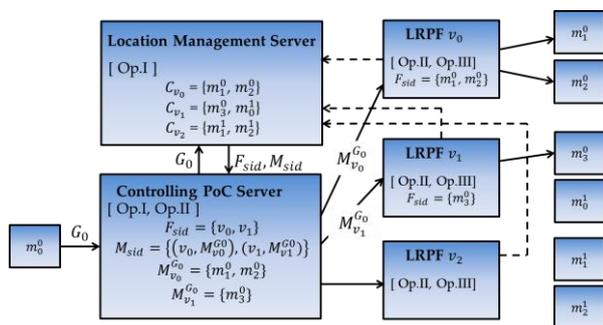

Figure 9. An example of the proposed scheme

IV. PERFORMANCE EVALUATION

In this section, we perform the simulation study to see the effect of the proposed scheme by reducing the outbound voice traffic of the Controlling PoC Server.

4.1 ASSUMPTIONS

Fig.10 depicts the network configuration used for the simulation. The PoC Server is placed in node 0 and a number of FTP sources are placed in node 3 and node 4 is

used as FTP sinks to see the effect of network congestion. In the shaded area of Fig.10, RTP packets for PoC compete with TCP packets for FTP for network resources to be transmitted to their destinations. $src(i)$ and $dest(i,j)$ nodes belong to the i -th group, where $0 \leq i < nGr$ and $0 \leq j < nGm$. nGr and nGm are the number of groups and the number of group members per group, respectively. RTP packets generated by $src(i)$ are transferred to the PoC Server in node 0 and then they are copied and forwarded to $dest(i,j)$ nodes for group communication. In the proposed scheme, we assume that both the LMS functionality and the PoC Server functionality are located in node 0 and the LRPF agent functionality is in every gateway, i.e., node 6, of destination networks.

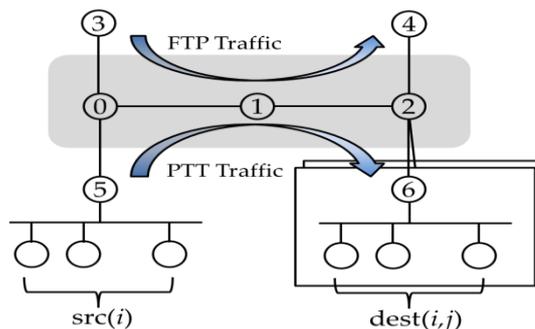

Figure 10. Network configuration for the simulation

We use the discrete-event network simulator *ns-3* [6] for the simulation study, which has been introduced as a replacement of the existing network simulator *ns-2*. To connect nodes, the class *PointToPointChannel* is used with attributes *DataRate* of 100Mbps and *Delay* of 1msec. $src(i)$'s and node 5 are connected using the class *CsmaChannel* with attributes *DataRate* of 100Mbps and *Delay* of 0.1msec to model the Ethernet although *ns-3* does not support the collision detect functionality. Destination networks are also connected using *CsmaChannel*. The queue size of *DropTailQueue* for both *PointToPointChannel* and *CsmaChannel* are fixed to 200. By this configuration, we can focus on the effect of network congestion for the outbound voice traffic of the PoC Server. Start times of $src(i)$ and FTP sessions are uniformly distributed in the time interval (1,3). G.729A is used as a voice codec since its bandwidth is low enough to be used in VoIP applications through the Internet [15]. We first assume that there is no bit error in transmission and then we perform the simulation to see the effect of the bit error.

4.2 SIMULATION RESULTS

We compare the performance of the proposed scheme with that of the existing PoC or PTT scheme in terms of MOS (mean opinion score) which is measured by using the E-model [16]. In legends of the following figures, 'ptt' and 'prp' represent the existing PoC/PTT scheme and the proposed scheme, respectively. We assume that the number of groups is 30, 40 and 50 and the number of group members is 10.

Fig.11 shows the MOS values of the existing PoC/PTT scheme and the proposed scheme. As the number of FTP sessions increases, we can find that the proposed scheme outperforms the existing PoC/PTT

scheme up to 95, 76 and 49% for 30x10, 40x10 and 50x10 group-members, respectively. MOS values of the proposed scheme are greater than 3.5 on the average, which means that some users are dissatisfied but most users are satisfied for the voice quality. But MOS values of the existing PoC/PTT scheme go down under 3.5 as the number of FTP session becomes greater than 30. Thus, we can find that the network congestion has a great effect on the performance of the existing PoC/PTT scheme. But the packet transmission of the proposed scheme was much less affected by the network congestion since the outbound voice traffic is significantly reduced by the number of group members compared to the existing PoC/PTT scheme.

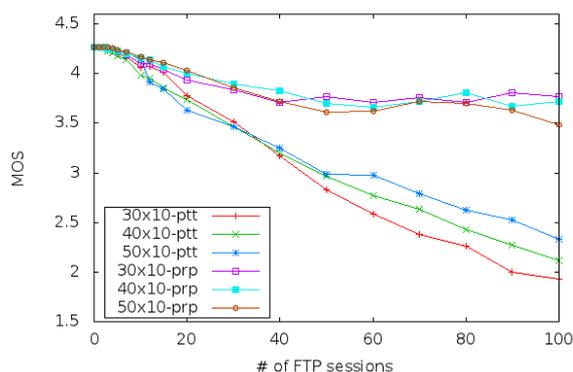

Figure 11. Comparison of the mean opinion score

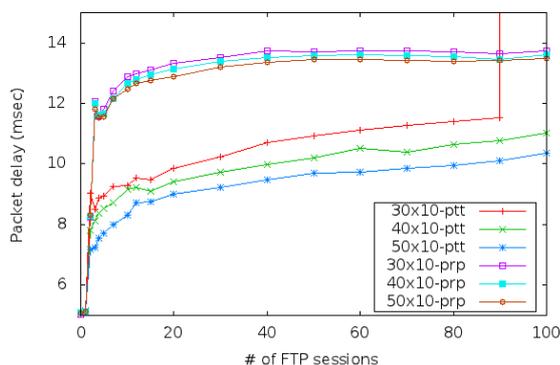

Figure 12. Comparison of the packet delay

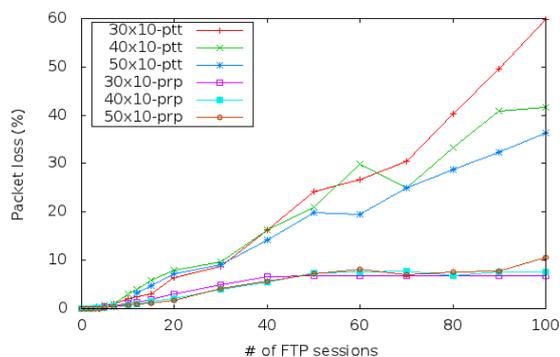

Figure 13. Comparison of the packet loss

Fig.12 and Fig.13 show the packet delay and the packet loss of the existing PoC/PTT scheme and the proposed scheme, which are two main components for the E-model. At first glance, the packet delay of the proposed scheme is larger than that of the existing PoC/PTT scheme. But the packet loss of the existing PoC/PTT scheme

becomes very larger than that of the proposed scheme as the number of FTP sessions increases. When network congestion happens, we can find that lost RTP media packets are the significant factor of losing MOS values, which degrades the overall end-to-end voice quality.

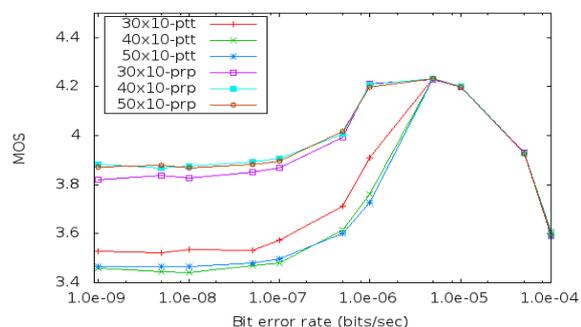

Figure 14. The effect of bit errors: MOS values (FTP=30)

Fig.14 shows MOS values when the bit error rate changes in case of 30 FTP sessions. As the bit error rate increases, the overall performance in terms of MOS values tends to be improved. When the bit error rate reaches 5e-6, all the simulation results show the best performance. After then, the overall performance degrades as the bit error rate increases. While the bit error rate is smaller than 5e-6, the FTP traffic dominantly uses the network. However, the FTP traffic makes no more influence to the PTT voice traffic while the bit error rate is greater than or equal to 5e-6 due to the congestion control of TCP which carries the FTP traffic, which will be explained in the simulation result of the packet loss in Fig.15.

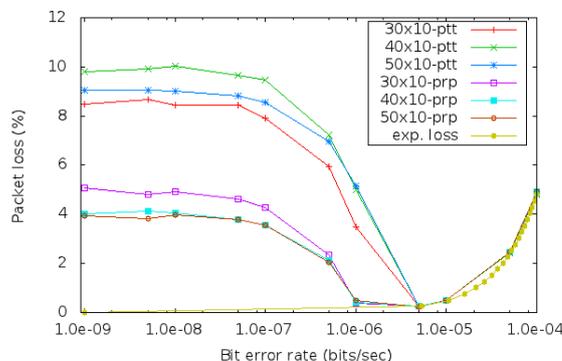

Figure 15. The effect of bit errors: packet loss (FTP=30)

The packet loss in Fig.15 shows also the same behavior as the simulation result in Fig.14. The expected packet loss, which is shown in Fig.15 as the line 'exp. loss,' can be obtained numerically. The RTP/UDP/IP header is of size 40 and G.729A generates 20 bytes per every 20 msec. Thus we can obtain the expected packet loss percentage in Eq.1 if we multiply the RTP media packet size by the bit error rate *ber*.

$$\text{Packet loss (\%)} = ber * (40 + 20) * 8 * 100 \quad (1)$$

The difference between the actual packet loss and the expected packet loss explains the effect of network congestion which results from TCP packet flows of FTP sessions. While the bit error rate is less than 5e-6, the packet loss is mainly affected by the FTP traffic. In this

case, the number of FTP sessions was assumed to be 30 so that there may be many TCP packet flows through the network, which prevent the outbound voice traffic from being forwarded to their destination PoC Clients. While the bit error rate is greater than or equal to $5e-6$, the packet loss shows the same result as the expected packet loss, which means that FTP sessions has no more effect on the outbound voice traffic.

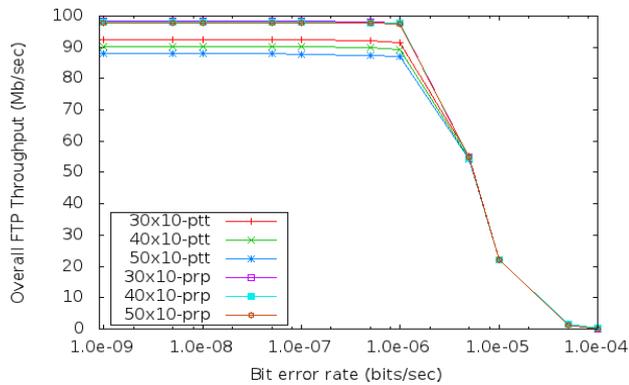

Figure 16. The effect of a bit error on the overall FTP throughput (FTP=30)

Fig.16 shows the overall FTP throughput for 30 FTP sessions as the bit error rate changes. We obtain this throughput by adding each throughput of 30 FTP sessions. While the bit error rate is less than or equal to $1e-7$, there is no significant performance degradation in terms of the overall FTP throughput. While the bit error rate is greater than $1e-7$ and less than $1e-6$, the overall FTP throughput declines a little bit but its effect on the RTP media packet has been diminished dramatically as shown in Fig.15, which results in the increase of MOS values in Fig.14. When the bit error rate is $5e-6$, the overall FTP throughput is about 55 Mbps and the outbound voice traffic is affected barely by the FTP traffic, which can be seen by the smallest packet loss in Fig.15 and the largest MOS value in Fig.14. As the bit error rate becomes greater than $5e-6$, the overall FTP throughput degrades dramatically to near 150 kbps. From Fig.15 and Fig.16, we can find that the network with the bit error rate greater than $1e-7$ has a significant effect on the TCP packet transmission as the bit error rate becomes larger but the small UDP packets such as RTP media packets carrying the voice data may be affected barely until the bit error rate becomes larger than $5e-6$.

The packet delay in Fig.17 also shows the same behavior at the center of the bit error rate $5e-6$. While the bit error rate is greater than or equal to $5e-6$, the packet delay seems very low. However, this low packet delay is meaningless because the packet loss is too high to get good end-to-end voice quality. Although the packet delay of the proposed scheme is greater than the one of the existing PoC/PTT scheme while the bit error rate is less than $5e-6$, the overall performance of the proposed scheme is much better than the one of the existing scheme due to the packet loss as shown in Fig.15.

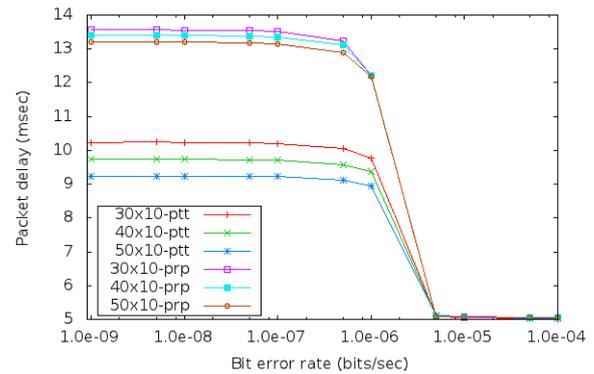

Figure 17. The effect of bit errors: packet delay (FTP=30)

V. CONCLUSION

In this paper, we proposed the efficient outbound voice traffic reduction scheme to improve the VoIP performance in the push-to-talk environment. The OMA PoC architecture has been standardized since 2005 to support the push-to-talk environment for the cellular network. In this paper, we used the OMA PoC architecture as the base network. We focused on the network performance in case of the network congestion since it has a great effect on the packet transmission. We have minimized the effect of the network congestion by reducing the outbound voice traffic of the Controlling PoC Server. We have presented three functionalities for the proposed scheme. The first one is the location reporting and packet forwarding (LRPF) agent functionality to obtain the location information of PoC Clients. The LRPF agent functionality can be located to either gateways or wireless access points because these nodes can easily see the packet transmission between PoC Clients in their network and the PoC Server. The second one is the location management server (LMS) functionality which is introduced to manage the location information of PoC Clients because the Controlling PoC Server can be determined after the SIP INVITE request is issued for the group communication and it is necessary to store the location information of PoC Clients somewhere. The last one is for the Controlling PoC Server where RTP media packets including voice data are copied and forwarded to their destination PoC Clients. The LMS functionality can be merged into one of PoC Servers for simplicity.

To see the performance of the proposed scheme, the discrete-event network simulator *ns-3* was used. We performed the simulation study in case of the network congestion which was caused by the FTP traffic using the same network resource. By reducing the outbound voice traffic of the Controlling PoC Server, the overall performance in terms of MOS has been greatly improved. We have shown the effect of TCP packets flows of FTP sessions on the packet delay and the packet loss, which are two main components affecting the E-model to obtain MOS values. Also we have shown the effect of the bit error rate on the overall performance of the proposed scheme. The bit error rate has a significant effect on TCP packets due to the TCP congestion control, but it has little effect on the RTP media packet until the bit error rate becomes larger than $5e-6$. Thus the proposed scheme outperforms the existing PoC/PTT scheme significantly when network congestion happens. Other network

congestion scenarios will be considered as a further research in case that either the UDP traffic such as media streaming or mixed traffic of FTP and UDP packets are used.

ABSTRACT: This paper reports the importance of familiarity within the distributed team and how it affects the performance of a distributed team. Various factors which influence the familiarity are presented. Pros and cons and the impact of these factors are discussed and reported in this paper.

Keywords: Team Familiarity, Global Software Engineering, Distributed team, Team Performance, Task Familiarity, Task complexity

I. INTRODUCTION

Now days, in organizations around the globe, employees who tend to work in distributed teams are increasing [7] [8] [9]. Employees who work in these teams work through tasks which are independent of each other but with a common goal, spread across distributed locations and roles communicating virtually through different types of media [8][9][10][11]. These teams totally rely on sharing knowledge between the members present in the team. This Knowledge sharing may include various activities which rely on the familiarity between the team members.

In various fields varying from science to software production, the development organizations focus mainly on finding ways to improve those factors which play an important role in organizations success [1][2]. A lot of attention is being focused on these factors which improve the overall productivity of the organization which in turn leads to success [3][4][5][6]. One such important factor that increases the organization success rate and productivity is the persisting familiarity between the team members. The following sections elucidate how team familiarity influences the overall performance of a team in a distributed setting and contributed to the success of an organization.

II. TEAM FAMILIARITY

Team familiarity or the familiarity between team members working in an organization can also be stated as the degree to which two members of a team identify themselves to be familiar based on the experience with work they had in the past [5]. Familiarity between team members helps the team members to work on independent tasks as well as efficiently communicate and co-ordinate. It can also be defined as the information or knowledge that the members present in a team consists or have an idea on the independent or unique tasks and activities in their area of work [12]. It is the collaboration, coordination and communication between the members of a team [13]. Team members who work together for a long time can actually have more familiarity within themselves and the tasks [14].

They share knowledge through which they can effectively interact with each other [15]. Team familiarity does not let alone contributes to the performance of a team, there are factors such as task complexity and task familiarity which influence team familiarity [16], which in return indirectly influences the team's overall performance and the co-ordination complexity involved in a team. Figure 1 explain the factors which influence the team familiarity and what factors get influenced by team familiarity in a distributed team. Lets us now consider looking at how task complexity and task familiarity affect team familiarity.

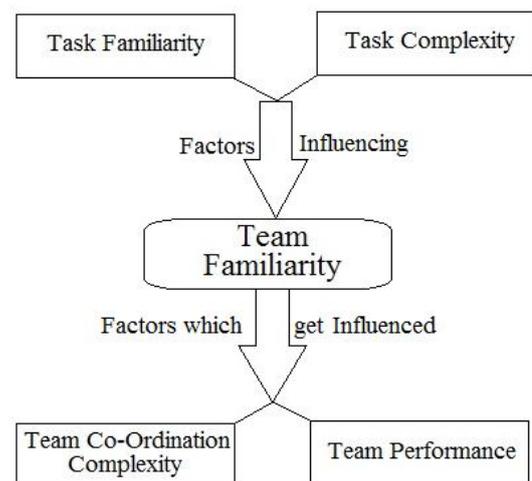

Fig.1 Factors influencing team familiarity and those which get influenced by it.

III. INFLUENCE OF TASK COMPLEXITY AND TASK FAMILIARITY ON TEAM FAMILIARITY

A study conducted by Goodman et.al [18] suggests that task familiarity influences the overall performance as, in distributed team environment each and every task needs unique requirements, configurations and activities from the team members. Knowledge which can be shared on these can improve the communication and coordination between the tasks and hence can improve the productivity. A study conducted by Argote et.al [19] reports that team members having some familiarity with the task can have a great effect on the performance when some characteristics of the task make it difficult for the members of the team to understand. Whereas, a study conducted by Goodman et.al [20] suggests that familiarity with the task is more effective for the simple or not so complex tasks. Familiarity is important in familiarity of the team members when there is a larger task as there would be a lot of changes to be handled, team members with prior experience and familiarity with the task can help in exactly locating where

the changes need to be made. The familiarity of the team members actually helps in negotiating with the complexity of the tasks making it easier to work in distributed teams with more team familiarity.

Empirical evidence suggests that familiarity with the task within the team members improves the performance of the team. A study Goodman et.al [18] conducted on distributed teams suggests that performance increased with the experience and familiarity of the task and has decreased the complexity of the task, i.e with the tasks being more complex in nature, though there exists familiarity in the teams and tasks the total output of performance in distributed task decrease with the increase in the complexity of the task. Simon's study [17] suggests that individuals who work on independent task may find it difficult to find solutions to problems than those who work together. Also a previous experience on how to solve the complex problem might help the fellow individuals to solve the problem while working in a distributed team. Through these observations, one can incur that team members who are familiar in dealing with task complexity might help in improving the performance of the distributed team.

IV. INFLUENCE ON TEAM CO-ORDINATION COMPLEXITY AND TEAM PERFORMANCE

Teams which have prior shared working experience or familiarity between the team members can start tasks with good expectations from the team members and can actually help in effectively communicating and can improve the team performance [21]. A better understanding of how their work contributes and how to obtain help from the fellow team members can help in improving the performance of the distributed team [21]. When the members of a team are familiar with the fellow team members, coordinating and understanding their roles and complement each other while working out on tasks helps in improving the performance of the team [21]. A study conducted by Harisson et.al [22] suggests that familiarity between team members helps in reducing the uncertainty and improves the team coordination; it actually helps in reducing the team coordination complexity and increase the trust between the team members. According to a study made by Campbell et.al [23] suggests that team familiarity will reduce the subjective complexity while coordinating with each other as they can think about ways as how to increase chances of effectively working, increasing the productivity.

V. ADVANTAGES AND DISADVANTAGES OF TEAM FAMILIARITY

Advantages:

- Team familiarity will help in reducing the extra efforts needed for improving coordination. Hence will save time, resources and money. Thus it always helps in improving the abilities to improve the communication and coordination between team members.
- It helps in increasing the trust between the team members which always help in improving the overall performance in distributed teams.
- Familiarity within the team members helps in reducing the need for frequent communication.

- It helps in providing collective knowledge about a task and helps in sharing knowledge between team members [22].
- It helps the team members to effectively channelize their work and distribute their work. It helps in making accurate and efficient work routines.

Disadvantages:

- To have familiarity between team member's organizations often arrange meetings parties and trips, which actually increases the overhead costs and making it more costly.
- If more and more time is spent in focusing on the familiarity between the team members, it affects the budgets and schedules.

VI. ANALYSIS & DISCUSSION

After having read and analyzing the reports of studies and articles published in the area of familiarity and how does it improve team performance, we can state that familiarity between the teams actually helps in improving the team's performance in a distributed setting. The familiarity of team members also depends on the familiarity with the task which in turn depends on how complex the task is, familiarity also depends on the coordination complexities which exist in a distributed team and how they can improve the performance. Though there is plenty of evidence stating that familiarity helps in improving the performance of the distributed team, there is always conflicting evidences which report that it can be beneficial only when there is large task and only familiarity is beneficial when there are small tasks. So it always conflicting reports that how the familiarity is based on the task size.

VII. CONCLUSION

Familiarity between the team members helps in improving the performance in a distributed team. To support this, various reports are presented and discussed. We have also reported the factors which influence it and how they influence each other. The advantages and disadvantages of team familiarity are also reported and thoroughly discussed.

Design and Fabrication of Composite Bumper for Light Passenger Vehicles

S. Prabhakaran¹, K. Chinnarasu², M. Senthil Kumar³

¹(Department of Mechanical Engineering, PSG College of Technology, India)

²(Department of Mechanical Engineering, Kalaingar Karunanidhi Institute of Technology, India)

³(Department of Mechanical Engineering, PSG College of Technology, India)

Abstract: The fuel efficiency and emission gas regulation of passenger cars are two important issues in these days. The best way to increase the fuel efficiency without sacrificing safety is to employ fiber reinforced composite materials in the cars. Bumper is the one of the part having more weight. In this paper the existing steel bumper is replaced with composite bumper. In this work the design and fabrication of composite bumper made up of glass fiber reinforced polymer is carried out by which weight of the bumper can be reduced. Fabrication of composite bumper is carried out by hand layup process by using E- Glass/ Epoxy bidirectional laminates. Composite bumper is analysed and Charpy impact tests are carried out. Compared to steel bumper, the composite bumper is found to have 64% higher factor of safety and 80% less in cost. From the fabrication it was found that the weight reduction of 53.8% is achieved using composite material without sacrificing the strength.

I. Introduction

A bumper is a shield made of steel, aluminum, rubber, or plastic that is mounted on the front and rear of a passenger car. When a low speed collision occurs, the bumper system absorbs the shock to prevent or reduce damage to the car. In existing bumper the weight is more. In the present trends the weight reduction has been the main focus of automobile manufacturers.

Less fuel consumption, less weight, effective utilization of natural resources is main focus of automobile manufacturers in the present scenario. The above can be achieved by introducing better design concept, better material and effective manufacturing process.

Steel bumper have many advantages such as good load carrying capacity. In spite of its advantages, it stays back in low strength to weight ratio. It is reported that weight reduction with adequate improvement of mechanical properties has made composites as a viable replacement material for conventional steel.

In the present work, the steel bumper used in passenger vehicles is replaced with a composite bumper made of glass/epoxy composites. The thickness of the composite bumper is calculated by bending moment equation and other dimensions for both steel and composite bumper is considered to be the same. The objective was to compare the stress, weight, and cost savings.

II. Bumper

The bumper is a safety system is used to observe the low speed collision. It is placed in car body. The car bumper is designed to prevent or reduce physical damage to the front and rear ends of passenger motor vehicles in low-speed

collisions. Automobile bumpers are not typically designed to be structural components that would significantly contribute to vehicle crashworthiness or occupant protection during front or rear collisions. It is not a safety feature intended to prevent or mitigate injury severity to occupants in the passenger cars. Bumpers are designed to protect the hood, trunk, grille, fuel, exhaust and cooling system as well as safety related equipment such as parking lights, headlamps and taillights in low speed collisions.

The national highway traffic safety administration (NHTSA) produces some bumper standard to the light passenger vehicle. The bumper standard, prescribes performance requirements for passenger cars in low-speed front and rear collisions. It applies to front and rear bumpers on passenger cars to prevent the damage to the car body and safety related equipment. The bumper standards are,

- The front and rear bumpers on passenger cars should prevent the damage to the car body.
- Bumper should withstand at a speed of 2 mph across the full width and 1 mph on the corners.
- Bumper should also withstand 5 mph crash into a parked vehicle.
- Placement of the bumper is 16 to 20 inches above the road surface.

So all bumpers should satisfy the above standards.

2.1 Requirements of Bumper Material

- It should absorb more energy while collision.
- It should have good rust resistance.
- It should have high strength.
- Light in weight.
- Easy to manufacture in large quantity.
- Low cost.

III. Composite Bumper

In recent days, various materials like composites are experimented in almost all parts of the automobiles and it has also ventured into bumper. Due to reduction in weight, composite materials are preferred over conventional steel bumper. Composite bumper absorbs more collision energy than steel bumper.

3.1 Advantages of Composite Bumper

One of the most advantageous reasons for considering their use over steel is their reduced weight.

- Absorb more collision energy.
- Excellent corrosion resistance.
- High impact strength.

- Material properties of composite bumper allow rapid response to induced or release stress.

3.2 Glass Fiber

The aim of fiber reinforced plastics is to combine the stiffness and strength of fibrous material. This material has corrosion resistance, low density and mould ability. The majority of reinforced plastics produced today are glass reinforced epoxy or polyester resins, both of which are thermosetting.

Glass fibers have also been used with phenolics, silicones, polystyrene and polyvinyl chloride. Glass fibers are the obvious choice as reinforcing agents, principally because of the relative ease with which high strengths can be obtained fiber a few microns in diameters.

It is possible to produce composites with a range of strength according to glass content and nature of the reinforcement. The epoxy resins have lower shrinkage than the other resins.

3.2.1 Properties

Some of the basic properties of glass fiber are,

- Specific Strength
- Low density
- Corrosion resistance
- Impact resistance
- Electrical properties

3.2.2 Different Types of Glass Fibers

Glass is the most common fiber used in polymer matrix composites. The most commonly used glass fibers are E-glass, S-glass, R-glass, C-glass and D-glass fibers. The E in the E-glass stands for electrical as it was designed for electrical applications. E-glass fiber is a high quality glass fiber used as a standard reinforcement for all the resin systems and as a well complying with mechanical property requirements.

Thus E-glass fiber was found appropriate for our applications. In S-glass S stands for higher content of silica. It retains its strength at high temperature and has higher fatigue strength. It is used mainly in aerospace applications. In C-glass C stand for corrosion, it is designed to give improved surface finish. It is available usually in the form of a surface tissue for the reinforcement of corrosive barriers in chemical plant. In D-glass D stands for dielectric used for applications requiring low electric constants.

3.2.3 Advantages of Glass Fibers

Glass fiber is most widely used as are reinforcement of all composites due to the following advantages:

- Molten glass easily drawn into high-strength fibers
- Readily available/easy to fabricate
- Relatively strong fibers produce very high strength in composite form
- Chemically inert in plastics.

These materials are limited to low temperature applications where strength is important without the need for high rigidity. Typical uses for this material are boat hulls, flooring materials and automobile bodies.

The main type of glass used is E-glass. However, it is used for many other purposes now such as decorations and structural applications.

3.3 Epoxy Resin

Epoxy resins are the most commonly used resins. They are low molecular weight organic liquids containing epoxide groups. Epoxide has three members in its ring, 1 oxygen and 2 carbon atoms. The reactions of Epichlorohydrin with phenols or aromatic amines make most epoxies. Hardeners, plasticizers and fillers are also added to produce epoxies with a wide range of properties of viscosity, impact, degradation, etc. Although epoxy is costlier than other polymer matrices, it is the most popular PMC matrix. More than two thirds of the polymer matrices used in aerospace applications is epoxy based. The main reasons for epoxy being the most used polymer matrix materials are

- Good compatibility with Glass fiber
- High strength
- Low viscosity and low flow rates, which allow good wetting of fibers and misalignment of fibers during processing
- Low shrink rates which reduce the tendency of gaining large shear stresses of the bond between epoxy and its reinforcement.
- Available in more than 20 grades to meet specific property and processing requirements.

IV. Design of Composite Bumper

For designing the composite bumper an already existing ambassador steel bumper is used as mould. Dimensions are assumed as same as that of steel bumper for fabrication.

4.1 Dimensions And Properties of Existing Steel Bumper

Effective length	= 0.975m
Total length	= 2.055m
Thickness	= 0.002m
Effective breath	= 0.078m
Total breath	= 0.172m
Weight	= 5.16kg
Material	= mild steel (chromium coated)
Tensile strength	= 460MPa (design data book)
Density	= 7800 kg/m ³

The moment for steel and composite bumper is assumed to be same. Therefore the moment for steel is

$$\frac{M}{I} = \frac{\sigma}{y}$$

Where,

M = Bending moment (Nm)

I = Moment of inertia (m⁴)

σ = Tensile strength (N/m²)

y = d/2,

d = thickness of the bumper (m)

b = breadth of bumper (m)

Moment of inertia for rectangular section:

$$I = bd^3/12$$

There are three sections in the bumper I₁, I₂, I₃ respectively.

$$I_1 = 0.058 \times 0.002^3/12 = 3.86 \times 10^{-11} \text{ m}^4$$

$$I_2 = 0.078 \times 0.002^3/12 = 5.2 \times 10^{-11} \text{ m}^4$$

$$I_3 = 0.058 \times 0.002^3/12 = 3.86 \times 10^{-11} \text{ m}^4$$

$$I = I_1 + I_2 + I_3 = 1.2932 \times 10^{-10} \text{ m}^4$$

Tensile strength of the steel = 460 x 10⁶ N/m² (from PSG data book)

The moment equation,

$$\frac{M}{1.2932 \times 10^{10}} = \frac{460 \times 10^6}{\frac{0.002}{2}}$$

M = 59.4872 Nm.

4.2 Thickness of the Composite Bumper

Thickness of the composite bumper can be determined by the formula,

$$\frac{M}{I} = \frac{\sigma}{y}$$

There are three individual sections, so to find them individually by using above formula,

$$\frac{59.4872}{\frac{0.058x d_1^3}{12}} = \frac{490 \times 10^6}{\frac{d_1}{2}}$$

$d_1 = 3.543 \times 10^{-3} \text{ m}$

$$\frac{59.4872}{\frac{0.078x d_2^3}{12}} = \frac{490 \times 10^6}{\frac{d_2}{2}}$$

$d_2 = 3.055 \times 10^{-3} \text{ m}$

$$\frac{59.4872}{\frac{0.058x d_1^3}{12}} = \frac{490 \times 10^6}{\frac{d_1}{2}}$$

$d_3 = 3.543 \times 10^{-3} \text{ m}$

Average thickness (d) = $d_1 + d_2 + d_3 / 3 = 3.38 \text{ mm}$

A layer of E-glass mat thickness is 0.2mm, so 17 layers are required for fabricating composite bumper.

4.3 Force Acting On the Bumper (F)

Force (F) = m*a

Where,

m = mass of the vehicle crashed on the bumper (1554kg)

a = acceleration due to gravity (m/sec^2)

$a = (u - v) / t$

Where,

v = Final velocity after collapsing (m/sec)

u = Initial velocity before collapsing (m/sec)

u = 8km/hr = 2.22 m/s (taken from NHTSA)

t = time taken for collapsing (sec)

$a = (2.22 - 0) / 0.1 = 22.22 \text{ m/sec}^2$

Force (F) = 1554 x 22.22 = 34529.88 N

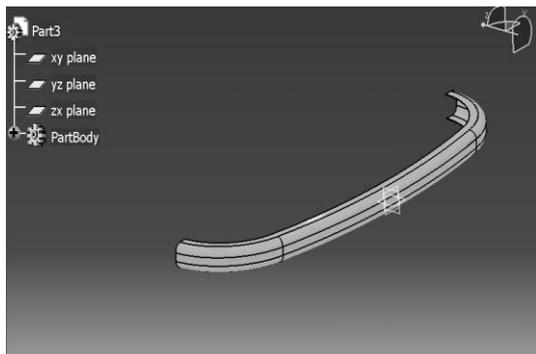

Fig 4.1 Model of the Bumper

4.4 Model of the Bumper

The load applied on the bumper is not a point load; it is a uniformly distributed load (pressure load). So calculation pressure load is given below.

Pressure (P) = F/A

F = force acting on the bumper = 34529.88 N

A = front area cross section = 2055 x 78 = 160290 mm^2

P = 34529.88 / 160290 = 0.13 N/mm^2

4.5 Drafted Model of the Bumper

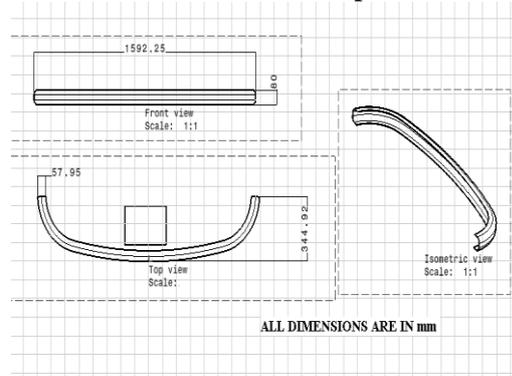

Fig 4.2 Drafted Model of the Bumper

V. Fabrication of Composite Bumper

In Hand lay-up, liquid resin is applied to the mould and then fiber glass is placed on the top. A roller is used to impregnate the fiber with resin. Another resin and reinforcement layer is applied until a suitable thickness builds up. It is very flexible process that allows the user to optimize the part by placing different types of fabric and mat materials. Because the reinforcement is placed manually, it is also called the hand lay-up process. Though this process requires little capital, it is labor intensive.

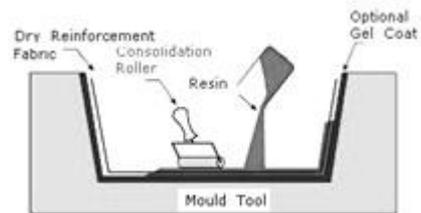

Fig 5.1 Hand Layup Process

5.1 Basic Raw Material

- E-Glass fibers
- Epoxy resin
- Hardener
- Wax

5.2 Tools Required

The mould design for the hand lay-up process is very simple as compared to other manufacturing process because the process requires room temperature to cure with low pressures. In this project existing bumper is used as mould.

5.3 Fabrication of Bumper

In the hand lay-up process the thickness of the composite part is built up by applying a series of fiber glass layers and liquid resin layers. A roller is used to squeeze out the excess resin and create uniform distribution of the resin throughout the surfaces. By the squeezing action of the

roller, homogeneous fiber wetting is obtained, the part is then cured at room temperature for about one week and once solidified it is removed from mould. The cost making one composite bumper is around Rs.820.

5.4 Advantages of Hand Lay-up Process

Very low capital investment is required for this process because there is negligible equipment cost as compared to other processes.

- The process is very simple and versatile. Any fiber type material can be selected with any fiber orientation.
- The cost of making a prototype part is very low because a simple mold can be used to make the part. In addition, the raw material used for this process is liquid resin, mat and fabric, material, which are less expensive than preparing material.

5.5 Limitations of Hand Lay-Up Process

- The process is labor incentive.
- The process is mostly is suitable for prototype as well as for making large structures.
- Because of its open mold nature,
- Styrene emission is major concern.
- The quality of the part produced is consistent form part to part. High fiber volume fraction cannot be manufactured using this process.

VI. Charpy Impact Test

The purpose of impact testing is to measure a material’s ability to resist high rate reading a material’s ability to resist impact often is one the determining factor in the service life of the material. Impact testing commonly consists of charpy and izod specimen configuration.

6.1 Charpy Impact Test Machine

The charpy impact test, also known as the charpy v-notch test, is a standardized high strain rate test which determines the amount of energy absorbed by a material during fracture. This absorbed energy is a measure of a given material’s toughness and acts as a tool to study temperature-dependent brittle-ductile transition. It is widely applied in industry, it is easy to prepare and conduct and result can be obtained quickly and cheaply. But major disadvantage is that all results are only comparative.

Fig 6.1 Charpy Impact Test Machine

6.2 Charpy Test Specimens

Charpy test specimens normally measure 55*10*6mm and have a notch machined across one of the larger faces. The notch dimensions are v-shaped notch, 2mm deep, with 45° angle and 0.25mm radius along the base.

6.3 Experimental Result

DESCRIPTION	COMPOSITE	STEEL
Cross sectional area, A (mm ²)	40	40
Impact value ,I (J)	294	163
Impact energy (J/mm ²) (I/A)	7.35	4.07

Table 6.1 Experimental Result

VII. Analysis of Composite Bumper

The Ansys computer program is a large scale multipurpose finite element program, which may be used for solving several classes of engineering analyses. The analysis capabilities of Ansys include the ability to solve static and dynamic structural analyses, steady state and transient heat transfer problems, mode frequency and buckling eigen value problems, static or time varying magnetic analyses and various steps of field and coupled-field applications. In this project Ansys 10.0 has been used as a tool to achieve the project target. The static-nonlinear analysis is carried out to find out the deformation, stress distribution over the structure.

7.1 Description for Steel and Composite Bumper

DESCRIPTION	STEEL	COMPOSITE
Element type	Solid186	Solid191
Pressure Load (N/mm ²)	0.13	0.13
Young’s modulus(N/mm ²)	2x10 ⁵	78x10 ³
Poisson ratio	0.3	0.27

Table 7.1 Description for Steel and Composite Bumper

7.2 Boundary Condition

Two ends of the bumper are fixed for supporting purpose. It is common for both steel and composite bumper. Bumper is arrested at 547.88mm from center to both the ends.

7.3 Stress Distribution for Steel Bumper

Fig 7.1 Stress Distribution for Steel Bumper

Maximum stress = 369.168 N/mm²
 Minimum stress = 0.003924 N/mm²
 Ultimate stress for steel = 460MPa (PSG design data book)
 Factor of safety = Ultimate stress/Working stress = 460/369.16 = 1.2

7.4 Stress Distribution of Composite Bumper

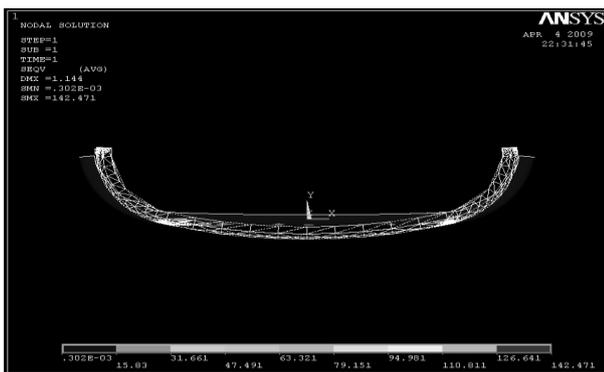

Fig 7.2 Stress Distribution of Composite Bumper

Maximum stress = 142.471 N/mm²
 Minimum stress = 0.302x 10⁻³ N/mm²
 Ultimate stress for composite = 490MPa (composite hand book)
 Factor of safety = ultimate stress/Working stress = 490/142.471 = 3.4

7.5 Results of FEA

DESCRIPTION	STEEL BUMPER	COMPOSITE BUMPER
Max. stress (N/mm ²)	369.168	142.471
Min. stress (N/mm ²)	0.003924	0.302x 10 ⁻³
FOS	1.2	3.4

DESCRIPTION	STEEL BUMPER	COMPOSITE BUMPER	% OF REDUCTION
Weight	5.15	2.38	53.78%
Cost	3600	820	77.22%
Impact strength	3.25	7.35	-
Max stress(N/mm ²)	369.168	142.471	-
F.O.S	1.2	3.4	-

Table 7.3 Comparison

IX. Conclusion

Design, fabrication and testing of steel and composite bumper (using glass fiber material) are completed and also composite bumper is analyzed and compared with steel bumper. The steel bumper weighs about 5.15Kg where the weight of composite bumper is 2.38kg. Which is 53.8% lesser than steel bumper. It is proved that fuel economy of the vehicle is improved as the composite bumper weighs less when compared with steel bumper. Cost of composite bumper is Rs. 820/- which is 80% less than steel bumper. Impact strength of composite bumper is 7.35 J/mm² where steel bumper is 3.25 J/mm². The existing and composite bumper are analysed in ANSYS10.0 and the Maximum stress induced in the composite bumper is 159.36 N/mm² where steel is 292.669 N/mm². Factor of safety for composite bumper is increased by 64%. From the study, it is concluded that fiber reinforced plastic material is a suitable material for manufacturing the bumper.

Effect of Acoustic on Students' Performance in Secondary Classroom Environment: A Review

Mohammad Moslemi Haghghi¹, Loh Ee Chiao²,
Mahmud Bin Mohd Jusan³

**(Department of Architecture, Universiti Teknologi Malaysia, Malaysia)*

*** (Department of Education, Universiti Teknologi Malaysia, Malaysia)*

**** (Department of Architecture, Universiti Teknologi Malaysia, Malaysia)*

ABSTRACT: Poor acoustical environments in school, makes reduction of the talking signal, which may impact teachers' voice problems, reduce students' performance and enhance off-task behavior of them. Not only teachers, but also students implied that because of weak acoustic of the class, the interaction and communication have problem in the classroom. The aim of this paper is to understand the effects of acoustic troubles in the classroom on students' working based on their viewpoints and solve their problems. Most of researchers used qualitative and quantitative methods to collect data for their research from the school students. Among all elements students' opinion and their requirements according to the performance and noise are mostly three options. Students put more emphasis on distance and proximity between student-teacher. Other options like white noise, reverberation are the following and last step respectively to make appropriate situation for students' acoustic problems according to students' viewpoint. Consequently, arrange appropriate seating is the major element that can answer the acoustical problems and boost students' performance in the classroom environment.

Keywords: Acoustic, Classroom, Noise, Performance, Student

I. INTRODUCTION

Teaching space are the highest spots in educational-instructional activities. Speech in a classroom is transferred through a grouping of direct and reflected sound from the teacher to students. Direct sound moves to the listener in a straight line, without being reflected from its source. Reflect sound before traveling to listener, arrives at some objects or surfaces in a room [1], [2]. In the classroom, the main sources of energy are reflected sound at distances which eliminated of the teacher and direct sound energy is highest prevalent at distances near to the teacher [3]. Reflected and direct sounds improve classroom communication and make capable students in the classroom to hear the teacher when combined properly in a quiet classroom [4].

Research has shown that new as well as old school has acoustical problems and can seriously influence a child's capability to comprehend [5], [6]. To prepare sound systems and evaluate room acoustics acoustic principles have been clarified and technologies to explain the acoustical troubles in classrooms [7], [4]. From the other point of view, most students would have hard moments to understand hear and the teacher of classroom if being in a

classroom was the similar as being out-of-doors since direct sound is comparatively weak [8], [1]. The energy of the speech of human -at close distance is comparatively weak noticeable in microwatts [9].

Classrooms do not need a great deal of sound diffusion and designed mostly for listening to speech [4]. But the absorptive and reflective attributes are significantly essential of the room. The absorption and reflection of sounds can interfere when not controlled correctly in classroom listening. For instance, some of the most regularly used carpet on foam rubber padding and acoustic ceiling tile as absorbent materials in school classrooms. These kinds of materials absorb high-frequency sounds much better than low-frequency sounds. Consonant sounds, which are mainly high frequency, are not returned well when the floor and ceiling are treated with these materials and speaking fluency is destroyed [1], [10].

Same as acoustic, physical environment in the classroom influences students' performance. Students are more probably to have difficulty to be on their duty, since they are not able to listen successfully in school; also cooperation and obedience are hard to support [11]. Specifically, poor class room acoustics are also influenced children with one-sided losses and minimal hearing losses [12], [13]. Students that have learning shortages may be adversely influenced due to the fact that they regularly require syntactic, semantic, phonologic, and pragmatic disarranges that restrict their interaction capabilities in poor classroom acoustics [14], [15]. Consequently, to generate strong district in the classroom and promote students' learning, classroom needs relax manner and attractiveness [16], [17].

II. LITERATURE REVIEW

While constructing new places for schools, there are a number of objects needs into consideration—starting with the location. Building by the side of a highway, an airport or train tracks is noticeably not suggested. But it is not just outside noise must be considered, building schools that optimize speech intelligibility and reduce reverberation make suitable classroom about acoustics.

Acoustical problems in schools prepare the learning difficulties for all group of study such as school of beginners, second- language learners, youngsters with hearing losses and children with learning shortages [7], [18]. because school beginners language, speech, and listening talents have not developed, school beginners have more problems learning in classrooms compare to others

and making it hard for both young students and teachers to speak with each other [19], [20].

Several teachers are able to project their voices with strong voices without tiring for long amount of time. Others teachers have comparatively weak voices and when imposed to raise their voice level, they become stressed. Teachers are also more exhausted when teachers transfer their voices to compensate for high noise levels at the end of the day of school [7]. Noise levels of classroom sometimes are too high that teacher can conquer with verbal attempt and the result is damage of a teacher's vocal mechanism [21]. Noise of the classroom has been exposed to influence teachers' function [22], [23]. For instance, one scientist [23] gained data regarding the effects of noise in the classroom from more than 1.200 teachers.

Some researchers have concentrated on the impacts of noise, distance, and reverberation. Moreover, there is more concentration to listen the troubles of unusual students, students which are disengagement, the voice of teacher, and teacher tiredness [24], [7]. The perfect conveyance of information about acoustic is essential for best academic success in a classroom. The teacher's voice level, background noise and distance from the teacher to the child are acoustical variables that can compromise perceptual abilities.

Background noise levels relate to all typical noise sources offer in a learning space (excepting students' sound within that educational space and teachers' sound) and also it would be narrow to confirm sufficient speech interaction. Background noise inside the classroom related to any unwanted aural that students' needs, or wants, to comprehend and hear but this noise disturb them [25].

Inside the class the noise sources contain interior noise (noise that makes of inside the building, but outside of the classroom, such as classrooms next to lecture rooms, canteens, and/or busy corridors), exterior noise (noise which is produced from outdoor of the building, such as local construction, traffic of airplane, playground and vehicle transportation) and noise of room (noise that is produced inside the class) [26], [27]. To conceal the teacher's talking the capability of classroom noise depends on amount of acoustical factors [28], [29]. Background noise is capable of compromise educational performance, spelling skills and reading, attentiveness, attention, and behavior in children [30], [31].

The noise levels incline to influence focus and consideration more critically in children with high anxiety levels or lower IQs [32]. Background noise levels were significantly connected to read scores in elementary school-age children in classrooms [33]. Reductions in classroom noise had a considerable result on rising attentiveness, focus and sharing behavior among children [34].

Reflected sound waves or Echoes are postponed and adequately strong to be separate from the original sound source. They are probable to happen where the behind wall has a tough surface such as classrooms. Echoes impact the level, intelligibility and quality of the sound although they are not generally heard as separate phenomena [1], [35]. Classroom echoes are frequently more of a problem than classroom reverberation despite the fact that much highlighting has been located on reverberation [8], [36]. The most significant acoustical crisis within classrooms is extreme white noise even though classroom

echoes, modes, and reverberation can influence speech intelligibility in a room, which covers the teacher's talking.

The last factor that affects speech awareness is the gap between teacher and student in the classroom. Actual distance from the student to the teacher, Holliman and Anderson named it proximity and calculated in centimeters [37]. The direct sound field controls in the listening environment when proximity relatively adjacent to the child. Compare to students in any other row, the first two rows students' performance was better [37].

The space between students and teacher can powerfully impact speaking comprehension. Since the significant distance of the room is reached, speech perception scores reduce [38], [39]. A current study of the influence of student-teacher proximity on speech recognition marks was managed with students between 5 to 7 years of age by Crandell [18]. Student's scores were associated to the proximity between student and teacher [40]. Students' positions when it is close to the rear of the class were related with weaker academic performance [41].

III. INDICATORS

Scientists know that students merit the best ideal environment for studying, particularly in a classroom someplace they are able to hear clearly the teacher's speech (closeness). Students also have to answer to the question and focus entirely on their learning. Experiments of classrooms in secondary school level exposed that extreme background noise, which contests the speaking of teachers and decreasing reverberation and background noise inside the classrooms would be maximum valuable to the students with weak acoustics that can create the educational plan unreachable for the students.

The three acoustical independent variables affect students' performance in Fig. 1. Therefore, it is significant to obviously explain and describe the main viewpoints of efficient characteristics in the framework of following performance of students' area based on their requirements.

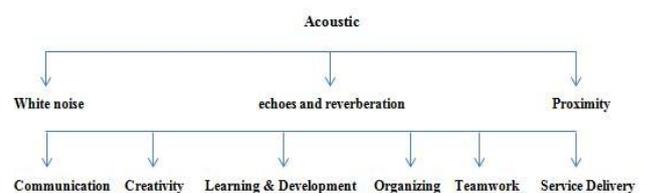

Fig. 1. Influences of acoustic features on students' performance

IV. METHODOLOGY AND FINDING

Most of researchers employed mix method to gather information of students within the classroom. They used questionnaire to obtain pure information which directly take of students' requirements and their points of view. By investigating of students about acoustic crisis in the classroom and compare with other researchers' experiments according the acoustical problems, we could get suitable knowledge to solve students' problems.

Qualitative and quantitative approaches allow understanding students' interaction, learning and physical attribute on students' performance. For example, most of researchers prepared questionnaire as a quantitative method to determine the connection of students' performance and

noise effects, especially measured the students' beliefs about acoustic problem in the classroom. Extract students' viewpoints may be determined by suppositions depend on previous knowledge or by accessibility within the classroom.

For the qualitative part, most of authors were emphasized on observation as a qualitative method to reach deep opinion of students and get the real beliefs. Generally, students were asked to indicate which elements of noise affected more on their performance in the classroom and were observed to measure which items affects more compare to others. By this way, most of analyses showed that physical elements of classroom especially echoes and noise were noticeable enough to disturb the learning of students and quality of their performance even slight hearing disorder.

Several researchers also employed interview to identify information from students and recognizes complete opinion of students based on their performance. Majority of interviews part used an open-ended style and based on the questionnaire data partial of that used as a semi-structure. According to the data gained of interviews with several of students and study of the related literature several items were arranged so cautiously to collect students' opinion of their studying and to contain performance.

The amount of elements needed by the investigation based on eigenvalue principles is three. Features are called based on the significances of the points into consideration. First of all is called "White noise" and the other one is entitled "reverberation and echoes" and the last-objected is identified as "proximity".

By comparing of researchers and analyzing of their finding, double suggestions could be proposed; firstly, decreasing distance between a speaker and listener improved the capability of listening perception in the significant distance of the classroom. Next, the significant distance in typical classrooms, for highest speaking perception is merely at distances that are comparatively adjacent to the teacher. Younger students are in danger for noise intervention is the greatest populations of students and they have higher perceptual troubles compare to adults.

V. CONCLUSION AND SUGGESTIONS

Classroom acoustics problems are an extensive educational topic that needs extra research. All students and teachers are affected by poor classroom acoustics. Some crucial acoustical variables (noise, reverberation, and distance) in this research are offer in a classroom environment which measured on the students' performance. The majority of students emphasized their requests powerfully and considered the acoustical situations in interaction environments, especially focus on proximity as a major element inside the classroom. Proximity between students and teachers has the greatest effect on performance of students.

Next feature which students considered about that was white noise in class area which influenced their performance extremely. Decreasing background noise inside the classrooms would be highly useful to the performance of students. In order to recover the acoustical environment problems in the classroom, the following recommendations may be employed based on architectural perspectives:

The greatest critical key around acoustic troubles based on requirements of students is modifying the seat arrangement to organize the finest and useful proximity for students and improve their performance. Soft architecture or flexible components inside the classroom are sections which can be simply change position by teachers in a classroom place. Similar features contain chairs and tables. Replacing the seat composition is the easiest and cheapest solution for any designer and teacher to achieve students' requirements within the classroom. Consequently, discover the finest arrangement improves teacher-student communication certainly.

ABSTRACT: An open-end winding induction motor, fed by two 2-level inverters connected at either end produces space vector locations, identical to those of a conventional 3-level inverter. In this paper, two switching algorithms are proposed to implement space vector PWM for the dual inverter scheme. The proposed algorithms do not employ any look-up tables. The time consuming task of sector identification is altogether avoided in both these algorithms. The proposed algorithms employ only the instantaneous reference phase voltages for the implementation of the space vector PWM. The harmonic content of the three phase currents in the motor are analyzed with an appropriate variation in its modulation index in both the proposed algorithms and compared simultaneously. Thus the performance in terms of harmonic analysis is carried out using MATLAB/SIMULINK for an open end induction motor drive.

Keywords: Dual-inverter, space vector modulation, Open-end winding induction motor.

I. INTRODUCTION

Various PWM schemes are presented for the two-level inverters and their effects on the load are also continuously investigated. Thrive to get improved performance is on the anvil employing suitable PWM techniques [1]-[6] or using multi-level inverters. Multi-level inverters are finding increasing research opportunities and it is clearly evident in the past few years. This is due to the reduced total harmonic distortion (THD) in the output voltage and genesis of higher voltage with use of series connections of lower voltage rating switching devices. Various derivative of this power circuit and the associated PWM schemes are also reported in the recent past [6]-[14].

Two space vector modulation techniques are suggested, which obviate the need for the sector identification. Also these PWM schemes do not employ any look-up table, thus reducing the memory requirement. Fig.1 shows the basic open-end winding induction motor drive operated with a single power supply. The symbols v_{a0} , v_{b0} and v_{c0} denote the pole voltages of the inverter-1. Similarly, the symbols $v_{a'0}$, $v_{b'0}$ and $v_{c'0}$ denote the pole voltages of inverter-2. The space vector locations from individual inverters are shown in Fig.2. The numbers 1 to 8 denote the states assumed by inverter-1 and the numbers 1' through 8' denote the states assumed by inverter-2 [1-5]. Table-1 summarizes the switching state of the switching devices for both the inverters in all the states. In Table-1, a '+' indicates that the top switch in a leg of a given inverter is turned on and a '-' indicates that the bottom switch in a leg of a given inverter is turned on.

As each inverter is capable of assuming 8 states independently of the other, a total of 64 space vector combinations are possible with this circuit configuration. The space vector locations for all space vector combinations of the two inverters are shown in Fig.3. In Fig.3, |OA| represents the DC-link voltage of individual inverters, and is equal to $V_{dc}/2$ while |OG| represents the DC-link voltage of an equivalent single inverter drive, and is equal to V_{dc}

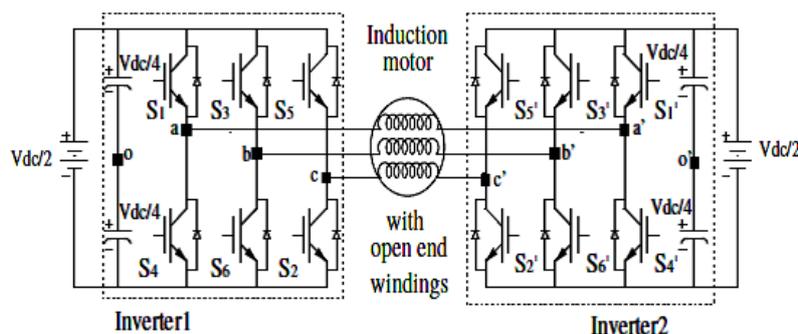

Fig.1: Power circuit configuration of dual two-level inverter

TABLE 1: Switching states of the individual inverters

state of inverter 1	Switches turned on	State of Inverter-2	Switches turned on
1 (+ - -)	S6, S1, S2	1' (+ - -)	S6', S1', S2'
2 (+ + -)	S1, S2, S3	2' (+ + -)	S1', S2', S3'
3 (- + -)	S2, S3, S4	3' (- + -)	S2', S3', S4'
4 (- + +)	S3, S4, S5	4' (- + +)	S3', S4', S5'
5 (- - +)	S4, S5, S6	5' (- - +)	S4', S5', S6'
6 (+ - +)	S5, S6, S1	6' (+ - +)	S5', S6', S1'
7 (+ + +)	S1, S3, S5	7' (+ + +)	S1', S3', S5'
8 (- - -)	S2, S4, S6	8' (- - -)	S2', S4', S6'

The following PWM strategies are proposed in this paper:

1. The Decoupled PWM strategy
2. The Biasing inverter PWM strategy

II. DECOUPLED PWM SCHEME:

The reference voltage vector to be realized by the dual inverter is shown as V_{ref} in Fig.2. It can be resolved into two equal and opposite half components as $V_{ref}/2$ and $-V_{ref}/2$. The vector addition of the later and the former results in the generation of actual reference vector as:

$$V_{ref} = V_{ref}/2 - (-V_{ref}/2) \tag{1}$$

These individual reference voltages are synthesized separately by the two two-level inverters using SVPWM and are depicted in Fig.3 from Fig.2 & 3 it can be identified that

$$OV \angle \theta = ov_1 \angle \theta - ov_2 \angle (180 + \theta) \tag{2}$$

The voltage vector OV_1 is synthesized by inverter-1 and OV_2 by inverter-2 respectively and are given as:

$$OV_1 = v_{a0}e^{j0} + v_{b0}e^{j\frac{2\pi}{3}} + v_{c0}e^{j\frac{4\pi}{3}} \tag{3}$$

$$OV_2 = v_{a'0}e^{j0} + v_{b'0}e^{j\frac{2\pi}{3}} + v_{c'0}e^{j\frac{4\pi}{3}} \tag{4}$$

where v_{a0}, v_{b0}, v_{c0} are three-phase pole voltages of inverter-1 and $v_{b'0}, v_{b'0}, v_{c'0}$ are three-phase pole voltages of inverter-2 The actual vector can now obtained using the vectors defined in eqns.(3) & (4) as:

$$OV = V_{aa'}e^{j0} + V_{bb'}e^{j\frac{2\pi}{3}} + V_{cc'}e^{j\frac{4\pi}{3}} \tag{5}$$

$$V_{aa'} = V_{a0} - V_{a'0} \tag{6}$$

$$V_{bb'} = V_{b0} - V_{b'0} \tag{7}$$

$$V_{cc'} = V_{c0} - V_{c'0} \tag{8}$$

Where $v_{aa'}, v_{bb'}, v_{cc'}$ are the three-phase phase voltages of the dual-inverter fed induction motor drive.

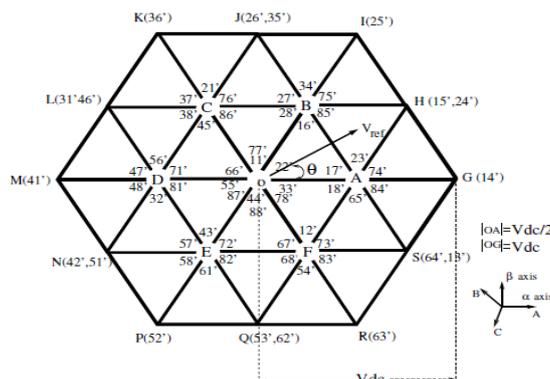

Fig.2: Space vector locations of dual two-level inverter

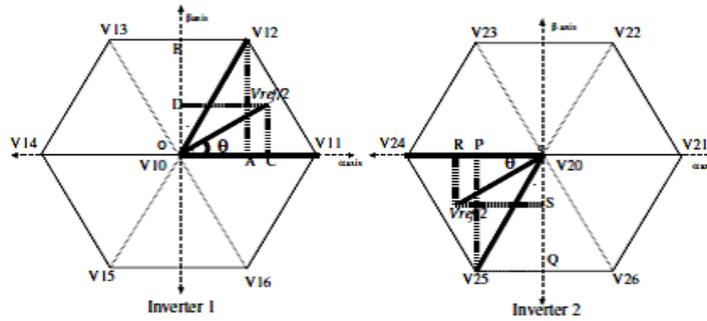

Fig.3: Principle of decoupled PWM technique and switching voltage vector, reference voltage vector projection on α and β axis

In Fig.3, the switching vectors V_{1x}, V_{2x} ($x=0, 1, 2, 3, 4, 5, 6$) for inverter-1 & 2 can be identified and are defined as:

$$V_{1x} = \frac{2}{3}V_{dc} (S_{A1} + S_{B1}e^{j\frac{2\pi}{3}} + S_{C1}e^{j\frac{4\pi}{3}}) \quad (9)$$

$$V_{2x} = \frac{2}{3}V_{dc} (S_{A2} + S_{B2}e^{j\frac{2\pi}{3}} + S_{C2}e^{j\frac{4\pi}{3}}) \quad (10)$$

The reference voltage vector (V_{ref} in Fig.2) is situated at an angle θ w.r.t the α -axis. The references to the individual inverter would then be $V_{ref}/2$ where one is at angle ' θ ' while the other is at an angle ' $180+\theta$ ' both measured w.r.t the β -axis (Fig.3). The respective references are synthesized by the inverters and the switching vectors for inverter-1 can be identified as V_{11}, V_{12} & V_{10} and V_{24}, V_{25} & V_{20} for inverter-2 (Fig.3)

With the decoupled SVPWM technique, the reference vector V_{ref} is decoupled into two equal halves as described in the previous section. These space vectors are shown in Fig.3 and are said to fall in sector 1 (for inverter-1) and sector 4 (for inverter-2). With inverter-1 and 2, the space vectors $V_{ref}/2, -V_{ref}/2$ respectively are realized in the average sense using three nearest voltage vectors of the sector in which the tip of reference vector lies. To realize $V_{ref}/2$, inverter-1 switches between vectors $V_{10}, V_{11}, V_{12}, V_{17}$ with timing intervals of $T_{10}/2, T_{11}, T_{12}, T_{17}/2$ respectively for the center-spaced PWM. Similarly, inverter-2 switches between $V_{20}, V_{24}, V_{25},$ and V_{27} with timing intervals of $T_{20}/2, T_{24}, T_{25},$ and $T_{27}/2$ respectively.

III. RESULTS & DISCUSSIONS FOR THE DECOUPLED PWM STRATEGY

The dual two-level inverter with decoupled SVPWM switching scheme feeding power to open end winding induction motor drive is simulated using Matlab/SIMULINK simulation software. Then the results are verified experimentally. A total of 48 samples is chosen in the entire work covering one cycle of the output voltage, irrespective of the modulation index of the drive (speed of the motor).

The gating pulses of the top switching devices of the individual inverters (depicting the timings T_{ga}, T_{gb}, T_{gc} for inverter-1 and $T_{ga'}, T_{gb'}, T_{gc'}$ for inverter-2) are shown in Fig.4. The three phase pole voltages of the individual inverters will be a replica of the gating pulses shown in Fig.6 except for their voltage levels.

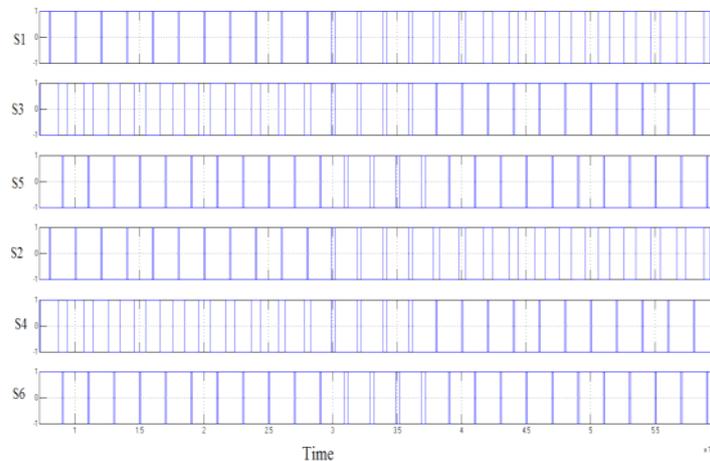

Fig.4: Gating Pulses for Inverter-1(T_{ga}, T_{gb}, T_{gc}) and Inverter-2($T_{ga'}, T_{gb'}, T_{gc'}$) for the modulation index 0.75

Here, the modulation index is defined as the ratio of the length of the reference space vector (V_{ref}) and the DC-bus voltage (V_{dc}). The experimentally obtained a-phase pole voltages of the two inverters, difference in a-phase pole voltages, motor a-phase voltage and the motor a-phase no-load current for a modulation index of 0.75 are as shown in the fig(5).

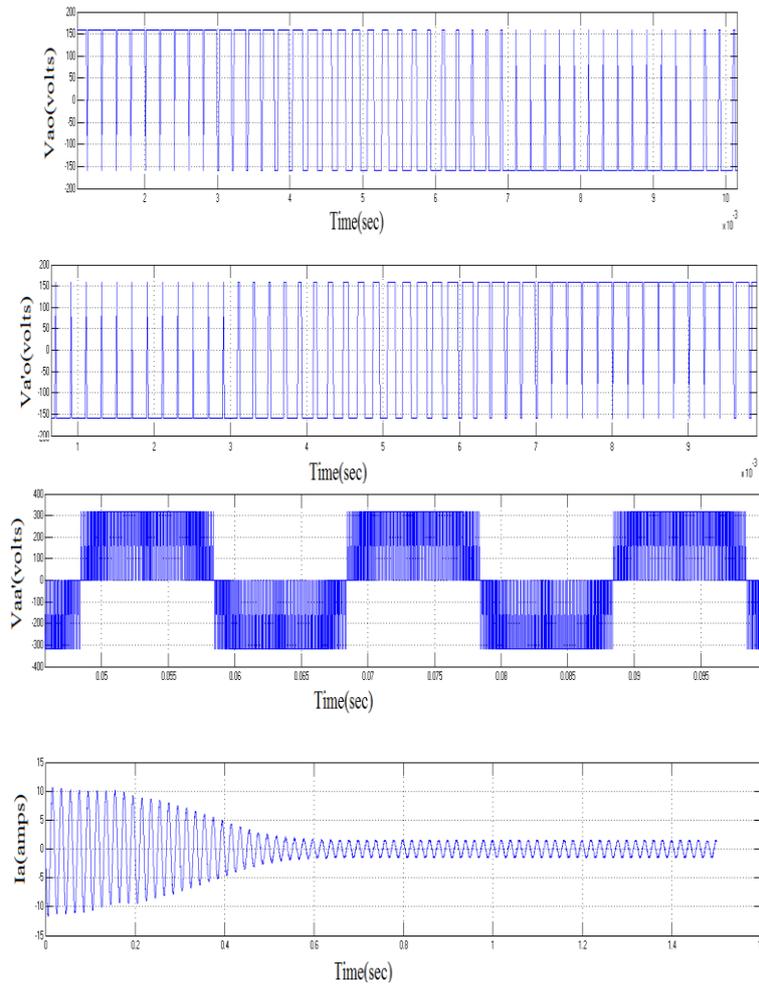

Fig.5: Simulated pole voltages of inverter-1 and inverter-2 (Top 2 traces), Difference in a-phase pole ($V_{aa'}$) voltages (3rd trace), motor a-phase current (4th trace), for a modulation index of 0.75.

IV. THE BIASING INVERTER PWM STRATEGY

This PWM strategy is based on the observation that the space vector combinations at the vertices and the center of a given sub-hexagon are obtained by clamping one inverter with an active state, while the other inverter assumes all the eight states. Consequently, one inverter may be employed as the biasing inverter to realize the biasing vector and the other inverter may be switched around this biasing vector. Figure 6 shows the basic operating principle of this PWM strategy.

In Fig 6, **OT** represents the reference vector with its tip situated in sector-7. It is resolved into two components **OA** and **AT**. The vector **OA** may be output with inverter-1 with its state clamped at 1(+--, Table-1) throughout the sampling time interval. The vector **AT** is realized in the average sense by switching inverter-2 around the sub hexagonal center, A. Alternatively, the biasing vector **OA** may be output with inverter-2 with its state clamped at 4'(-++, Table-1) throughout the sampling time interval. In that case, the switching vector **AT** is generated with inverter-1.

The modified instantaneous voltage phase references corresponding to the switching vector **AT** are denoted by V_a, V_b and V_c obtained by the following procedure:

1. The instantaneous phase references V_a^*, V_b^* and V_c^* corresponding to the reference vector **OT** are transformed into the corresponding equivalent two-phase system references V_{α}^* and V_{β}^* using the classical three phase to two phase transformation given by:

$$\begin{bmatrix} v_{\alpha}^* \\ v_{\beta}^* \end{bmatrix} = \begin{bmatrix} \frac{3}{2} & 0 & 0 \\ 0 & \frac{\sqrt{3}}{2} & -\frac{\sqrt{3}}{2} \end{bmatrix} \begin{bmatrix} v_a^* \\ v_b^* \\ v_c^* \end{bmatrix}$$

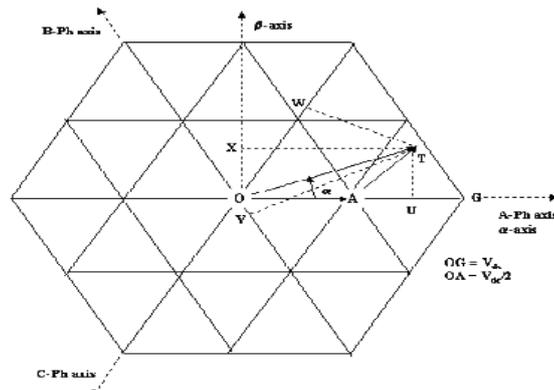

Fig.6: Principle of biasing inverter PWM strategy

- The sub-hexagonal center situated nearest to the tip of the reference vector **OT** is then determined.
- The coordinates of the nearest sub-hexagonal center in the V_α - V_β plane (the point 'A' in this example, Fig.26), denoted as $V_{\alpha,nshc}$ and $V_{\beta,nshc}$ are known for all the six sub-hexagonal centers. For example, the coordinates of the point 'A' in the V_α - V_β plane are given by $(V_{dc}/2, 0)$.
- Since the vector **OA** is output by the biasing inverter, the coordinates of the switching vector (**AT** in the present case) denoted as $V_{\alpha,sw}$ and $V_{\beta,sw}$ are given

$$V_{\alpha,sw} = V_\alpha^* - V_{\alpha,nshc} \text{ and } V_{\beta,sw} = V_\beta^* - V_{\beta,nshc}$$

- The modified reference phase voltages V_a, V_b and V_c for the switching inverter are then obtained by transforming $V_{\alpha,sw}, V_{\beta,sw}$ into the corresponding three phase variables by using the classical two phase –three phase transformation given by:

$$\begin{bmatrix} v_a \\ v_b \\ v_c \end{bmatrix} = \begin{bmatrix} 2/3 & 0 \\ -1/3 & 1/\sqrt{3} \\ -1/3 & -1/\sqrt{3} \end{bmatrix} \begin{bmatrix} V_{\alpha,sw} \\ V_{\beta,sw} \end{bmatrix}$$

- If inverter-2 is employed as the biasing inverter, the modified references are used directly to generate the switching vector **AT** with inverter-1. On the other hand, if inverter-1 is used as the biasing inverter, it is obvious that the modified references must be negated to generate the switching vector **AT** with inverter-2.

V. RESULTS & DISCUSSIONS FOR THE BIASING INVERTER PWM STRATEGY

The dual two-level inverter with biasing SVPWM switching scheme feeding power to open end winding induction motor drive is simulated using Matlab/SIMULINK simulation software. Then the results are verified experimentally.. A DC-bus voltage of 200 volts is chosen to run the drive and V/f control is maintained in the entire speed range of the induction motor. A total of 48 samples is chosen in the entire work covering one cycle of the output voltage, irrespective of the modulation index of the drive (speed of the motor).

The gating pulses of the top switching devices of the individual inverters (depicting the timings T_{ga}, T_{gb}, T_{gc} for invrter-1 and $T_{ga'}, T_{gb'}, T_{gc}'$ for inverter-2) are obtained simultaneously shown in Fig.7.The three phase pole voltages of the individual inverters will be a replica of the gating pulses shown in Fig.8 except for their voltage levels.

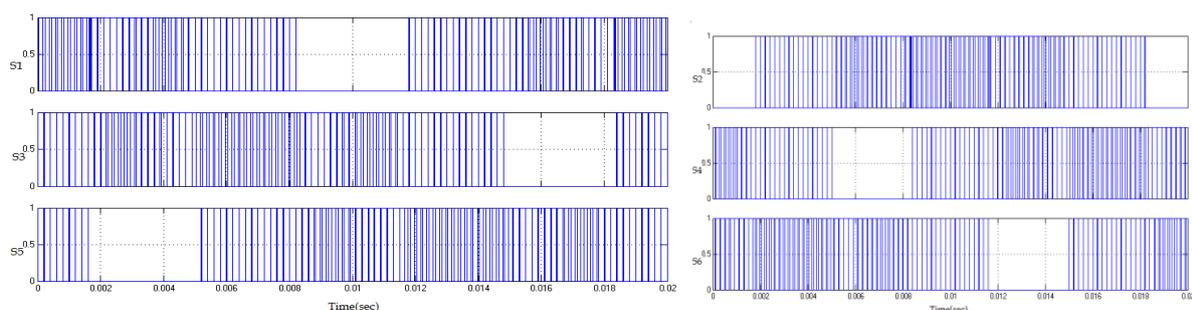

Fig.7: Gating Pulses for Inverter-1(T_{ga}, T_{gb}, T_{gc}) and Inverter-2($T_{ga}', T_{gb}', T_{gc}'$) for the modulation index 0.75

Here, the modulation index is defined as the ratio of the length of the reference space vector (V_{ref}) and the DC-bus voltage (V_{dc}).The experimentally obtained a-phase pole voltages of the two inverters, difference in a-phase pole voltages, motor a-phase voltage and the motor a-phase no-load current for a modulation index of 0.75 are as shown in the fig(8).

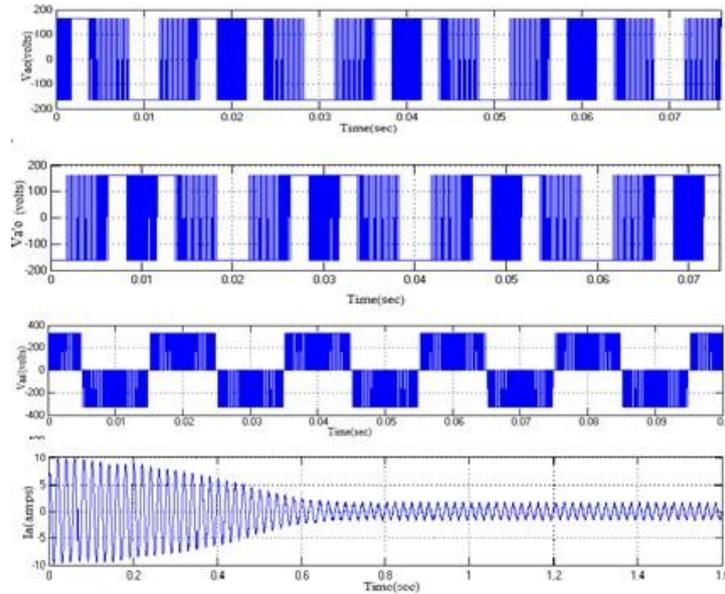

Fig. 8: Simulated pole voltages of inverter-1 and inverter-2 (Top 2 traces), Difference in a-phase pole ($V_{aa'}$) voltages (3rd trace), motor a-phase current(4th trace), for a modulation index of 0.75.

The comparison in terms of harmonic content for both the cases when the motor is fed by decoupled inverter and biasing inverters is done by the total harmonic distortion along with the respective change in the corresponding modulation index. For instance the simulated results of harmonic distortion for both the cases for a modulation index of 0.75 are as shown in fig (9).

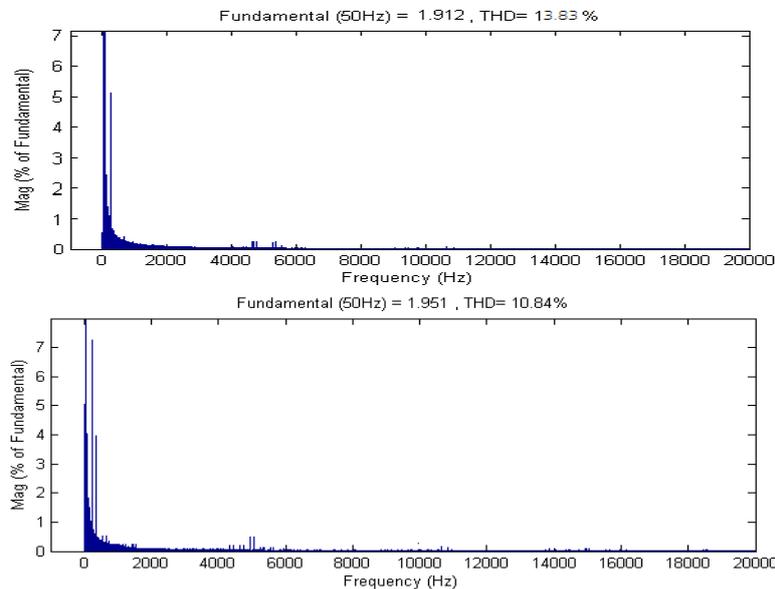

Fig. 9: Simulated Results Of %THD for Decoupled inverter fed (Top trace) and Biasing inverter fed (Bottom trace) Induction motor drive for a modulation index of 0.75

Various changes in the %THD at different levels of Modulation index are presented in table (2).With this it is reiterated that as the modulation index increases, the harmonic content in the motor phase currents is reduced.

Table (2): Total Harmonic Distortion of line currents of the induction motor for different modulation index

S.No	Operating Frequency	Modulation Index	Decoupled SVPWM Inverter Fed Induction Motor Drive	Biasing SVPWM Inverter Fed Induction Motor Drive
			Phase Current(I_a)	Phase Current(I_a)
			% THD	% THD
(1)	50	0.1	16.55	14.26
(2)	50	0.2	16.47	14.01
(3)	50	0.4	14.29	13.19
(4)	50	0.75	13.83	10.84
(5)	50	0.9	8.57	8.28

VI. CONCLUSION:

The dual two-level inverter is capable of generating three level output voltage using the SVPWM switching schemes. With the biasing inverter PWM strategy the reference space vector is reproduced in the average sense by switching amongst the vector combinations available at the nearest three vertices. Consequently the switching ripple with this strategy is lesser than the decoupled PWM strategy. The rms value of this harmonic content is decreasing with the increase in the modulation index of the dual-inverter feeding the open-end winding induction motor. In Biasing inverter PWM strategy, THD of the motor phase currents is low compared to that of Decoupled PWM algorithm.

Abstract: To turn the business application of a software project to system specification is a big challenge in business environment. Since the business analysts and system analysts have their own perspective, the modeling of business processes is necessary to facilitate both the perspectives and for a better coordination. Many applications of such business processing model have given rise to problems at support models. As such maintaining consistency at such related models has become a big challenge for business modeling theory and practice. In this paper we project a theory to find out the consistency between the models is not coined and it is very much necessary to find out the inconsistencies so that change propagation between the models can be achieved. Behavioral profile, as a solution to the inappropriateness of behavioral equivalence notions will be proposed. This model is expected to resolve the behavioral constraints of a process model. Through this model, profiles can be computed efficiently in public time for sound free-choice Petri nets with reference to their number of places and transitions. We develop a slow model that verifies process consistency described in a Petri net graph. We provide both Structural Analysis and Behavioral Profiles to evaluate process consistency.

Key Words: Process Models, Petri nets, Behavioral Profiles, Structural Analysis, Process Modeling.

I. Introduction

Translating business requirements into system specification is a crucial task of any software engineering project in a business environment. The modeling of business processes has been identified as an important step towards bridging the gap between business and software development, and, among others, facilitating structured design [1], business-IT alignment [2], or engineering of process-aware information systems [3]. There are different solutions that should contribute to a smooth progression from business analysis to software implementation. Methodologies for integrated system design propose to derive technical realizations from business requirements directly via refinements [4], [5], [6]. In the same vein, the standardization of the Business Process Modeling Notation (BPMN) [7] by the OMG received much attention, due to the translation to the Web Services Business Process Execution Language (BPEL) [8] that is part of the specification. There are also various tools on the market that support business process modeling and corresponding transformations. We already mentioned that business analysts and software designers tend to model the same business process in quite different ways, which often impedes efficient communication. Clearly, pragmatics is an inherent feature of every conceptual model. While mapping and reducing the reality are essential for creating model, the purpose of the model determines what to map and what to reduce [11]. As business analysts and software designers have quite diverging concerns when looking at a business process, it is no surprise that business process models differ from software design models of the same process significantly. We will argue throughout this article that a formal concept for discussing the consistency of an alignment between two process models is missing. It is needed for identifying inconsistencies, as well as to enable

change propagation between these models. In the software engineering community, consistency refers to a 'degree of uniformity, standardization, and freedom of contradictions' [12].

An alignment of process models requires the identification of model correspondences, which is a well-researched topic in the database community. Correspondences relate elements that have matching semantics in the context of an alignment of two models (note that the semantics might differ in absolute terms). Given a set of correspondences, the question whether two data models are consistent is similar to the question whether a mapping between data schemas is valid, which is known from the field of data integration. In this area, various properties for evaluating the validity of a schema mapping have been proposed. For instance, compatibility of a mapping between two schemas requires the existence of a pair of instances that satisfies the constraints of the mapping as well of the respective schemas [13]. Translated into the domain of behavioral models, this yields a consistency notion, which requires the existence of a single trace that is possible in both models after the corresponding elements have been resolved. Again, we might draw the analogy to behavioral models under the assumption of behavioral constraints as the elementary elements. For a given projection between two models, that is a partial correspondence relation, all behavioral constraints on traces of one model are preserved in the traces of the other model. There is a multitude of equivalence criteria in the linear time – branching time spectrum [14]. This criterion is still rather strict, and might not be appropriate for deciding on a consistent alignment between two process models. First, trace equivalence is not invariant to so-called forgetful refinements of activities [15]. Forgetful refinement refers to a change, in which an activity is forgotten due to its

replacement with an empty activity. As a consequence, we argue that, for our purpose, a notion of consistency that guarantees 'freedom of contradictions' as required by [12] should be less strict than a notion requiring all information of one model to be present in another model as well. Furthermore, all behavioral equivalence criteria being discussed in this area, including trace equivalence [14], provide a true/false result.

We introduce the formal concept of a behavioral profile and structural analysis. These profiles capture the essential behavioral constraints of a process model and apply the structural analysis, such as mutual exclusion of activities or partial order. The behavioral profile enables us to overcome three major shortcomings of an application of trace equivalence in an alignment scenario and structural analysis verifies the accuracy and consistency measures captured during behavioral profiling.

- 1) Behavioral profiles are less sensitive to projections than trace equivalence. We will show that behavioral profiles of two process models remain unchanged even if additional start and end branches are introduced in one of the models.
- 2) The structure of a behavioral profile provides us with a straight-forward way to define a degree of consistency ranging from 0 to 1.0, referred to as the degree of profile consistency. In this way, we can feed back detailed information to business analysts and software designers on how far and where two models deviate from each other.
- 3) The concept of a behavioral profile builds on formal properties of free-choice Petri nets. This class of nets has been used for the formalization of most process modeling languages. The derivation of a behavioral profile and the calculation of a degree of profile consistency and structural analysis of the consistency measured have been implemented to demonstrate the applicability of our approach. In this article, we also report the findings from checking consistency between partially overlapping of example process models, a collection of benchmark process models that describe the functionality of specific business software. We introduce consistency measurement by using behavioral profiles and structural analysis in section2, We provide consistency measurement for aligned process models in section3, and we also provide Experiment and Result analysis in section4.

II. Consistency Measurement by using Behavioral Profiles and Structural Analysis

Business process change is at the very core of business process management, which aims at enabling flexible adaptation to changing business needs. However, the wide variety of drivers for business process modeling initiatives, reaching from business evolution to process enactment, results in multiple models that overlap in content due to serving different purposes. That, in turn, imposes serious challenges for the propagation of changes between these process models.

Now a day, Business Process Management (BPM) has a broad field of application, reaching from process evolution to process enactment. The *purpose* guides the creation of every particular process model. It is a consequence of this observation that companies create

different models for the same process. These models reside on different levels of abstraction and assume different modeling perspectives depending on what is appropriate with respect to the modeling goal. The flexibility to adapt business processes in order to respond to changing business needs is at the very heart of BPM. Therefore, the *propagation of changes* between several related process models is a major use case for model alignment. According to Gartner, change is of high relevance to the key elements of the BPM discipline, which are *'keeping the business process model in sync with process execution [and] enabling rapid iteration of processes and underlying systems for continuous process improvement and optimization'*.

In our proposal presents a novel approach to change propagation between business process models. Its central contribution is the definition and application of a technique for dealing with overlapping process models that are not defined in terms of a hierarchical refinement. This technique is based on the notion of a behavioral profile which captures a set of dedicated behavioral aspects of a process model. Given a change in the source model, our approach isolates a potential *change region* in the target model grounded on the behavioral profile of corresponding activities. In this way, process modelers can quickly assess the necessity to propagate the change. If change propagation seems to be appropriate, the change region spots the position where to extend the model.

A. Process Models

Our notion of a process model is based on a graph containing activity nodes and control nodes, which, in turn, captures the commonalities of process description languages.

Behavioral Profiles

The Behavioral profile aims at capturing Behavioral aspects of a process in a fine-grained manner. That is, it consists of three relations between nodes of a process graph. These relations are based on the notion of weak order. Two nodes or flow arcs of a process model are in weak order if there a trace in which one node occurs after the other. Note that we require only the existence of such a trace. Thus, weak order does not have to hold for all traces of the model.

- The strict order relation $x \succ P(y)$ and $y \neg \succ P(x)$
- The exclusiveness relation $x \neg \succ P(y)$ and $y \neg \succ P(x)$
- The observation concurrency relation $x \succ P(y)$ and / or $y \succ P(x)$

The set of all three relations is the Behavioral profile. Two process models with equivalent behavioral profiles may differ in the trace equivalence, in contrast the two process models with identical trace equivalence can also identical in behavioral profiles.

Correspondence Relation: if the relation between two process models is left unique and is not functional

Aligned Transitions: let a_1, a_2 correspondence to a and c_1, c_2 correspondence to c . if transition observed from a_1 to c_1, a_1 to c_2, a_2 to c_1 or a_2 to c_2 then the transition relation between a to c is aligned transition.

Projected Firing sequence: In a sequence considered, the set of aligned sequences is referred as firing sequence.

Trace Consistency of Alignment: If Aligned transitions of a projected firing sequence contain trace equivalence then it reflects as Trace consistency of alignment.

B. Structural analysis: The structural analysis of dynamic lumped process models forms an important step in the model building procedure and it is used for the determination of the solvability properties of the model, too. This analysis includes the determination of the degree of freedom, structural solvability, differential index and the dynamic degrees of freedom. As a result of the analysis, the decomposition of the model is obtained and the calculation path can be determined. This way the appropriate numerical method for solving the model can be chosen efficiently. Moreover, advice on how to improve the computational properties of the model by modifying its form or its specification can also be given.

Effective graph-theoretical methods have been proposed in the literature based on the analysis tools developed by, for the determination of the most important solvability property of lumped dynamic models: the differential index. The properties of the dynamic representation graph of process models described by semi-explicit DAE-systems have also been analyzed there in case of index 1 and higher index models. Beside the algorithm of determining the differential index by using the representation graph, a model modification method has also been proposed in the literature, which results in a structurally solvable model even in the case of higher index models.

C. Structural solvability

As a first step, we consider a system of linear or nonlinear algebraic equations in its so called *standard form* where $x_j (j = 1, \dots, N)$ and $u_k (k = 1, \dots, K)$ are unknowns, $y_i (i = 1, \dots, M)$ are known parameters, $f_i (i = 1, \dots, M)$ and $g_k (k = 1, \dots, K)$ are assumed to be sufficiently smooth real-valued functions. The system of equations above is structurally solvable, if the Jacobian matrix $J(x \setminus u)$ referring to the above model is non-singular.

$$y_i = f_i(x, u), i = 1, \dots, M \quad u_k = g_k(x, u), k = 1, \dots, K$$

Consider a system of equations in standard form. We construct a directed graph to represent the structure of the set of equations in the following way. The vertex-set corresponding to unknowns and parameters is partitioned as

$$X \cup U \cup Y, \quad \text{where}$$

$$X = \{x_1, \dots, x_N\}, U = \{u_1, \dots, u_k\} \text{ and}$$

$Y = \{y_1, \dots, y_M\}$. The functional dependence described by an equation is expressed by arcs coming into y_i or u_k respectively from those x_j and u_l , which appear on its

right-hand side. This graph is called the representation graph of the system of equations.

A Menger-type linking from X to Y is a set of pair-wise vertex-disjoint directed paths from a vertex in X to a vertex in Y . The size of a linking is the number of directed paths from X to Y contained in the linking. In case $|X| = |Y|, (M = N)$, a linking of size X is called a complete linking. The graphical condition of the structural solvability is then the following:

Linkage theorem: Assume that the non-vanishing elements of partial derivatives / and graphs, in the standard form model are algebraically independent over the rational number field O . Then the model is structurally solvable if and only if there exists a Menger-type complete linking from X to Y on the representation graph.

We can adapt the graphical techniques to DAE- systems, as well. An ordinary differential equation of a DAE-system can be described by the following equation:

$$x' = f(x_1, \dots, x_n)$$

Here x denotes an arbitrary variable depending on time. x' denotes the derivative of x with respect to time and x_1, \dots, x_n are those variables which have effect on variable x' according to the differential equation.

In DAE-systems there are two types of variables. **Differential variables** are the variables with their time derivative present in the model. Variables, which do not have their time derivative present, are called **algebraic variables**. The derivative x' is called **derivative** (velocity) **variable**.

D. Dynamic representation graph

The value of differential variables is usually computed by using a numerical integration method. Therefore a system of equations including also differential equations can be represented by a **dynamic graph**. A dynamic graph is a sequence of static graphs corresponding to each time step of the integration. On a dynamic graph there are directed arcs attached from the previous static graph to the succeeding static graph that are determined by the method applied for solving the ordinary differential equations. In case of a single step explicit method, the value of a differential variable at time $t+h$ is computed using the corresponding differential value and its value at a previous time t . For example, when the explicit Euler method is used:

$$x(t+h) = x(t) + h \cdot x'(t)$$

where h denotes the step length during the numerical integration. The structure of a dynamic graph assuming explicit Euler method for solving differential equations is shown in **Fig. 1**.

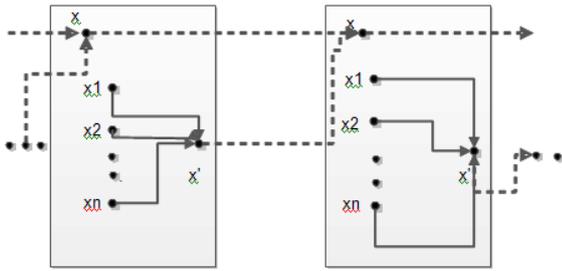

Fig 1: Dynamic Graph model for Euler method

The structural analysis based on graph theoretical technique is carried out in steps performed sequentially. The first step is to rewrite the model into its standard form. The second step is the assignment of types to vertices in the representation graph. The important types of vertices determined by the model specification are the following:

• **<S>(set)-type variables:** These represent variables, which are assigned to the specified given values. In the case of a dynamic representation graph assuming explicit method for solving the differential equations, the differential variables will be labeled by type <S*> because their initial value can be obtained from the initial values, and then their values can be calculated step by step by numerical integration. Labels <S> and <S*> are treated the same way during the analysis.

• **<G>(given)-type variables:** A variable assigned to a specific value of a left hand side is a <G>-type variable. Unlike the <S>-type variables, the values of the right hand side variables will be suitably adjusted so as to preserve the equality of the two sides.

According to the representation graph, the value of every variable which has incoming arcs only from vertices labeled by type <S> can be calculated by simple substitution into the corresponding equation. These variables become **secondarily labeled by type <S>**, and this process can be repeated if necessary. Omitting all vertices labeled primarily, secondarily, etc. by type <S> and all arcs starting from them from the representation graph we obtain the **reduced graph**. The classification of vertices of a reduced graph is as follows:

- all initial vertices form the unknown variable set X
- all terminal vertices labeled by type <G> constitute the known variable (parameter) set Y,
- all other vertices constitute the known variable set Y.

Dynamic process models can be described by **semi- explicit DAEs** as follows:

$$z_1 = f(z_1, z_2, t), z_1(t_0) = z_{10}$$

(1)

$$0 = g(z_1, z_2, t)$$

(2)

The most important structural computational property of DAE models is the differential index. By definition the differential index of the semi-explicit DAE (Equations (1)-(2)) is one if one differentiation is sufficient to express z_2 as a continuous function of z_1, z_2 and t . One differentiation is sufficient if and only if the Jacobian matrix g_{z_2} is non-singular.

In our earlier work we have proved that the differential index of the models investigated in is equal to 1

if and only if there exists a Menger-type complete linking on the reduced graph at any time step t .

If the differential index of the investigated model is greater than 1 then there is no Menger-type complete linking on the static graph at any time step t . The properties of a static graph of a dynamic model, which has differential indexes are as follows.

1. Let us form the following variable sets.

I_0 is the set of the differential variables belonging to the over specified sub graph,

D_0 is the set of the derivative variables referring to the differential variables of set I_0 ,

I_1 is the set of differential variables from which directed paths lead to the derivative variables in the set D_0 ,

D_1 is the set of derivative variables referring to the differential variables of set I_1, \dots ,

I_k is the set of differential variables from which directed paths lead to the derivative variables in the set D_{k-1} ,

D_k is the set of derivative variables referring to the differential variables of set I_k, \dots ,

2. Let n be the smallest natural number for which the set D_n contains some derivative variables of the underspecified sub graph. Then the differential index of the model is

$$v_d = n + 2$$

If there is no such number n then the model is not structurally solvable.

In our earlier work we have shown that the important properties of the representation graph including the differential index of the models are independent of the assumption whether a single-step, explicit or implicit numerical method is used for the solution of the differential equations.

III. Consistency measurement for aligned process models:

The previously defined concept of a behavioral profile allows us to formally discuss the notion of a degree of profile consistency between a pair of process models. We will use the classical notion of trace equivalence, which we extend to trace consistency, as a benchmark.

Consistency based on Trace Equivalence

As a benchmark for our consistency analysis, we define a notion of consistency based on the trace equivalence criterion. First, we adapt the trace equivalence criterion for model alignments yielding the notion of trace consistency. Second, the degree of trace consistency is introduced based on the amount of traces of one model that have a counterpart in the other model. We already mentioned in Section 2 that the application of trace equivalence in an alignment setting requires that all parts that have been subject to projection are discarded.

Consistency based on Behavioral Profiles

In general, our notion of consistency based on behavioral profiles, i.e., profile consistency, is grounded on the preservation of behavioral relations for corresponding activities. In contrast to the notion of a trace consistent alignment, it does not require the correspondence relation to be injective. Instead, it allows for 1:n (and even n:m) correspondences. Therefore, this notion can be applied to vertical as well as horizontal alignments. Preservation of the behavioral relation is only required in case there are no overlapping correspondences.

Interpretation of Profile Consistency

As exemplified in the previous section, the degree of profile consistency ranges between 0 and 1.0 for two process models and a correspondence relation. Still, a degree of 1.0 does not imply that both models are (projected) trace equivalent. This stems from the fact that the underlying behavioral profile represents a behavioral abstraction; apparently, the degree of profile consistency quantifies the quality of an alignment with respect to the **order of potential activity occurrences**. A degree of 1.0 guarantee the all these constraints are equal for the aligned activities of two models. A degree of 0.9, in turn, indicates that the constraints on the order of potential activity occurrences are equal solely for 90% of the relations between aligned activities. However, we assume these thresholds to be highly dependent on a specific project setting. Once a degree of profile consistency below 1.0 is observed, the question of how to locate the source of inconsistency has to be addressed. According to our approach, inconsistencies manifest themselves in different relations of the behavioral profile of two process models for a pair of aligned activities.

This information can directly be provided to business analysts and system analysts in order to judge on the necessity of the inconsistency. While this kind of feedback allows for locating the inconsistency directly in case of only a few inconsistent profile relations (e.g., caused by an interchanged order of two activities in a sequence), it might be inappropriate if a big number of profile relations is inconsistent. Imagine two process models containing a set of aligned activities in sequential order and assume that one of these activities in one model would now be moved to a branch that is executed concurrently to the remaining activities. Then, all behavioral relations between this activity and the remaining activities would be inconsistent, such that feedback on the set of activities that show inconsistent relations would be of little help. Instead, we would consider the biggest subset of aligned activities that show consistent behavioral relations among each other to be valuable feedback on the observed inconsistencies. For the aforementioned case, the single activity having inconsistent relations with all other activities might be identified by this approach.

IV. Experiments and Results Analysis

After preprocessing of the benchmark models, we are able to analyze its consistency. As mentioned before, we establish correspondences between events and functions with equal labels. Further on, we extract all pairs of process models that are aligned by at least two correspondences. For such a pair, we then calculate the consistency measures,

that is, trace consistency, the degree of trace consistency, and the degree of profile consistency of the alignment and finally analyzed the accuracy of the degree of profile using structural analysis.

The results are optimistic from the experiments conducted on bench mark business models represented in Petrinet format. We consider the consistency measurement systems WF systems (WF), and Behavior profiling (BP) analysis to compare with the proposed Behavior Profiling and Structural Analysis (BP&SA). We can find the significant benefit of BP&SA over other models. Fig 2 represents the comparison of optimality in consistency measurement between BP&SA and other two models. In fig 3 we can observe the computational over head of the WF. Here BP is having slight advantage over BP&SA, which can be negligible while considering the accuracy achieved through BP&SA in consistency measurement.

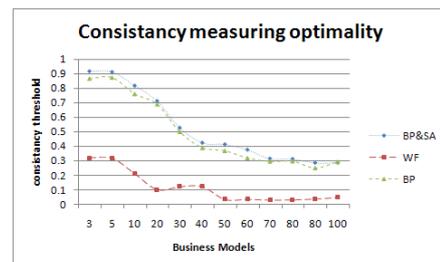

Fig 2: Optimality in Consistency Measurement

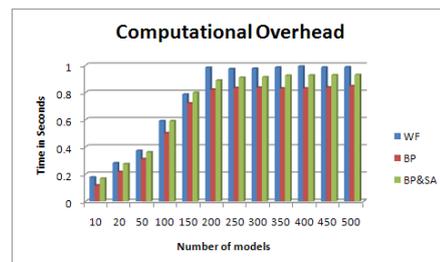

Fig 3: Computational Overhead comparison report

V. Conclusion:

.we have discussed alignment issues between related process models at different abstract levels and different perspectives.. We proposed the concept of behavioral profile that captures the essential behavioral constraints of a process model. Such behavioral profiles are used for the definition of the formal notion of profile consistency. Behavioral profiles provide three major advantages in contrast to the existing notion of trace equivalence and consistency measures that build up it. Finally, the concept of a behavioral profile builds informal properties of free-choice Petri nets. We proved that profile consistency can be checked for sound free-choice WF-systems in $O(n^3)$ time with n nodes.

. There are several directions for future research based on behavioral profiles. We have emphasized the fact that different interrelated process models and variants are utilized for the development of process-aware information systems.. We are optimistic that algorithms can be defined to synthesize process model from a behavioral profile, as there exist synthesis techniques to build Petri nets from transition systems and from traces. Such algorithms might

not only take one profile as input. We are currently experimenting with building integrated process models from two behavioral profiles and their alignment.

Abstract: Unified Power Flow Controller (UPFC) has its unique capability to control simultaneously real and reactive power flows on a transmission line as well as to regulate voltage at the bus where it is connected, this device creates a tremendous quality impact on power system stability. These features become even more significant knowing that the UPFC can allow loading of the transmission lines close to their thermal limits, forcing the power to flow through the desired paths. This will give the power system operators much needed flexibility in order to satisfy the demands that the deregulated power system will impose. The controller used in the control mechanism has an important effect on the performance of UPFC and it operates in several modes of operations using different control mechanisms based on Proportional-Integral controller has been studied. In this paper a proposed control method, ANFIS based controller has been developed by using ANFIS EDITOR of MATLAB using Takagi-Sugeno Inference system and this will applied to STATCOM part of the detailed model of UPFC. The MATLAB simulation results shows that ANFIS controller has an effective power flow control, less settling time and less overshoot when compared to PI controller in different operating modes.

Key words: ANFIS, FACTS, Power System, UPFC.

I. Introduction

The static series synchronous compensator (SSSC) can control active and reactive in a transmission line in a small range via stored energy in capacitor DC-link where static synchronous compensator (STATCOM) with injecting reactive power can regulate the bus voltage in a transmission line. Unified Power Flow Controller (UPFC) is the most versatile and complex Flexible AC Transmission Systems (FACTS) equipment that has emerged for the control and optimization of power flow in power transmission systems [1-3]. It has the combining features of both series converter and shunt converter based FACTS devices, and is capable of realizing voltage regulation, series compensation, and phase angle regulation at the same time. Therefore, the UPFC is capable of independently controlling the active power and reactive power on the compensated transmission line [4, 5]. The electric utilities are continuously looking for new devices that will enable interconnected systems to have increased power transfer abilities with transmission lines. UPFC and IPFC are FACTS devices that can control the power flow in transmission line by injecting active and reactive voltage component in form series to the transmission line. The UPFC is a flitting multi-purpose FACTS device that extends their capability to inject shunt current or series voltage that involve real power flow as well With UPFC, the real and reactive power can be controlled independently. The unified power flow controller is capable of controlling all the power system parameters such as

voltage magnitudes, phase angles, and effective line impedance simultaneously consists of two voltage source Converters (VSCs) that are connected to a common DC-link. One of the VSCs is connected in series with a transmission line while the other one is connected in shunt with the same transmission line. The DC bus of both VSCs are supplied through a common DC capacitor, hence UPFC combines the functions of a STATCOM and a SSSC. STATCOM maintains constant the bus voltage and provide energy for DC link of SSSC and it can regulate capacitor's voltage of DC link, SSSC with injection controllable voltage controls the active and reactive power flow control in the transmission line.

It can simultaneously perform the function of transmission line real/reactive power flow control in addition to UPFC bus voltage/shunt reactive power control. The control mechanism and the controller have important effect on the performance of UPFC. In literature, several control mechanisms are used in the UPFC model. A novel fuzzy inference system is proposed and used to improve the dynamic control of real and reactive power .control scheme is used in the control mechanism of UPFC. In the simulation results, there is a high Overshoot values occurred both real power and bus voltage during the three phase faults applied. However, the real power value is increased but there is no value changed in the reactive power. In the simulation results, the variation of the real power direction can be observed easily. According to results; the values of real and reactive power are changed in large values with UPFC because of the low values of bus voltage. This paper presents the performance evaluation of UPFC in different modes by using different control mechanisms based on PI and ANFIS based controllers. "Takagi-Sugeno Inference System" is used in the decision making of fuzzy model.

II. Unified Power Flow Controller

Unified power flow controller (UPFC) is a combination of static synchronous compensator (STATCOM) and a static synchronous series compensator (SSSC) which are coupled via a common dc link, to allow bi-directional flow of real power between the series output terminals of the SSSC and the shunt output terminals of the STATCOM and are controlled to provide concurrent real and reactive series line compensation without an external electric energy source. The UPFC, by means of angularly unconstrained series voltage injection, is able to control, concurrently or selectively, the transmission line voltage, impedance and angle or alternatively, the real and reactive power flow in the line. The UPFC may also provide independently controllable shunt reactive compensation. Viewing the operation of the UPFC from the standpoint of conventional power transmission based on reactive shunt compensation, series compensation and phase shifting, the UPFC can fulfil all these functions and thereby meet

multiple control objectives by adding the injected voltage V_{inj} with appropriate amplitude and phase angle.

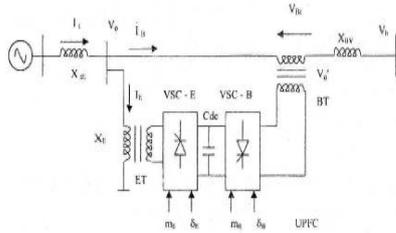

Fig 1. UPFC Installed in SMIB System

A combination of SHUNT controller and SERIES controller action is works as a unified power flow controller (UPFC) is used to control the power flow in a 500 kV transmission system. The SSSC and STATCOM located at the left end of the 75-km line L2, between the 500 kV buses B1 and B2, is used to control the active and reactive powers flowing through bus B2 while controlling voltage at bus B1. It consists of two 100-MVA, three-level, 48-pulse GTO-based converters, one connected in shunt at bus B1 and one connected in series between buses B1 and B2. The shunt and series converters can exchange power through a DC bus. The series converter can inject a maximum of 10% of nominal line-to-ground voltage (28.87 kV) in series with line L2. This pair of converters can be operated in three modes: Unified Power Flow Controller (UPFC) mode, when the shunt and series converters are interconnected through the DC bus. When the disconnect switches between the DC buses of the shunt and series converter are opened, two additional modes are available: Shunt converter operating as a Static Synchronous Compensator (STATCOM) controlling voltage at bus B1 Series converter operating as a Static Synchronous Series Capacitor (SSSC) controlling injected voltage, while keeping injected voltage in quadrature with current.

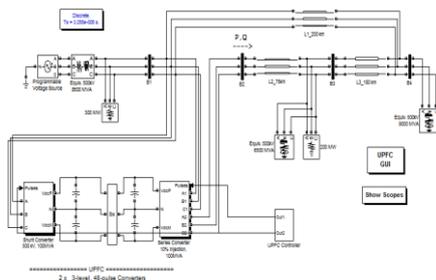

Fig 2. UPFC Simulink Model

III. Power control in UPFC mode:

Open the UPFC GUI block menu. The GUI allows you to choose the operation mode (UPFC, STATCOM or SSSC) as well as the Pref/Qref reference powers and/or Vref reference voltage settings. Also, in order to observe the dynamic response of the control system, the GUI allows you to specify a step change of any reference value at a specific time. Make sure that the operation mode is set to "UPFC (Power Flow Control)". The reference active and reactive powers are specified in the last two lines of the GUI menu. Initially, Pref= +8.7 pu/100MVA (+870 MW) and Qref=-0.6 pu/100MVA (-60 Mvar). At t=0.25 sec Pref is changed to +10 pu (+1000MW). Then, at t=0.5 sec, Qref is changed to +0.7 pu (+70 Mvar). The reference voltage of the shunt converter will be kept constant at Vref=1 pu during the

whole simulation 0.8 sec. When the UPFC is in power control mode, the changes in STATCOM reference reactive power and in SSSC injected voltage as are not used. Run the simulation for 0.8 sec. Open the "Show Scopes" subsystem. Observe on traces 1 and 2 of the UPFC scope the variations of P and Q. After a transient period lasting approximately 0.15 sec, the steady state is reached (P=+8.7 pu; Q=-0.6 pu). Then P and Q are ramped to the new settings (P=+10 pu Q=+0.7 pu). Observe on traces 3 and 4 the resulting changes in P Q on the three transmission lines. The performance of the shunt and series converters can be observed respectively on the STATCOM and SSSC scopes. If you zoom on the first trace of the STATCOM scope, you can observe the 48-step voltage waveform V_s generated on the secondary side of the shunt converter transformer superimposed with the primary voltage V_p and the primary current I_p . The dc bus voltage varies in the 19kV-21kV range. If you zoom on the first trace of the SSSC scope, you can observe the injected voltage waveforms V_{inj} measured between buses B1 and B2.

IV. VAR control in STATCOM mode:

In the GUI block menu, change the operation mode to "STATCOM (VAR Control)". Make sure that the STATCOM references values (1st line of parameters, [T1 T2 Q1 Q2]) are set to [0.3 0.5 +0.8 -0.8]. In this mode, the STATCOM is operated as a variable source of reactive power. Initially, Q is set to zero, then at T1=0.3 sec Q is increased to +0.8 pu (STATCOM absorbing reactive power) and at T2=0.5 sec, Q is reversed to -0.8 pu (STATCOM generating reactive power). Run the simulation and observe on the STATCOM scope the dynamic response of the STATCOM. Zoom on the first trace around t=0.5 sec when Q is changed from +0.8 pu to -0.8 pu. When Q=+0.8 pu, the current flowing into the STATCOM is lagging voltage, indicating that STATCOM is absorbing reactive power. When Qref is changed from +0.8 to -0.8, the current phase shift with respect to voltage changes from 90 degrees lagging to 90 degrees leading within one cycle. This control of reactive power is obtained by varying the magnitude of the secondary voltage V_s generated by the shunt converter while keeping it in phase with the bus B1 voltage V_p . This change of V_s magnitude is performed by controlling the dc bus voltage. When Q is changing from +0.8 pu to -0.8 pu, Vdc (trace 3) increases from 17.5 kV to 21 kV.

V. Series voltage injection in SSSC mode:

In the GUI block menu change the operation mode to "SSSC (Voltage injection)". Make sure that the SSSC references values (3rd line of parameters) [Vinj_Initial Vinj_Final StepTime] are set to [0.0 0.08 0.3]. The initial voltage is set to 0 pu, then at t=0.3 sec it will be ramped to 0.8 pu. Run the simulation and observe on the SSSC scope the impact of injected voltage on P and Q flowing in the 3 transmission lines. Contrary to the UPFC mode, in SSSC mode the series inverter operates with a constant conduction angle (Sigma= 172.5 degrees). The magnitude of the injected voltage is controlled by varying the dc voltage which is proportional to V_{inj} (3rd trace). Also, observe the waveforms of injected voltages (1st trace) and currents flowing through the SSSC (2nd trace). Voltages and currents stay in quadrature so that the SSSC operates as a variable inductance or capacitance.

VI. Anfis Controller

The ANFIS is the abbreviated of *adaptive neuro-fuzzy inference system*[13]. The performance of this method is like both ANN and FL. In both ANN and FL case, the input pass through the input layer (by input membership function) and the output could be seen in output layer (by output membership functions). Using a given input/output data set, the toolbox function ANFIS construct a fuzzy inference system (FIS) whose membership function parameters are tuned (adjusted).This adjustment allows your fuzzy systems to learn from the data they are modeling. Rule structure is essentially predetermined by the users' interpretation of the characteristic of the variables in the model. ANFIS applies FIS technique to data modeling [14]. We can choose membership function parameters automatically using ANFIS tool in MATLAB. Using ANFIS we can apply fuzzy inference to a system for which we already have a collection of input/ output data sets of parameters .Gradient vector reduce some error measures. This error measures is usually defined by the sum of the squared difference between the actual and desired outputs. ANFIS uses either back propagation or a combination of least squares estimation. Collect input/output data in a form that will be usable by ANFIS for training. You can create, train and test Sugeno type fuzzy systems using the ANFIS editor GUI. GUI includes four distinct areas to support a typical work flow (1>Loading ,plotting and clearing data (2)Generating or loading the initial FIS structure (3) training the FIS.(4)Validating the trained FIS. To get the FIS (Fuzzy inference system) from ANFIS tool, Training data is required for this, simulations were carried out on the original model with different values of voltage amplitude the data is shown in table below

Table I: Testing Data

Sr.No	input data	Output data
1	.9707	.9703
2	.9776	.7763
3	.9795	.6468
4	.9812	.5821
5	.983	.5174

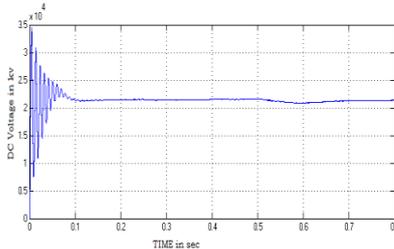

Fig 11. Variation of DC Voltage as per change in V_{inj} with PI Controller

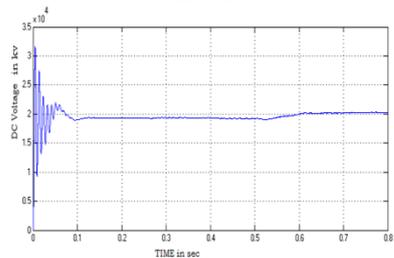

Fig 12. Variation of DC Voltage as per change in V_{inj} with ANFIS based Controller

VIII. Conclusion

Simulation results show that ANFIS based controlled slightly increases the power flow control by increasing the damping rate and decreases the amplitude of low frequency oscillations. Results comparison between conventional PI controller and the proposed ANFIS based controller for UPFC indicates that the proposed ANFIS based controller has less settling time and less overshoot when compared with the conventional PI controller.

Charging a Battery with the Electric Organ Discharge of Malapterurus Electricus Catfish

Hangnilo Robert

Laboratoire d'Électrotechnique, de Télécommunication et d'informatique Appliqué, LETIA ; Ecole Polytechnique d'Abomey-Calavi, EPAC, Université d'Abomey-Calavi, UAC ; 01BP2009 Cotonou-Bénin.

Abstract: Energy providing to meet user's requirements is an endless cause of concern. The people living in the developed countries, (G8) represent 13.1% of the world's population. That 13.1% consumed in 2002 about 1500 Giga Joules per habitant in energy. For the remaining countries' development, the need in energy will increase up to 500% in relation with the current level of need. Hence, it is necessary to harness new pollution free sources of energy like solar renewable energies. To meet that challenge of energy by taking into account the worldwide warming pollution we have studied *Malapterurus electricus* catfish in order to extract the electric energy contained in the electric organ discharge (EOD) of the catfish by charging a battery of accumulators.

Keywords - Energy challenge, electric organ discharge, *Malapterurus electricus*, worldwide warming pollution

I. Introduction

So many rivers flow through the Benin Republic, (see the map in Fig. 1-a.). *Malapterurus electricus* (Fig. 2-a.) that ever strongly electric catfish is a typical African knife fish, [1]. It is widespread in the sweet waters in the Republic of Benin, [2]. The country counts among the ever weakly equipped countries in the world. It is also an obvious fact that energy providing to the different end users as industries, transport, households and services in a country is the main activity on which depends the development of all others branches of the economy of that countr

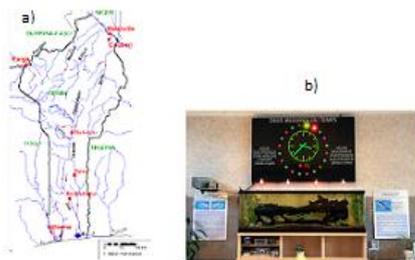

Figure 1. a - Hydrography of Benin Republic
b - Biological stopwatch in Nancy aquarium

Hence, every source of energy holding some potentiality must be scanned especially as that source is widespread in the considered area. It is just the case of the given catfish the EOD of which can reach 600 V with a frequency of 300 Hz! *Malapterurus electricus* is a true source of energy, [3].

Electric catfish are of course a subject of research all around the world. A team of scientists in Nancy University (France) has developed an application based on an electric catfish driving a stopwatch, (Fig. 1-b.). As we can see in Fig. 2-b., our team of research has succeeded in lighting in our laboratory a LED with the EOD of a very small size *Malapterurus electricus* catfish that weighs 19 g.

Malapterurus electricus can live in aquarium; its food habit and the characteristics of the water in its habitat are well known, [4], [5]. A battery-farming of that knife fish is quiet probable. In this way the feasibility of an energy farming centered on that catfish is quite conceivable.

The present paper reports the results of charging a 12 V battery of accumulators which really is the battery of a motorcycle Sanya 111-C type, see Fig. 9.

II. Materials and method

Figure 2. a- *Malapterurus electricus* catfish living in aquarium in LETIA, b- *Malapterurus Electricus* switching on a LED in LETIA

2.1 Determination of the electrical energy characteristics produced by the *Malapterurus electricus* catfish

We have determined the electrical characteristics of the EOD of *Malapterurus electricus* catfish. An individual of that catfish of 15 cm of length and 64.9 g of live body weight was farmed in an aquarium (Fig. 3.) in order to follow its feeding behaviour, its physical characteristics, the electrical parameters of its EOD and the parameters of the water in the aquarium, (see Table 1). The results show that *Malapterurus electricus* produces intermittent bursts of a frequency framed with 250 and 300 Hz, Fig. 4. Each burst lasted about half a second. The electrical organ discharge displayed on the oscilloscope showed a single curve whose dual amplitude having up to 29 V, see Table 2. Discharges were more regularly during a night (or in darkness) than during a day (or under lighting), see Fig. 5 and 6. Thus *Malapterurus electricus* is a typical bioelectrical voltage generator

Table 1
Average value of the parameters of the water in the aquarium

Period	Temperature, °C	PH	Conductivity, µS/cm	Oxygen ratio, mg/l
Morning, 8 o'clock	26.3	8.49	25.07	7.67
Midday, 12 o'clock	29.32	8.51	25.10	7.98
Evening, 7 o'clock	27.55	8.5	25.00	7.95
Night, 3 o'clock	26.05	8.48	25.04	7.23

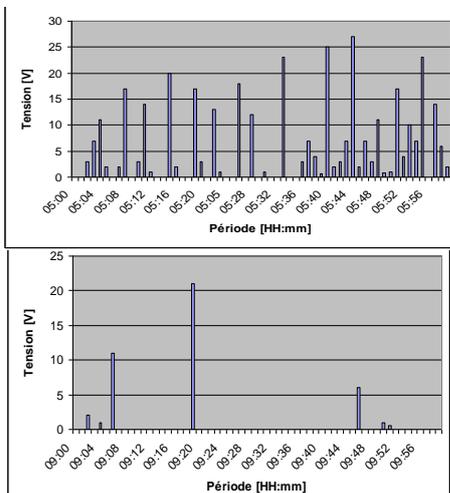

Figure 5. Recorded EOD on: a- 13/10/10 at night; b- 14/10/10 during the day time

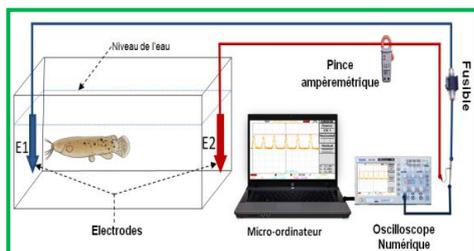

Figure 6. Connecting the catfish to an end user

2.2 Modeling the electric organ discharge of the Malapterurus electricus catfish

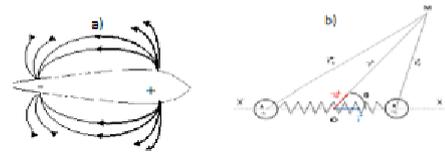

Figure 7a- Malapterurus electricus as an electric Dipole; b-Electromechanic model of the catfish

The electric dipole theory is applied for modeling the catfish, see Fig. 7-a. Malapterurus electricus is considered as a particular system of electric charges that are linked by a spring, see Fig. 7-b. Taking into account the main forces of that system of electric charges and applying the dynamic law, we got a non linear differential equation that we solve by the Adomian decomposition technique, [6]. Neglecting the viscous force ($F_v = 0$), we found the solution for that particular case as following:

$$x(t) = \sqrt[3]{\frac{\lambda}{\beta}} (1 - \cos 3\sqrt{\beta} t)^{\frac{1}{3}}, \quad (1)$$

We put the relation (1) in the equation of the electric potential $V(M)$ of an electric dipole and we obtain relation (2):

$$V(M) = \frac{1}{4\pi\epsilon_0} \frac{2q(a+x)}{r^2} \cos \theta, \quad (2)$$

The result of Simulation that model (2) in Matlab is similar to the EOD of the catfish and to a Graetz bridge rectifier output voltage in power electronics as we can see in Fig. 4 and 8-b. In fact that EOD of the electromechanical model is unidirectional like the catfish one. From now it becomes clear for us how to connect Malapterurus electricus to an end user application as lighting a LED or charging a battery.

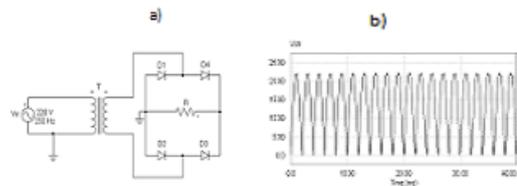

Figure 8 a- Graetz bridge rectifier; b- Output voltage of the rectifier and/or simulating result of the electromechanical model

III. Results and discussion

We know that Malapterurus electricus catfish produces strong EOD only in darkness, [2]. To reach the goal we have hidden the aquarium of the catfish with a colored paper as shown in Fig. 9- a. We stimulate the catfish from time to time by touching it carefully with a piece of wood. With the help of an interface, figure 10, the energy of the EOD of the fish is conveyed towards the battery, Fig. 9-b. Within three days the battery's voltage rises from 6 V to 9.83 V as we can notice in Table. 3. That result is given by a single catfish with a very small size! A manual exciting of the catfish cannot allow a quick operating process of charging a battery with the EOD of Malapterurus electricus of course. Hence, it is necessary to mechanize the exciting

process of the catfish. For many catfish the electronic interface must include a chopper that will reduce the output voltage of the biological source of energy to the required value that can be 12 V or a multiple of it.

	6.6	7.9	8.9	8.9	9.1	9.1	9.3	9.3	9.5	9.6	9.7	9.8

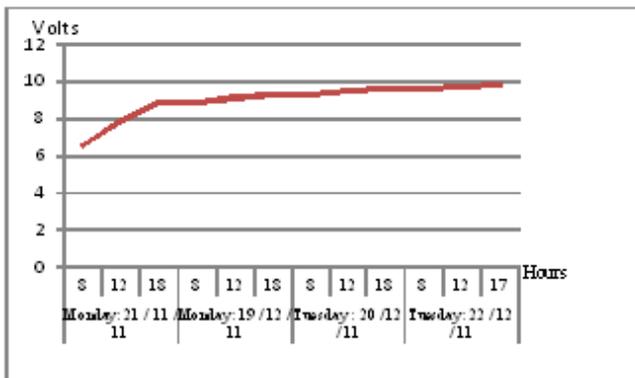

Figure 10. Characteristics of the charging of the battery

IV. Conclusion

Malapterurus electricus is really a bioelectrical voltage generator. The present study aims to use the EOD of that catfish for charging a battery in order to diversify energy sources in the Republic of Benin. An individual of *M. electricus* of 15 cm length and 64.9 g live body weight was used for the target. It was kept in an aquarium in polyvinyl chloride material. Within four days and some hours per day we have succeeded in raising the potential difference of a battery from 6 V to 9.83 V. The feasibility of the utilization of *Malapterurus electricus* catfish as a power source is now established. The recharging duration of the battery will decrease with the increasing of the number of the catfish in the aquarium. The catfish was not excited all the time during the four days recharging process. To stimulate the catfish we use to touch it carefully with a piece of wood. We'd get better from the catfish by mechanizing that operation.

Early Detection of Powdery Mildew Disease for Betelvine Plants Using Digital Image Analysis

Mr.J.Vijayakumar¹ Dr.S.Arumugam²

¹Research scholar, Nandha College of Technology- Erode. Tamilnadu, India

²Chief Executive officer, Nandha Educational Institution - Erode. Tamilnadu, India.

Abstract: The fresh leaves of betelvine are generally known as paan in India. Betelvine plants are infected variety of diseases in the entire plantation without any early indications of the diseases. The aim of this paper is to recognize powdery mildew disease in the betelvine plants using digital image analysis techniques. The digital images of the betelvine leaves at various stages of the powdery mildew disease are collected from different plants using a high resolution digital camera and it is stored with JPEG format. The digital image analyses of the leaves are done using the image processing toolbox in MATLAB which provides the standard patterns of the digital images. Using RGB encoding technique the red, green and blue components of the preprocessed image were separated, which forms the pattern to be compared. These patterns and images of various healthy betelvine leaves at different stages in various days are collected and stored in the system. The standard deviation for all sample leaves is computed and calculated values are stored in the system. The standard deviation of test leaves are computed and compared with the stored values. As the result of this comparison, it is identified whether test leaves are affected by powdery mildew disease or not. Finally this analysis helps to recognize the powdery mildew disease can be identified before it spreads to entire crop.

Keywords: Keywords: Betelvine, Powdery mildew Disease and Oidium piperis

I. Introduction

Piper Betel L generally known as Vetrilai in Tamil. The Piper betle is a glabrous climbing vine belonging to the family *Piperaceae*. The betelvine leaf is used in a number of traditional medicines for the treatment of stomach complaints, infections and as a general refresher. Some evidence suggests that betelvine leaves have immune boosting properties as well as anti-cancer properties. Lots of research is going on in the field of betelvine diseases analysis for various centers within the country under the name "ALL INDIA NETWORKING PROJECT IN BETELVINE". During cultivation betelvine is very much affected by diseases and insects that outcome in big loss for the farmers. The most important diseases of betelvine leaf are Powdery mildew, Foot Rot, Leaf Rot and Leaf Spot. It occurs in a very virulent form and if not controlled, causes widespread injure and even total demolition of the entire of betelvine plantations. The farmer is not able to identify the disease at an early stage to initiate preventive action due to the non-availability of modern technology. So for each

farmer, to have access to the modern technology there is a need to construct modern commercial farm. This has been the base to develop a new tool to identify the disease well in advance to enhance the cultivation. Digital Image processing is used as a tool for early identification of the Powdery mildew disease.

II. COMPUTERIZED BETELVINE PLANT POWERY MILDEW DISEASE IDENTIFICATION

Basically when a farmer visualizes the disease, seen as a change in the form of color or appearance the disease is in the matured stage after which diagnosis cannot save the plant. The disease spreads to the entire crop and the entire plantation gets destructed within few days. Powdery mildew disease emerges on the undersurface of the leaves as white to brown powdery patches. Human eye cannot predict the disease at an early stage. So we are using computerized image analyzing system in which minute change in the form of color in leaves can be detected at an early stage.

III. POWDERY MILDEW DISEASE

Powdery mildew is sourced by *Oidium piperis*. The disease shows on the undersurface of the leaves as white to brown powdery patches. The photograph is shown in figure 1 and figure 2 for front and back view of Powdery mildew infected betelvine leaf. These infected areas gradually increase in size and repeatedly combine with each other. They vary in size from a few to 40mm in diameter and are covered by dusty growth which is fairly thick in cases of sever attack. Areas on the upper surface corresponding to patches on the under surface appear yellowish, raised and irregular in outline. Young leaves when attacked fail to grow and become deformed, the surface being cracked and the margin turned inwards.

Figure1:Front view

Figure 2: Back view

Such leaves present a pale appearance and drop with slight disturbance. The disease is more prevalent in old plantations. The disease has been reported to be in the leaves only and it has been found to disappear during the hot season.

IV. METHODS FOR DISEASE IDENTIFICATION

The betelvine leaves are properly washed to remove the dust components. Digital imaging technique is divided in three phases respectively as,

- Normal or uninfected leaves phase,
- Fully Infected leaves phase
- Test leaves phase

Normal or uninfected leaves phase consists of without any disease infected in the betelvine leaf. Fully Infected leaves phase consisted of visually identifiable infected leaf, samples are collected for normal leaves and various stages of Powdery mildew disease. Test leaves phase consists of visually unidentifiable infected leaf, samples are collected at various stages of the Powdery mildew disease. Fifteen samples from each phase were taken for this paper. The size of all the digital images are 256 x 256. To eliminate the background using photo shop 7.0 and background was chosen to be white and these digital images are stored in the system. This stored digital images are given as input to the MATLAB file and the R,G,B colour components are separated and find the mean values for all healthy and infected leaves and calculated values are stored in the system. For the test leaf, compute standard deviation and compare all the stored values, to recognize the diseased betelvine leaf affected by powdery mildew disease.

V. RESULT

The result of the paper is all the normal and infected leaves are given as input to the MAT LAB and RGB color components are separated. The standard deviation are calculated for front and back view of each component and calculated standard deviation values are stored in the system and test leaves are given as input to the MAT LAB and RGB color components are separated and the standard deviation values are calculated for front and back view of each component and calculated standard deviation values are stored in the system. To compare all the stored results and identify either disease infected or not in the test betelvine leaf, the standard deviation values of Red component for normal leaves, infected leaves and test leaves front and back views are shown in figure 3 and figure 4 . The standard deviation values of green component for normal leaves, infected leaves and test leaves front and back views are shown in figure 5 and figure 6 . The standard deviation values of Blue component for normal leaves, infected leaves and test leaves front and back views are shown in figure 7 and figure 8.

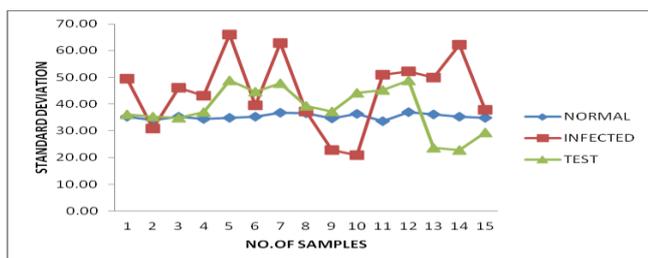

Figure 3: Front View for Red Component

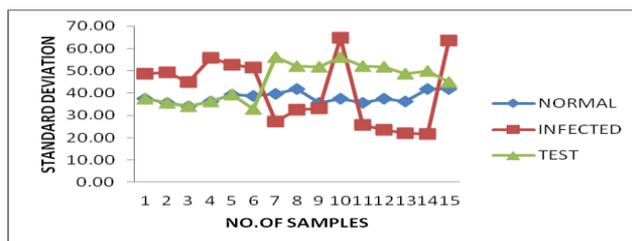

Figure 4: Back View for Red Component

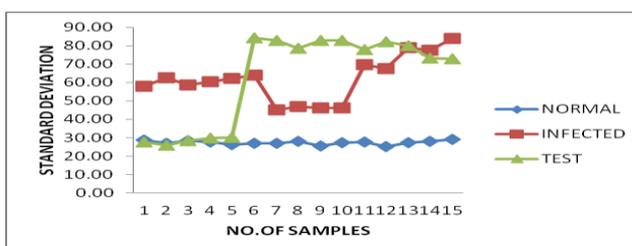

Figure 5: Front View for Green Component

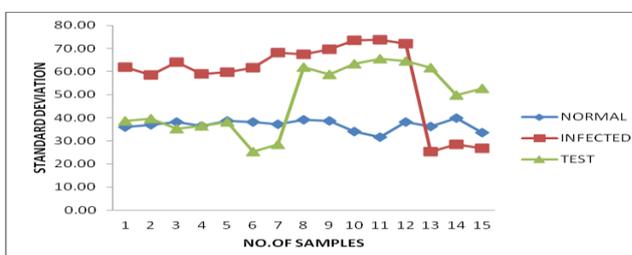

Figure 6: Back View for Green Component

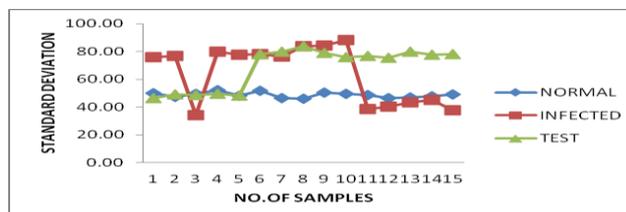

Figure 7: Front View for Blue Component

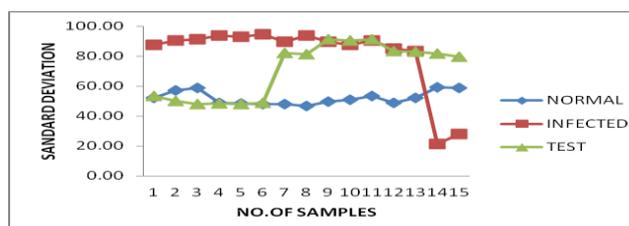

Figure 8: Back View for Blue Component

In normal leaves, front view of Red component standard deviation value ranges from 33.53 to 36.89 and back view of Red component standard deviation value ranges from 34.07 to 41.89. In infected leaves, front view of Red component standard deviation value ranges from 20.97 to 65.96 and back view of Red component standard deviation value ranges from 21.61 to 64.84. In test leaves, first five samples of front view Red component standard deviation value ranges from 33.53 to 36.89 and back view of Red component standard deviation value ranges from 34.07 to 41.89 and last ten samples of front view Red component standard deviation value ranges from 20.97 to 65.96 and

back view of Red component standard deviation value ranges from 21.61 to 64.84. In normal leaves, front view of green component standard deviation value ranges from 25.21 to 29.14 and back view of green component standard deviation value ranges from 31.66 to 39.78. In infected leaves, front view of green component standard deviation value ranges from 45.24 to 84.09 and back view of green component standard deviation value ranges from 25.30 to 73.72. In test leaves, first five samples of front view green component standard deviation value ranges from 25.21 to 29.14 and back view of green component standard deviation value ranges from 31.66 to 39.78 and last ten samples of front view green component standard deviation value ranges from 45.24 to 84.09 and back view of green component standard deviation value ranges from 25.30 to 73.72. In normal leaves, front view of blue component standard deviation value ranges from 46.02 to 52.31 and back view of blue component standard deviation value ranges from 46.78 to 59.27. In infected leaves, front view of blue component standard deviation value ranges from 34.25 to 88.34 and back view of blue component standard deviation value ranges from 21.06 to 94.66. In test leaves, first five samples of front view blue component standard deviation value ranges from 46.02 to 52.31 and back view of blue component standard deviation value ranges from 46.78 to 59.27 and last ten samples of front view blue component standard deviation value ranges from 34.25 to 88.34 and back view of blue component standard deviation value ranges from 21.06 to 94.66.

To compare all the fifteen test sample leaves of standard deviation values from stored standard deviation values of normal and infected leaves. The result is first five test sample leaves are uninfected or normal leaves and the remaining ten test sample leaves are infected leaves.

VI. CONCLUSION

The above proposed methods convey that the betelvine plants disease can be identified disease infected or not in the betelvine leaf and thus preventive action can be taken well in advance such that the entire plantation can be saved before the disease starts to spread. The method of detecting the disease is cost effective and non-destructive as it only requires the digital photograph of the leaf samples in random. The efficiency of the system can be increased by taking the camera parameters, as the camera parameters are considered constant in this project. Periodic inspection of the farm is required to prevent the disease. This method can also be extended to detect diseases of all kind to initiate early preventive action.

AUTHOR'S BIOGRAPHY

Mr.J.Vijayakumar received the Bachelor of Engineering in Electronics and Communication Engineering from Maharaja Engineering College under Bharathiar university-Coimbatore in the year of 2003 and Master of Engineering in Applied Electronics from Bannari Amman Institute of Technology under Anna university-Chennai in the year of 2005. He is doing Ph.D. work in Anna University of Technology- Coimbatore under the guidance of Dr. S. Arumugam. He is working as Assistant Professor in the Department of Electronics and Communication Engineering in Nandha College of Technology- Erode. His area of interest is Digital Image Processing.

Dr.S.Arumugam completed his bachelor degree in Electrical and Electronics Engineering and M.Sc(Engg)., in Applied Electronics both from PSG College of Technology under University of Madras and Ph.D., in Computer Science and Engineering from Anna University. He has been serving in the Directorate of Technical Education since 1974 onwards. He retired from Government service as additional Director of Technical Education and Chairman Board of Examinations. He served as Chief member of various boards of studies. He is a fellow member in IE, IETE, senior member in CSI and member in IEEE. He has guided 15 Ph.D scholars and 23 Ph.D scholars are working under his guidance. He has so far published over 100 papers in various National and International Journals and Conferences. His area of interest is Digital Image Processing. Presently he is working as Chief Executive officer, Nandha Educational Institution-Erode.

Evaluation of Flexural Properties of Fly Ash Filled Polypropylene Composites

Abstract: In recent time's polymer waste disposal is a challenging task as the quantity of polymer waste is increasing day by day. In this research work particulate composites have been developed from recycled polypropylene filled with fly ash. Fillers are used along with various commodities as well as engineering polymers to improve the properties of polymers. The performance of filled polymers is generally determined on the basis of the interface attraction of filler and polymers. Fillers of widely varying particle size and surface characteristics are responsive to the interfacial interactions with polymers. The present study deals with the effect of particle size and its concentration on the properties of fly ash filled polypropylene composites. Five different particle sizes of fly ash are used for sample preparation. Concentration of fly ash is also varied from 0, 10%, 15%, 20%, 25% by weight in the polypropylene. The composite test specimens are prepared using injection molding machine with hand lay up technique as per ASTM D3641 standards. Bending tests on the specimens are carried out by using tensometer. Flexural strength and modulus are calculated from the obtained load values and the result is analyzed for the prepared samples.

Keywords: Polypropylene, Composite, Fly ash, Flexural properties.

I. Introduction

Particulate composites have received considerable interest in the materials field because of their potential for large gains in mechanical and morphological properties. Thermoplastic polymers and especially polypropylene are produced and used today in vast quantities. However, they are seldom used as pure polymers and are usually combined with mineral fillers like fly ash, graphite etc. Fillers find application in the polymer industry almost exclusively, e.g. to improve mechanical, thermal, electrical properties and dimensional-stability. The low modulus of isotropic polypropylene means that it is unsuitable for many load bearing applications. In order to improve the stiffness of polypropylene, two main routes will be considered here. The first route is to improve stiffness by the introduction of foreign fillers, such as glass fibers, to create polypropylene composite materials. The second route is the exploitation of the inherent molecular strength by uncoiling the molecules and orienting them in the direction of loading, so that the load is transferred by the stiff carbon backbone rather than by weak intermolecular bonds.

Fly ash is finely divided mineral residue resulting from combustion of coal in electric generating plants. Fly ash consist mostly of SiO_2 , Al_2O_3 , and Fe_2O_3 and are present in inorganic incombustible matter present in coal that has been fused during combustion to glassy amorphous structure. Fly ash used in cement industry could be used as filler in plastic products and depending upon the source of coal, contain elements like carbon, Ti, Mg, etc. So the fly ash has combined properties of spherical particles and that of metals and metal oxides.

Polypropylene (PP) is a thermoplastic polymer used in a wide variety of applications including packaging, textiles (e.g., ropes, thermal underwear and carpets), stationery, plastic parts and reusable containers of various types, laboratory equipment, loudspeakers, automotive components, and polymer banknotes. Most commercial polypropylene is isotactic and has an intermediate level of crystallinity between that of Low-Density PolyEthylene (LDPE) and High-Density PolyEthylene (HDPE). Polypropylene is normally tough and flexible, especially when copolymerized with ethylene. This allows polypropylene to be used as an engineering plastic, competing with materials such as acrylonitrile butadiene styrene. Polypropylene has good resistance to fatigue. The melting of polypropylene occurs as a range, so a melting point is determined by finding the highest temperature of a differential scanning calorimetry chart. Perfectly isotactic Polypropylene has a melting point of 171°C (340°F). In this investigation we studied the effect of fly ash with five varying particle sizes and concentration on flexural properties.

Utilization of fly ash as filler for unsaturated polyester resin was studied by Saroja Devi et al.[1]. Measurement of the specific heat of plastic waste fly ash composite material using differential scanning calorimetry was observed by Fujino and Honda [2]. Structure and strength properties of Polypropylene Polymethyl methacrylate fly ash blends developed by Navin Chand and Vashishtha [3]. Mechanical properties of natural rubber filled with fly ash was prepared and observed by Hundiwale et al.[4]. Effect of fly ash on the mechanical, thermal, dielectric, rheological and rphological properties of filled nylon 6 was studied by Suryasarathi Bose and Mahanwar [5]. Utilization of fly ash as filler for polybutyleneterephthalate-toughened

epoxy resin was developed by Ramakrishna et al. [6]. Thermal and Electrical behavior of vinyl ester resin matrix composites filled with fly ash particles was studied by Dipa Ray et al. [7]. Preparation and dynamic mechanical properties of polyurethane-modified epoxy composites filled with functionalized fly ash particulates was observed by Gaohui Wu et al. [8]. Effect of fly ash content, particle size of fly ash, and type of silane coupling agents on the properties of recycled polyethylene terephthalate / fly ash composites was investigated by Seena Joseph et al.[9]. Correlation of mechanical and structural properties of fly ash filled-isotactic polypropylene composites was studied by Dilip Chandra Deb Nath, Bandyopadhyay [10]. Effect of particle size and concentration of fly ash on properties of polyester thermoplastic elastomer composites was examined by Sreekanth et al. [11]. Mechanical and structural properties of polypropylene composites filled with graphite flakes were studied by Akinci [12]. Mechanical properties of epoxy resin – fly ash composite were developed by Manoj Singla and Vikas Chawla [13]. Polyetheretherketone (PEEK) composites reinforced with fly ash and mica was developed by Rahail Parvaiz.et al.[14]. Furfuryl palmitate coated fly ash used as filler in recycled polypropylene matrix composites was observed by Shubhalakshmi Sengupta et al. [15]. Review of literature survey shows that different type of properties like mechanical, thermal, dielectric, rheological, morphological were studied on the particulate composites made from graphite, silica as a filler and thermoplastic materials like Polyaryletherketone, Polybutadiene, Polybutylene, Polybutylene terephthalate, Polycaprolactone as a matrix medium. How ever there is a limited literature available on the particulate composites especially made from Polypropylene and fly ash. Hence in the present study particulate composites made from polypropylene and fly ash are fabricated and studied for flexural properties and the results are analyzed.

II. Sample Preparation

2.1 Material

Polypropylene granules were purchased from Maram polymers Pvt.Ltd, Vijayawada, Andhra Pradesh, India and the filler fly ash was obtained from Vijayawada Thermal Power Station, Kondapalli, Andhra Pradesh, India were used in the sample preparation.

2.2 Fabrication

The polypropylene granules along with fly ash were melted in the vertical injection molding machine with two heating zones set at 160^o and 120^o. The weights of fly ash in the composite were 0, 10%, 15%, 20% and 25% of total weight of polypropylene. The samples of fly ash/PP composites with varying particle sizes (53-75 μ m to 212-300 μ m) and also varying concentration were prepared by vertical injection machine as shown in Figure 2.1, as per ASTM D 3641Standards. Figure 2.2 shows the plain polypropylene sample and the fly ash filled poly propylene composite sample is shown in Figure 2.3. Sufficient pressure is applied on the sample to eliminate voids in the composite. Samples were air cooled at room temperature.

Figure 2.1: Hand Operated Vertical Injection Machine

Figure 2.2: Plain polypropylene sample

Figure 2.3: Fly ash filled polypropylene composite sample

2.3 Mechanical testing of composites

The fabricated specimens were tested using a 2 ton capacity - Electronic Tensometer, METM 2000 ER-I model, with a cross head speed of 2 mm/min in accordance with standard ASTM D790 under ambient conditions. The schematic representation of load application is as shown in Figure 2.4. Load and elongation values are determined for all samples. Utilizing the experimental values of load and elongation, flexural strength (f_s), flexural modulus and elongation at break were determined. Reported values are the average of five samples in all measurements. Some of the tested samples are shown below in the following figures from Figure 2.5 to Figure 2.9.

Figure 2.5: 15 percentage of fly ash at 212-300 microns

Figure 2.6: 20 percentage of fly ash at 76-105 microns

Figure 2.7: 20 percentage of fly ash at 76-105 microns

Figure 2.8: 25 percentage of fly ash at 150-211 microns

Figure 2.9: 25 percentage of fly ash at 76-105 microns

Figure 2.10: 25 percentage of fly ash at 212-300 microns

2.4 Calculation of flexural properties

The flexural stress, flexural strain, flexural modulus and percentage of elongation at break values of the composites were determined by substituting load and elongation values in the below formulae.

$$\text{Flexural stress } \sigma_f = \frac{3PL}{2bd^2} \quad (\text{for a rectangular cross section})$$

$$\text{Flexural strain } \epsilon_f = \frac{6Dd}{L^2}$$

$$\text{Flexural modulus } E_f = \frac{L^3m}{4bd^3}$$

Following are the notations used in above formulae

σ_f = Stress in outer fibers at mid point, (MPa)

ϵ_f = Strain in the outer surface, (mm/mm)

E_f = Flexural Modulus of elasticity, (MPa)

P = Load, (N)

L = Support span, (mm)

b = Width of test beam, (mm)

d = Depth of test beam, (mm)

D = Maximum deflection of the center of beam, (mm)

m = The gradient (i.e., slope) of the initial straight-line portion of the load deflection curve, (P/D), (N/mm)

The obtained values are shown below in the Table 1, Table 2 and Table 3.

III. Results And Discussion

From Table 1, it was observed that as the addition of filler decreases the flexural strength. From Figure 3.1, it was observed that rate of flexural strength decrease when large particle sizes were used. This is because of the particle agglomeration at higher filler contents. Particle agglomeration tends to reduce the strength of a material because the agglomerates are weak point in material and break easily when a stress is applied to them. These points then acts as stress concentrator. Agglomerations resulting from larger sized filler particles will produce weaker materials than composites having well dispersion of small sized particles. The rate of decrease of flexural strength is higher in the case of larger particle size of fly ash.

From Figure 3.2, shows the variation of flexural strength with the variation in size of the particles used in polypropylene fly ash filled composites. It was observed that smaller particles showed higher value of flexural strength. For smaller particles, as particle size decreases, interfacial area/unit volume is increased, and hence, flexural strength is increased. The effect of filler on flexural strength may be due to the counterbalance of two phenomenon's with the increase in the filler content in a polymer composite there is increase in effective surface fracture energy, size of voids and agglomeration of filler particles. The dispersed particles make the crack propagation path longer, absorb a portion of energy and enhance the plastic deformation.

Table 1: Flexural Strength of fly ash filled polypropylene composites with fly ash at different sizes and varying percentage content of fly ash

Fly ash sizes → Percentage of fly ash ↓	53-75µm	76-105µm	106-149µm	150-211µm	212-300µm
0%	56.88	56.88	56.88	56.88	56.88
10%	72.38	59.23	70.71	71.25	73.62
15%	70.29	53.53	59.73	66.18	55.71
20%	66.02	54.44	57.30	61.16	51.36
25%	60.99	57.94	56.80	57.39	44.99

Table 2 shows the values of flexural modulus and from the Figure 3.3, shows the percentage of fly ash at different sizes added to the polypropylene. Figure 3.4, shows the variation of flexural modulus of fly ash composite with filler content and particle size. Flexural modulus increases for smaller filler loading decreases for larger filler loading. Rate of increase is more for smaller particle size than larger ones. Because smaller particles have higher surface area than larger ones, these particles can have higher interaction with matrix at lower concentration of filler. Agglomeration if present, the apparent volume occupied by the filler is increased and agglomeration results in bigger particles by which void space is generated, which can be responsible for strain propagation. The increase in the flexural modulus of PP fly ash composite is due to the increase in the crystalline of composites by addition of fly ash.

Table 2: Flexural Modulus of fly ash filled polypropylene composites with fly ash at different sizes and varying percentage content of fly ash

Fly ash at sizes →	53-75µm	76-105µm	106-149µm	150-211µm	212-300µm
Percentage of fly ash ↓					
0%	1591.19	1591.19	1591.19	1591.19	1591.19
10%	1673.33	1506.43	1419.05	1259.15	954.54
15%	2295.47	1940.71	1936.34	1504.68	1276.62
20%	2719.27	2481.59	2390.72	1943.33	1696.05
25%	2565.48	2011.49	1696.05	1329.05	1429.54

Table 3 shows the values of percentage of elongation at break of the composites and from the Figure 3.5, shows the amount of fly ash different sizes added to the polypropylene and the percentage elongation at break is also decreases on addition on filler as shown in Figure 3.6. This is due to the interference of filler in the mobility or deformability of the matrix. This interference is created through the physical interaction and immobilization of the polymer matrix by the presence of mechanical restraints, there by reducing the elongation at break. Fly ash with smaller particle size show higher values of elongation at break when compared to larger particle size.

Table 3: Percentage Elongation at Break for fly ash filled polypropylene composites of fly ash at different sizes and varying percentage content of fly ash

Fly ash at sizes →	53-75µm	76-105µm	106-149µm	150-211µm	212-300µm
Percentage of fly ash ↓					
0%	8.91	8.91	8.91	8.91	8.91
10%	7.33	4.43	3.75	3.66	3.46
15%	4.86	3.92	3.66	3.53	3.46
20%	3.97	2.59	2.53	2.29	2.21
25%	2.60	2.56	2.50	2.05	1.97

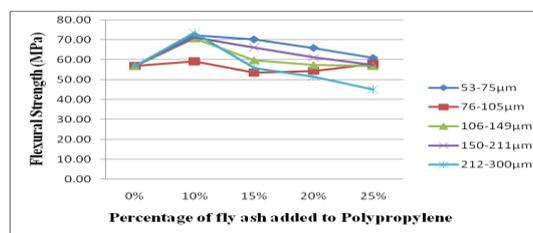

Figure 3.1: Variation of Flexural strength with percentage of fly ash added to the polypropylene Composite

Figure 3.1 shows the flexural strength values of fly ash filled composites at different sizes of fly ash at varying percentages of fly ash. Figure 3.2 shows the flexural strength of fly ash filled composites at smaller particle size and larger particle size i.e.(at 53-75 microns of size and 212-300 microns of size).It was noticed that flexural strength value increases for smaller particle size and the flexural strength value decreases for the larger particle size. This is due to the smaller particle have more surface area when compared to the larger particle.

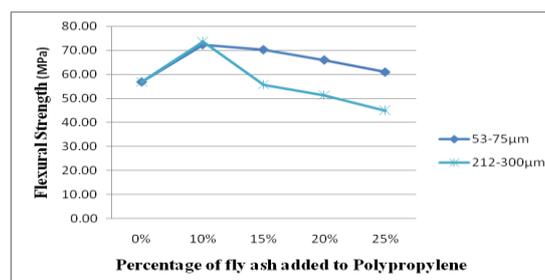

Figure 3.2: Flexural strength variation between the smaller Size particle and the larger Size particle added to polypropylene Composite

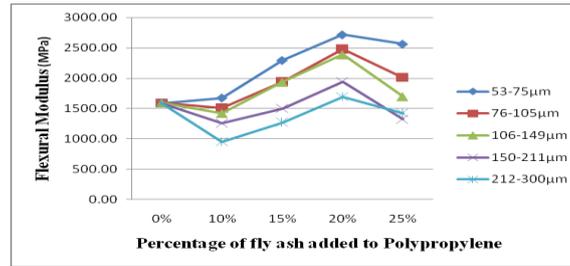

Figure 3.3: Variation of Flexural modulus with percentage of fly ash added to the polypropylene Composite

Figure 3.3 shows the flexural modulus values of fly ash filled composites at different sizes of fly ash at varying percentages of fly ash. Figure 3.4 shows the flexural modulus of fly ash filled composites at smaller particle size and larger particle size i.e. (at 53-75 microns of size and 212-300 microns of size). It was noticed that flexural modulus value increases for smaller particle size and the flexural modulus value decreases for the larger particle size.

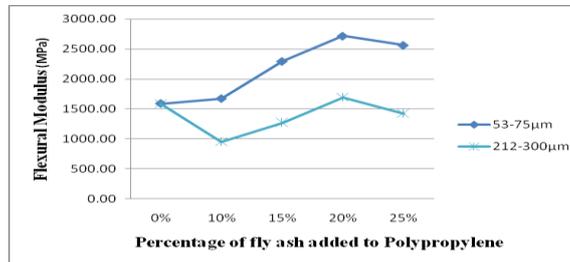

Figure 3.4: Flexural Modulus variation between the smaller Size Particle and the larger Size particle added to polypropylene Composite

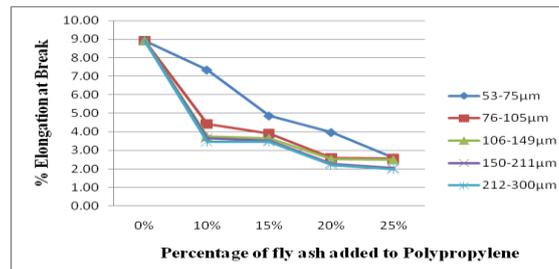

Figure 3.5: Variation of Flexural modulus with percentage of fly ash added to the polypropylene Composite

Figure 3.5 shows the percentage elongation at break values for fly ash filled composites at different sizes with varying percentages of fly ash content with the polypropylene. Figure 3.6 shows the percentage elongation at break of fly ash filled composites for smaller particles and larger particles i.e. (at 53-75 microns of size and 212-300 microns of size). It was noticed that percentage elongation at break value decreases for smaller particle size and the percentage elongation at break value goes on decreasing for the larger particle size.

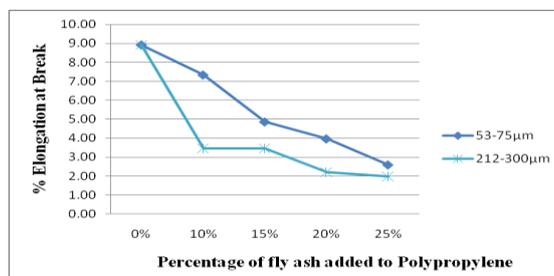

Figure 3.6: Percentage Elongation at Break between the smaller Size particle and the larger Size particle added to polypropylene Composite

IV. CONCLUSION

The flexural properties of fly ash filled polypropylene composites were evaluated in the present research work. Fly ash is found to be good filler for polypropylene matrix composites. With fly ash added to the Polypropylene improves flexural strength and flexural modulus, but dramatically decreases percentage elongation at break. Finest particles showed best flexural strength at all concentrations. The mechanical properties of the composite were found to be a function of the particle size, aspect ratio, the dispersion, the particle orientation, the interfacial interaction between the minerals and the polymer matrix. Spherical shaped filler, such as fly ash gives significant improvement in stiffness due to better surface area for interaction. It is concluded that composites with fly ash at smaller particle size showed significant improvement mechanical properties of composite when compared to the larger particle size of the composites.

ABSTRACT: We developed the theoretical and experimental method for chromatic dispersion of Borosilicate Crown microstructure optical fiber from scalar effective index method (SEIM) and TBC has been reported. To maintain the flat and zero dispersion in photonic crystal fiber (PCF) different air hole diameter has been introduced. Here we use Borosilicate Crown glass as a core material. A photonic crystal fiber with large effective mode area and flat dispersion property may be very usefull for next generation optical data.

Keywords: Effective Refractive Index (n_{eff}), Photonic Crystal Fiber (PCF), Scalar Effective Index Method (SEIM), Transparent Boundary Condition (TBC).

I. INTRODUCTION

In these years PCF [1,2] is very attracted in the research group because of many of their attractive properties [3] as high birefringence, very high and low nonlinearity, wideband dispersion [4-10] flattened characteristics, endlessly single mode guiding [11,12], fiber sensors [13, 14] and fiber lasers [15,16]. Many research papers have published some optical properties of PCFs such as unique chromatic dispersion, which are almost impossible for the conventional optical fibers. Most PCFs are used silica as core material and core is surrounded by air holes called photonic crystal structure [17-20]. The PCF is made by a single material. Here we use Borosilicate crown glass as core material. Borosilicate glass was first developed by German glassmaker otto Schott in the late 19th century. Most borosilicate glass is cololeless 70 % silica, 10% boron oxide, 8% sodium oxide, 8% potassium oxide and 1% calcium oxide are used in the manufacture of borosilicate glass. Borosilicate crown glass (BK7) is an optical material used in a large fraction OPTICS products. It is relatively hard glass, doesn't scratch easily. Another important feature of BK7 is very good transmission down to 350 nm. Due to these properties, BK7 are widely used in the optics industry.

In this paper , we proposed two layer cladding PCF characterized by a common air hole space (pitch) and two different air hole diameters. The structure can ensure flat dispersion in a wide wavelength range and simple than the existing designs.

II. PROPOSED STRUCTURE

Figure 1. shows the proposed PCF. The inner three layer of cladding is composed of a common air hole pitch Λ and

diameter d_1 and outer three layer of cladding is composed diameter d_2 , where d_1 is less than d_2 . To achieve larger mode area we design the air holes of inner rings are chosen smaller. We have investigated the dispersion for different air hole diameter of inner and outer ring.

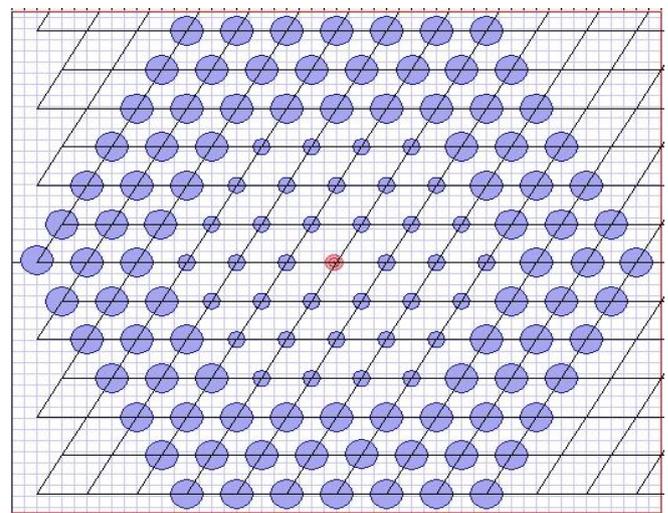

Figure 1. Proposed PCF.

Structure Parameter-

1. $d_1 = 0.5 \mu\text{m}$, $\Lambda = 2.0 \mu\text{m}$ and $d_2 = 1.5 \mu\text{m}$
2. $d_1 = 0.6 \mu\text{m}$, $\Lambda = 2.0 \mu\text{m}$ and $d_2 = 1.4 \mu\text{m}$
3. $d_1 = 0.7 \mu\text{m}$, $\Lambda = 2.0 \mu\text{m}$ and $d_2 = 1.3 \mu\text{m}$
4. $d_1 = 0.8 \mu\text{m}$, $\Lambda = 2.0 \mu\text{m}$ and $d_2 = 1.2 \mu\text{m}$

The wafer chosen is of Borosilicate crown glass with 1.5168 refractive index and the air hole refractive index is 1.0. In figure 1 we have change the inner and outer ring air hole diameter.

The value of refractive index of Borosilicate crown glass can be calculated by Sellemier formula [21,22].

III. EQUATIONS

The first paragraph under each heading or subheading should be flush left, and subsequent paragraphs should have

$$n^2 - 1 = \sum_i \left(\frac{A_i \lambda^2}{\lambda^2 - \lambda_i^2} \right) \quad (1)$$

Total dispersion is always calculated by adding waveguide dispersion and material dispersion.

$$D_T = D_W + D_M$$

Waveguide dispersion D_W is defined as –

$$D_W = -\left(\frac{\lambda}{c}\right) \frac{d^2}{d\lambda^2} n_{eff} \quad (2)$$

Where λ is the operating wavelength and c is the velocity of light in a vacuum [25].

IV. SIMULATION RESULTS

The effective refractive index difference is increased between proposed PCF and conventional PCF.

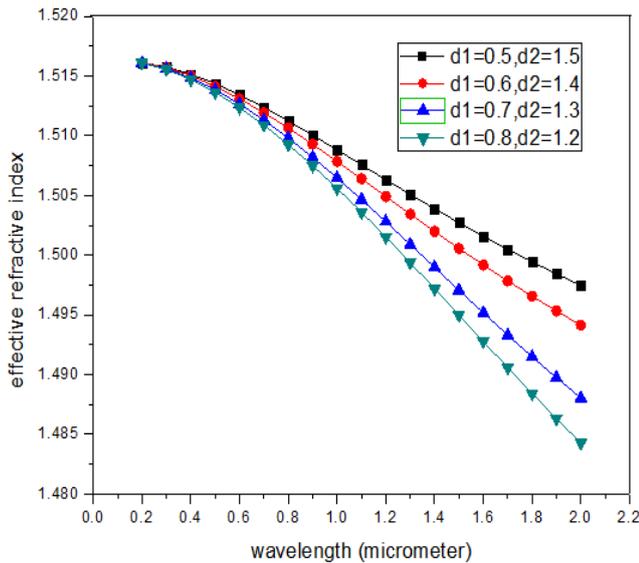

Figure 2. Shows the difference between effective refractive index of conventional PCF and Proposed PCF.

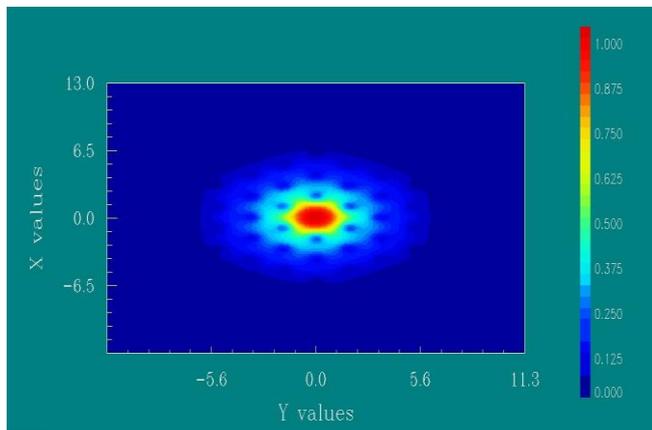

Figure 3. Shows mode field pattern of proposed PCF.

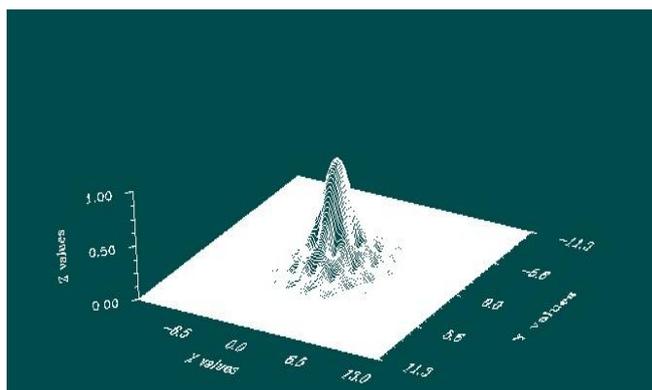

Figure 4. 3-D mode field pattern of proposed PCF.

The wafer is designed for width 26 μm and thickness 22.5166 micrometer. Material dispersion is always unchanged for any structure (hexagonal or square). It is also independent of structure parameter as air hole diameter ‘ d ’ and pitch ‘ Λ ’.

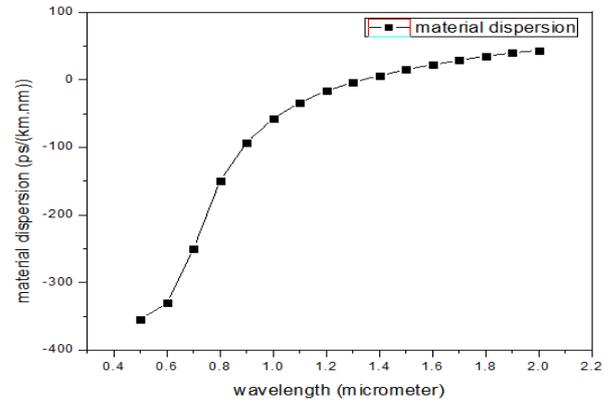

Figure 5. Material dispersion of Borosilicate crown glass PCF.

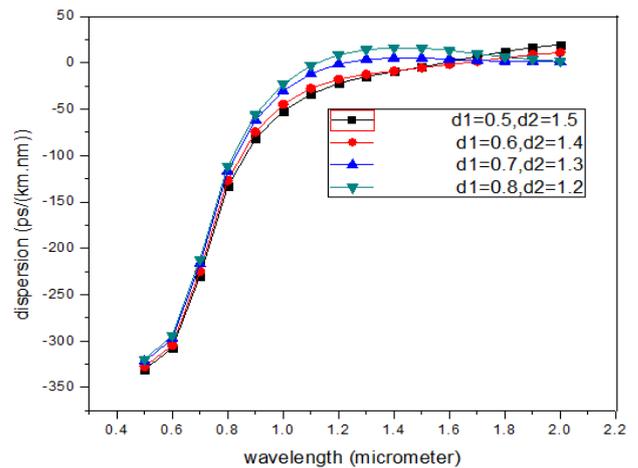

Figure 6. Chromatic dispersion of the proposed PCF for different values of the air hole diameters d_1 and d_2 when air hole spacing ‘ Λ ’ = 2.0 μm .

The proposed Borosilicate crown glass PCF makes almost flat dispersion.

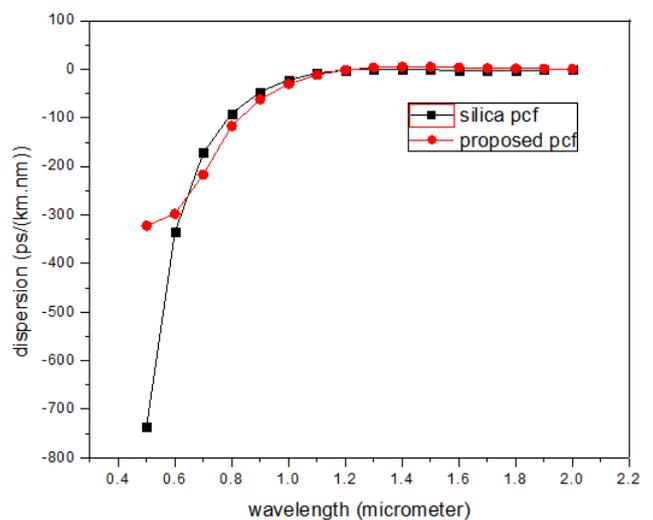

Figure 7. Shows the chromatic dispersion of proposed Borosilicate crown glass PCF and silica glass PCF when pitch ' Λ ' = 2.0 μm , d_1 = 0.7 μm and d_2 = 1.3 μm .

V. CONCLUSION

The above results indicate that the proposed Borosilicate crown glass PCF has almost zero and flat dispersion in low wavelength range as silica glass PCF. But Borosilicate crown glass has good properties (like cheaper, good transmission, easy availability) compare to silica glass. So we can use Borosilicate crown glass as a core material on the place of silica glass. Borosilicate crown glass can substitute of silica glass.

Authors Profile

Mahesh Chand received the B.E. degree in Electronics & Communication Engineering in 2005 from Govt. Engineering College, Ajmer, Rajasthan and pursuing in M.Tech from Suresh Gyan Vihar University, Jaipur. He is currently Assistant Professor and Head in EEE Department, RIET, Jaipur. He has published four books and one research paper in national journal. His current research includes Photonic Crystal Fiber.

Sandhya Sharma received the B.E and M.E degree from M.B.M Engineering College, Jodhpur, Rajasthan. She has total 16 years of teaching & Research experience. Presently she is Assistant Professor in Suresh Gyan Vihar University.

Ravindra Kumar Sharma received the B.E. degree in Electronics & Communication Engineering in 2008 from University of Rajasthan, Jaipur and pursuing M.Tech. In Digital Communication from Arya College of Engineering & I.T. He is currently Assistant Professor in the department of E&C, Rajdhani Institute of Technology & Management, Jaipur. He has published five research paper in various International Journals He is also associate of The Institution of Engineers (India). His current research includes photonic crystal fiber

Modeling and Structural analysis of heavy vehicle chassis made of polymeric composite material by three different cross sections

ABSTRACT: The chassis frame forms the backbone of a heavy vehicle, its principle function is to safely carry the maximum load for all designed operating conditions.

This paper describes design and analysis of heavy vehicle chassis. Weight reduction is now the main issue in automobile industries. In the present work, the dimensions of an existing heavy vehicle chassis of a TATA 2515EX vehicle is taken for modeling and analysis of a heavy vehicle chassis with three different composite materials namely, Carbon/Epoxy, E-glass/Epoxy and S-glass /Epoxy subjected to the same pressure as that of a steel chassis. The design constraints were stresses and deflections. The three different composite heavy vehicle chassis have been modeled by considering three different cross-sections. Namely C, I and Box type cross sections. For validation the design is done by applying the vertical loads acting on the horizontal different cross sections. Software is used in this work PRO – E 5.0 for modeling, ANSYS 12.0 for analysis.

Keywords: heavy vehicle chassis, Static analysis, Carbon/Epoxy, E-glass/Epoxy and S-glass /Epoxy,

I. INTRODUCTION

Automotive chassis is a skeletal frame on which various mechanical parts like engine, tires, axle assemblies, brakes, steering etc. are bolted. The chassis is considered to be the most significant component of an automobile. It is the most crucial element that gives strength and stability to the vehicle under different conditions. Automobile frames provide strength and flexibility to the automobile. The backbone of any automobile, it is the supporting frame to which the body of an engine, axle assemblies are affixed. Tie bars, that are essential parts of automotive frames, are fasteners that bind different auto parts together.

Automotive frames are basically manufactured from steel. Aluminum is another raw material that has increasingly become popular for manufacturing these auto frames. In an automobile, front frame is a set of metal parts that forms the framework which also supports the front wheels. It provides strength needed for supporting vehicular components and payload placed upon it.

Automotive chassis is considered to be one of the significant structures of an automobile. It is usually made of a steel frame, which holds the body and motor of an automotive vehicle. More precisely, automotive chassis or automobile chassis is a skeletal frame on which various mechanical parts like engine, tires, axle assemblies, brakes, steering etc are bolted. At the time of manufacturing, the body of a vehicle is flexibly molded according to the structure of chassis. Automobile chassis is usually made of light sheet metal or composite plastics. It provides strength

needed for supporting vehicular components and payload placed upon it. Automotive chassis or automobile chassis helps keep an automobile rigid, stiff and unbending. Auto chassis ensures low levels of noise, vibrations and harshness throughout the automobile. The different types of automobile chassis include:

Ladder Chassis: Ladder chassis is considered to be one of the oldest forms of automotive chassis or automobile chassis that is still used by most of the SUVs till today. As its name connotes, ladder chassis resembles a shape of a ladder having two longitudinal rails inter linked by several lateral and cross braces.

Monocoque Chassis: Monocoque Chassis is a one-piece structure that prescribes the overall shape of a vehicle. This type of automotive chassis is manufactured by welding floor pan and other pieces together. Since monocoque chassis is cost effective and suitable for robotized production, most of the vehicles today make use of steel plated monocoque chassis.

Backbone Chassis: Backbone chassis has a rectangular tube like backbone, usually made up of glass fibre that is used for joining front and rear axle together. This type of automotive chassis or automobile chassis is strong and powerful enough to provide support smaller sports car. Backbone chassis is easy to make and cost effective.

II. SPECIFICATION OF THE PROBLEM

The objective of the present work is to design and analyses, of steel chassis made and also polymeric composite heavy vehicle chassis made of three different composite materials viz., Carbon/Epoxy, E-glass/Epoxy and S-glass /Epoxy composites. polymeric composite heavy vehicle chassis was created in Pro-E. Model is imported in ANSYS 12.0 for analysis by applying normal load conditions. After analysis a comparison is made between existing conventional steel chassis and polymeric composite heavy vehicle chassis viz., Carbon/Epoxy, E-glass/Epoxy and S-glass /Epoxy in terms of deflections and stresses, to choose the best one.

III. COMPOSITE MATERIALS:

A composite material is defined as a material composed of two or more constituents combined on a macroscopic scale by mechanical and chemical bonds.

Composites are combinations of two materials in which one of the material is called the “matrix phase” is in the form of fibers, sheets, or particles and is embedded in the other material called the “reinforcing phase”.

Another unique characteristic of many fiber reinforced composites is their high internal damping capacity. This leads to better vibration energy absorption within the material and results in reduced transmission of noise to neighboring structures. Many composite materials offer a combination of strength and modulus that are either comparable to or better than any traditional metallic materials. Because of their low specific gravities, the strength to weight-ratio and modulus to weight-ratios of these composite materials are markedly superior to those of metallic materials.

The fatigue strength weight ratios as well as fatigue damage tolerances of many composite laminates are excellent. For these reasons, fiber composite have emerged as a major class of structural material and are either used or being considered as substitutions for metal in many weight-critical components in aerospace, automotive and other industries.

High damping capacity of composite materials can be beneficial in many automotive applications in which noise, vibration, and hardness is a critical issue for passenger comfort.

IV. SPECIFICATION OF EXISTING HEAVY VEHICLE CHASSIS:

Table 1 shows the specifications of a TATA 2515EX OF STEEL HEAVY vehicle. The typical chemical composition of the material is 0.565C, 1.8% Si, 0.7%Mn, 0.045%P and 0.045% S.

Table: 1 Specifications of heavy vehicle chassis

S.No	Parameters	Value
1	Total length of the chassis (Eye to Eye)	8200 mm
2	Width of chassis	80 mm
3	Thickness of chassis	6 mm
4	Front cabin chassis length	2400 mm
5	Front cabin chassis area	492800 mm ²
6	Front cabin chassis applying load	19620 N
7	Backbody chassis length	5800 mm
8	Backbody chassis area	1200000 mm ²
9	Backbody chassis applying load	196200 N
10	Young's Modulus of steel chassis	2.1e5 N/mm ²
11	Density of steel chassis	7.86*10 ⁻⁶ N/mm ²

V. STRUCTURAL ANALYSIS OF HEAVY VEHICLE CHASSIS:

Dimensions of polymeric composite heavy vehicle chassis (PCHVC) are taken as that of the conventional steel heavy vehicle chassis (SHVC). PCHVC consists of 4 layers (thickness of each layer, 1.5mm). Width of the chassis is 80mm. Since the properties of PCHVC vary with directions

of fiber, a 3-D model of chassis is used for analysis in ANSYS 12.0. The loading conditions are assumed to be static. The element chosen is SHELL LAYERED 46, which is a layered version of the 8-node structural shell model. The element has six degrees of freedom at each node : translations in the nodal x, y, and z directions and rotations about the nodal x, y, and z-axes. The finite element analysis is carried out on steel chassis as well as on three different types of polymeric composite heavy vehicle chassis. From the analysis the equivalent stress (Von-mises stress) and displacements

were determined and are shown in figure 1-30. Table 2 - 4 shows the comparative analysis of steel chassis and polymeric composite heavy vehicle chassis of three different materials.

IX. CONCLUSIONS

To observe the all results and to compare the polymeric composite heavy vehicle chassis and steel heavy vehicle chassis with respect to weight, stiffness and strength.

By employing a polymeric composite heavy vehicle chassis for the same load carrying capacity, there is a reduction in weight of 73%~80%, natural frequency of polymeric composite heavy vehicle chassis are 32%~54% higher than steel chassis and 66~78% stiffer than the steel chassis.

Present used material for chassis is steel. I have considered polymeric composites Carbon/Epoxy, E-glass/Epoxy and S-glass /Epoxy for chassis material. Based on the results, it was inferred that carbon/epoxy polymeric composite heavy vehicle chassis I-SECTION chassis has superior strength and stiffness and lesser in weight compared to steel and other polymeric composite materials and other cross sections considered in this investigation.

From the results, it is observed that the polymeric composite heavy vehicle chassis is lighter and more economical than the conventional steel chassis with similar design specifications.

Reviewing Testability of Object Oriented Systems for Non-Functional Specifications

Vaishali Chourey¹, Dr. Meena Sharma²

**(Department of Computer Science, Medi-Caps Institute, Indore, M.P. India)*

*** (Department of Computer Science, IET-DAVV Indore, M.P. India)*

ABSTRACT: *The object oriented programming proves to be the most beneficial paradigm for scalable and maintainable software development. An object characterizes special features like encapsulation, inheritance, modularity and polymorphism. The processes in Test Driven Design closely relate the agile methodology and strengthen the need of testing during the development stages. The UML specifies the architecture of the system. The design follows the specification and hence the implementation. The whole process adopts the language of UML from beginning of software through requirements specification till the deployment. The evaluation of software so as to be testable needs additional efforts. The weaker or ignored issues like the testing for non-functional requirements still need to be accommodated in the test design. The paper reviews the weaknesses of the object oriented systems and the models to be testable. It also includes metrics that quantifies the structural complexity of system to test its understandability and maintainability.*

Keywords: *Models, Object Oriented Testing, Model Based testing, metric based evaluation, Weighted Complexity.*

I. INTRODUCTION

Software engineering bridges its strengths to design and document the software development process through the use of various models. Booch, Jacobson and Rumbaugh[1] conceptualized the behavioral, functional and implementation specific models that were sufficient to describe the elements and their relations in any object oriented software systems. Their contribution to the software engineering field for the same has been widely exercised in industry. The models have been the curious issue in the testing phenomenon whereby the testing is not delayed till the implementation phase but it goes simultaneously as it proceeds in the life cycle. This makes model based testing an interesting and exploratory research area. Model driven methodology proved its worth with the variety of software developed in varied areas. Any degree of complexity can be easily expressed with a set of diagrams. Whether it is structural or architectural specification or functional description, the use of objects and object design languages like UML has facilitated the tasks of project managers. It has even groomed the language of communication amongst the team of developers in any organization. Along with these the software industry benefits with the automated tools for programming high order languages. Altogether this has summed to an approach for robust and manageable code being developed quickly and efficiently. Software Testing is also a major phase in the development of the system for assuring its reliability

and behavioral compliance to the requirements specified. A fact that 40-50% of the software development efforts are shared by testing makes it an important aspect.

The work in this paper compiles the major contributions in the areas of object oriented paradigm and its importance in the development phases. The section II contains an overview of the OO system and their characteristics. The section III contains the modeling language UML and the various diagrams with their importance. Section IV summarizes the issues that restrict testability of the designs. Section V contains the realization of theories related to class design metrics to map it to testing process. It brings the quantification of non-functional parameters like understandability and such attributes to contribute to testing results.

II. OBJECTS AND OBJECT ORIENTED DESIGN

All the literature pertaining to the objects and object oriented design addresses the software projects commendable threats namely inadequate and unstable requirement, inadequate customer communications, poor team communications, unnecessary complexity and ineffective team behavior. Software projects are governed by the list of requirements specified by the customer who is the end user of the whole process. Thus the whole process is based on requirements that are actually the specifics of the system and the needs that are captured. The requirements once finalized do not change often, but the specification for building a piece of implementation of software are changed frequently and added throughout the development cycle. The challenge is to cope up with this frequent updates. Secondly the requirements must be verified with the customer before the design starts. Thus the interactions must conform to the initiation of the project. The next problem begins when the requirements that are verified are not "exactly" communicated to the developer team and an ambiguity occurs. The same requirement must flow properly to the developers. So, we have to make the models that are descriptions to the requirements graphically, thus lessening the probability of ambiguity in documentation if it was textual. As the analysis completes, the design of core transactions and implied operations have to be prepared. The behavior has to be formally or "pseudo-conventionally" specified with models so that they can be codified easily. This defines the system in the form of subsystem, components, classes, objects and their inter-relations like association, hierarchy and collaborations. Thus the system is added with another issue of its structural complexity because of its inter-related artifacts. The task of project

management is to clearly pass through these phases and bring up the system in its entirety.

Not only limited to the planning and development, but testing also is the requirement of the system and theories indicate the fact that effectiveness of object oriented technology lies in testing that goes parallel to development. Whether it is agile development process or any other technology, that depends on objects and specifies that the testing of models be made simultaneous. This reduces the risks from getting accumulated. There are many justifications to the development of models and their usages.

III. UNIFIED MODELLING LANGUAGE OR THE UML

The UML is defined [1] as “A language to specify, visualize, construct and document the artifacts of a software-intensive system.” It is a standard language for writing the blueprints of software. Ranging from the enterprise solutions to distributed web based applications; UML conceptualizes the artifacts of the system developed in object oriented languages. Thus, UML is inherently applicable to architecture centric, iterative and incremental project development. This language has rules and vocabulary for physical and conceptual representation of the software. The language has a collection of diagrams and relative specifications to handle the complexity of the system. For the enumeration, we have:

Table 1: Diagrams and Relevance in Software Project Management

Diagram	Purpose
Use case Diagram	This diagram models and organizes the behavior of the system through its functionalities and services <i>to-through-for</i> actors of the system.
Class Diagram	This represents the set of classes, interfaces and their relationships. This diagram addresses the static and process view of the system.
Object Diagram	This diagram emphasises on the objects and their relationships.
Sequence Diagram	This is an interaction diagram that emphasises the time ordering of messages.
Collaboration Diagram	This is an interaction diagram that emphasises the structural organization of the objects that send and receive messages.
State-chart Diagram	This diagram addresses the dynamic view of the system especially useful in modelling reactive systems.
Activity Diagram	This is a diagram to model the functions of the system and emphasises flow of control among objects. It represents the sequence, concurrency and synchronization of various activities performed by the system.
Component Diagram	This diagram expresses the organization and dependencies

	among a set of components.
Deployment Diagram	This diagram shows the configuration of run-time processing nodes and corresponding components.

The generality in the models and their *express*-ability makes it applicable to various areas like production, deployment and maintenance of software. However in the software development organization, the diagrams are conveniently adopted by analysts and end users for specifying the requirements, structure and behavior of the system. The architects who design the systems to satisfy the requirements specified and the developers who code the architecture into executables use the modeling conventions for communication and documentation. This is equally benefiting the quality assurance personnel who verifies and validates the system for its structure, behavior, functionality and other requirements. The monitoring of the development is emulsified with the process. This is the strength of UML widely acceptable by researchers and used by industries.

The UML has been an immensely popular issue in industry and research for Model Based Testing (MBT). [6] Models are the simplified version and representation of the systems and so are easily amenable for automated test case generation. Models can be classified into formal, semi-formal and informal models. Formal models are mathematically derived [3] from techniques of calculus theory, logic, state machines, markov chains etc., semi-formals combine the diagrams in ad-hoc conventions and are used in industries. Behavioral models are very significant for the test case generation [10, 12] as the bugs are indicated during test of a specific run or implementation of specific functionality of the system. Several research work and industry cases record the diagrams [5] with the Object Oriented Testing Strategies to test various aspects of the software. The table below describes it as:

UML Diagram	Test Coverage	Type of Test	Fault Model
Class Diagram State Diagram	Code	Unit	Error Handling, correctness,
Class Diagram Interaction Diagram	Functional	Functional	Functional Behavior Integration Issues API Behavior
Usecase Diagram Activity Diagram Interaction Diagrams	Operational Scenarios	System	Contention Synchronization Workload Recovery
Class Diagram Interaction Diagram	Functional	Regression	Unexpected Behavior through system alterations
Usecase Diagram Deployment Diagrams	Inter-System Communications	Deployment Solution	Interoperability issues

Table 2: Diagrams and Associated Tests

IV. ISSUES IN OBJECT ORIENTED TESTING

The Object Oriented Testing requires additional techniques for its execution apart from the conventional ones. The testing takes two broad forms of Functional testing or Black box testing where the fulfillment of functional requirements is tested. Another is the Structural testing that tests for the structure of classes, their interactions and their states during execution of any method or activity. Structural testing is the white box testing of the OO systems.

The characteristic of object orientation makes testing rigorous over each iteration and phase of development [3-5]. The increments that are models like the analysis model is tested for requirement specific documentation and use cases. The design model is tested with the corresponding class diagram, interaction diagrams and activity diagrams.

Structural testing with methods and their code that contains statement, decision and path coverage are tested. All methods that are defined, newly added with the increment in functionality, inherited methods and methods that are redefined needs to be tested. The classes are tested for the state transitions during n activity, transaction flows are tested with messages that the classes share, exception testing for the exceptional behavior and conditions that a class may represent.

Object oriented nature poses difficulties to test a class without additional methods to access all the functionalities defined in the class and access its states. Each new instance for inheritance requires retesting. It is easy to test conditions, decisions, loops and exceptions within a class but it is difficult with the set of interaction amongst classes and requires special techniques. There are hierarchical structures but absence of hierarchical control flow makes the execution testing difficult. Integrated classes are thus tested with techniques like thread based testing, use based testing and cluster based testing. System testing is done for the recovery of systems from faulty conditions, security tests for unauthorized accesses, stress testing for load during execution and performance testing for reliability and availability with optimized execution.

Heterogeneity in Models:

Each model describes a different perspective of the same system, thus the testing of the object oriented models take different versions for each model[12]. There are contributions where these models have been used to generate test cases and respective test scripts are generated through automated process. The inputs to these test generators are the set of diagrams associated. Pretschner in his paper [4] presents a detailed discussion reviewing model based test generators. The studies in the area indicate that different test suites with the same coverage may detect fundamentally different number of errors. Also the above table [table 2] indicates that the single diagram alone may not suffice with the exhaustive test of a single type. During the development the industry follows ad-hoc modeling and do not comply with a defined set of diagrams. In such cases where the industry has its own conventions for design and documentation, it is required that the organizations develop their own framework and corresponding tools to build, manage and maintain test models.

Choice of Models in Test Generation:

An example system for the GPS navigation system for a car developed has to be tested for its functions and operations. A model based test brings up the test for the vehicle's position hereby ignoring other functionalities for the display and user interaction features [6]. Another test to the model may test a separate aspect of the system like route planning or route display and so on. The crucial factor is that the aspects are independent tests and they do not interact in terms of aspects. Thus not only diagrams but behavior also segregates the tests with diagrams.

Skills, Audience and Tools:

The issue arises when the testers need to be educated and trained on modeling practices. So far when the testing was confined to code, developers of the corresponding language who had an expertise could manage the testing. Thus the object oriented- model based testing expects modeling skills for the developers and the tester both. The limitation to the model based testing approach converges to the idea that only trained and technically apt audience can and are expected to create, read, review and maintain models. The concept is insufficient to bridge the gap between the models that are characterized with the quality of being best for human understanding and ones that are optimal for testing. Thus the tools that need to be customized with the testability of models have to be developed within the organization's development framework. There exists the limitation for behavior testing tools available for universal applicability.

Scope:

Models have a specific importance when the requirements are being matched to implementation parameters like class, methods or objects. The models however deal only with the superficially expressed behavior of the system which is the high level abstraction. Most of the models confined to the views of the system do not completely fit to the testing essentials. Thus in the early stages of development, the testers end up with almost prohibitive tasks of modelling parts of really large and complex systems. Summarizing, models constructed during the early development process lack several details of implementation that are required to generate test cases.

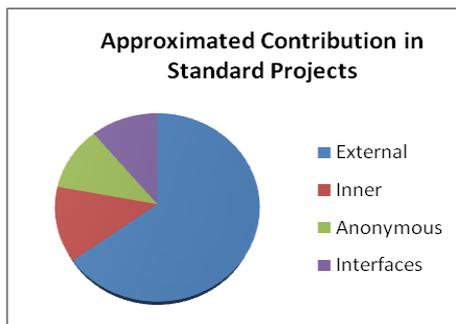

Also for the short development cycles, if there are new releases every week, that also reflects early construction phase of object oriented software development, the diagrams or models do not change accordingly. MBT do not pay off with such projects and more versatile tools are required for testing such typical projects. MBT are fruitful and can be used after releases have achieved a certain degree of stability in its features.

Features of Programming Languages:

Encapsulation [4] restricts the visibility of object states and *observ*-ability of intermediate test results. Inheritance causes invisible dependencies amongst hierarchically related classes. The approach that was devised for preventing code redundancy inhibits code dependencies of varied forms. The child classes that inherits parent's methods cannot be tested without testing the parent class. Abstract classes are the serious conditions where they can never be tested. Polymorphism extends to a limit of

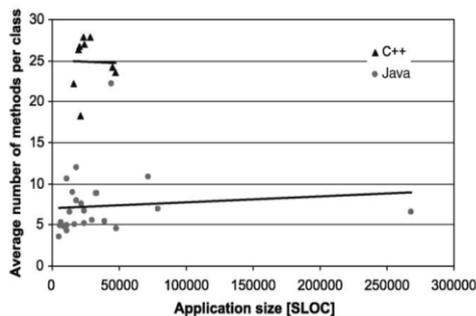

testing all possible conditions, paths for execution and potential errors that it may scope into the classes.

The literature on object orientation defines its strength as Open-Close Principle. The modules are open for extension but close for modification. This, when applied to classes, testing and maintainability is sacrificed. For any new behavior minor-or-major the classes are open for the inheritance. This becomes redundant with series of modifications hereby increasing the complexity of the system. The numbers of classes grow proportionally with the increment in form of new requirements, refined requirements or just additional classes in the development model. A research paper by John D. Mc Groger [17] proves through a formula derived that works as a multiplier function to estimate number of classes after each iteration.

(a)

The number of classes and the relationships amongst them contributes to structural complexity and is referred to in many researches, there by calculating cyclomatic complexity to quantify the attribute.

(b)

Fig 2: (a) Average Metric Values for Percentage of Classes of Each Type
 (b) Average Metric value for the Number of Methods per Class

The above facts have been referred from the research [13, 18] done on various projects that estimate the total number of classes coded and the nature of classes along with the number of methods within each class. The average is depicted in statistics as above figures Fig 2 (a) and (b). Thus the number of classes and methods within each class has a vast average estimated and it is technically not feasible to test all the methods and a mid-way taking necessary implementations pass through the tests. Can the un-tested classes create errors and are there more intense testing methods to check the addition of classes and verify them, i.e making each class testable, is still a question to the project managers.

Also it is well proved that object oriented features like polymorphism, inheritance and encapsulation [18] create wide opportunities for the bugs to creep into the system that was less prevalent in traditional systems. It is also well exemplified in many cases like if many server objects function correctly at top level, but there is nothing to prevent a new client class from using it correctly. Thus, not only testing but developing becomes tedious and testing gets extended over a prolonged duration while final implementation gets ready.

The most important part of the analysis of system is calculating the complexity. Complexity is formally defined as the degree to which system or component has a design or implementation that is difficult to understand and verify [21]. This can be included in the system test that validates maintainability and understandability.

The classes may be analyzed with the metrics that measure the aspects of classes and the interactions amongst them[7]. These measures tells us more about our design and help quantify the maintainability. A change in one class will affect code in other classes, it should be minimal and classes with high dependency must be kept in same package. There are some metrics as:

Intra Class Metrics:

There are metrics at class level that may be helpful to calculate the complexity of the system. They can be reuse ratio, specialization ratio, number of external methods called, number of methods called in class hierarchy, number of local methods called, number of instance variables, number of modifiers, number of interfaces implemented and number of packages imported.

LCOM (Lack of Cohesion Methods): This metric refers the correlation between methods and the local instance variables of the class. High cohesion indicates good class subdivision.

Unweighted Class Size: This is calculated as number of methods and attributes of a class.

Inter Class Metrics:

This is measured by coupling at class level. Coupling is defined as a representation of the references between classes. If a class refers another class or it is being referenced then we measure it as coupling. There are parameters that still need to be standardized and can be defined as: Coupling between classes, Fan Out, Fan In, Efferent Coupling, Afferent Coupling. (Originally defined by Chidamber & Kemerer)[20].

Response for Class: It measures the coupling of classes in terms of method calls. It is the sum of number of methods in the class and the number of distinct method calls made by the methods in the class.

Message Passing Coupling: This metric measures the number of number of messages passing among objects of the class. A large value indicates high coupling and classes seem to be more dependent on each other. This increases the complexity of the system.

The above mentioned parameters are non-weighted measures, there are also metrics with weighted parameters like [22]:

Weighted Class Complexity (WCC): The calculation is based on calculating the complexity of operations by considering corresponding cognitive weights. The cognitive weights are used to measure the complexity of the logical structures of the software that reside in the code as methods. They are classified and weighed as sequence ($w=1$), branch ($w=2$), iteration ($w=3$) and call ($w=2$) [15]. Initially the weight of individual method in a class is calculated by associating a weight with each method (member function) and add all the weights. This is weight due to methods and is called Method Complexity (MC). If there are n methods in a class then total method complexity is given by:

$$= \sum^n MC_n$$

The next step computes the total complexity due to attributes in the class and is denoted by N_a .

The complexity of a single class is called Weighted Class Complexity (WCC) and is given by:

$$WCC = N_a + \sum^n MC_n$$

If the total number of classes in the code is x then:

$$\text{TotalWeightedClassComplexity} = \sum WCC_x$$

The above weighted complexity calculation can be explained with the help of an example. The system comprises of following classes:

- Person*
- Student*
- Employee*
- Faculty*
- Administration*

The code exists like the one specified below and at each level, the complexity is calculated simultaneously.

/ Person Class is inherited by Student and Employee Class */*

```
PERSON CLASS
class Person
{
string name; int age; char gender;
public:
Person(string="",int=0, char='\0'); // W p1=1
Person(const Person &person); //copy constructor W p2=1
void print()const; //Wp3=Wp31+Wp32=2+1=3
string getName(){ // Wp4=1
return name; }
int getAge(){ //Wp5=1
return age;}
char getGender(){ //Wp6=1
return gender; }
};
//Person-default constructor
```

```
Person :: Person(string in, int ia, char is)
{ name = in; age = ia; gender = is; }
//Person-copy constructor
```

```
Person :: Person(const Person &p)
{ name = p.name; age = p.age; gender = p.gender; }
void Person :: print()const
{ cout<<"Name\t : "<<name<<"\n' ; //Wp31=1
cout<<"Age\t : "<<age<<"\n' ;
if (gender=='F') //Wp32=2
cout<<"Gender\t : Female" <<"\n' ;
else cout<<"Gender\t : Male" <<"\n' ; }
```

```
STUDENT CLASS
class Student: public Person{ int sid; float gpa;
public:
Student(const Person &p,int student_id,float igpa):
Person(p) //WS1=1
{ sid = student_id;
gpa = igpa; }
void print()const; };
//WS2=WS21+WS22*WS23=1+2*2=5
void Student :: print()const
{ Person :: print();
cout<<"S.ID\t:"<<sid<<"\nGPA\t:"<<gpa<<endl;
//WS21=1
if (gpa>=2.0) //WS22=2
cout<<" Student is successful"<<endl;
else {if (gpa>=1.7) //WS23=2
cout<<"Student must improve GPA" <<endl;
else
cout<<"Student must repeat" <<endl; } }
```

```
/* ***** EMPLOYEE CLASS ***** */
class EMPLOYEE: public Person{ float salary;
public: EMPLOYEE::EMPLOYEE(const Person &p, float
sal):Person(p) ,salary(sal){ //WE1=1
EMPLOYEE(const EMPLOYEE
&EMPLOYEE):Person(EMPLOYEE){
salary=EMPLOYEE.salary; } //WE2=1
void print()const; }; //WE3=1
void EMPLOYEE::print() const{ Person::print();
cout<<"salary: "<<salary<<endl; }
```

FACULTY

```
class Faculty: public EMPLOYEE{
string branch;
public: Faculty(const EMPLOYEE &e, string
b):EMPLOYEE(e),branch(b) //WF1=1
{}
void print()const; }; //WF2=1
```

```
/* ***** ADMINISTRATIVE CLASS ***** */
class Administrative: public EMPLOYEE{string duty;
public:
Administrative(const EMPLOYEE &e,string
d="\0"):EMPLOYEE(e){duty=d; } //WA1=1
void print() const; }; //WA2=1
void sendMessage(string msg, Faculty &fac) //WA3=1
{cout<<"The incoming message :"<<msg<<"\nMessage
to"; cout<<fac.getName(); }
```

```

MAIN
int main(void)
{
Person * per[3];
per[0]=new Person ("Aysegul",27,'f');
per[1]=new Person ("Remzi",23,'m');
per[2]=new Person ("Ali",30,'m');
EMPLOYEE EMPLOYEE1(* per[0],1000);
EMPLOYEE1.print();
Student student1(* per[1],9299,3.5);
student1.print();
EMPLOYEE EMPLOYEE2(* per[0],2000);
Administrative
admEMPLOYEE(EMPLOYEE1,"Secretary");
Faculty facEMPLOYEE(EMPLOYEE2,"Computer");
admEMPLOYEE.sendMessage("Today there is a seminar at
your university. You are in
vited",facEMPLOYEE);
}

```

The example is referred from the research of [22] metric based calculation of complexity. This exactly computes the java code for complexity. The idea is to use the same derivations for the design where the classes are decided with its member functions and relations are defined. So far the calculation is based only on methods, attributes and relationship. The structural complexity is majorly due to relations and this can be well defined for class diagram and object (collaboration specifically) diagrams. The same calculations can be made during the iterations when classes grow and at each step the complexity may be curbed.

Thus, the re-arrangement of classes to maintain a proper metric can prove the system to be consistent in terms of growing number of classes and dependencies amongst classes. Lesser the complexity, more manageable is the design.

V. CONCLUSION AND FUTURE WORK

An object benefits with its features of modularity, abstraction, encapsulation and inheritance but it was never predicted that the growing amount of code and maintenance classes bears loads on testing parameters. All the models have independent importance but require to be modified for testing individual aspects of the system. Several methods to derive a testable version of the UML have to be devised so that testing is not in the span of development but has intermediate phases upon stable models being developed. A future enhancement thereby adding the class complexity metrics to model based testing tools may be a convenient way to validate the understandability and maintainability parameters.

Abstract: In this paper presents a regularized image interpolation algorithm, an image resolution enhancement technique based on interpolation of the high frequency sub-band images obtained by using one of the multi resolution algorithm discrete wavelet transform (DWT) and the input image. Edges in images convey a great deal of information, but wavelet transforms do not provide an economical representation. Thus, popular wavelet-based decomposition and restoration techniques perform poorly in the presence of edges. The edges are enhanced by introducing an intermediate stage by using stationary wavelet transform (SWT) which is the one of the Multi-Resolution Transforms (MRT). DWT is applied in order to decompose an input image into different sub-bands. Then the high frequency sub-bands as well as the input image are interpolated and are being modified by using high frequency sub-band obtained through SWT. Then high frequency and low frequency of these sub-bands are combined to generate a new high resolution image by using inverse DWT (IDWT). The quantitative and visual information results are showing the Enhancement of the edges of an input image robustly by introducing an intermediate stage by using Multi-Resolution Transforms (MRT)

Keywords: Image interpolation, Image super resolution, Multi-Resolution Transforms (MRT), Robustness.

I. INTRODUCTION

Image enhancement plays key role in digital processing so we focus on the importance of the representation of information for various image processing tasks. The way in which manipulation of information is represented brings out certain types of features while hiding others. Signal compression and estimation applications also rely heavily on having an efficient representation of image data; we would like to approximate a signal with a few number of parameters. Therefore, we seek a transform which yields an efficient representation while bringing out the desired features of the signal [1]. Resolution has been frequently referred as an important aspect of an image. Images are being processed in order to obtain more enhanced resolution. Interpolation is One of the commonly used technique for image resolution enhancement. It has been widely used in many applications in image processing such as facial reconstruction, multiple description coding, and super resolution. Interpolation is the process of using known data values to estimate unknown data values. Various interpolation techniques are often used in this project. Interpolation as used here is different to

"smoothing", the techniques discussed here have the characteristic that the estimated curve passes through all the given points. The idea is that the points are in some sense correct and lie on an underlying but unknown curve, the problem is to be able to estimate the values of the curve at any position between the known points[2-3]. The methods Nearest neighbor interpolation, Bilinear interpolation, and Bi-cubic interpolation are three well known interpolation techniques. Bilinear interpolation is an extension of linear interpolation for interpolating functions of two variables.

Bicubic interpolation is an extension of cubic interpolation for interpolating data points on a two dimensional regular grid. The interpolated surface is smoother than corresponding surfaces obtained by bilinear interpolation or nearest-neighbor interpolation. Bicubic interpolation can be accomplished using either Lagrange polynomials, cubic splines, or cubic convolution algorithm [4].

In this correspondence we mainly deal with image interpolation techniques to enhance the image quality in the basis of resolution. In image processing the terminology "resolution" represents the number of pixels in an image, which determines the physical size of the image, and at the same time it also represents the fidelity to high-frequency details in the image. By this reason, resolution is a fundamental issue in evaluating the quality of various image processing systems. Image interpolation is used to derive a higher resolution image from a low resolution image, and therefore it is most important in multi-resolution or high-resolution image processing. For example, the spatial scalability function in MPEG-2 and wavelet-based image processing techniques require image interpolation techniques [5]. On the other hand, high-resolution image processing applications such as digital High Definition Tele-Vision (HDTV), aerial photos, medical imaging such as scanning, and military purpose images, need high-resolution image interpolation algorithms. Recently, it can also be used in changing the format of various types of images and videos, and in increasing the resolution of images.

Image resolution can be measured in various ways. Basically, resolution quantifies how close lines can be to each other and still be visibly resolved. The measure of how closely lines can be resolved in an image is called spatial resolution, and it depends on properties of the system creating the image [6].

Image resolution enhancement in the wavelet domain is a relatively new research topic and recently many new algorithms have been proposed. Discrete wavelet transform (DWT) is one of the recent wavelet transforms

used in image processing. DWT decomposes an image into different sub-band images, namely low-low (LL), low high (LH), high-low (HL), and high-high (HH). Another recent wavelet transform which has been used in several image processing applications is stationary wavelet transform (SWT). In short, DWT is similar to SWT, used in down-sampling, hence the sub-bands will have the same size as the input image.

In this paper, we are proposing a robust image enhancement technique which generates sharper high resolution image. The proposed technique uses DWT as well as SWT. DWT uses to decompose a low resolution image into different sub bands. Then the details have been interpolated using bicubic interpolation. The details obtained by SWT of the input image are being incremented into the interpolated high frequency subbands in order to correct the estimated coefficients. In parallel, the input image is also interpolated separately. Finally, corrected interpolated high frequency subbands and interpolated input image are combined by using inverse DWT (IDWT) to achieve a high resolution output image. The proposed technique has been compared with conventional enhancement techniques. The conventional techniques used are the following: Interpolation techniques.

→Bilinear interpolation and

→Bicubic interpolation.

→Wavelet zero padding (WZP).

→Super resolved interpolated technique

According to the quantitative and qualitative experimental results, the proposed technique over performs the aforementioned conventional for image resolution enhancement.

II. IMAGE RESOLUTION ENHANCEMENT

Quality in Digital Imagery obtained by enhancement (wanted e.g. for visual inspection or for machine analysis), there is no knowledge about the source of degradation. If the source of degradation is known, one calls the process image restoration. Both are iconical processes, viz. input and outputs are images. Many different, often elementary methods are used to improve images in some Part. The problem is, of course, not well defined, as there is no objective improve for image quality. Here, we discuss a few recipes that have shown to be useful both for the human observer and/or for machine recognition. These methods are very problem-oriented: a method that works fine in one case may be completely inadequate for another problem.

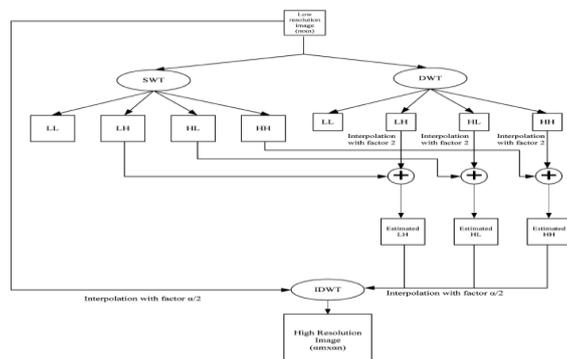

Figure 1: Block diagram of the super resolved interpolation algorithm.

By using interpolation we can enhance image for this we have to concentrate on its high frequency aspects (i.e.,edges),that is smoothing caused by interpolation .To increase the quality of the super resolved image we must preserve the edges. For this work, DWT has been used to protect the high frequency sub-bands of the image .DWT coefficients are inherently interpolable that means it is redundancy and shift invariance[7]- [9].

In this work, we are using one level DWT (with Daubechies 9/7 as wavelet function) to decompose an input image into different sub-band images like approximations and details means three high frequency sub-bands like LH, HL, and HH contain the high frequency components of the input image and LL contain the Low frequency components of the input image[10]. In the super resolved interpolation technique, bicubic interpolation with enlargement factor of 2 is applied to high frequency sub-band images. Down sampling in each of the DWT sub-bands causes information loss in the respective sub-bands. That is why SWT is employed to minimize this loss.

The SWT high frequency sub-bands and the interpolated high frequency sub-bands have the same size because here we are not using down sampling so that they can be added with each other. For the further higher enlargement the new corrected high frequency sub-bands can be interpolated. Also it is known that in the wavelet domain, the low resolution image is obtained by low-pass filtering of the high resolution image. In other words, low resolution of the original image means image consists of low frequency sub-band. Therefore, instead of using low frequency sub-band, which contains less information than the original high resolution image, we are using the input image for the interpolation of low frequency sub-band image. Using input image instead of low frequency sub-band increases the quality of the super resolved image. Fig. 1 illustrates the block diagram of the super resolved image interpolation enhancement technique[11].

By interpolating input image by $\alpha/2$, and high frequency sub-bands in DWT by 2 and added to high frequency bands to obtain estimated high frequency bands, α in the intermediate and final interpolation stages respectively, and then by applying IDWT, as illustrated in Fig. 1, the output image will contain sharper edges than the interpolated image obtained by interpolation of the input image directly. This is due to the fact that, the interpolation of isolated high frequency components in high frequency sub-bands and using the corrections obtained by adding high frequency sub-bands of SWT of the input image, will preserve more high frequency components after the interpolation than interpolating input image directly.

We are proposing an image resolution enhancement technique which generates sharper high resolution image. The proposed technique uses DWT to decompose a low resolution image into different sub-bands. Then the three high frequency sub-band images have been interpolated using bi-cubic interpolation with factor 2. The Low frequency sub-bands obtained by SWT of the input image are being interpolated bicubic with factor 2 and subtracts original image gets difference image, added to bicubic interpolated high frequency bands in order to correct the estimated coefficients. In parallel, the input image is also interpolated separately

Finally, corrected interpolated high frequency sub-bands and interpolated input image are combined by using inverse DWT (IDWT) to achieve a high resolution output image. The proposed technique has been compared with conventional enhancement techniques [12]-[15]. We propose a Multi resolution-enhancement technique using interpolated DWT high-frequency sub band images and the input low-resolution image. Inverse DWT (IDWT) has been applied to combine all these images to generate the final resolution-enhanced image. In order to achieve a sharper image, we propose to use an intermediate stage for estimating the high frequency sub bands by utilizing the difference image obtained by subtracting the input image and its interpolated LL sub band[16].

performance of the super resolved image by using SWT only (SWT-SR) is also included in the table. The results in Table I indicate that the proposed technique over-performs the aforementioned conventional and state-of-art image resolution enhancement techniques. Table I also indicates that the proposed technique over-performs the aforementioned conventional image resolution enhancement techniques.

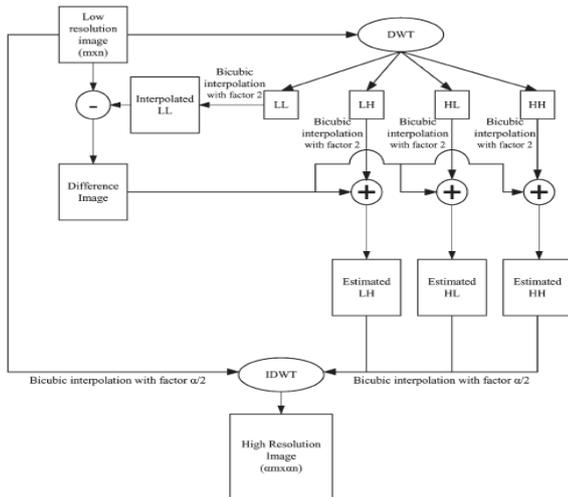

Figure 2: Block diagram of the proposed algorithm

The proposed technique has been compared with standard interpolation techniques, wavelet zero padding (WZP), super resolved bicubic interpolated where the unknown coefficients in high-frequency sub bands are replaced with zeros.

In all steps of the proposed satellite image resolution enhancement technique, Daubechies wavelet transform as mother wavelet function and bicubic interpolation as interpolation technique have been used.

III. RESULTS AND DISCUSSIONS

The Super resolved image of Baboon's picture using proposed technique is shown Fig. 3 the image in (f) are much better than the low resolution image in (a), Bilinear interpolated image (b), Bicubic image (c), Super resolved image using WZP (d) and super resolved image by using the interpolation (e). Note that the input low resolution images have been obtained by down-sampling the original high resolution images. In order to show the effectiveness of the proposed method over the conventional resolution enhancement techniques, four well-known test images such as Lena, Elaine, Baboon, and Peppers etc., with different features are used for comparison[17]. Table I compares the PSNR performance of the proposed technique using bicubic interpolation with conventional and state-of-art resolution enhancement techniques: bilinear, bicubic, Super resolved image using WZP, and Super resolved image using bilinear interpolation preserving image interpolation. Additionally, in order to have more comprehensive comparison, the

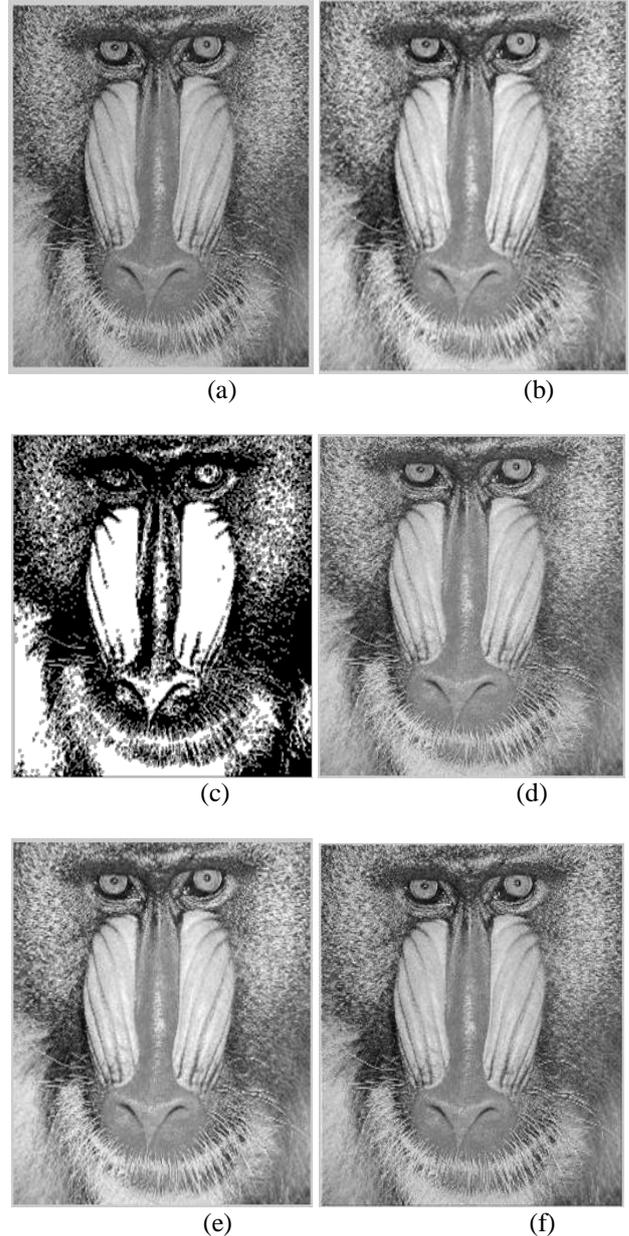

Fig.3 (a) Original low resolution Baboon's image. (b) Bilinear interpolated image (c) Bicubic interpolated image. (d) Super resolved image using WZP. (e) Super resolved image using bilinear interpolation (f) Proposed technique.

IV. CONCLUSION

The proposed technique has been tested on well-known benchmark images, where their PSNR and visual results show the superiority of proposed technique over the conventional image resolution enhancement techniques. The image resolution enhancement technique based on the interpolation of the high frequency sub-bands obtained by DWT, correcting the high frequency sub-band estimation by using SWT high frequency sub-bands, and the input image. The proposed technique uses DWT to decompose an image into different sub-bands, and then the high frequency sub-band images have been interpolated. The interpolated high frequency sub-band coefficients have been corrected by using the high frequency sub-bands achieved by SWT of the input image. An original image is interpolated with half of the interpolation factor used for interpolation the high frequency sub-bands. Afterwards all these images have been combined using IDWT to generate a super resolved imaged. Here we are using interpolation to gets the robustness. The proposed technique has been tested on well-known benchmark images, where their PSNR and visual results show the superiority of proposed technique over the conventional and state-of-art image resolution enhancement techniques.

Abstract: In this paper, we propose various types of moments like Legendre moments, complex moments and Zernike Moments invariants. In the past decades has been extensively investigated about moment invariants. In Zernike moments we construct to derive set of invariants which is simultaneously invariant to similarity transformation and to convolution with spread spectrum(PSF). In this mainly two contributions are provided, The frame work for theoretical is derived from Zernike moments of a blurred image and the way to construct the one of invariant moment combined geometric blur invariants. To evaluate the performance of the invariants with various PSFs and similarity Transformations. Experimental results show that the propose dinvariants perform better to compared with other invariants like Legendre moments and complex Moments.

Keywords: Moment Invariants, Legendre Moments, Complex moments, Zernike Moments, Pattern Recognition

I. INTRODUCTION

Analysis and interpretation of an image which was acquired by a real (i.e. non-ideal) imaging system is the key problem in many application areas such as remote sensing, astronomy and medicine, among others. Since real imaging systems as well as imaging conditions are usually imperfect, the observed image represents only a degraded version of the original scene. Various kinds of degradations (geometric as well as radiometric) are introduced into the image during the acquisition by such factors as imaging geometry, lens aberration, wrong focus, motion of the scene, systematic and random sensor errors, etc.

Size and orientations are important concern in recognition objects. The history about invariants includes so many techniques [1]–[5], Fourier descriptors [6] and point set invariants [7]–[10] have been Proposed. Among them, moment invariants have been extensively used for image description in object recognition [11], [12], image classification [13] and scene matching. However, much less attention has been paid to invariants with respect to changes of the image intensity function (known as radiometric invariants) as to joint radiometric- geometric invariants. The principle behind doing the blur is not too hard, although it seems like magic. What we do is take the image and the kernel, and perform the Fourier transform on them both. We then multiply the two together and inverse transform back.[14]

This is exactly the same as performing the long convolution. In image terms this means that each pixel in the source image gets spread over and mixed into surrounding pixels. Another way to look at this is that each pixel in the destination image is made up out of a mixture of surrounding pixels from the source image. The operation we need for this is called convolution. A quick diversion here to discuss a problem which often crops up: Imagine you want to blur a shape which is on a transparent background. You've got an empty image, and you draw a shape on it, then blur the image. blur to sharpen an image as well as blur it using a technique called un-sharp masking.

Orthogonal functions have been around for a very long time. The best known are the sine and cosine. Two functions or vectors are orthogonal if their inner product (defined as the sum of the product of their corresponding elements) is zero. An important class of orthogonal functions is orthogonal polynomials, which are orthogonal over various intervals of the real axis. Important orthogonal polynomials include Legendre, Hermite, Chebyshev, etc. Legendre polynomials, which are orthogonal over $[-1, 1]$, can be taken as a product $P(x)P(y)$, and the result is an orthogonal set of polynomials over a square. Zernike working in optics in the 1930's derived a set of polynomials that are orthogonal over a unit disk, i.e., $r \leq 1$. [15]

Orthogonal moments are computed similar to regular moments, except that the set of orthogonal polynomials replaces the x^p or $x^p y^q$ monomial in all the above equations. That is, where $h_{pq}(x, y)$ is the pq -th orthogonal polynomial, and R is the region over which the polynomials are defined. for Legendre and Zernike polynomials, and where we have subtracted the centers, which can be determined from the centroid or some other means, so that the resulting moments are location invariant.

Zernike polynomials are orthogonal over the unit disk and are specified in polar coordinates in terms of a real valued radial component $R_n(r)$ which is a polynomial of order n , and a complex exponential component: There are two ways of viewing moments, one based on statistics and one based on arbitrary functions such as $f(x)$ or $f(x, y)$. As a result moments can be defined in more than one way.[16]

Moments are the statistical expectation of certain power functions of a random variable. The most common moment is the mean which is just the expected value of a random variable: where $f(x)$ is the probability density function of continuous random variable X . More generally, moments of order $p = 0, 1, 2, \dots$ can be calculated as $m_p = E[X^p]$. These are sometimes referred to as the raw moments.

There are other kinds of moments that are often useful. One of these is the central moments $\mu_p = E[(X-\mu)^p]$.

However, moments are easy to estimate from a set of measurements. The p -th moment is estimated as and the p -th central moment is estimated as where is the average of the measurements, which is the usual estimate of the mean.

II. PROPOSED CONCEPT

A. Legendre Moments:

The Legendre of order $(m + n)$ are defined as:

$$\lambda_{mn} = \frac{(2m+1)(2n+1)}{4} \int_{-1}^1 \int_{-1}^1 P_m(x)P_n(y)f(x,y)dx dy \quad (1)$$

where

$$m, n = 0, 1, 2, 3, \dots$$

P_m and P_n are the Legendre polynomials and $f(x,y)$ is the continuous image function. The Legendre polynomials are a complete orthogonal basis set defined over the interval $[-1, 1]$ For orthogonality to exist in the moments, the image function $f(x,y)$ is defined over the same interval as the basis set, where the n^{th} order Legendre polynomial is defined as:

$$P_n(x) = \sum_{j=0}^n a_{nj} x^j \quad (2)$$

and a_{nj} are the Legendre coefficients given by:

$$a_{nj} = (-1)^{(n-j)/2} \frac{1}{2^n} \frac{(n+j)!}{\left(\frac{n-j}{2}\right)! \left(\frac{n+j}{2}\right)! j!} \quad \text{where } n-j = \text{even} \quad (3)$$

So, for a discrete image with P_{xy} current pixel

$$\lambda_{mn} = \frac{(2m+1)(2n+1)}{4} \sum_x \sum_y P_m(x)P_n(y)P_{xy} \quad (4)$$

and x, y are defined over the interval $[-1, 1]$.

B. Complex Zernike Moments:

The Zernike polynomials were first proposed in 1934 by Zernike. Their moment formulation appears to be one of the most popular, outperforming the alternatives (in terms of noise resilience, information redundancy and reconstruction capability). The pseudo-Zernike formulation proposed by Bhatia and Wolf further improved these characteristics. However, here we study the original formulation of these orthogonal invariant moments.

Complex Zernike moments are constructed using a set of complex polynomials which form a complete orthogonal basis set defined on the unit disc $(x^2 + y^2) \leq 1$. They are expressed as A_{pq} Two dimensional Zernike

moment.

$$A_{mn} = \frac{m+1}{\pi} \int_x \int_y f(x,y)[V_{mn}(x,y)]^* dx dy \quad \text{where } x^2 + y^2 \leq 1 \quad (5)$$

Where $m = 0, 1, 2, 3, \dots$

And defines the order $f(x,y)$ is the function being described and * denotes the complex conjugate. While n is an integer (that can be positive or negative) depicting the angular dependence, or rotation, subject to the conditions:

$$m - |n| = \text{even}, |n| \leq m \quad (6)$$

And $A_{mn}^* = A_{m,-n}$ is true. The Zernike polynomials $V_{mn}(x,y)$ Zernike polynomials expressed in polar coordinates

$$V_{mn}(r, \theta) = R_{mn}(r) \exp(jn\theta) \quad (7)$$

Where (r, θ) are defined over the unit disc

$$j = \sqrt{-1} \text{ and } R_{mn}(r)$$

is the orthogonal radial polynomial, defined as $R_{mn}(r)$ orthogonal radial polynomial

$$R_{mn}(r) = \sum_{s=0}^{\frac{m-|n|}{2}} (-1)^s F(m, n, s, r) \quad (8)$$

where:

$$F(m, n, s, r) = \frac{(m-s)!}{s! \left(\frac{m+|n|}{2} - s\right)! \left(\frac{m-|n|}{2} - s\right)!} r^{m-2s} \quad (9)$$

C. Zernike Moments of the Blurred Image :

In this subsection, we establish the relationship between the Zernike moments of the blurred image and those of the original image and the PSF. To that end, we first consider the radial moments.

Applying (1) to blurred image $g(x,y)$, we have a

$$\begin{aligned}
 D_{q+2k,q}^{(g)} &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} (x - \hat{j}y)^{q+k} (x + \hat{j}y)^k g(x, y) dx dy \\
 &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} (x - \hat{j}y)^{q+k} (x + \hat{j}y)^k \\
 &\quad \times \left[\int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} h(a, b) f(x - a, y - b) da db \right] \\
 &\quad \times dx dy \\
 &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} h(a, b) \\
 &\quad \times \left[\int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} ((x - \hat{j}y) + (a - \hat{j}b))^{q+k} \right. \\
 &\quad \times ((x + \hat{j}y) + (a + \hat{j}b))^k \\
 &\quad \times f(x, y) dx dy \left. \right] da db \\
 &= \sum_{m=0}^{q+k} \sum_{n=0}^k \binom{q+k}{m} \binom{k}{n} \\
 &\quad \times \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} (x - \hat{j}y)^m (x + \hat{j}y)^n f(x, y) dx dy \\
 &\quad \times \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} (a - \hat{j}b)^{q+k-m} (a + \hat{j}b)^{k-n} h(a, b) da db \\
 &= \sum_{m=0}^{q+k} \sum_{n=0}^k \binom{q+k}{m} \binom{k}{n} D_{m+n, m-n}^{(f)} \\
 &\quad \times D_{q+2k-m-n, q+n-m}^{(h)}.
 \end{aligned}
 \tag{10}$$

Applying blurred image $g(x,y)=g(r,\theta)$ and using above equation, we obtain

$$\begin{aligned}
 Z_{q+2l,q}^{(g)} &= \sum_{k=0}^l \sum_{m=0}^{q+k} \sum_{n=0}^k \binom{q+k}{m} \binom{k}{n} \\
 &\quad \times c_{l,k}^q D_{m+n, m-n}^{(f)} D_{q+2k-m-n, q+n-m}^{(h)}.
 \end{aligned}
 \tag{11}$$

the radial moments can also be expressed as a series of Zernike moments

$$D_{q+2l,q}^{(f)} = \sum_{k=0}^l d_{l,k}^q Z_{q+2k,q}^{(f)}
 \tag{12}$$

$$d_{i,j}^q = \frac{i!(q+i)!\pi}{(i-j)!(q+i+j+1)!}, \quad 0 \leq j \leq i \leq l.
 \tag{13}$$

We have

$$D_{m+n, m-n}^{(f)} = \sum_{i=0}^n d_{n,i}^{m-n} Z_{m-n+2i, m-n}^{(f)}
 \tag{14}$$

$$D_{q+2k-m-n, q+n-m}^{(h)} = \sum_{j=0}^{k-n} d_{k-n,j}^{q+n-m} Z_{q+n-m+2j, q+n-m}^{(h)}.
 \tag{15}$$

By using above two eqn's we obtain

$$\begin{aligned}
 Z_{q+2l,q}^{(g)} &= \sum_{k=0}^l \sum_{m=0}^{q+k} \sum_{n=0}^k \sum_{i=0}^n \sum_{j=0}^{k-n} \binom{q+k}{m} \binom{k}{n} c_{l,k}^q d_{n,i}^{m-n} \\
 &\quad \times d_{k-n,j}^{q+n-m} Z_{m-n+2i, m-n}^{(f)} Z_{q+n-m+2j, q+n-m}^{(h)}.
 \end{aligned}
 \tag{16}$$

III. MATLAB/SIMULINK RESULTS

In this evaluation, we also use the images shown in Fig. 1. The testing set was generated by adding motion blur, averaging blur with zero-mean. This was followed by adding a white Gaussian noise with different standard deviations and salt-and-pepper noise with different noise densities. Because the actual size of the PSF is usually unknown in practical application, in order to evaluate the performance of the different methods under such a situation.

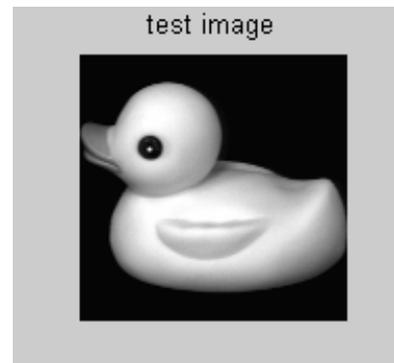

Figure 1:-Original Image

Figure 2: Combined invariants to similarity transform

We have computed the ZMIs, CMIs, and LMIs up to order $M=1,3,5,\dots, 17$. The mean classification rates under different noise conditions for different values of M are shown in Fig. 3,4. It can be observed that the rate first increases, reaches the maximum value and then decreases for all three methods. In other words, there should exist an optimal order for each type of moment invariants. This behavior has also been observed and pointed out by Liao

and Pawlak in image reconstruction due to the noise influence [17]. In this experiment, the optimal order for CMIs is $M=7$ (the feature vector includes 17 invariants), for LMIs (the feature vector has 21 invariants), and $M=9$ for ZMIs (with 26 invariants).

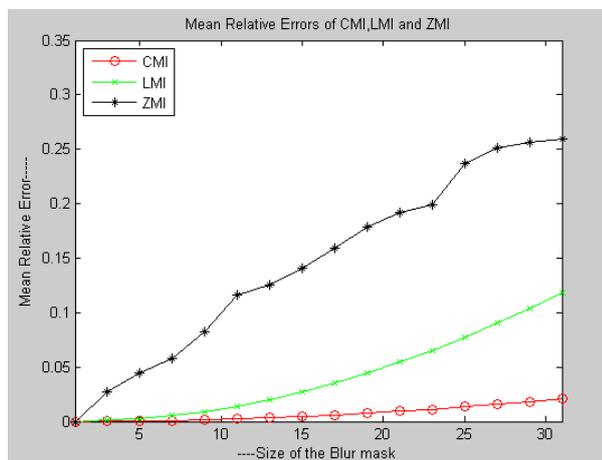

Figure 3: Mean relative errors of CMIs, LMIs, and ZMIs for motion blurred versions of the images

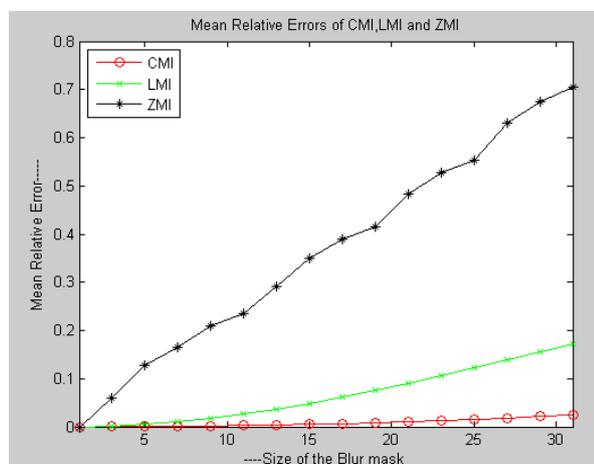

Figure 4: Mean relative errors of CMIs, LMIs, and ZMIs for average blurred versions of the image

It can be seen that the proposed descriptors ZMI is compared with CMIs And Legendre moments.

The figures 3, 4 are to calculate the mean relative error corresponding invariants. And to compare invariants are like Legendre and complex.

IV. VI CONCLUSION

In this paper, we have proposed a method to construct a set of combined geometric-blur invariants using the orthogonal Zernike moments. The relationship between the Zernike moments of the blurred image and those of the original image and the PSF has been established. Based upon this relationship, a set of invariants to convolution with circularly symmetric PSF has been derived. The advantages of the proposed method over the existing ones are the following: 1) The proposed descriptors are simultaneously invariant to similarity transformation and to convolution. Using these invariants, the image deblurring and geometric normalization process can be well avoided. 2) Like the method reported in [17], our method can also derive the

even order invariants. The experiments conducted so far in very distinct situations demonstrated that the proposed descriptors

Abstract: Image quality is a characteristic of an image that measures the perceived image degradation (typically, compared to an ideal or perfect image). Imaging systems may introduce some amounts of distortion or artifacts in the signal, so the quality assessment is an important problem. JPEG compression is the most prevalent technique or method for image codec's. But it suffers from blocking artifacts. In this paper a comparison of the perceptual quality of de-blocked images based on various quality assessments metric is done. We study the efficiency of de-blocking algorithms for improving visual signals degraded by blocking artifacts from compression. Rather than using only the perceptually questionable PSNR, we instead propose a block-sensitive index, named PSNR-B, that produces objective judgments that accord with observations. The PSNR-B modifies PSNR by including a blocking effect factor. We also use the perceptually significant SSIM index, which produces results largely in agreement with PSNR-B. Simulation results show that the PSNR-B results in better performance for quality assessment of deblocked images than PSNR and a well-known blockiness-specific index.

Keywords: Blocking effect, deblocking, distortion, image quality assessment, quantization.

I. INTRODUCTION

Many practical and commercial systems use digital image compression when it is required to transmit or store the image over limited resources. JPEG compression is the most popular image compression standard among all the members of lossy compression standards family. JPEG image coding is based on block based discrete cosine transform. BDCT coding has been successfully used in image and video compression applications due to its energy compacting property and relative ease of implementation. After segmenting an image in to blocks of size $N \times N$, the blocks are independently DCT transformed, quantized, coded and transmitted. One of the most noticeable degradation of the block transform coding is the "blocking artifact". These artifacts appear as a regular pattern of visible block boundaries. This degradation is the result of course quantization of the coefficients and of the independent processing of the blocks which does not take in to account the existing correlations among adjacent block pixels [1]. In order to achieve high compression rates using BTC with visually acceptable results, a procedure known as deblocking is done in order to eliminate blocking artifacts.

Blocking effects are common in block-based image and video compression systems. Blocking artifacts are more serious at low bit rates, where network bandwidths are limited. Significant research has been done on blocking artifact reduction [2]–[4]. Most blocking artifact reduction methods assume that the distorted image contains noticeable amount of blocking. The degree of blocking depends upon several parameters, the most important of which is the quantization step for lossy compression. Little research has done on comparing the perceptual quality of de-blocked images. The recent advent of powerful modern image quality assessment (IQA) algorithms[5] that compare well with human subjectively makes this plausible. Here we investigate quality assessment of de-blocked images, and in particular we study the effects of the quantization step of the measured quality of de-blocked images. A de-blocking filter can improve image quality in some aspects, but can reduce image quality in other regards.

We perform simulations on the quality assessment of De-blocked images. We first perform simulations using the conventional peak signal-to-noise ratio (PSNR) quality metric and a state of the art quality index, the structural similarity (SSIM) index. The PSNR does not capture subjective quality well when blocking artifacts are present. The SSIM metric is slightly more complex than the PSNR, but correlates highly with human subjectively. We also propose a new de-blocking quality index that is sensitive to blocking artifacts in de-blocked images. We name this peak signal-to-noise ratio including blocking effects (PSNR-B). The simulation results show that the proposed PSNR-B correlates well with subjective quality and with the SSIM index, and performs much better than the PSNR.

We study a variety of image and video de-blocking algorithms, including low pass filtering, projection onto convex sets (POCS), and the H.264 in-loop filter. The image improvements afforded by these algorithms is measured using the PSNR, PSNR-B, and SSIM. Rather than relying on PSNR, which correlates poorly with subjective judgment, we utilize PSNR-B which is designed specifically to assess blocky and de-blocked images (but has no proven perceptual significance) in conjunction with the SSIM index, which is perceptually significant, but has not been demonstrated on de-blocked images[6]

To remove blocking effect, several de-blocking techniques have been proposed in the literature as post process mechanisms after JPEG compression, depending on the angle from which the blocking problem is tackled. If de-blocking is viewed as an estimation problem, the simplest solution is probably just to low pass the blocky JPEG

compressed image. More sophisticated methods involve iterative methods such as projection on convex sets and constrained least squares[7],[8]

II. BASED ON QUALITY ASSESSMENT

We consider the class of quality assessment (QA) methods that are full-reference (FR) QA, which compares the test (distorted) image with a reference (original) image. In this paper, the distorted images will ostensibly suffer from blocking artifacts or from the residual artifacts following de-blocking.

A. Peak Signal To Noise Ratio(PSNR):

The simplest and most widely used FR QA metrics are the peak signal-to-noise ratio (PSNR) and the mean-squared error(MSE) [2], [4]. Let \mathbf{x} and \mathbf{y} represent the vectors of reference and test image signals, respectively. Let e be the vector of error signal between \mathbf{x} and \mathbf{y} . If the number of pixels in an image is N , then

$$MSE(\mathbf{x}, \mathbf{y}) = \frac{1}{N} \sum_{i=1}^N e_i^2 = \frac{1}{N} \sum_{i=1}^N (x_i - y_i)^2 \quad (1)$$

$$PSNR(\mathbf{x}, \mathbf{y}) = 10 \log_{10} \frac{255^2}{MSE(\mathbf{x}, \mathbf{y})} \quad (2)$$

The PSNR is an attractive QA metric since it is mathematically simple and has clear physical meaning. However, the PSNR does not correlate well with perceived visual quality [3]–[6].

B. Structural Similarity Index Metric(SSIM):

The structural similarity (SSIM) metric aims to measure quality by capturing the similarity of images [1]. A product of three aspects of similarity are measured: luminance, contrast, and structure. The luminance comparison function $l(\mathbf{x}, \mathbf{y})$ for reference image \mathbf{x} and test image \mathbf{y} is defined as

$$l(\mathbf{x}, \mathbf{y}) = \frac{2\mu_x\mu_y + C_1}{\mu_x^2 + \mu_y^2 + C_1} \quad (3)$$

Where σ_x and σ_y are the standard deviation of \mathbf{x} and \mathbf{y} , respectively, and C_1 is a stabilizing constant.

The structure comparison function is $c(\mathbf{x}, \mathbf{y})$ defined as

$$c(\mathbf{x}, \mathbf{y}) = \frac{2\sigma_x\sigma_y + C_2}{\sigma_x^2 + \sigma_y^2 + C_2} \quad (4)$$

Where σ_{xy} and $\sigma_x\sigma_y$ are the standard deviation of \mathbf{x} and \mathbf{y} , respectively, and C_2 is a stabilizing constant.

The structure comparison function $s(\mathbf{x}, \mathbf{y})$ is defined as

$$s(\mathbf{x}, \mathbf{y}) = \frac{\sigma_{xy} + C_3}{\sigma_x\sigma_y + C_3} \quad (5)$$

Where σ_{xy} is the correlation between \mathbf{x} and \mathbf{y} C_3 is also a constant that provides stability

The SSIM index is obtained by combining the three comparison functions

$$SSIM(\mathbf{x}, \mathbf{y}) = [l(\mathbf{x}, \mathbf{y})]^\alpha \cdot [c(\mathbf{x}, \mathbf{y})]^\beta \cdot [s(\mathbf{x}, \mathbf{y})]^\gamma \quad (6)$$

The parameters are set as

$$\alpha = \beta = \gamma = 1 \text{ and } C_3 = C_2/2$$

$$SSIM(\mathbf{x}, \mathbf{y}) = \frac{(2\mu_x\mu_y + C_1)(2\sigma_{xy} + C_2)}{(\mu_x^2 + \mu_y^2 + C_1)(\sigma_x^2 + \sigma_y^2 + C_2)} \quad (7)$$

Local SSIM statistics are estimated using a symmetric Gaussian weighting function. The mean SSIM index pools the spatial SSIM values to evaluate the overall image quality

$$SSIM(\mathbf{x}, \mathbf{y}) = \frac{1}{M} \sum_{j=1}^M SSIM(\mathbf{x}_j, \mathbf{y}_j) \quad (8)$$

where M is the number of local windows over the image, and \mathbf{X}_j and \mathbf{Y}_j are image patches covered by the j 'th window

III. QUANTIZATION STEP SIZE AND IMAGE QUALITY

Quantization is a key element of lossy compression, but information is lost. There is a tradeoff between compression ratio and reconstructed image/video quality. The amount of compression and the quality can be controlled by the quantization step. As the quantization step is increased, the compression ratio becomes larger, and the quality generally worsens. However, there has not been a study made of how perceptual quality suffers as a function of step size, or the degree to which de-blocking augments perceptual quality. The emergence of new and powerful IQA indices suggests this possibility.

In block transform coding, the input image is divided into $L \times L$ blocks, and each block is transformed independently into transform coefficients. An input image block is transformed into a DCT coefficient block

Figure 1: Block diagram for reference, decoded, and de-blocked images

$$B = T b T^t \quad (9)$$

Where T is the transform matrix and T^t is the transpose matrix of T . The transform coefficients are quantized using a scalar quantizer.

$$\tilde{B} = Q(B) = Q(T b T^t) \quad (10)$$

The quantization operator in (10) is nonlinear, and is a many-to-one mapping from R^{L^2} to R^{L^2}

In the decoder, only quantized transform coefficients \tilde{B} are available. The output of the decoder is

$$\tilde{b} = T^t \tilde{B} T = T^t Q(T b T^t) T \quad (11)$$

Let Δ represent the quantization step. It is well known that the PSNR is a monotonically decreasing function of Δ . The SSIM index captures the similarity of reference and test images. As the quantization step size becomes larger, the structural differences between reference and test image will

generally increase, and in particular the structure terms (\mathbf{x}, \mathbf{y}) in (5) will become smaller. Hence, the SSIM index would be a monotonically decreasing function of the quantization step size Δ .

IV. DEBLOCKING FILTER AND DISTORTION CHANGE

As before, \mathbf{x} is the reference (original) image and \mathbf{y} is the decoded image that has been distorted by quantization errors. Let $\hat{\mathbf{y}}$ represent the de-blocked image and \mathbf{f} represent the de-blocking operation $\hat{\mathbf{y}} = \mathbf{f}(\mathbf{y})$. Fig. 1 shows a block diagram depicting the flow of reference, decoded, and de-blocked images. Let $\mathbf{M}(\mathbf{x}, \mathbf{y})$ be the quality metric between \mathbf{x} and \mathbf{y} . The goal of the de-blocking operation \mathbf{f} is to maximize $\mathbf{M}(\mathbf{x}, \mathbf{f}(\mathbf{y}))$ given image \mathbf{y} .

De-blocking is a local operation. The de-blocking operation may improve the appearance of the image in some regions, while degrading the quality elsewhere. Let α_i be the distortion between the i 'th pixels of \mathbf{x} and \mathbf{y} , expressed as squared Euclidean distance

$$d(x_i, y_i) = \|x_i - y_i\|^2 \quad (12)$$

Next, we define the distortion decrease region (DDR) \mathcal{A} to be composed of those pixels where the distortion is decreased by the de-blocking operation

$$i \in \mathcal{A}, \text{ if } d(x_i, \hat{y}_i) < d(x_i, y_i) \quad (13)$$

The amount of distortion decrease for the i th pixel in the DDR \mathcal{A} is

$$\alpha_i = d(x_i, y_i) - d(x_i, \hat{y}_i) \quad (14)$$

The distortion may also increase at other pixels by application of the de-blocking filter. We similarly define the distortion increase region (DIR) \mathcal{B}

$$i \in \mathcal{B}, \text{ if } d(x_i, y_i) < d(x_i, \hat{y}_i) \quad (15)$$

The amount of distortion increase for the i 'th pixel β_i in the DIR \mathcal{B} is

$$\beta_i = d(x_i, \hat{y}_i) - d(x_i, y_i) \quad (16)$$

We define the mean distortion decrease (MDD)

$$\bar{\alpha} = \frac{1}{N} \sum_{i \in \mathcal{A}} (d(x_i, y_i) - d(x_i, \hat{y}_i)) \quad (17)$$

Where N is the number of pixels in the image. Similarly the mean distortion increase (MDI) is

$$\bar{\beta} = \frac{1}{N} \sum_{i \in \mathcal{B}} (d(x_i, \hat{y}_i) - d(x_i, y_i)) \quad (18)$$

A reasonable approach for designing a de-blocking filter would be to seek to maximize the MDD and minimize the MDI. This is generally a very difficult task and of course, may not result in optimized improvement in perceptual quality. Lastly, let $\bar{\gamma}$ be the mean distortion change (MDC), defined as the difference between MDD and MDI.

$$\bar{\gamma} = \bar{\alpha} - \bar{\beta} \quad (19)$$

If $\bar{\gamma} < 0$, then the de-blocking operation is likely unsuccessful since the mean distortion increase is larger than the mean distortion decrease. We would expect a successful de-blocking operation to yield $\bar{\gamma} > 0$. Nevertheless, these conditions are not equated with

levels of perceptual improvement or loss. De-blocking can be considered as an image restoration problem. Let $\mathcal{N}(x_i)$ represent the de-blocking operation function and $\mathcal{N}(x_i)$ represent a neighborhood of pixel x_i .

A low pass filter is a simple de-blocking filter. An $L \times L$ low pass filter can be represented as

$$g(\mathcal{N}(x_i)) = \sum_{k=1}^{L^2} h_k \cdot x_{i,k} \quad (20)$$

While low pass filtering does reduce blocking artifacts, critical high frequency information is also lost and the image is blurred. While the distortion will certainly decrease for some pixels that define the DDR, the distortion will likely increase for a significant number of pixels in DIR. Indeed, it is quite possible that $\bar{\gamma} < 0$ could result. Moreover, blur is perceptually annoying.

A variety of nonlinear methods have been proposed to reduce the blocking artifacts, while minimizing the loss of original information [7]–[14]. For example, de-blocking algorithms based upon projection onto convex sets (POCS) have demonstrated good performance for reducing blocking artifacts and have proved popular [7]–[12]. In POCS, a low pass filtering operation is performed in the spatial domain, while a projection operation is performed in the DCT domain. Typically, the projection operation is a clipping operation on the filtered coefficients, confining these to fall within a certain range defined by the quantization step size. Since the low pass filtering and the projection operations are performed in different domains, forward DCT and inverse DCT (IDCT) operations are required. The low pass filtering, DCT, projection, IDCT operations compose one iteration, and multiple iterations are required to achieve convergence. It is argued that under certain conditions, POCS filtered images converge to an image that does not exhibit blocking artifacts [7], [10], [11]. As another example, the H.264 in-loop de-blocking filter is a key component in the H.264 video coding standard [17]. It is claimed that the in-loop filtering significantly improves both subjective and objective video quality [15]. The key idea of the H.264 in-loop filter is to adaptively select the filtering operation and the neighborhood using the relative pixel location with respect to the block boundary and the local gray level gradient information. Generally, the MDI value is reduced while the MDD value is similar to low pass filtering. The H.264 in-loop filter uses separate 1-D operations and integer multiplications to reduce complexity. However, it still requires a large amount of computation. In fact, the H.264 in-loop filter requires about one-third of the computational complexity of the decoder [15].

V. PSNR INCLUDING BLOCKING EFFECTS

In the following, we propose a new block-sensitive image quality metric which we term peak signal-to-noise ratio including blocking effects (PSNR-B). As the quantization step size increases, blocking artifacts generally become more conspicuous. Blocking artifacts are gray level discontinuities at block boundaries, which are ordinarily oriented horizontally and vertically. They arise from poor representation of the block luminance levels near the block boundaries [18].

The following definitions are relative to an assumed block-based compression tiling, e.g., 8 x 8 blocks as in JPEG compression. For simplicity, assume that an integer number of blocks comprise the image, viz., that horizontal and vertical dimensions are divisible by the block dimension. The definitions apply whether the image is compressed, not-compressed, or de-blocked following decompression.

y ₁	y ₂	y ₃	y ₄	y ₅	y ₆	y ₇	y ₈
y ₉	y ₁₀	y ₁₁	y ₁₂	y ₁₃	y ₁₄	y ₁₅	y ₁₆
y ₁₇	y ₁₈	y ₁₉	y ₂₀	y ₂₁	y ₂₂	y ₂₃	y ₂₄
y ₂₅	y ₂₆	y ₂₇	y ₂₈	y ₂₉	y ₃₀	y ₃₁	y ₃₂
y ₃₃	y ₃₄	y ₃₅	y ₃₆	y ₃₇	y ₃₈	y ₃₉	y ₄₀
y ₄₁	y ₄₂	y ₄₃	y ₄₄	y ₄₅	y ₄₆	y ₄₇	y ₄₈
y ₄₉	y ₅₀	y ₅₁	y ₅₂	y ₅₃	y ₅₄	y ₅₅	y ₅₆
y ₅₇	y ₅₈	y ₅₉	y ₆₀	y ₆₁	y ₆₂	y ₆₃	y ₆₄

Figure 2: Example for illustration of pixel blocks

Let N_{HB}, N_{HB}^C, N_{VB} be the number of pixel pairs in $\mathcal{H}_B, \mathcal{H}_B^C, \mathcal{V}_B$ respectively. If B is the block size, then

$$\begin{aligned} N_{HB} &= N_V \left(\frac{N_H}{B} \right) - 1 \\ N_{HB}^C &= N_V(N_H - 1) - N_{HB} \\ N_{VB} &= N_H \left(\frac{N_V}{B} \right) - 1 \\ N_{VB}^C &= N_H(N_V - 1) - N_{VB}. \end{aligned} \tag{21}$$

Fig. 2 shows a simple example for illustration of pixel blocks with $N_H=8, N_V=8, B=4$. The thick lines represent the block boundaries. The sets of pixel pairs in this example are

$$\begin{aligned} \mathcal{H}_B &= \{(y_4, y_5), (y_{12}, y_{13}), \dots, (y_{60}, y_{61})\} \\ \mathcal{H}_B^C &= \{(y_1, y_2), (y_2, y_3), (y_3, y_4), (y_5, y_6), \dots, (y_{63}, y_{64})\} \\ \mathcal{V}_B &= \{(y_{25}, y_{33}), (y_{26}, y_{34}), \dots, (y_{32}, y_{40})\} \\ \mathcal{V}_B^C &= \{(y_1, y_9), (y_9, y_{17}), (y_{17}, y_{25}), (y_{33}, y_{41}), \dots, (y_{56}, y_{64})\}. \end{aligned} \tag{22}$$

Then we define the mean boundary pixel squared difference (DB) and the mean non boundary pixel squared difference (DcB) for image y to be

$$\begin{aligned} D_B(\mathbf{y}) &= \frac{\sum_{(y_i, y_j) \in \mathcal{H}_B} (y_i - y_j)^2 + \sum_{(y_i, y_j) \in \mathcal{V}_B} (y_i - y_j)^2}{N_{HB} + N_{VB}} \\ D_B^C(\mathbf{y}) &= \frac{\sum_{(y_i, y_j) \in \mathcal{H}_B^C} (y_i - y_j)^2 + \sum_{(y_i, y_j) \in \mathcal{V}_B^C} (y_i - y_j)^2}{N_{HB}^C + N_{VB}^C}, \end{aligned} \tag{23}$$

Generally, as the quantization step size increases, (DB) will increase relative to (DcB) and blocking artifacts will become more visible. Of course, this does not establish any level of correlation between and perceptual annoyance. Also define the blocking effect factor

$$BEF(\mathbf{y}) = \eta \cdot [D_B(\mathbf{y}) - D_B^C(\mathbf{y})] \tag{24}$$

Where

$$\eta = \begin{cases} \frac{\log_2 B}{\log_2(\min(N_H, N_V))}, & \text{if } D_B(\mathbf{y}) > D_B^C(\mathbf{y}) \\ 0, & \text{otherwise} \end{cases} \tag{25}$$

emphasizes the BEF as a function of block size. The assumption here is that the visibility of blocking effects increases with block size.

Of course, there can be multiple block sizes in a particular decoded image/video. For example, there can be 16 X 16 macro blocks and 4 X 4 transform blocks, both contributing to blocking effects, as in H.264 video coding

$$BEF_k(\mathbf{y}) = \eta_k \cdot [D_{B_k}(\mathbf{y}) - D_{B_k}^C(\mathbf{y})] \tag{26}$$

The BEF over all block sizes is defined as

$$BEF_{Tot}(\mathbf{y}) = \sum_{k=1}^K BEF_k(\mathbf{y}) \tag{27}$$

The mean-squared error including blocking effects (MSE-B)

for reference image \mathbf{x} and test image \mathbf{y} is then defined as the sum of the MSE (\mathbf{x}, \mathbf{y})

$$MSE-B(\mathbf{x}, \mathbf{y}) = MSE(\mathbf{x}, \mathbf{y}) + BEF_{Tot}(\mathbf{y}) \tag{29}$$

Finally, we propose the PSNR-B as

$$PSNR-B(\mathbf{x}, \mathbf{y}) = 10 \log_{10} \frac{255^2}{MSE-B(\mathbf{x}, \mathbf{y})} \tag{30}$$

The MSE term in measures the distortion between the reference image and the test image, while the BEF term in specifically measures the amount of blocking artifacts just using the test image. The BEF itself can be used as a no reference quality index, similar to the generalized block-edge impairment metric (GBIM) and the mean noticeable blockiness score (MNBS) [20]. These no-reference quality indices claim to be efficient for measuring the amount of blockiness, but may not be efficient for measuring image quality relative to full-reference quality assessment. On the other hand, the MSE is not specific to blocking effects, which can substantially affect subjective quality. We argue that the combination of MSE and BEF is an effective measurement for quality assessment considering both the distortions from the original image and the blocking effects in the test image. The associated quality index PSNR-B is obtained from the MSE-B by a logarithmic function, as is the PSNR from the MSE. The PSNR-B is attractive since it is specific for assessing image quality, specifically the severity of blocking artifacts.

IV. MATLAB RESULTS

Now we present simulation results for de-blocking filters for H.264 video coding. The H.264 encoding and decoding simulations are performed using the H.264 reference. The in-loop de-blocking filter is a key component in H.264 video coding. If the filter is selected by an encoding parameter, in-loop filtering is performed both in encoding and in decoding. If it is not selected, in-loop filtering is not performed either in encoding or in decoding. In H.264, the quantization step size is controlled by the quantization parameter (QP) during encoding [16]. The QP can take 52 values ranging from 0 to 51, and the quantization step is doubled for each increment of six in the QP [19]. In H.264 coding, the quantization step is the same for all transform coefficients as determined by the QP. To assess the in-loop filter using the quality indices, the size of a group-of-pictures (GOP) is set as eight with one I-frame and seven P-frames. In the simulations, 16 frames are encoded and decoded. The quality indices were applied on the original (reference) and decoded images at each frame, and the quality scores were then averaged over the 16 frames

A. PSNR Analysis:

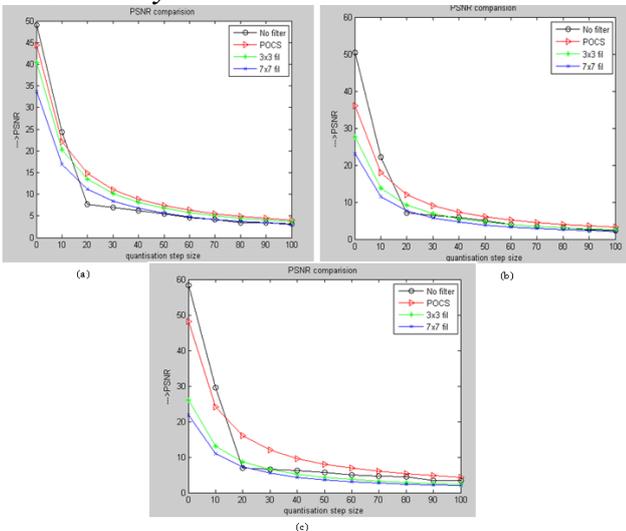

Fig. 3 PSNR comparison of filters for H.264 videos.

Fig. 3 examines the H.264 in-loop filter and low pass filters using the PSNR as an analysis tool. The 3x3 and 7x7 low pass filters do not provide improvement compared to not filtering for small to medium quantization step sizes. The low pass filters produce slight improvement compared to not filtering for on the Foreman and Mother and Daughter videos. The in-loop filter gave a slight improvement of PSNR compared to not filtering for mid-to-large quantization steps on the Foreman, Mother and Daughter, and Hall Monitor videos. The in-loop filter did not produce improvements compared to not filtering on the complex Mobile video, according to the PSNR. However, the PSNR is of dubious value when assessing perceptual quality.

B. SSIM Analysis:

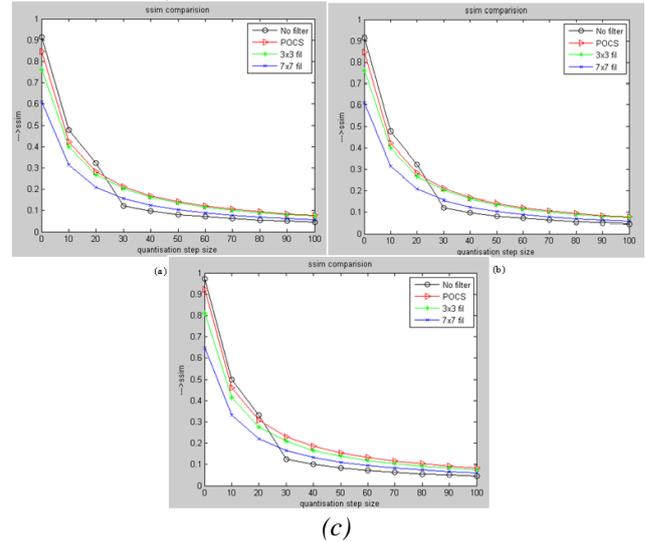

Figure 4: SSIM comparison of filters for H.264 videos

Fig. 4 studies the de-blocking methods using the SSIM index. The in-loop filter produced improvement in the SSIM values compared to not filtering for mid-to-large quantization steps on the Foreman, Mother and Daughter, and Hall Monitor videos. As the quantization step was increased, the in-loop filter systematically produced larger SSIM values. The 3x3 filter also produced improvement according to SSIM as compared to not filtering on the Foreman, Mother and Daughter, and Hall Monitor videos, when the quantization step was greater than 40. For the Mobile video, the in-loop filter produced SSIM values almost the same as those for not filtering while the low pass filters gave lower SSIM values. This is clear evidence that the in-loop filter works well, according to the perceptually relevant SSIM index.

C. PSNR-B Analysis:

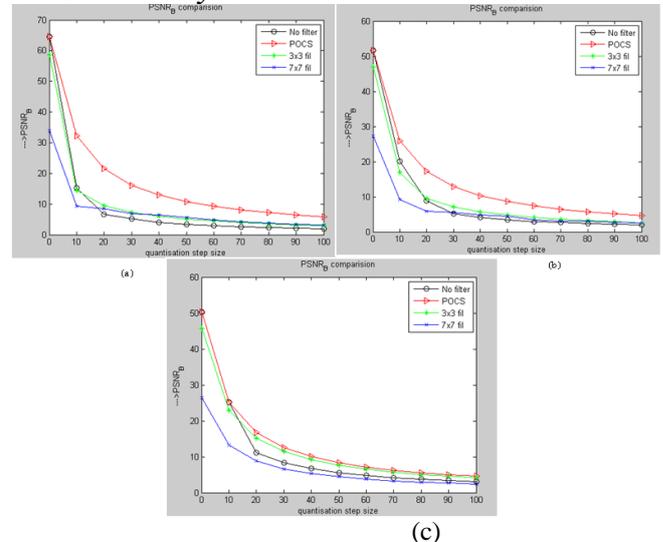

Fig. 5. PSNR-B comparison of filters for H.264 videos

Fig. 5 analyzes the in-loop filter using PSNR-B. PSNR-B produces trends similar to SSIM and visual analysis, while the PSNR shows different trends. For mid-to-large quantization steps, PSNR-B shows that the in-loop filter delivers marginal improvement as compared to not filtering,

while the PSNR shows little change on the Foreman, Mother and Daughter, and Hall Monitor videos. For a large quantization step, the PSNR-B comparison in Fig. 5 shows that the 3x 3 and 7x 7 filters deliver improvements,

V. CONCLUSION

Here we proposed the block-sensitive image quality index PSNR-B for quality assessment of de-blocked images. It modifies the conventional PSNR by including an effective blocking effect factor. In simulations, we compared relevant image quality indices for de-blocked images. The simulation results show that PSNR-B results in better and good performance than PSNR for image quality assessment of these impaired images. By comparison, the blockiness-specific index GBIM effectively assesses blockiness, but has limitations for image quality assessment. PSNR-B shows similar trends with the perceptually proven index SSIM. It is attractive since it is specific for assessing image quality, specifically the severity of blocking artifacts. The PSNR-B takes values in a similar range as PSNR and is, therefore, intuitive for users of PSNR, while it results in better performance for quality assessment of de-blocked images.

Abstract: In OFDM systems, the major obstacle is that the multiplex signal exhibits a very high peak-to-average power ratio (PAR). In this paper, a new novel method to reduce the PAR. A simple and attractive technique is Active constellation extension used. However, we observe it cannot achieve the minimum PAR when the target clipping level is set below an initially unknown optimum value. A low clipping ratio is the problem in OFDM system to overcome this AEC algorithm with adaptive clipping control. However, the simulation results show our algorithm can reach the minimum Peak to Average for several clipping ratios, and also in AWGN channel we calculate the tradeoff between PAR and the loss in E_b/N_0 .

Keywords: Peak-to-average ratio (PAR), active constellation extension (ACE), adaptive, OFDM, BER, AWGN.

I. INTRODUCTION

Orthogonal frequency division multiplexing is a very attractive technique for high speed data transmission in mobile communications due to various advantages such as high spectral efficiency, robustness to channel fading, immunity to impulse interference, and capability of handling very strong multi-path fading and frequency selective fading without having to provide powerful channel equalization. In recent years, several industrial standards based on OFDM have been emerged, such as the Terrestrial Digital Video Broadcast (DVB-T), the IEEE 802.11 Wireless Local Area Network (WLAN) scheme, as well as the IEEE 802.16 Broadband Wireless Access (BWA), particularly, Wireless Metropolitan Area Networks (IEEE 802.16d) WiMAX.

Besides a lot of advantages, some drawbacks become apparent, when using OFDM in transmission systems. A major obstacle is that the multiplex signal exhibits a very high peak-to-average power ratio (PAR). Therefore, nonlinearities may get overloaded by high signal peaks, causing inter modulation among subcarriers and, more critical, undesired out-of-band radiation. If RF power amplifiers are operated without large power back-offs, it is impossible to keep the out-of-band power below specified limits. This leads to very inefficient amplification and expensive transmitters so that it is highly desirable to reduce the PAR [3]. Several schemes have been proposed to reduce the PAPR. These techniques can mainly be categorized into Signal scrambling techniques and Signal distortion techniques [1]. Signal scrambling techniques are all variations on how to scramble the codes to decrease the PAPR. Coding techniques can be used for signal

scrambling. Golay complementary sequences, Shapiro-Rudin sequences, M-sequences, Barker codes can be used to efficiently reduce the PAPR. However, with the increase in the number of carriers, the overhead associated with exhaustive search of the best code would increase exponentially. More practical solutions of the signal scrambling techniques are block coding, selective mapping and partial transmit sequences.

In this paper, to solve the low clipping ratio problem of CBACE, we introduce a new method of ACE for PAR reduction. Here, The PAR reduced by extending some modulation constellation points without any loss of data in outside of constellation. The cost of this is low and complexity also low, so that's why we proposing Active constellation extension. The algorithm provides a suboptimal solution to the given clipping ratio, because the clipping ratio is predetermined at the initial stage. However, the CB-ACE algorithms have a low clipping ratio problem in that they cannot achieve the minimum PAR.

In this correspondence clipping ratio problem of CBACE, we introduce a new method Active constellation extension for to reduce the PAR. Our algorithm based on the clipping with an adaptive clipping control, which allows us to find the optimal clipping level. simulation results shows that our algorithm can achieve the minimum Peak to Average Ratio regardless of the low target clipping level, and also calculate the tradeoff between PAR and BER over an AWGN channel in terms of clipping ratio.

II. TOPICS RELATED TO PROPOSED CONCEPT

A. Peak to Average Ratio:

OFDM signals have a higher peak-to-average ratio (PAR) often called a peak-to-average power ratio (PAPR) than single-carrier signals do. The reason is that in the time domain, a multicarrier signal is the sum of many narrowband signals. At some time instances, this sum is large and at other times is small, which means that the peak value of the signal is substantially larger than the average value. This high PAR is one of the most important implementation challenges that face OFDM, because it reduces the efficiency and hence increases the cost of the RF power amplifier, which is one of the most expensive components in the radio.

B. The PAR Problem:

When transmitted through a nonlinear device, such as a high-power amplifier (HPA) or a digital to analog converter (DAC) a high peak signal, generates out-of-band energy (spectral regrowth) and in-band distortion

(constellation tilting and scattering). These degradations may affect the system performance severely. The nonlinear behavior of an HPA can be characterized by amplitude modulation/amplitude modulation (AM/AM) and amplitude modulation/phase modulation (AM/PM) responses. Figure (1) shows a typical AM/AM response for an HPA, with the associated input and output back-off regions (IBO and OBO, respectively).

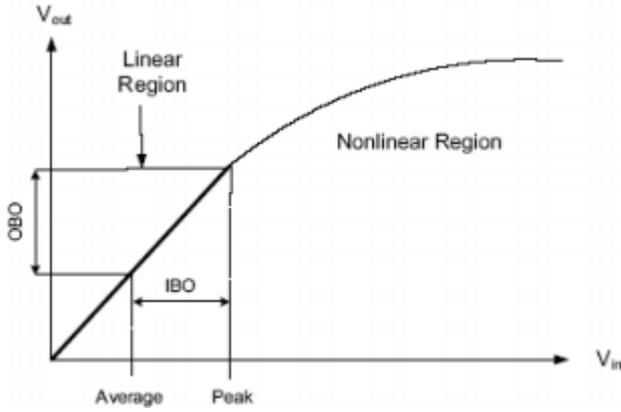

Figure 1: A typical power amplifier response

To avoid such undesirable nonlinear effects, a waveform with high peak power must be transmitted in the linear region of the HPA by decreasing the average power of the input signal. This is called (input) back off (IBO) and results in a proportional output back off (OBO). High back off reduces the power efficiency of the HPA and may limit the battery life for mobile applications. In addition to inefficiency in terms of power, the coverage range is reduced, and the cost of the HPA is higher than would be mandated by the average power requirements. The input backoff is defined as:

$$IBO = 10 \log_{10} \frac{P_{in\ sat}}{P_{in}}$$

Where $P_{in\ sat}$ is the saturation power, above which is the nonlinear region, and P_{in} is the average input power. The amount of backoff is usually greater than or equal to the PAR of the signal. The power efficiency of an HPA can be increased by reducing the PAR of the transmitted signal. Clearly, it would be desirable to have the average and peak values are as close together as possible in order to maximize the efficiency of the power amplifier. In addition to the large burden placed on the HPA, a high PAR requires high resolution for both the transmitter's DAC and the receiver's ADC, since the dynamic range of the signal is proportional to the PAR. High-resolution D/A and A/D conversion places an additional complexity, cost, and power burden on the system.

III. CB-ACE IN OFDM SYSTEMS

An OFDM signal consists of the sum of N independent signals modulated in the frequency domain onto sub channels of equal bandwidth. As a continuous-time equivalent signal, the oversampled OFDM signal is expressed as

$$x_n = \frac{1}{\sqrt{JN}} \sum_{k=0}^{JN-1} X_k e^{j2\pi \frac{k}{JN} n}, \quad n = 0, 1, \dots, JN-1 \quad (1)$$

where N is the number of subcarriers; X_k are the complex data symbols using phase-shift keying (PSK) or quadrature amplitude modulation (QAM) at the k th subcarrier; and J is the oversampling factor where $J \geq 4$, which is large enough to accurately approximate the peaks [4]. In matrix notation, (1) can be expressed as $\mathbf{x} = \mathbf{Q}^* \mathbf{X}$, where \mathbf{Q} is the inverse discrete Fourier transform (IDFT) matrix of size $JN \times JN$, \mathbf{X} denotes the Hermitian conjugate, the complex time-domain signal vector \mathbf{X} .

$$\mathbf{X} = [X_0, X_1, X_2, \dots, X_{\frac{JN}{2}-1}, 0, X_{\frac{JN}{2}}, X_{\frac{JN}{2}+1}, \dots, X_{JN-1}]^T$$

Here, we do not consider the guard interval, because it does not impact the PAR, which is defined as

$$PAR(\mathbf{x}) \triangleq \frac{\max_{0 \leq n \leq JN-1} |x_n|^2}{E[|x_n|^2]}, \quad (2)$$

Note that (2) does not include the power of the anti-peak signal added by the PAR reduction. Let \mathcal{I}_a be the index set

$$\begin{aligned} & \min_{\mathbf{c}} \|\mathbf{x} + \mathbf{Q}^* \mathbf{C}\|_{\infty}^2 \\ & \text{subject to: } X_k + C_k \text{ be feasible for } k \in \mathcal{I}_a, \\ & C_k = 0, \text{ for } k \notin \mathcal{I}_a \end{aligned} \quad (3)$$

where \mathbf{C} is the extension vector whose components, C_k are non zero only if $k \in \mathcal{I}_a$

However, this optimal solution for this ACE formulation of PAR reduction is not appropriate for practical implementation due to high computational complexity. Thus, the CB-ACE algorithms are introduced [1], [2]. The basic idea of the CB-ACE algorithm is to generate the anti-peak signal for PAR reduction by projecting the clipping in-band noise into the feasible extension area while removing the out-of-band distortion with filtering. Thus, the CB-ACE method is considered as a repeated-clipping-and filtering (RCF) process with ACE constraints as follows:

$$\mathbf{x}^{(i+1)} = \mathbf{x}^{(i)} + \mu \tilde{\mathbf{c}}^{(i)} \quad (4)$$

where μ is a positive real step size that determines the convergence speed, i is the iteration index, the initial signal is, $\mathbf{x}^{(0)}$ and $\tilde{\mathbf{c}}^{(i)}$ is the anti-peak signal at the i th iteration as follows:

where $c_n^{(i)}$ is the clipping sample, which can be obtained as follows:

$$c_n^{(i)} = \begin{cases} (|x_n^{(i)}| - A) e^{j\theta_n}, & \text{if } |x_n^{(i)}| > A \\ 0, & \text{if } |x_n^{(i)}| \leq A \end{cases}, \quad (5)$$

where $\theta_n = \arg(-x_n^{(i)})$. The clipping level A is related to the clipping ratio γ as $\gamma = \frac{A^2}{E[|x_n|^2]}$. In general, we expect more

PAR reduction gain with a lower target clipping level; the existing CBACE algorithms cannot achieve the minimum PAR for low target clipping ratios, because the reduced power by low clipping decreases the PAR reduction gain in ACE. The original symbol constellations move toward the origin with the decreasing clipping ratio in [6], which places the clipped signal constellations outside the feasible extension region. The number of \mathcal{E}_a , corresponding to the number of reserved tones in tone reservation (TR), as in [7], decreases with low clipping ratio, which in turn degrades the PAR reduction capacity in ACE.

IV. PROPOSED CONCEPT AND ALGORITHM

The main objective of our proposed algorithm is to control both the clipping level and convergence factor at each iteration and to iteratively minimize the peak power signal greater than the target clipping level. The cost function is defined as

$$\xi(I^{(i)}) \triangleq \min_{\mu, A} \|\mathbf{x}^{(i)} + \mu \tilde{\mathbf{c}}^{(i)} - A e^{j\Phi^{(i)}}\|_2^2 \quad (6)$$

Where $\Phi^{(i)}$ is the phase vector of $\mathbf{x}^{(i)} + \mu \tilde{\mathbf{c}}^{(i)}$ at the i th iteration and $I^{(i)}$ represents the set of time indices at the i th iteration,

$$I^{(i)} = \{n \text{ s.t. } n \in [0, N-1]\}$$

Step 0: Initialize the parameters

- Select the target clipping level A .
- Set up the maximum number of iterations L .

Step 1: Set $i = 0$, $\mathbf{x}^{(0)} = \mathbf{x}$ and $A^{(0)} = A$.

Step 2: Compute the clipping signal in (5); if there is no clipping signal, transmit signal, $\mathbf{x}(i)$.

Step 3: Transfer the clipping signal into the anti-peak signal subject to ACE constraint;

Convert into $\mathbf{c}^{(i)}$ into $\tilde{\mathbf{c}}^{(i)}$

- Project $\mathbf{c}^{(i)}$ onto the feasible region in ACE and remove the out-of-band of $\tilde{\mathbf{c}}^{(i)}$
- Obtain $\tilde{\mathbf{c}}^{(i)}$ by taking the IDFT.

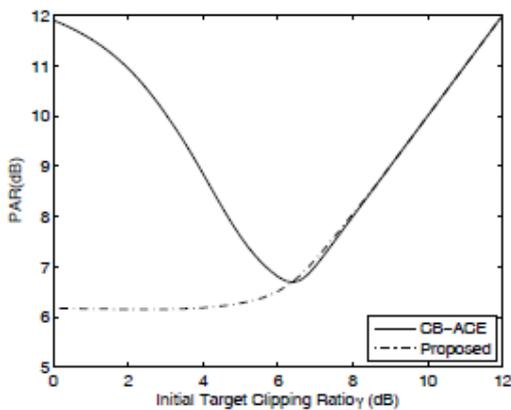

Figure 2: The achievable PAR of CB-ACE and the proposed algorithm for an OFDM signal with a 12dB PAR, for different initial target clipping ratios.

Step 4: Update $\mathbf{x}^{(i)}$ in (4) and A minimizing (6). Compute the optimal step size μ

$$\mu = \frac{\Re[\langle \mathbf{c}^{(i)}, \tilde{\mathbf{c}}^{(i)} \rangle]}{\langle \tilde{\mathbf{c}}^{(i)}, \tilde{\mathbf{c}}^{(i)} \rangle}, \quad (7)$$

where \Re defines the real part and $\langle \cdot, \cdot \rangle$ is the complex inner-product. Adjust the clipping level A

$$A^{(i+1)} = A^{(i)} + \nu \nabla_A, \quad (8)$$

Where the gradient with respect to A is

$$\nabla_A = \frac{\sum_{n \in I_1^{(i)} \cup I_3^{(i)}} |c_n^{(i+1)}|}{N_p} \quad (9)$$

and ν is the step size with $0 \leq \nu \leq 1$ and N_p is the number of peak samples larger than A .

Step 5: Increase the iteration counter, $i = i+1$. If $i < L$, go to *Step 2* and repeat; otherwise, transmit signal, $\mathbf{x}^{(i)}$.

Compared to the existing CB-ACE with complexity of order $(JN \log N)$, the complexity of our proposed algorithm slightly increases whenever the adaptive control is calculated in (8). However, this additional complexity of the adaptive control is negligible compared to that of order $O(JN \log N)$.

V. MATLAB/SIMULINK RESULTS

In this section, we illustrate the performance of our proposed algorithm using computer simulations. In the simulations, we use an OFDM system with 2048 subcarriers and M-QAM constellations on each subcarrier. To approximate the continuous-time peak signal of an OFDM signal, the oversampling rate factor $J = 8$ is used in (1). For a fast convergence rate, the optimal adaptive scaling is applied. Fig. 2 compares the achievable PAR of CB-ACE with the optimal adaptive scaling with that of our proposed algorithm for an OFDM signal with an initial 12dB PAR and 16-QAM modulation, for different target clipping ratios γ from 0dB to 12dB. In the case when CB-ACE is applied, we find the minimum achievable PAR, 6.62dB, is obtained with a target clipping ratio of 6.4dB, which shows that CB-ACE depends on the target clipping ratio, as we mentioned in the previous section. The PAR reduction gain becomes smaller with a decreasing target clipping ratio from the optimal value of 6.4dB. Thus, we must carefully select the target clipping ratio

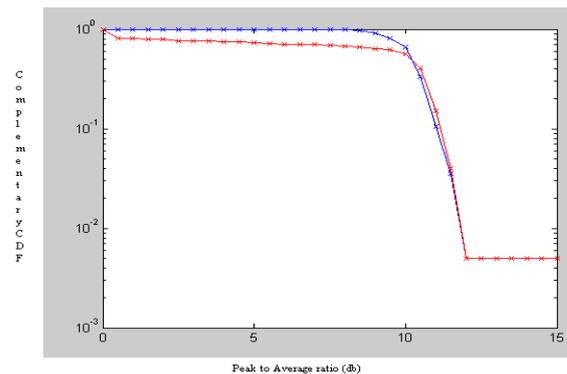

Figure-3 PAR CCDF comparison of the CB-ACE and the proposed method for different initial target clipping ratios

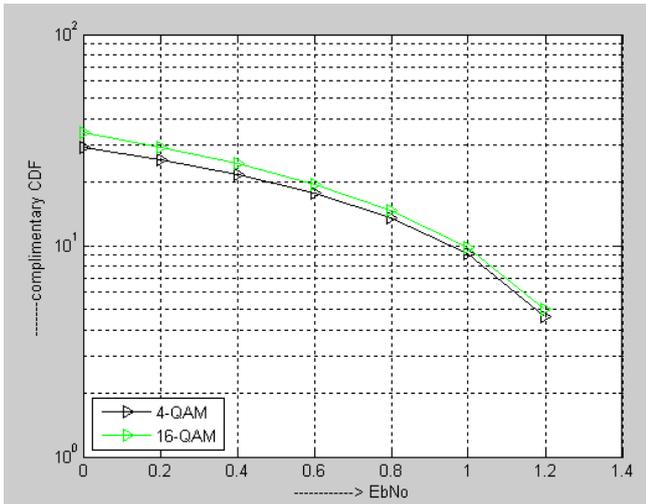

Figure 4: PAR for CCDF 10^{-3} vs loss in E_b/N_0 at the BER of 10^{-3} for different QAM constellation orders of the proposed algorithm.

for CB-ACE. On the other hand, we observe that our proposed algorithm can achieve the lower minimum PAR even when the initial target clipping ratio is set below the CB-ACE optimal value of 6.4dB. It is obvious that our proposed algorithm solves the low target clipping ratio problem associated with the CB-ACE, as shown in Fig.3 . Fig. 4 considers two algorithms: CB-ACE and our proposed method for three different initial target clipping ratios, $\gamma = 0\text{dB}$, 2dB , and 4dB , in terms of their complementary cumulative density function (CCDF). The solid line curve at the right is plotted for the original OFDM signal. The marked lines correspond to the PAR reduced signals of CB-ACE and our proposed method after 10-iterations, which we have confirmed is sufficient for convergence. For a 10^{-3} CCDF, CB-ACE with initial target clipping ratios of $\gamma = 0\text{dB}$, 2dB , and 4dB can achieve a 0.14dB, 0.89dB, and 2.95dB PAR reduction from the original PAR of 12dB, respectively. In other words, when the target clipping ratio is set low, the achievable gain in PAR reduction decreases, which is opposite to our general expectation, but is consistent with the trend shown in Fig.1. On the other hand, our proposed algorithm shows about a 5.6dB reduction gain in PAR at 10^{-3} CCDF for all three of the initial low target clipping ratios. Fig. 4 plots the performance of our proposed algorithm considering both PAR and loss in E_b/N_0 over an AWGN channel for the different M-QAM symbols. The x-axis indicates the loss in E_b/N_0 with respect to E_b/N_0 of the original OFDM signal for a given targeted BER of 10^{-3} , and the y-axis shows the required PAR at a CCDF of 10^{-3} . The tradeoff curves for M-QAM symbols is plotted as a function of the target clipping ratio γ , ranging from 10dB to 0dB in increments of -1dB. The curve with triangles down is for QAM, the curve with triangles up is for 16-QAM, and the one with squares is for 64-QAM. For a clipping ratio of 10dB, the three curves meet each other at a PAR of 10dB. As the clipping ratio decreases, the symbols move toward the bottom right direction; the achievable PARs for different constellation sizes are moving to their minimum points with a decreasing clipping ratio. Our proposed algorithm reaches the minimum PARs: 5.55dB, 6.42dB, and 7.07dB for QAM, 16-QAM, and 64-QAM, respectively. These different minimum PARs come

from the inherent ACE constraint that the higher the order of the constellation, the less flexibility [5]. However, we observe that the loss in E_b/N_0 for each different constellation is about 1.06dB, even though the achievable minimum PAR depends on the constellation size. It is clear that our proposed algorithm provides the tradeoff curve between PARs and the loss in E_b/N_0 for the M-QAM constellations as a function of the target clipping ratio.

VI. CONCLUSION

In this paper propose a new novel method to reduce the PAR. A simple and attractive technique is Active cancellation extension used. However, we observe it cannot achieve the minimum PAR when the target clipping level is set below an initially unknown optimum value. A low clipping ratio is the problem in OFDM system to overcome this AEC algorithm with adaptive clipping control. The minimum Peak to Average for several clipping ratios, and also in AWGN channel we calculate the tradeoff between PAR and the loss in E_b/N_0 .

Modified Energy Aware Geographic Routing Protocol for Mobile Ad-Hoc Network

Anand Gautam¹, Shiva Prakash²

Department of Computer Science & Engineering, Madan Mohan Malaviya Engineering College,
Gorakhpur-273010, U. P., INDIA

Abstract: Mobile ad hoc networks (MANET) are characterized by multi-hop wireless links and resource constrained nodes. One of the major challenge in mobile ad hoc networks (MANETs) is link failures due to mobility as well as nodes energy constraint. The more challenging goal is to provide energy efficient routes in MANET to improve network life time because node have limited lifetime. The Geo-routing has been widely regarded as efficient and scalable. However, it used constant transmission power model for communication and route selection is not based on energy. In this paper we proposed a model of energy aware geographic routing scheme with variant transmission power model. This can improve performance of existing protocol in form of less energy. We explain this concept with help of example that show the improvement of existing EGR.

Keywords: Energy efficient, location information, mobile ad hoc network.

I. INTRODUCTION

A Mobile Ad-hoc network (MANET) is consists of mobile routers connected wirelessly to each other where each node is free to move. This results in a continuously changing topology. Some examples of the possible uses of ad hoc networking include business associates sharing information during a meeting, soldiers relaying information for situational awareness on the battlefield and emergency disaster relief personnel coordinating

In recent years, geographic routing algorithms have been extensively studied due to the popularity and availability of positioning services such as the global positioning system (GPS). Geographic routing is a promising candidate for large-scale wireless ad hoc networks due to its simplicity and scalability and takes advantage of the location information of the nodes are the very valuable for wireless networks. Since geographic routing does not require a route management process, it carries a low overhead compared to other routing schemes, such as proactive, reactive, and hybrid topology based routing protocols. Geographic routing protocols work on the assumption that every node is aware of its own position in the network; via mechanisms like GPS or distributed localization schemes and that the physical topology of the network is a good approximation of the network connectivity. In other words, these routing protocols assume that if two nodes are physically close to each other, they would have radio connectivity between them, which is true in most cases. Hence the protocols use node location information to route packets from source to destination. One big advantage of geographic routing schemes is the fact that there is no need to send out route requests or periodic connectivity updates. This can save a

lot of protocol overhead and consequently, energy of the nodes. The most significant difference between MANETs and traditional networks is the energy constraint. Some applications such as environment monitoring need MANETs to run for a long time. Therefore, extending the lifetime of MANETs is important for every MANET routing protocol. However, most geographic routing algorithms take the shortest local path, depleting the energy of nodes on that path easily. The nodes located on the boundaries of holes may suffer from excessive energy consumption since the geographic routing tends to deliver data packets along the whole boundaries by perimeter routing if it needs to bypass the hole.

There should be a mechanism at node for robust communication of high priority messages. This can be achieved by keeping nodes all the time powered up which makes nodes out of energy and degrades network life time. Also, there can be a link or node failure that leads to reconfiguration of the network and re-computation of the routing paths, route selection in each communication pattern results in either message delay by choosing long routes or degrades network lifetime by choosing short routes resulting in depleted batteries. Therefore the solutions for such environments should have a mechanism to provide low latency, reliable and fault tolerant communication, quick reconfiguration and minimum consumption of energy. Routing protocols have a critical role in most of these activities. To measure the suitability and performance of any given protocol, some metrics are required. On the basis of these metrics any protocol can be assessed against its performance [3]. This can save a lot of protocol overhead and consequently, energy of the nodes. The most significant difference between MANETs and traditional networks is the energy constraint. Some applications such as environment monitoring need MANETs to run for a long time.

Therefore, extending the lifetime of MANETs is important for every MANET routing protocol. However, most geographic routing algorithms take the shortest local path, depleting the energy of nodes on that path easily. The nodes located on the boundaries of holes may suffer from excessive energy consumption since the geographic routing tends to deliver data packets along the whole boundaries by perimeter routing if it needs to bypass the hole. This can enlarge the hole because of the excessive energy consumption of the whole boundary nodes. We call this a whole diffusion problem. Many geographic routing protocols assume that the geographic information is accurately available. In fact, all location services update their geographic information periodically. Typically, there can be a time difference between the update of and the demand for this information, which introduces inaccuracy

in the geographic information the accuracy of GPS, is limited.

In most cases location information is needed in order to calculate the distance between two particular nodes so that energy consumption can be estimated. Consequently, we should define the packet destination as an area rather than a point. In this paper we will present Modified Energy-Aware Geographic Routing (MEGR) Protocol, novel geographic routing algorithm combining local position information and balancing node energy consumption. It forecasts the destination node's movement to ensure packet delivery and to prolong the network lifetime. We also use various model for providing energy efficient path.

The remaining part of this paper is organized as follows: In section II we will discuss the literature review of energy aware geographic routing and we will discuss the problem statement with help of example in section III. We will propose a model with help of example in section IV and finally we conclude the paper and give future scope in section V.

II. LITERATURE REVIEW

In case of location-aware routing mechanisms, the nodes are often aware of their exact physical locations in the three-dimensional world. This capability might be introduced in the nodes using Global Positioning System (GPS) or with any other geometric methods. Based on these concepts, several geocast and location-aware routing protocols have already been proposed. The major feature of these routing protocols is that, when a node knows about the location of a particular destination, it can direct the packets toward that particular direction from its current position, without using any route discovery mechanism. Recently, some of the researchers proposed some location-aware protocols that are based on these sorts of idea. Some of the examples of them are Geographic Distance Routing (GEDIR)[18], Location-Aided Routing (LAR)[2], Greedy Perimeter Stateless Routing (GPSR)[3], Geo-GRID[20], Geographical Routing Algorithm (GRA)[21], etc. Other than these, there are a number of multicast routing protocols for MANET. Some of the mentionable multicast routing protocols are: Location-Based Multicast Protocol (LBM)[22], Multicast Core Extraction Distributed Ad hoc Routing (MCEDAR)[23], Ad hoc Multicast Routing protocol utilizing Increasing id-numberS (AMRIS)[24], Associativity-Based Ad hoc Multicast (ABAM)[25], Multicast Ad hoc On-Demand Distance-Vector (MAODV) routing [26], Differential Destination Multicast (DDM)[27], On-Demand Multicast Routing Protocol (ODMRP)[28], Adaptive Demand-driven Multicast Routing (ADMR) protocol [29], Ad hoc Multicast Routing protocol (AMRoute)[30], Dynamic Core-based Multicast routing Protocol (DCMP)[31], Preferred Link-Based Multicast protocol (PLBM)[32], etc. Some of these multicast protocols use location information and some are based on other routing protocols or developed just as the extension of another unicast routing protocol. For example, MAODV is the multicast-supporting version of AODV.

Early research of geographic routing includes DREAM [1] and LAR [2] that proposed constrained flooding. The *expected zone* is defined by predicting the boundary of the destination node's movement. In both protocols, prediction

is made based on the time difference between sending data and the location information's update, as well as the destination node's speed. We adopt this approach in our routing protocol and describe it in the fourth section. In the LAR protocol, before the transmission of a data packet, the source node finds a route by flooding routing packets in its *request zone*. In the DREAM protocol, however, according to the location information, the data packet is flooded in a restricted directional range without sending a routing packet. Although this kind of forwarding effectively guarantees delivery, its energy use is notably high, especially in large-scale networks. Recently, *Local maxima* in geographic routing have received much attention. Many routing protocols for planar network graphs are presented for solving this problem, such as GFG [3], GPSR [4], GOAFR+ [5] and CLDP [6].

In the following, we review the shared characteristics of these geographic routing algorithms. Geographic routing schemes use greedy routing where possible. In greedy routing, packets are stamped with the position of their destination; and a node forwards a packet to a neighbor that is geographically closer to the destination. Local maximum may exist where no neighbor is closer to the destination. In such cases, greedy forwarding fails, and making progress toward the destination requires another strategy. In particular, the packet needs only to find its way to a node closer to the destination than the local maximum; at that point, greedy routing may once again make progress.

Note that if the graph is not planar, face routing may fail. Wireless networks connectivity graphs typically contain many crossing edges. A method for obtaining a planar sub graph of a wireless network graph is thus needed. Greedy routing operates on the full network graph, but to work correctly, face routing must operate on a planar sub graph of the full network graph. Geographic routing algorithms planarize graphs using two planar graph constructs that meet that requirement: the Relative Neighborhood Graph (RNG) and the Gabriel Graph (GG). The RNG and GG give rules for how to connect vertices placed in a plane with edges based purely on the positions of each vertex's single-hop neighbors. Up to the present, literature, such as GOAFR+, CLDP and LCR [15], has focused on methods of deleting these crossing links.

However, there are several drawbacks to pure geographic routing. In certain circumstances, one cannot guarantee delivery by greedy routing, for example, when there is the rapid movement of nodes. Because of this, the location information of a destination node is rather inaccurate. Secondly, greedy routing is a single-path transmission process which means once the process drops a data packet the whole routing fails. Thirdly, there have been several schemes to overcome the *Local maxima*.

All the schemes can be classified into two categories: perimeter routing [5, 6] and the back pressure rule [7, 8]. In perimeter routing the system tends to route data packets along the boundaries of holes, but the perimeter routing cannot avoid the excessive energy consumption and data congestion in these nodes. Using the back pressure rule, the system returns the data packets to the upstream node in an attempt to find another route to the destination. This rule may generate an additional routing overhead.

Mobile networks use a power-aware routing protocol in [17]. However, to save energy as much as possible, its

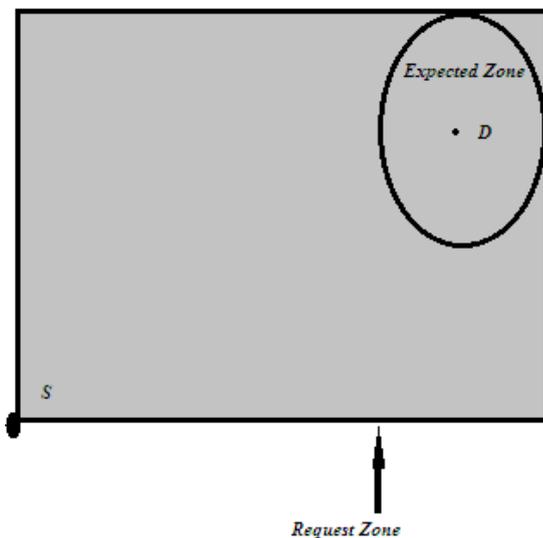

iterative relay process will result in unacceptable end-to-end delay. Due to the non-linear attenuation of wireless signals, it is possible that one hop consumes more energy than multiple hops. Yet it can be impractical to change from one hop to several, following the mechanism in [17]. The end-to-end delay may increase significantly, especially in a high-density network.

III. PROBLEM STATEMENT

In recent years various works has been done in the field of energy aware geographic routing but a lot of work has to be done in the near future by overcoming the problems still lies in the geographic routing protocol so that we can be able to sends the packet from source to destination without fear of loss of packets, higher packet delivery ratio, low energy consumption etc. But when we talk about the Energy Aware Geographic Routing there are still a lot of problem are there which is discussed below:

3.1 Need of EGR: As we know that in EGR, to make routing decision it uses local position information and residual energy and also uses prediction of range of a destination's movement. EGR uses the concept of Location aided routing (LAR) and Distance effect algorithm for mobility (DREAM).

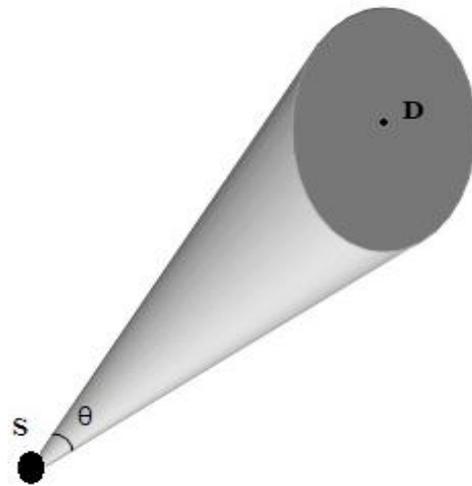

In LAR protocol, before the transmission of a data packet, a source node finds a route by flooding routing packets in its request zone.

(a)The model of LAR

But LAR fails when there is a large scale network and also uses high energy.

To solve out this problem the DREAM routing protocol comes into existence. In DREAM protocol, according to the location information the data packet is flooded in a restricted directional range without sending a routing packet.

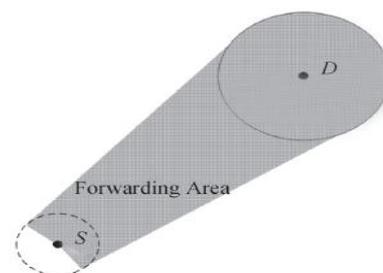

(b)The model of DREAM

In DREAM, if source is quite far away from destination, the angle θ will be too small for source to find the next hop.

3.2 Need of MEGR: To remove the problem of DREAM EGR comes into existence which works as follows:

(a) Dissemination of location and energy information: EGR assume the existence of a mechanism such as GPS system that allows each node to be aware of its location and residual energy.

(b) Forwarding Data packets: To remove the problem of DREAM it uses the concept of tangent lines between two circle, first circle is centered on source node whose radius is the transmission distance of source node and other one is destinations expected zone.

(c) The model of EGR

In EGR it uses a mechanism for choosing the next hop in the flooding area and uses a single path before destination expected zone.

If node i is located in forwarding area the i chooses the next hop from it neighbor nodes given by:

$$\text{NEXTHOP} = k \quad e_{\text{remain}}^k = \max \{ e_{\text{remain}}^j \}, j \in N_i$$

It means i chooses the next hop k with the most residual energy from all its neighbors nodes whose position are closer to destination than i .

If node i is in expected zone it directly relay the packet to the destination.

The main problem with EGR that it uses the constant power model means it always sends the packet to the node which has maximum energy which will leads to the depleting of energy very fast as well as it also suffers from taking decision of route request and gives a single path.

IV. PROPOSED MODEL

To make energy efficient routing protocol than EGR we modified the Energy Aware Geographic Routing (EGR) [1] protocol to solve out the problem lies in the EGR we proposed a new routing protocol named Modified Energy Aware Geographic Routing Protocol (MEGR) in which we use the variant power model as well as we use the decision of route request will be taken at destination for choosing the best path through which we can increase the network lifetime.

In MEGR, a source node that requires sending a packet to destination acquires the address of the destination. After preparing the packet by adding appropriate information in the header, we calculate the distance from each of its neighbors to the destination and also calculate the minimum energy required for sending a packet. We choose the path that requires minimum energy. But also in route request phase we find the paths which have highest energy by comparing available residual energy and minimum energy required. If the available energy is less than the minimum energy required we append the residual energy of that node the move to the next node. In this way after reaching the destination we wait for Δt time which is less than the TTL. After that time we find the total route request packet reach at the destination. The destination will choose the path for route reply that has highest energy.

The distance between two points on the earth surface can be calculated by using its latitude and longitude coordinates. Hence in our approach we will divide the network into x-axis and y-axis. The parameter used to calculate the distances are defined below:-

DISTANE = Distance in meters between first and second point.

DISTANCE_x = x-axis distance between the first and second point.

DISTANCE_y = y-axis distance between the first and second point.

X₁ = x-axis of the first point in degrees.
 Y₁ = y-axis of the first point in degrees.
 X₂ = x-axis of the second point in degrees.
 Y₂ = y-axis of the second point in degrees.

DISTANCE_x = x₂ - x₁
 DISTANCE_y = y₂ - y₁

$$DISTANCE = \sqrt{(DISTANCE_x)^2 + (DISTANCE_y)^2}$$

After calculating the distance, for given threshold energy E_{th}. The minimum transmit energy E_{min} can be calculated by giving formula:

$$E_{min} = \frac{E_{th} * D^n}{K}$$

Where D is the distance between two nodes,
 n is the path loss exponent whose value is lies between 2-4,
 K is a constant. Here, K= 2.8 x 10⁻¹⁰ μJ/(byte-m⁴)
 E_{th} in the LAN 802.11 is 3.652 x 10⁻¹⁰ mW.

Hence in this way we can modify the EGR now we can explain our model by taking the appropriate example.

4.1 Example:

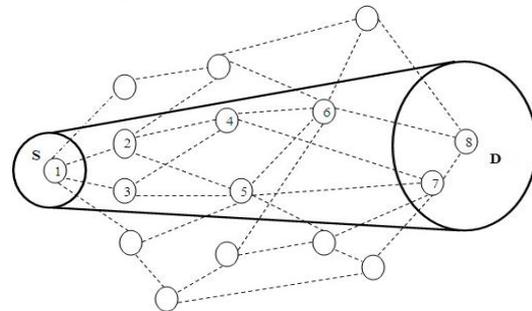

Fig 4.1

Node number	Location of nodes	Residual Energy(Joule)
1	-5,0	500
2	-3,2	300
3	-3,-2	100
4	0,2	400
5	0,-2	600
6	3,2	500
7	5,-2	300
8	6,3	200

By using the concept of the EGR we find the path 1-2-5-6-8 which is explained below:

In EGR, we choose the next hop which is having the maximum energy.

So.

Source (1) has two neighbors 2, 3

Residual energy of 2=300J

Residual energy of 3=100J

Therefore, Source (1) will choose next hop 2

Hence distance between node 1 and 2

$$D(1, 2) = 2.82 \text{ m}$$

Now, the minimum transmit energy

$$E_{min}(1, 2) = 82.483 \text{ Joule}$$

Again, Node 2 has two neighbors 4, 5

Residual energy of 4=400J

Residual energy of 5=600J

Therefore, node 2 will choose next hop 5

Hence distance between node 2 and 5

$$D(2, 5) = 4 \text{ m}$$

Now, the minimum transmit energy

$$E_{min}(2, 5) = 333.89 \text{ Joule}$$

Again, Node 5 has two neighbors 6, 7

Residual energy of 6=500J
 Residual energy of 7=300J
 Therefore, node 5 will choose next hop 6
 Hence distance between node 5 and 6

$$D(5, 6) = 5 \text{ m}$$

Now, the minimum transmit energy

$$E_{\min}(5, 6) = 815.714 \text{ Joule}$$

Now at last node 6 has only one neighbor 8
 Hence distance between node 6 and 8

$$D(6, 8) = 3.16 \text{ m}$$

So the minimum energy

$$E_{\min}(6, 8) = 130.42 \text{ Joule}$$

Therefore,

$$\text{Total energy required in EGR} = 82.483 + 333.89 + 815.714 + 130.42 = 1357.507 \text{ Joule}$$

In MEGR

For Source node 1: we calculate the distance between 1 and 2 as well as 1 and 3.

$$\text{Distance}(1,2) = 2.82 \text{ m}$$

$$\text{Distance}(1,3) = 2.82 \text{ m}$$

Now we will calculate the minimum energy required for both the paths

$$E_{\min}(1,2) = 82.483 \text{ J}$$

$$E_{\min}(1,3) = 82.483 \text{ J}$$

In this case we choose the next hop 2 because it has total energy 300 Joule which has greater than node 3.

Now for node 2: We calculate the distance between 2 and 4 as well as 2 and 5.

$$\text{Distance}(2,4) = 3 \text{ m}$$

$$\text{Distance}(2,5) = 4 \text{ m}$$

Now we will calculate the minimum energy required for both the paths

$$E_{\min}(2,4) = 105.847 \text{ J}$$

$$E_{\min}(2,5) = 333.89 \text{ J}$$

In this case we choose the next hop 4 because it requires only 105.847 joule energy for transmitting the packet while its residual energy is 400 joule.

Now for node 4: We calculate the distance between 4 and 6 as well as 4 and 7.

$$\text{Distance}(4, 6) = 3 \text{ m}$$

$$\text{Distance}(4, 7) = 6.40 \text{ m}$$

Now we will calculate the minimum energy required for both the paths

$$E_{\min}(4,6) = 105.847 \text{ J}$$

$$E_{\min}(4,7) = 2188.228 \text{ J}$$

In this case we choose the next hop 6 because it requires only 105.847 joule energy for transmitting the packet while its residual energy is 500 joule.

Now for node 6: We calculate the distance between 6 and 8.

$$\text{Distance}(6, 8) = 3.16 \text{ m}$$

Now we will calculate the minimum energy required for the path

$$E_{\min}(6,8) = 130.42 \text{ J}$$

In this case we can reach the destination the destination reply on this path which we have followed shown below:-
 1-2-4-6-8

4.2 Analysis of the MEGR: When we compare the MEGR with EGR then we can see that Total energy required for sending a packet from source to destination is very less in MEGR.

$$\text{Total energy required in EGR: } 82.483 + 333.89 + 810.714 + 130.42 = 1357.454 \text{ Joule.}$$

$$\text{Total energy required in MEGR: } 82.483 + 105.847 + 105.847 + 130.42 = 424.651 \text{ Joule.}$$

Hence in MEGR we can reduce the energy consumption more than three times than EGR.

4.3 Algorithm for MEGR:

(a) Route Request

Step1: Initialize network (Source, Destination)

Step2: For every node of the network

Step3: Find $LOC(N_x, N_y)$ // Find location of all nodes where N is the set of nodes defined in the network.

Step4: Find neighbors (S, D) // Detect neighbors of the node and add it to the LET.

Step5: Calculate Distance (n, d) // Calculate distance of all neighbors node.

Step6: Calculate minimum transmit energy (E_{\min})

Step7: If ($E_{\min} > E_{\text{residual}}$)

Add E_{residual} of the neighbor node that have high residual energy.

Else

Route request is send at the next hop.

Step8: When route request is reach at the destination

Wait Δt time where ($\Delta t < TTL$).

Step9: Choose the best path

Step10: End

V. CONCLUSION AND FUTURE SCOPE

As per literature review we come to know that as route selection is not based on energy efficiency in and use constant power model for packet transmission. Our proposed solution for these existing problem in EGR can be improved. In this we presented Modified Energy Aware Geographic Routing protocol which gives better results to minimize energy consumption and Delay time and extends network lifetime. We will present simulation of our proposed Modified EGR protocol in our future work. It can be improved to find accurate information for faulty location of Geographical based information.

An Efficient Online Voting System

Ankit Anand¹, Pallavi Divya²

*(Department of Computer Science Engineering, BITS Bhopal/ Rajiv Gandhi Technical University, Bhopal, India)

** (Department of Computer Science Engineering, Punjab Technical University, Punjab, India)

ABSTRACT: This paper deals with design, build and test a online voting system that facilitates user (the person who is eligible for voting), candidate (Candidate are the users who are going to stand in elections for their respective party), Election Commission Officer (Election Commission Officer who will verify whether registered user and candidates are authentic or not) to participate in online voting. This online voting system is highly secured, and it's design is very simple, ease of use and also reliable. The proposed software is developed and tested to work on Ethernet and allows online voting. It also creates and manages voting and an election detail as all the users must login by user name and password and click on his favorable candidates to register vote. This will increase the voting percentage in India. By applying high security it will reduce false votes.

Keywords: CSS, HTML, Java Script, JDBC, JSP, MYSQL, ORACLE, Servlet, WAMP.

I. INTRODUCTION

Voting schemes have evolved from counting hands in early days to systems that include paper, punch card, mechanical lever and optical-scan machines. Electronic voting systems provide some characteristic different from the traditional voting technique, and also it provides improved features of voting system over traditional voting system such as accuracy, convenience, flexibility, privacy, verifiability and mobility. But it suffers from various drawbacks such as Time consuming, Consumes large volume of pare work, No direct role for the higher officials, Damage of machines due to lack of attention, Mass update doesn't allows users to update and edit many item simultaneously. These drawbacks are overcome by Online Voting System. Online Voting System is a voting system by which any Voter can use his/her voting rights from anywhere in the country. We provide a detailed description of the functional and performance characteristics of online voting system. Voter can cast their votes from anywhere in the country without visiting to voting booths, in highly secured way. That makes voting a fearless of violence and that increases the percentage of voting.

1.1 Problem Background

In the recent years there are many literature on online voting has been developed. While online voting has been an active area of research in the recent years, efforts to develop real-world solutions have just begun posing several new challenges.

The use of insecure Internet, well documented cases of incorrect implementations and the resulting security Breaches have been reported recently. These challenges and concerns have to be resolved in order to create public trust in online voting.

1.2 Problem Statement

Online Voting are simple, attractive and ease to use. It reduces manual efforts and bulk of information can be handled easily. But out of all these features there are some drawbacks with this system are, there can be software failure issue, insecure access of internet and also voter should be familiar with internet.

1.3 Research Objective

The main objective of this study is an important step towards streamlining this effort is to develop a framework and identify necessary properties that a secure and trusted online voting system must satisfy to reduce discovery redundancy. Such a framework will allow us to evaluate as well as compare the merits of existing and future candidate online voting schemes. System should support multi-user environment. System should be fully automated. System should provide concrete security features like creating users and assigning privileges to users of the system. System should be capable to keep track of all the detailed descriptions of the client and the whole details of services offered by the client organization.

Various outputs (reports) should be available online any time. System should be able to handle extremely large volumes of data (i.e. large database support).

1.4 Scope of Study

The scope of the project is that it will use the ID and password created by user to register him/her in the voting site, through this all the details of voter are saved in database. And it will act as the main security to the votes system.

Advanced technology: It is an advanced technology used now a day. It increases the internet knowledge of the users which is very necessary for current generation.

Internet: It is an online facility and hence very useful for the users. Voters can vote from anywhere at any time in India.

E-Mails: Election Commission can send the error report to a particular user if he/she entered false information.

E-SMS: People who have not internet connection they cannot check the emails or not have email they can be informed by SMS on their mobile. Today many websites provide free SMS to the mobile. Election Commission can use these to send any information.

II. LITERATURE REVIEW

2.1 Background

This software is being developed for use by everyone with a simple and self explanatory GUI. This is software that can be used by people to vote in an election. All the user must do is login and click on his favorable candidates to register his vote. The development and testing is done on Ethernet. While online voting system has been an active area of research in recent years, the use of insecure Internet, well documented cases of incorrect implementations reported recently. These challenges are to be resolved so that public should cast their vote in secure and convenient way. Proposed online voting system is a voting system by which any Voter can use his/her voting rights from anywhere in country. Online voting system contains:

- a) Voter's information in database.
- b) Voter's Names with ID and password.
- c) Voter's vote in a database.
- d) Calculation of total number of votes.

Various operational works proposed in the system are:

Recording information of the Voter in database.

Checking of information filled by voter.

Discard the false information.

Each information is sent to election commission.

2.2 Product Perspective

The product is an election conducting tool with a simple GUI. The product is developed using Java. Though product is stand-alone, it requires Java Virtual Machine (JVM).

2.3 User Characteristics

Users are considered to be technically novices but expected to be able to use a computer / hand held terminal (HHT), and to click against the favorable candidate on the GUI.

2.4 Product Functions

The product has a server back-end which takes care of authenticating the users and maintaining necessary data structures. The GUI at the server's end enables creating the polls on behalf of the client. The users must connect to the server to authenticate their identification against the password and then vote using the GUI at their end.

2.5 Overview of Data Requirements

The internal memory requirement will be constant or linearly dependent on the number of users depending on the provision of changing the vote at a later time. In such a case the actions will be stored in a data structure which will be referred to when needed. The external data about the candidates (with photographs) and the posts or the poll questions and the answers will be given as input only at the serverend.

2.6 Assumptions and Dependencies

The user is assumed to have JVM on his system irrespective of its hardware and software configuration. The other requirements are strongly design based and can be only made concrete in the design stage. We also assume that all the clients running this software are not blocked by firewalls, proxies, etc.

2.7 Constraints

GUI is only in English.

Login and password is used for identification of Voter.

III. SALIENT FEATURE

On-line polling is software system through which a voter can give votes through registering themselves on the voting website. all the information in sites which has been entered are stored in database .for each page in the website have its own database table.

Each voter has to enter his all basic information like name, sex, religion, nationality, criminal record e.t.c. This is the first page of the website known as the welcome page. It has all the page options like Home, Polling Dates, Register, Login, about us, Contact us, FAQs.

3.1 Home

It is the welcome page of the website, having all the feature options of the website.

Fig 1: Home

3.2 Registration

This is the register page, where the voter, candidate and election commission officer can register themselves. They all have to enter basic information best of their known .All the information registered in the website are saved in the respective database .The Election Commission officer has authority to accept eligible user and suitable candidate, otherwise he/she has right to reject their registration.

Fig 2: Registration

3.2 Login

User Login: After registering into the website, this information is saved to the database and sent to the election commission. The user can Login to the website with his unique USERNAME and PASSWORD generated through registration. There is a option for FORGOT PASSWORD, in case user forget his password then he/she can go with option of forgot password.

Candidate Login: After registration candidate can see his/her profile and can edit his/her profile. The candidate has facilitated with all the latest news update regarding election.

Election commission officer login: After login election commission officer will verify whether user and candidate is authentic or not.

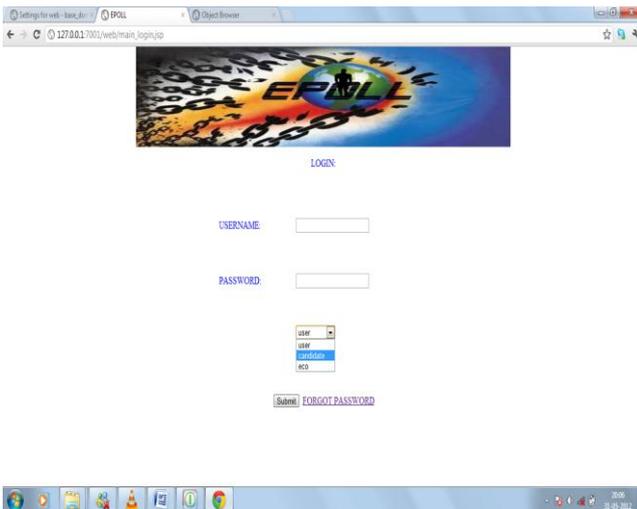

Fig 3: Login

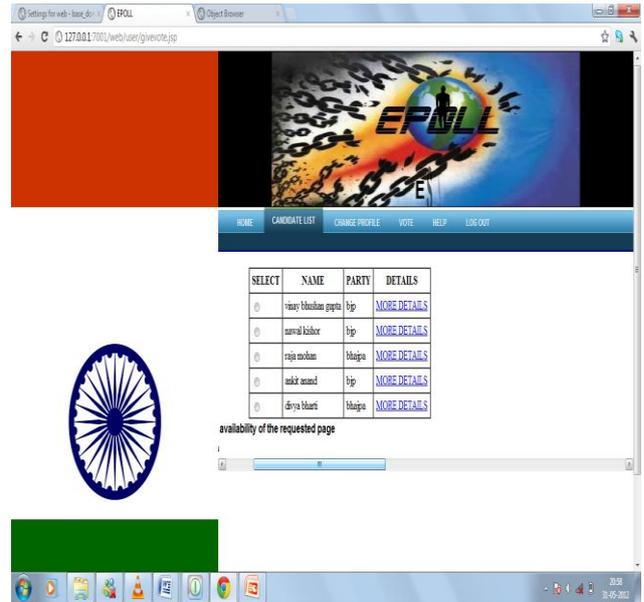

Fig 4: Choice of candidates for voting

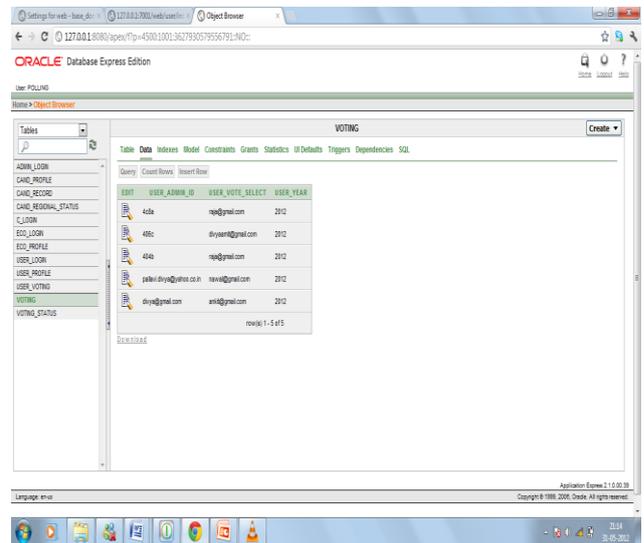

Fig 5: Database object browser, voting status

IV. RESOURCES

We create this software application with following resources

- Front end: - JAVA (JSP,Servlet,JDBC,java mail,EJB2.0)
- Back end: - ORACLE/MYSQL
- Design: - HTML
- Validation: - CSS (Cascading Style Sheet)
- Platform: - JavaScript
- J2EE

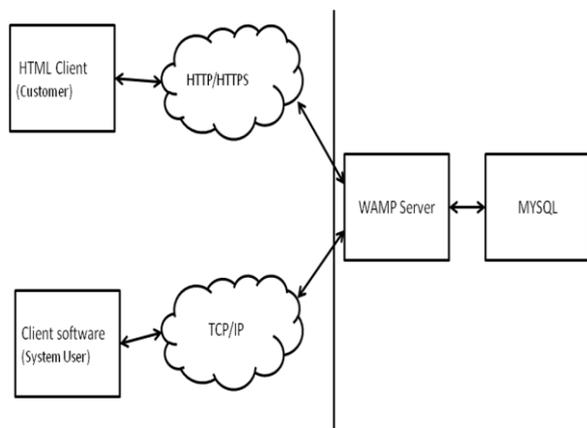

Fig 6: Communication Interfaces

The above diagram shows the connectivity between the client side, application server and database server. The client or customer can access the HTML server or client software. These are connected to the WAMP Server (WAMP) by a TCP/IP which is a communication protocol used to connect the teachers or parents to the internet. This WAMP Server now directly communicates with the database made in MYSQL. All the enquiries or data will be retrieved from the database.

V. CONCLUSIONS

Our proposal enables a voter to cast his/her vote through internet without going to voting booth and additionally registering himself/herself for voting in advance, proxy vote or double voting is not possible, fast to access, highly secure, easy to maintain all information of voting, highly efficient and flexible. Hence, by this voting percentage will increase drastically.

The using of online voting has the capability to reduce or remove unwanted human errors. In addition to its reliability, online voting can handle multiple modalities, and provide better scalability for large elections. Online voting is also an excellent mechanism that does not require geographical proximity of the voters. For example, soldiers abroad can participate in elections by voting online.

An Efficient Clustering Scheme for Vehicular Ad Hoc Networks

Miss. S. Poongodi^{#1}, Mrs. P. Tamilselvi^{*2}

[#] II M.E Communication Systems

^{*}Associate Professor

Department of Electronics and Communication Engineering

SNS College of Technology, Coimbatore, Affiliated to Anna University of Technology Coimbatore, India

Abstract: Several medium access control protocols have been proposed in the recent past in vehicles for accessing radio channels and for distributing timely safety messages for inter-vehicle communication in Vehicular Ad hoc Networks (VANETs). As contention period for channel access is high in Medium Access Control (MAC), MAC is unable to distribute timely safety messages. To reduce the contention, Region based Clustering Mechanism (RCM), which caters to the reduction of contention by limiting the number of vehicles for each cluster, is applied with MAC protocols. RCM also resolves the competition among vehicles to access radio channels for inter-vehicle communication. Ad Hoc On-Demand Distance Vector (AODV) routing protocol is used for providing shortest path between source and destination so as to increase the amount of packet reception with less energy than the existing method.

Keywords: Ad Hoc On-Demand Distance Vector (AODV), Medium Access Control (MAC), Safety-Critical Application (SCA), Region based Clustering Mechanism (RCM), Vehicular Ad-hoc Network (VANET).

I. INTRODUCTION

Vehicular Ad Hoc Network (VANET) consists of wireless routers or wireless nodes. Normally, the transmission range of VANET is 100 to 300 meters range. Inter-vehicle communication takes place with ad-hoc networks. Information such as speed and position of each vehicle is known by other vehicles.

VANET is an important mode of inter-vehicle communication for Intelligent Transportation Systems (ITS) [1], [2]. In such a network, each vehicle is equipped with a wireless communication and an on-board GPS device. Data forwarding is then performed collaboratively among vehicles in a multihop relaying manner. One of the most important applications for VANET is the distribution of active safety messages to improve driver safety, namely Safety-Critical Application (SCA) that requires timely and reliable message dissemination. Information about SCA is exchanged so as to notify the drivers about the car accident and to perform control actions in coordinated systems [3]. Other applications are also permitted for shortening the deployment cost of VANET and for speeding up its adoption period. Medium Access Control (MAC) protocols of VANET resolve contentions among vehicles for channel access. The dominant standard for vehicular networks is IEEE

802.11p based Dedicated Short Range Communications (DSRC) [4], [5]. Its random access mechanism is based on IEEE 802.11 Distributed Coordination Function (DCF) relying on the Carrier Sense Multiple Access/Collision Avoidance (CSMA/CA) mechanism. Other important MAC protocols include ADHOC, MAC [6], [7] that are designed for an European project. These protocols depend upon a Time Division Multiple Access (TDMA) based protocol called Reliable R-ALOHA (RR-ALOHA) for radio access control; Space Division Multiple Access (SDMA) [8], [9] wherein the geographical area is divided into multiple space division units and one radio channel is dedicated to serve the vehicle in a space division unit. Important issues related to MAC for VANET include mobility (i.e., the MAC protocol should support vehicles to leave and join inter-vehicle communications at high speed), delay bounded (i.e., the communication must be delay bounded and real-time), scalability (i.e., VANET should scale itself according to the number of vehicles present), bandwidth efficiency (i.e., the radio resource should be utilized in an efficient and fair manner), cost (i.e., for cost-efficient and reliable communications, VANET should be fully decentralized), and fairness (i.e., every vehicle should get a fair chance to get the radio channel). The challenge of successfully deploying VANET services lies in ensuring timely and reliable data delivery for mobile vehicles.

The MAC protocols for radio channel access among vehicles are effective under light traffic load. However, when the number of vehicles in the vicinity is large, the protocols may not be able to ensure the desired service due to lack of radio resource (e.g., more contentions among vehicles for random access based protocols like CSMA/CA, and less chance to be allocated a time slot for TDMA based protocols like RRALOHA) and cause a longer contention period to obtain radio resource. Fig. 1 shows the Vehicular Ad Hoc Network.

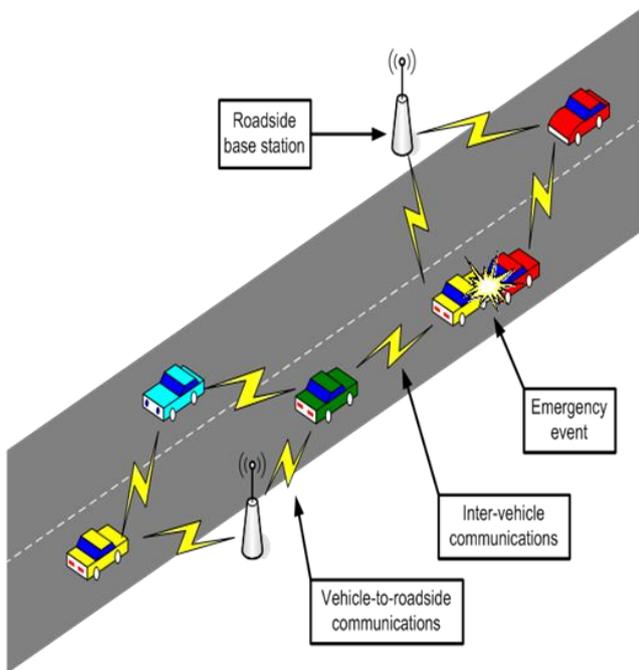

Fig. 1 Vehicular Ad-hoc Network

In the literature, several methods (e.g., [10], [11], [12]) have been proposed to reduce the contention period. DUCHA [10] utilizes dual-channel to separate control packets and data packets. Request To Send (RTS) and Clear To Send (CTS) are transmitted on a separate control channel to avoid the collisions with data packets. Fast Collision Resolution (FCR) algorithm [11] redistributes the back off counters to speed up the collision resolution. The FCR algorithm uses a smaller contention window for each station with successful packet transmission and reduces the back off counter exponentially when a station detects a number of consecutive idle slots. MAC-SCC [12] schedules data transmissions to reduce the back off time. The control channel is used to schedule data transmissions by using two different Network Allocation Vectors (NAVs) for the data channel and the control channel, respectively.

Region-based Clustering Mechanism (RCM) is used to improve the performance of MAC operations for VANET [13]. In RCM, the service area is divided into a set of region units and the number of vehicles is limited in each region unit for the contention of radio channels. Each region unit is then associated with a non-overlapping radio channel pool. Since the number of vehicles in each region unit is limited, the contention period is reduced and the throughput is increased. Note that this proposed idea can be applied on top of existing methods (e.g., [10], [11], [12]) to improve the contention period performance of MAC protocols for VAENT). RCM is formed with the limited number of vehicles in [13]. In RCM, there is no central controller for channel access. The contention resolution is required to obtain a channel. DSRC(Dedicated Short Range Communication) protocol is used in the existing method which produces the reduced packet transfer and throughput. In the proposed system, Ad- Hoc On-Demand Distance Vector (AODV) protocol is used to maintain shortest path between vehicles.

II. PROPOSED SYSTEM

Fig. 2 shows the block diagram of the proposed system. In the proposed system, mobile nodes are self-configured into an integrated network with distributed control. The connection between nodes in the network is in such a way that it has peer-to-peer communication links. NS-2 tool is used for network creation. Wireless channel is used with Omni antenna. The topological dimension and number of nodes are set according to the requirements.

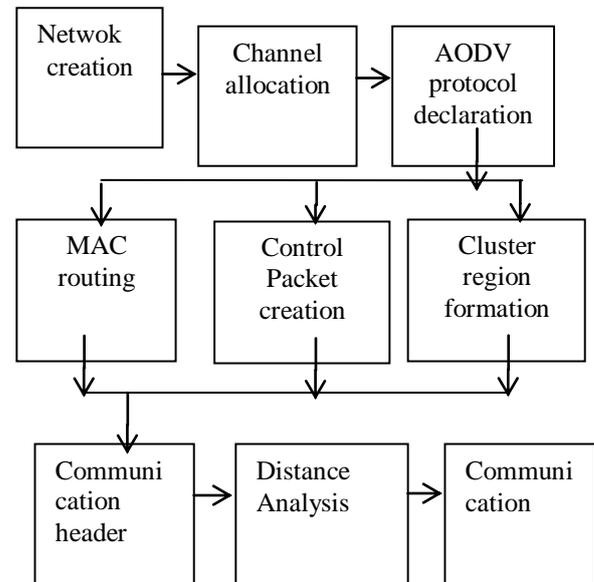

Fig. 2 Block diagram of the proposed system

Network is created with the mobile nodes. Total area is divided into clusters. Then, channel is allocated for each cluster without any overlap for avoiding congestion. AODV protocol is used for selecting the shortest path between source and destination as it does not need any central administrative system to control the routing process. Source node and the intermediate nodes store the next-hop information corresponding to each flow for data packet transmission.

Source nodes and destination nodes are connected with each other through the use of Transmission Control Protocol (TCP) or User Datagram Protocol (UDP). Clustering is formed with a limited number of mobile nodes so as to reduce the contention period spent for channel access. All the nodes of the region are grouped together into various clusters based on the vicinity of vehicles. These vehicles inter-communicate through ad hoc. Cluster head is otherwise known as a sink node because it maintains information about all the vehicles of a cluster. Each vehicle in a cluster moves with different speed and a particular distance is maintained among vehicles. Communication takes place from source to destination through the cluster head. When a cluster head fails, the other highest priority mobile node acts as the cluster head. When a mobile node (vehicle) moves from one cluster to another cluster, radio channel of current cluster with low latency is accessed.

A. Protocol Description

In [13], the R-ALOHA-based protocol is used as an example to show the ways to achieve contention resolution in RCM whereas in proposed system AODV protocol is used for achieving the shortest path among vehicles. Fig. 3 shows the AODV Protocol operation.

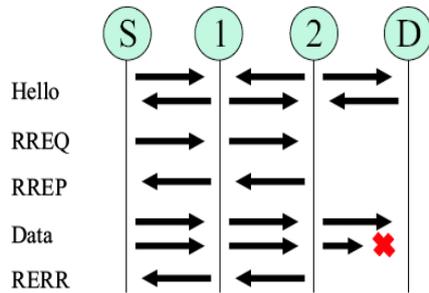

Fig. 3 AODV Protocol operation

AODV routing protocol is designed for use in ad-hoc mobile networks. AODV is a reactive protocol: the routes are created only when it is necessary. It uses traditional routing tables, one entry per destination, and sequence numbers to determine whether routing information is up-to-date and to prevent routing loops.

An important feature of AODV is the maintenance of time-based states in each node: a routing entry not recently used is expired. In case of a route that gets broken, the neighbours can be notified of any unnecessary happening. Route discovery is based on query and reply cycles. The route information is stored in all intermediate nodes along the route in the form of route table entries. The following control packets are used: Routing Request (RREQ) message is broadcasted by a node requiring a route to another node, Routing Reply (RREP) message is unicast back to the source of RREQ and Route Error (RERR) message is sent to notify other nodes of the loss of the link. HELLO messages are used for detecting and monitoring links to neighbours.

Routing protocols in mobile networks are subdivided into two basic classes:

- proactive routing protocols and
- reactive routing protocols

The proactive routing protocols (e.g. OLSR) are table-driven. They usually use link-state routing algorithms for flooding the link information. Link-state algorithms maintain a full or partial copy of the network topology and costs for all known links. The reactive routing protocols (e.g. AODV) create and maintain routes only on demand. They usually use distance-vector routing algorithms that keep information only about next hops to adjacent neighbours and costs for paths to all known destinations. Thus, link-state routing algorithms are more reliable, less bandwidth-intensive, but also more complex and compute- and memory-intensive.

In on-demand routing protocols, a fundamental requirement for connectivity is discovering routes to a node via flooding of request messages.

The AODV routing protocol does not need any central administrative system to control the routing process. AODV, a reactive protocol, tends to reduce the control traffic messages overhead at the cost of increased latency in finding new routes.

AODV reacts relatively fast to the topological changes in the network and updates only the nodes affected by these changes. The HELLO messages supporting the routes maintenance are range-limited for preventing unnecessary traffic overhead in the network. The AODV routing protocol saves storage place as well as energy. The destination node replies only once to the first request and ignores the rest.

The routing table maintains at most one entry per destination. When a node has to choose between two routes, the up-to-date route with a greater destination sequence number is always chosen. If a routing table entry is not used recently, the entry gets expired. When a not- valid route is deleted, the error packets reach all nodes through a failed link on its route to any destination which supports both unicasting and multicasting.

B. Algorithm

Step 1: The total area size 3500*3500 is set

Step 2: Mobile nodes are created

set n [\$ns node]

\$cbr_(\$index) set random_1

Step 7: Through the cluster head, the mobile nodes communicate with each other

Step 8: AODV protocol used for selecting the shortest path between the mobile nodes.

III. NETWORK SIMULATION

Simulation is done using ns-2.33 Software. Table 1 shows the simulation parameters. The transmission range is 250 meters. Here, the simulation time is 200 seconds. AODV protocol is used for the simulation.

Table 1 Simulation Parameters

Parameter	Value
Examined protocol	AODV
Traffic type	Constant bit rate(TCP)
Transmission range	250 m
Packet size	512 bytes
Data rate	1Mbps
Simulation time	200sec
Antenna type	Omni directional Antenna
Area	3500 m * 3500 m
Number of nodes	93

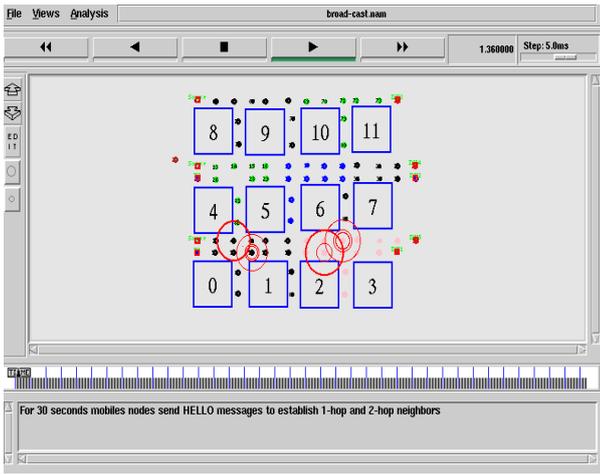

Fig. 4 Cluster formation

In Fig. 4, 93 mobile nodes are created. In this output, seven clusters are formed. When the node 27 leaves the region, the information (position) about this node is retained by node 28 which is the cluster head and this cluster head, in turn, multicast the information about node 27 to all the nodes (12, 13, 14, 15, 16, 25, 26, 29) of that cluster. The square box represents the building. The gap between the square box is the road way.

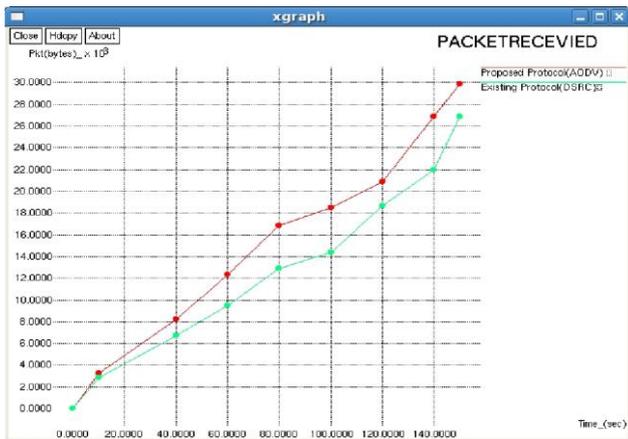

Fig. 5 Packet Reception

Fig.5 shows the simulated graph between time (in sec) and packet reception. In the AODV, the packet reception is high than the existing DSRC. The amount of packet reception gets increased with the increase in time.

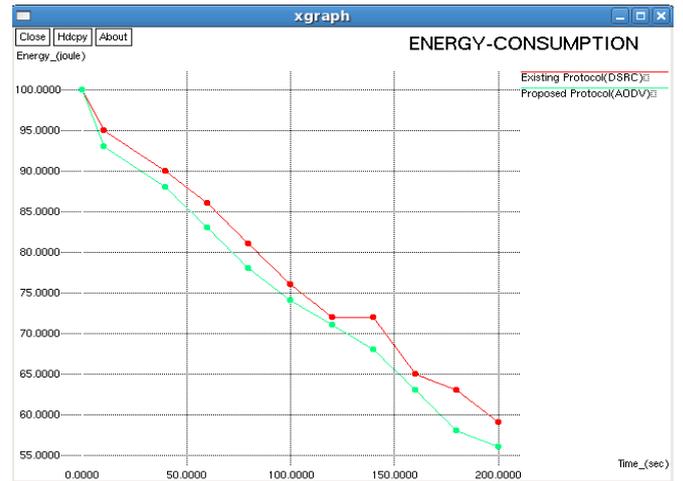

Fig. 6 Energy Consumption

Fig.6 shows the simulated graph between time (in sec) and energy consumption. The energy required for proposed AODV protocol is less compared to the existing method.

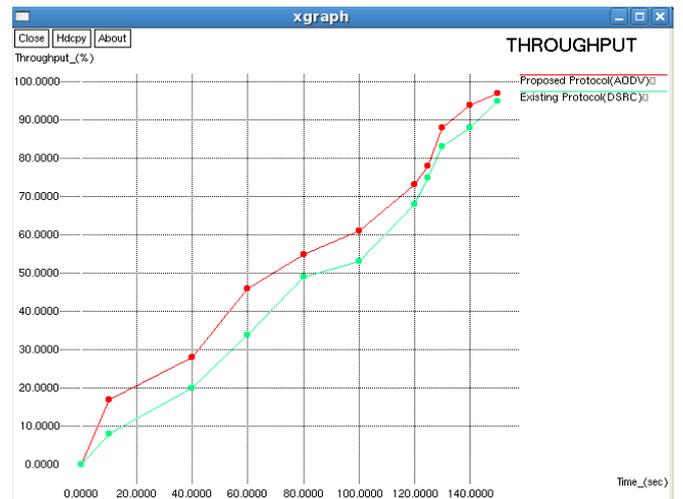

Fig. 7 Throughput

Fig. 7 shows the simulated graph between time (in sec) and throughput. In the proposed method, the throughput is increased more through the use of AODV protocol than the existing DSRC method. Table 2 shows the simulation results.

Table 2 Simulation Results

Time (in sec)	Parameters	Existing	Proposed(AODV)
140	Packet reception in bytes	21987	26882
150	Throughput	95%	97%

At the time of 140 (in sec), the packet reception for the proposed system is 21987 bytes and the packet reception of the existing method is 26882 bytes for the same time limit.

At the time of 150 (in sec), the throughput for the proposed method is 97% which is high by 2% than the existing method.

IV. CONCLUSION

Thus, the contention problem in VANET is solved by using region based global clustering mechanism. The long-life node of a cluster acts as the cluster head which maintains information all the nodes of that cluster. Source and destination nodes communicate with each other through cluster heads. AODV protocol facilitates the selection of the shortest path from source to destination by taking into account the minimum number of hop count and it increases packet reception and throughput.

Abstract: Image segmentation is the process of dividing an image into multiple parts. This is typically used to identify objects or other relevant information in digital images. maximum a posteriori probability (MAP) estimate is a mode of the posterior distribution. The MAP can be used to obtain a point estimate of an unobserved quantity on the basis of empirical data. It is closely related to Fisher's method of maximum likelihood (ML), but employs an augmented optimization objective which incorporates a prior distribution over the quantity one wants to estimate. MAP estimation can therefore be seen as a regularization of ML estimation. In this Paper our algorithm segment an image into regions with relevant Textures automatically there is no need of regions. The simulations shows the image edges very well. Comparing to six state-of-the-art algorithms, extensive experiments have shown that our algorithm performs the best.

Keywords: Image segmentation, graph cuts, maximum likelihood, maximum a posteriori, Markov random fields.

I. INTRODUCTION

A central problem, called *segmentation*, is to distinguish objects from background. For intensity images (ie, those represented by point-wise intensity levels) four popular approaches are: threshold techniques, edge-based methods, region-based techniques, and connectivity-preserving relaxation methods. Threshold techniques, which make decisions based on local pixel information, are effective when the intensity levels of the objects fall squarely outside the range of levels in the background. Because spatial information is ignored, however, blurred region boundaries can create havoc.

Edge-based methods center around contour detection: their weakness in connecting together broken contour lines make them, too, prone to failure in the presence of blurring. A region-based method usually proceeds as follows: the image is partitioned into connected regions by grouping neighboring pixels of similar intensity levels. Adjacent regions are then merged under some criterion involving perhaps homogeneity or sharpness of region boundaries. Over stringent criteria create fragmentation; lenient ones overlook blurred boundaries and over merge. Hybrid techniques using a mix of the methods above are also popular.

A connectivity-preserving relaxation-based segmentation method, usually referred to as the *active contour model*, was proposed recently. The main idea is to start with some initial boundary shape represented in the form of spline curves, and iteratively modify it by applying

various shrink/expansion operations according to some energy function. Although the energy-minimizing model is not new, coupling it with the maintenance of an "elastic" contour model gives it an interesting new twist. As usual with such methods, getting trapped into a local minimum is a risk against which one must guard; this is no easy task. In contrast to the heuristic nature of these approaches, computational geometry suggests a more algorithmic tack. One would first formalize a mathematical criterion for the "goodness" of a given segmentation. This would allow us to formulate the segmentation problem as an optimization problem under certain geometric constraints.

The problem of image segmentation and visual grouping has received extensive attention since the early years of computer vision research. It has been known that visual grouping plays an important role in human visual perception. Many computer vision problems, such as stereo vision, motion estimation, image retrieval, and object recognition, can be solved better with reliable results of image segmentation. For example, results of stereo vision based on image segmentation are more stable than pixel-based results. Although the problem of image segmentation has been studied for more than three decades, great challenges still remain in this research. Here we presented to apply normalized cuts to image segmentation [1] which is able to capture intuitively salient parts in an image. The normalized cuts has an important advantage in spectral clustering. However, it is not perfectly fit for the nature of image segmentation because ad hoc approximations must be introduced to relax the NP-hard computational problem. These approximations are not well understood and often lead to unsatisfactory results.

These approaches are physics-based models that deform under the laws of Newton mechanics, in particular, by the theory of elasticity expressed in the Lagrange dynamics. Many contour based segmentation algorithms[2]-[4] have been developed in the past two decades. One problem existing in these algorithms is that they are easy to get trapped in local minima. In addition, they need manually specified initial curves close to the objects of interest. Region-based approaches try to classify an image into multiple consistent regions or classes. Thresholding is the simplest segmentation method but its performance is usually far from satisfactory. Watershed segmentation [10], [11] is one of the traditional region-based approaches. The watershed transform is often used to segment touching objects. It finds intensity valleys in an image if the image is viewed as a surface with mountains (high intensity regions) and valleys (low intensity regions). Morphological operations are always used to handle the over-segmented

problem in the output obtained by the watershed transform. Usually, watershed is used for the segmentation of foreground and background (two class) of an image. For a general color image with many different regions, it often gives a bad result. It is also sensitive to the morphological structuring element.

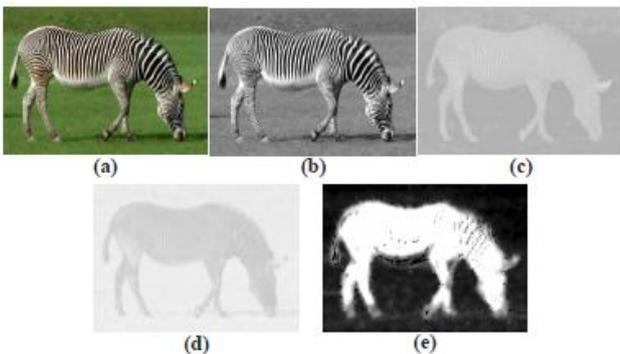

This paper proposes a new image segmentation algorithm based on a probability maximization model. An iterative optimization scheme alternately making the MAP and the maximum likelihood (ML) estimations is the key to the segmentation. We model the MAP estimation with MRFs and solve the MAP-MRF estimation problem using graph cuts. The result of the ML estimation depends on what statistical model we use. Under the Gaussian model, it is obtained by finding the means of the region features. It is shown that other statistical models can also fit in our framework. The main contributions of this work include: 1) a novel probabilistic model and an iterative optimization scheme for image segmentation, and 2) using graph cuts to solve the multiple region segmentation problem with the number of regions automatically adjusted according to the properties of the regions. Our algorithm can cluster relevant regions in an image well, with the segmentation boundaries matching the region edges. Extensive experiments show that our algorithm can obtain results highly consistent with human perception. The qualitative and quantitative comparisons demonstrate that our algorithm outperforms six other state-of-the-art image segmentation algorithms.

II. A NEW PROBABILISTIC MODEL

In this section, we first introduce the features used to describe the properties of each pixel, and then present the new probabilistic model. For a given image P, the features of every pixel p are expressed by a four-dimensional vector

$$\mathbf{I}(p) = (I_L(p), I_a(p), I_b(p), I_t(p))^T, \quad (1)$$

where $I_L(p)$, $I_a(p)$ and $I_b(p)$ are the components of p in the $L \times a \times b$ color space, and $I_t(p)$ denotes the texture feature of p. Several classical texture descriptors have been developed. In this paper, the texture contrast defined in [13] (scaled from [0; 1] to [0; 255]) is chosen as the texture descriptor. Fig. 1 shows an example of the features. The task of image segmentation is to group the pixels of an image into relevant regions. If we formulate it as a labeling problem, the objective is then to find a label configuration

$f = f_p$ where f_p is the label of pixel p denoting which region this pixel is grouped into. Generally speaking, a “good” segmentation means that the pixels within a region i

should share homogeneous features represented by a vector $\Phi(i)$ that does not change rapidly except on the region boundaries. The introduction of $\Phi(i)$ allows the description of a region, with which high level knowledge or learned information can be incorporated into the segmentation. Suppose that we have k possible region labels.[2]

$$\phi(i) = (\bar{I}_L(i), \bar{I}_a(i), \bar{I}_b(i), \bar{I}_t(i))^T \quad (2)$$

A four-dimensional vector is used to describe the properties of label (region) i, where the four components of $\Phi(i)$ have the similar meanings to those of the corresponding four components of $\mathbf{I}(p)$ and will be derived in Section II-B. let $\Phi = \{ \Phi(i) \}_g$ be the union of the region features. If P and $\Phi(i)$ are known, the segmentation is to find an optimal label configuration b f, which maximizes the posterior possibility of the label configuration[3]-[5].

$$\hat{f} = \arg \max_f \Pr(f|\Phi, P), \quad (3)$$

where Φ can be obtained by either a learning process or an initialized estimation. However, due to the existence of noise and diverse objects in different images, it is difficult to obtain Φ that is precise enough. Our strategy here is to refine Φ according to the current label configuration found by (3). Thus, we propose to use an iterative method to solve the segmentation problem. Suppose that Φ^n and f^n are the estimation results in the nth iteration. Then the iterative formulas for optimization are defined as

$$f^{n+1} = \arg \max_f \Pr(f|\Phi^n, P), \quad (4)$$

$$\Phi^{n+1} = \arg \max_{\Phi} \Pr(f^{n+1}|\Phi, P). \quad (5)$$

This iterative optimization is preferred because (4) can be solved by the MAP estimation, and (5) by the ML estimation. Based on this framework, next we will explain how the MAP and ML estimations are implemented.

A. MAP Estimation of f from Φ :

Given an image P and the potential region features Φ , we infer f by the Bayesian law, i.e., $\Pr(f|\Phi, P)$ can be obtained by

$$\Pr(f|\Phi, P) = \frac{\Pr(\Phi, P|f)\Pr(f)}{\Pr(\Phi, P)} \propto \Pr(\Phi, P|f)\Pr(f), \quad (6)$$

which is a MAP estimation problem and can be modeled using MRFs. Assuming that the observation of the image follows an independent identical distribution (i.i.d.), we define $\Pr(\Phi, P|f)$ as

$$\Pr(\Phi, P|f) \propto \prod_{p \in P} \exp(-D(p, f_p, \Phi)), \quad (7)$$

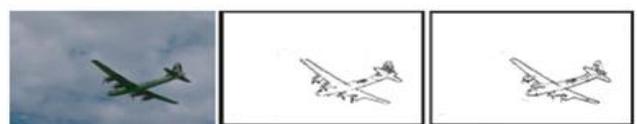

Figure 2: An example of the brightness contrast. (a) The original image. (b) The brightness contrast in the horizontal direction. (c) The brightness contrast in the vertical direction

where $D(p, f_p, \Phi)$ is the data penalty function which imposes the penalty of a pixel p with a label f_p for given Φ . The data penalty function is defined as

$$D(p, f_p, \Phi) = \|\mathbf{I}(p) - \phi(f_p)\|^2 \\ = (I_L(p) - \bar{I}_L(f_p))^2 + (I_\alpha(p) - \bar{I}_\alpha(f_p))^2 + \\ (I_b(p) - \bar{I}_b(f_p))^2 + (I_t(p) - \bar{I}_t(f_p))^2. \quad (8)$$

We restrict our attention to MRFs whose clique potentials involve pairs of neighboring pixels. Thus

$$\Pr(f) \propto \exp\left(-\sum_{p \in P} \sum_{q \in \mathcal{N}(p)} V_{p,q}(f_p, f_q)\right), \quad (9)$$

where $\mathcal{N}(p)$ is the neighborhood of pixel p , $V_{p,q}(f_p, f_q)$ called the smoothness penalty function, is a clique potential function, which describes the prior probability of a particular label configuration with the elements of the clique (p, q) . We define the smoothness penalty function as follows using a generalized Potts model[6]-[8].

$$V_{p,q}(f_p, f_q) = c \cdot \exp\left(\frac{-\Delta(p,q)}{\sigma}\right) \cdot T(f_p \neq f_q) \\ = c \cdot \exp\left(\frac{-|I_L(p) - I_L(q)|}{\sigma}\right) \cdot T(f_p \neq f_q), \quad (10)$$

where $\Delta(p,q) = I_L(p) - I_L(q)$ called brightness contrast, denotes how different the brightness of p and q are, $c > 0$ is a smoothness factor, $\sigma > 0$ is used to control the contribution of $\Delta(p,q)$ to the penalty, and $T(\cdot)$ is 1 if its argument is true and 0 otherwise. From our experiments, we found that $\sigma = 2(\Delta(p,q))$ is a good choice, where $\langle \cdot \rangle$ denotes the expectation of all the pairs of neighbors in an image. $V_{p,q}(f_p, f_q)$ depicts two kinds of constraints[11]. The first enforces the spatial smoothness; if two neighboring pixels are labeled differently, a penalty is imposed. The second considers a possible edge between p and q ; if two neighboring pixels cause a larger Δ , then they have greater likelihood to be partitioned into two regions. Figure. 2 is an example of the brightness contrast. In our algorithm, the boundaries of the segmentation result are pulled to match the darker pixels in Figure. 2(b) and (c), which are more likely to be edge pixels. From (6), (7), and (9), we have

$$\Pr(f|\Phi, P) \propto \left(\prod_{p \in P} \exp(-D(p, f_p, \Phi))\right) \cdot \\ \exp\left(-\sum_{p \in P} \sum_{q \in \mathcal{N}(p)} V_{p,q}(f_p, f_q)\right). \quad (11)$$

Taking the logarithm of (11), we have the following energy function[13].

$$E(f, \Phi) = \sum_{p \in P} D(p, f_p, \Phi) + \sum_{p \in P} \sum_{q \in \mathcal{N}(p)} V_{p,q}(f_p, f_q), \quad (12)$$

It includes two parts: the data term

$$E_{data} = \sum_{p \in P} D(p, f_p, \Phi) \quad (13)$$

and the smoothness term

$$E_{smooth} = \sum_{p \in P} \sum_{q \in \mathcal{N}(p)} V_{p,q}(f_p, f_q). \quad (14)$$

From (12), we see that maximizing $\Pr(f|\Phi, P)$ is equivalent to minimizing the Markov energy $E(f, \Phi)$ for a given Φ . [14]. In this paper, we use a graph cut algorithm to solve this minimization problem, which is described in Section III.

B. ML Estimation of Φ from f :

If the label configuration f is given, the optimal Φ should maximize $\Pr(f|\Phi, P)$, or minimize $E(f, \Phi)$ equivalently. Thus we have

$$\nabla_{\Phi} \log \Pr(f|\Phi, P) = \mathbf{0}, \quad (15)$$

Or

$$\nabla_{\Phi} E(f, \Phi) = \mathbf{0}, \quad (16)$$

Where ∇_{Φ} denotes the gradient operator. Since $V_{p,q}(f_p, f_q)$ is independent of Φ , we obtain

$$\nabla_{\Phi} \sum_{p \in P} D(p, f_p, \Phi) = \mathbf{0}, \quad (17)$$

where different formulations of $D(p, f_p, \Phi)$ lead to different estimations of Φ . For our formulation in (8), it follows that

$$\sum_{p \in P} D(p, f_p, \Phi) = \sum_i \sum_{f_p=i} \|\mathbf{I}(p) - \phi(i)\|^2. \quad (18)$$

Therefore, (17) can be written as

$$\frac{\partial}{\partial \phi(i)} \sum_{f_p=i} \|\mathbf{I}(p) - \phi(i)\|^2 = \mathbf{0}, \quad (19)$$

From (19), we obtain the ML estimation $\Phi = \Phi(i)$, where

$$\phi(i) = \frac{1}{num_i} \sum_{f_p=i} \mathbf{I}(p), \quad (20)$$

Note that when the label configuration $f = \{f_p/p\}$ is unknown, finding the solution of (17) is carried out by clustering the pixels into groups. In this case, the ML estimation is achieved by the K-means algorithm [12], which serves as the initialization in our algorithm described in Section III.

C. Non-Gaussian Modeling:

The definition of $D(p, f_p, \Phi)$ in (8) uses the Gaussian model to describe a uniform region. Some other distributions in the modeling of natural images, such as the exponential family distributions [17], [18], can also be used in our framework. Let us take another popular model, the Laplace model [19], as an example. To replace the Gaussian model with the Laplace model, we modify (7) as

$$\Pr(\Phi, P|f) \propto \prod_{p \in P} \exp(-D'(p, f_p, \Phi)), \quad (21)$$

where the data penalty is defined as

$$D'(p, f_p, \Phi) = |\mathbf{I}(p) - \phi(f_p)|. \quad (22)$$

With this data penalty, the MAP estimation is the same as when the Gaussian model is used. However, the ML estimation result is different from (20) and becomes

$$\phi(i) = \text{Median}\{\mathbf{I}(p)|f_p = i\}, \quad (23)$$

where Median { . } denotes the median of the elements in a set [15]. In addition to the above parametric models, we can also use non-parametric distributions to describe the region features. Similar to the parametric models, the data penalty functions are defined as the negative logarithm of different likelihood functions in different non-parametric models (e.g., a histogram clustering model is used. In summary, different statistical models lead to different definitions of the data penalty. Given different data penalties, the MAP estimations are the same, but the ML estimation results depend on the used models. In the rest of this paper, we only consider the Gaussian model[16]-[19].

III. THE PROPOSED ALGORITHM

We first give the description of the algorithm for image segmentation, and then prove its convergence.

A. Algorithm Description:

With $E(f; \Phi)$ defined in (12), the estimations of b and Φ in (4) and (5) are now transformed to

$$f^{n+1} = \arg \min_f E(f, \Phi^n) \quad (24)$$

$$\Phi^{n+1} = \arg \min_{\Phi} E(f^{n+1}, \Phi) \quad (25)$$

The two equations correspond to the MAP estimation and the ML estimation, respectively. The algorithm to obtain b and $\hat{\Phi}$ is described as follows.

Algorithm: Image segmentation:

Input: an RGB color image.

Step 1: Convert the image into $L^*a^*b^*$ space and calculate the texture contrast.

Step 2: Use the K -means algorithm to initialize Φ .

Step 3: Iterative optimization.

3.1: MAP estimation — Estimate the label configuration f based on current Φ using the graph cut algorithm [36].

3.2: Relabeling — Set a unique label to each connecting region to form a new cluster, obtaining a new f .

3.3: ML estimation — Refine Φ based on current f with (20).

Step 4: If Φ and f do not change between two successive iterations or the maximum number of iterations is reached, go to the output step; otherwise, go to step 3.

Output: Multiple segmented regions of the image.

We explain step 3.2 in more details here. After step 3.1, it is possible that two non-adjacent regions are given the same label. For example, the upper-left and the lower-right regions are both labeled by 1. After step 3.2, each of the

connected regions has a unique label. The MAP estimation is an NP-hard problem proposed to obtain an approximate solution via finding the minimum cuts in a graph model. Minimum cuts can be obtained by computing the maximum flow between the terminals of the graph. In [16], an efficient max-flow algorithm is given for solving the binary labeling problem. In addition, an algorithm, called α expansion with the max-flow algorithm embedded, is presented to carry out multiple labeling iteratively. In our algorithm, the α expansion algorithm is used to perform step 3.1. Besides the graph cuts, other techniques such as belief propagation can also be used to solve the MAP-MRF problem. One remarkable property of our algorithm is the ability to adjust the region number automatically during the iterative optimization with the relabeling step embedded into the MAP and ML estimations. Another property of our algorithm is that it is insensitive to the value of K in the initialization step with the K -means algorithm.

Now we analyze the computational complexity of the algorithm. In step 2, the K -means algorithm takes $O(NdKtk)$ time [12], where N is the number of pixels in an image, d is the number of features used to represent a pixel/region, K is the number of clusters, and tk is the number of iterations. In our application, $d = 4$, K is set to 10, and tk is set to 100. Both step 3.2 and step 3.3 take $O(N)$ time. In step 3, the main computational burden is the use of the graph cut algorithm (the α expansion) in step 3.1. The max-flow algorithm is linear in practice. The α expansion algorithm takes $O(NCnTan)$ time to carry out the MAP estimation during the n -th execution of step 3.1, where Cn is the number of label candidates and Tan is the number of iterations inside the α expansion. Let T be the number of executions of step 3.1. Then the computational complexity of our algorithm is $O(NdKtk) + O(NPT \sum_{i=1}^T CnTan)$. In general, Cn ranges from 1 to 50, Tan is less than 5, and T is less than 10.[20]

B. Algorithm Convergence:

We prove that the proposed algorithm is convergent in this section. Suppose that after the n th iteration, the energy is E_n , the configuration is f_n , and the union of region features is Φ_n . The MAP estimation is to estimate the configuration f_{n+1} by minimizing the energy. Therefore, after the MAP estimation step of the $(n+1)$ th iteration, the energy E_{MAP}^{n+1} decreases or keeps unchanged, i.e.,

$$E_{MAP}^{n+1} \leq E^n \quad (26)$$

Suppose that the configuration is $f_{relabeling}^{n+1}$ after the relabeling step. This step only changes the labels of some regions but not their features, i.e., for each pixel p ,

$$\phi(f_p^{n+1}) = \phi(f_{prelabeling}^{n+1}) \quad (27)$$

Therefore, from (8) and (13), the relabeling step does not change the data term. On the other hand, after the relabeling, for two neighboring pixels p and q .

$$T(f_p^{n+1} \neq f_q^{n+1}) = T(f_{prelabeling}^{n+1} \neq f_{qrelabeling}^{n+1}) \quad (28)$$

which implies that the relabeling step does not change the

smoothness term either (see (10) and (14)). Thus, after the relabeling step, the energy keeps unchanged, i.e.,

$$E_{\text{relabeling}}^{n+1} = E_{\text{MAP}}^{n+1} \quad (29)$$

Furthermore, since the ML estimation does not change the smoothness term but may reduce the data term or keeps it unchanged, we have

$$E^{n+1} \leq E_{\text{relabeling}}^{n+1} \quad (30)$$

So the energy keeps monotonically non-increasing during the iterations, i.e.,

$$E^{n+1} \leq E^n, \quad (31)$$

which completes the proof of the convergence of our algorithm.

IV. MATLAB RESULTS

We test the proposed algorithm by using Matlab, We classify part of the image in the Matlab "a dog" and show the segmentation results obtained by the algorithm in Figure 3 All the boundaries of the small regions with the numbers of pixels less than 100 are removed. From these example, we have the following observations.

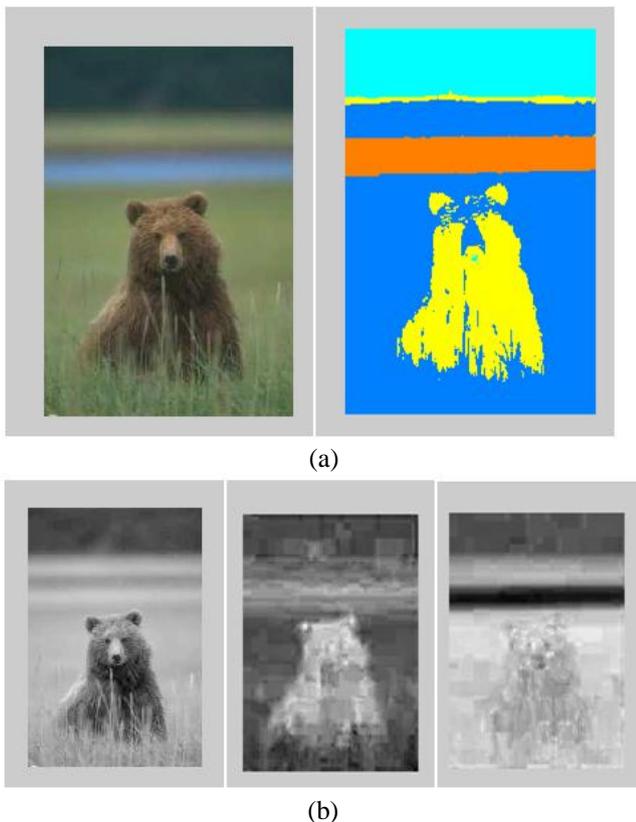

Figure 3 :a), (b) Segmentation results on the "dog" Quantitative comparisons are also important for objectively evaluating the performance of the algorithm. There have been several measures proposed for this purpose. Region differencing and boundary matching are two of them. Region differencing measures the extent to which one segmentation can be viewed as a refinement of the other. Boundary matching measures the average displacement error of boundary pixels between the results obtained by an algorithm and the results obtained from human subjects.

However, these two measures are not good enough for segmentation evaluation. For example, a segmentation result with each pixel being one region obtains the best score using these two measures. A strongly over-segmented result, which does not make sense to our visual perception, may be ranked good.

V. CONCLUSION

In this paper, we have developed a Extensive Technique for image segmentation algorithm. Our algorithm is formulated as a labeling problem using a probability maximization model. An iterative optimization technique combining the MAP and ML estimations is employed in our framework. Under the Gaussian model, the MAP estimation problem is solved using graph cuts and the ML estimation is obtained by finding the means of the region features. The qualitative and results demonstrate that our algorithm out performs than others. Our future work includes the extension of the proposed model to video segmentation with the combination of motion information technique , and the utilization of the model for specific object extraction by designing more complex features (such as shapes) to describe the objects.

Abstract: Orthogonal Frequency Division Multiplexing (OFDM) is a digital multi carrier modulation scheme, which uses a large number of closely spaced orthogonal sub-carriers. In frequency and time must be extremely good. An OFDM system offers inherent robustness to multi-path dispersion with a low-complexity receiver. In OFDM systems Cyclic Prefix uses to maintain orthogonality of transmission. Now days For transmission purpose Ultra-Wideband (UWB) systems use Multi-Band OFDM Techniques. In these the application like Wireless Personal Area Network (WPAN). It is Power limited by the regulation of FCC. CP forces the linear convolution with the channel impulse response to resemble a circular convolution in transmitted data sequence and introduces the ripples in Power spectral Density, So due to this Transmission reduces. The zero-pad suffix (ZPS) will have a flat PSD and hence does not suffer from the range degradation problem. In the UWB receiver, ZP removal requires use of a technique called as overlap and add (OLA) in order to capture the multipath energy of the channel and maintain the orthogonality in the received data. In this paper, we propose a method which adapts the length of Overlap-and-Add depending on the reception of current band. The Existing method shows high delay Spread channel like CM4. For this technique achieves the gain at 10-2 of BER.

Keywords: UWB Receiver, Multi Band OFDM System, Adaptive Over lap technique.

I. INTRODUCTION

Over the last year and half, ultra-wideband (UWB) communication systems have received significant attention from industry, media and academia. The reason for all this excitement is that this technology promises to deliver data rates that can scale from 110 Mbit/s at a distance of 10 meters up to 480 Mbit/s at a distance of two meters in realistic multi-path environments all while consuming very little power and silicon area. It is expected that UWB devices will provide low cost solutions that can satisfy the consumer's insatiable appetite for data rates as well as enable new consumer market segments. But for UWB systems to move from the lab environment to real-life system designs, engineers must battle traditional design issues such as complexity, power consumption, cost, and flexibility. Fortunately, an answer to these problems has arrived. By turning to a multiband OFDM approach, designers can overcome many of these barriers.

Even though the FCC has allocated the entire spectrum from 3.1 GHz and 10.6 GHz for UWB, it has been shown that using an upper frequency beyond 4.8 GHz leads to an improvement in the overall link margin of only 1 dB with current RF CMOS technology. This comes at the expense of higher complexity, and higher power consumption.

The minimal gains in the link budget and the increase in complexity and power consumption lead one to conclude that the bandwidth between 3.1 and 4.8 GHz will provide the most effective bandwidth for initial deployments of UWB devices. Indeed, limiting the upper frequency to 4.8 GHz also has several decided advantages, including shortening time to market, simplifying the design of the RF and analog front-end circuits (low noise amplifiers and mixers), making it more amenable to CMOS technology, and avoiding interference from the U-NII band, where IEEE 802.11a signals reside. Of course, limiting the bandwidth of UWB, at least initially, still leaves the possibility that the entire bandwidth will eventually be utilized. As RF technology improves, it will become more efficient to use the upper frequencies in the UWB range. If defined with forethought and proper planning, the UWB systems can accommodate an effective migration path to the upper end of the spectrum when market conditions dictate such a move.

The main advantage of building UWB communication systems based on spread-spectrum techniques are that these techniques are well understood and have been proven in other commercial technologies (ex. wideband CDMA). However, building RF and analog circuits as well as high speed analog-to-digital converters (ADCs) to process this extremely wideband signal is a challenging problem. In addition, the digital complexity needs to be quite large (at least 16 RAKE fingers) in order to capture sufficient multi-path energy to meet the range requirements of 10 meters for a 110 Mb/s system.

In addition to allocating spectrum, the FCC also specified that a UWB signal must occupy a minimum 10-dB bandwidth of 500 MHz. In many ways, this portion of the ruling has revolutionized the design of UWB communication systems. Instead of having to use the entire band to transmit information, the spectrum can now be divided into several sub-bands, whose bandwidth is approximately 500 MHz. By interleaving the symbols across sub-bands, UWB systems can still maintain the same transmit power as if they were using the entire bandwidth.

The advantage is that the information can now be processed over a much smaller bandwidth, thereby reducing the complexity of the design, reducing the power consumption, lowering the cost, and improving spectral flexibility and worldwide compliance. Other advantages of this approach include using lower-rate ADCs and simplifying the digital complexity. Systems built using this type of approach are often referred to as multiband systems. Now that we've taken a brief look at the different multi-band approaches available to designers, let's examine the OFDM-based multiband approach further.

Given the frequency band from 3.1 GHz to 4.8 GHz and the FCC requirement that UWB signals have to be at least 500 MHz, only three sub-bands can be used in the initial deployment of multi-band OFDM systems. Figure 1 illustrates one way to allocate the three sub-bands with the given frequency allocation.

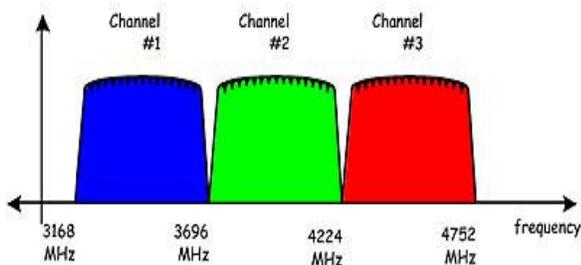

Figure 1: Frequency allocation of sub-bands for a multi-band OFDM system.

The frequency planning shown in Figure 1 was chosen for two reasons. First it allows sufficient guard band on the lower side of channel number 1 and the upper side of channel number 3 to simplify the pre-select filter's design. Second it ensures that both the transmitter and receive can switch to the next center frequency within a few nanoseconds. Figure 2 provides an example of how the OFDM symbols are transmitted in a multi-band OFDM system. This figure shows that the first OFDM symbol is transmitted on channel number 1, the second OFDM symbol is transmitted on channel number 3, the third OFDM symbol is transmitted on channel number 2, the fourth OFDM symbol is transmitted on channel number 1, and so on.

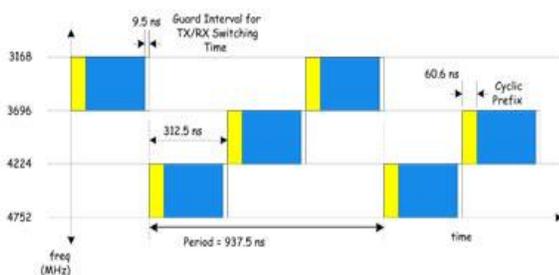

Figure 2: An example of time-frequency interleaving for the multi-band OFDM system

In Figure 2, it is assumed that time-frequency interleaving (TFI) is performed across just three OFDM symbols. In

practice, the TFI period can be much longer. The exact length and pattern of the TFI may differ from super frame to super frame and piconet to piconet.

From Figure 2, it is also apparent that a cyclic prefix (CP) is inserted at the beginning of each OFDM symbol and a guard interval (9.5 ns) is appended to each OFDM symbol. The guard interval has been inserted to ensure that only a single RF transmit and RF receiver chain are needed for all channel environments and all data rates and that there is sufficient time for the transmitter and receiver to switch to the next channel. A circular convolution in the time domain is equivalent to a multiplication operation in the discrete Fourier transform (DFT) domain. Hence, a one-tap frequency domain equalizer is sufficient to undo the effect of the multi-path channel.

The length of the CP determines the amount of captured multi-path energy. Any multi-path energy outside the CP window would result in inter-carrier-interference (ICI). The CP length should be chosen to minimize the performance degradation due to the loss in collected multi-path energy and the resulting ICI, while still keeping the CP overhead small. This paper proposes an adaptive reception technique for ZP based systems in an attempt to minimize ISI incursions from subsequent OFDM symbols. In section II, we review the impact of CP and ZP in OFDM systems in general, and outline one of the key motivation factors for this paper. In section III, we relook the ZP removal process in view of multi-band UWB system. In section IV, we discuss our proposed adaptive overlap-add technique. Section V discusses our simulation results and finally we conclude our paper in section VI

II. CP VS ZP IN OFDM BASED SYSTEM

In traditional OFDM systems, a cyclic prefix is used before the OFDM symbol in order to maintain the orthogonality in the received signal after passing through the multipath channel. However as CP introduces a structure in the symbols transmitted, the system suffers from the ripple in the power spectral density (PSD) necessitating power back-off in the transmitter which can be as large as 1.5 dB for MB-OFDM based system [9]. In an alternative, it was pointed out in [7], that we can use zero-padding instead of cyclic-prefix in the transmitted OFDM symbols. The transmission using ZP does not suffer from the ripple in PSD and hence can transmit at maximum power and hence to a longer distance. However to retain the circular convolution property, which essentially provides robustness against multipath channel for OFDM system and facilitates the use of a single-tap frequency domain equalizer in receiver, we require to do a slight modification in signal processing in OFDM receiver. CP based system, can simply discard the CP portion of the received symbol, however for ZP based system we need to do overlap-add (OLA) operation in the receiver shown in Figure 3.

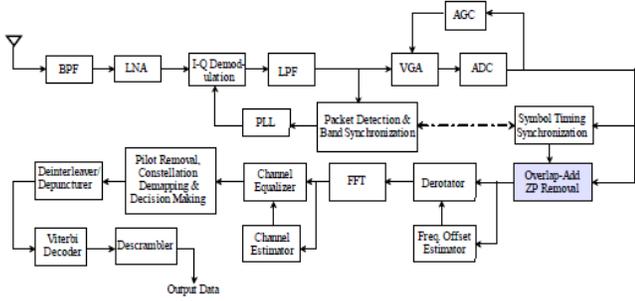

Figure 3: A typical MB-OFDM based receiver architecture

In general, the ZP length should be greater than the delay spread of the channel. As per ECMA-368, this length is 32 samples. Due to multipath propagation, the received OFDM symbol gets smeared at the most by 32 samples, as per assumption that channel length is not greater than 32 samples duration. To mimic what would have happened if there were CP in the transmitted symbol, we need to do overlap-add operation in the receiver. This is illustrated in Figure 4. First we should estimate the start point of true FFT window. As the FFT length in ECMA-368 is 128 samples, from that we should count and pick up 32 consecutive received samples starting from 129th sample onwards. Then we should do a sample-by-sample addition as following. If $r(n)$ is the received samples and $n \geq 0$ corresponds to the true FFT window start point, then overlap-add process modifies $r(n)$ as per eqn. (2).

$$r'(n) = r(n) + r(n+128) \text{ for } n = 0 \text{ to } 31, \\ = r(n), \text{ otherwise.} \quad (2)$$

Note that, CP based system is not very sensitive to symbol timing synchronization error. As long as we estimate the start of the FFT window in the portion of CP, the equalizer can correct the phase offset incurred due to the estimation error. However a ZP based system requires more accurate estimation of the start of FFT window. This is because in CP based system the circular convolution is an effect of natural phenomenon. The physical propagation of the OFDM signal through multipath channel causes linear convolution, which appears to be a circular convolution due to the cyclic property artificially maintained due to CP addition. However linear convolution does not appear naturally as circular convolution for ZP based system. Overlap-add operation makes sure this artificial circular convolution appearance, which depends on the true start point of the FFT window. Hence ZP based system is quite sensitive to the timing synchronization estimation error compared to CP based system. This is one of the key motivation factors of this paper.

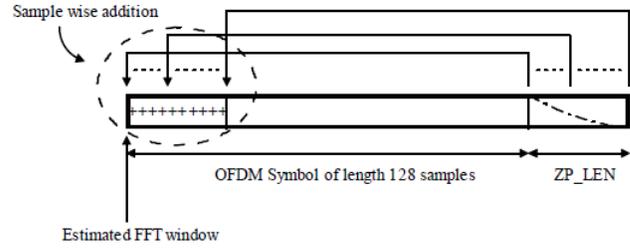

Figure 4: ZP removal by overlap-add operation using ZP length equal to 'ZP_LEN'. Note that, 'ZP_LEN' can be fixed (32 samples), as in traditional system, or could be variable depending on some parameter, as proposed in this paper

III. AN FOR ZP REMOVAL IN VIEW OF MULTI BAND TIMING SYNCHRONIZATION (MBTS)

In UWB, we see four type of channel models proposed for research and developmental work, they are CM1, CM2, CM3 and CM4. Without going into details of them, it should be highlighted that CM1 corresponds to small delay spread channel, whereas delay spread increases as we go towards CM4 [11 and references therein]. In [9] and [10], it is pointed out that there exists an overlap-add length ('ZP_LEN' in Fig. 4) for which the receiver performs optimally. This is because for small delay spread channel (say CM1 with a delay spread of 4 samples as one realization), if we use ZP_LEN = 32 samples, then we are essentially picking up some (28 in this example) pure noise samples during overlap-add process, which affects BER adversely. This essentially means we should estimate the channel delay spread and use a variable 'ZP_LEN' during overlap-add procedure, as outlined in [9-10]. The estimation of channel delay spread can be done in a few ways mainly from the cross-correlation characteristics in time domain in timing synchronizer block and one of the methods has been proposed in [9].

This type of adaptive overlap-add method based on estimation of channel delay spread is more beneficiary for small delay spread channel and hardly benefits anything for large enough delay spread channel. It also should be pointed out that the above method demands a very small estimation error in locating the FFT window, which is quite difficult to achieve in UWB system. On the other hand, in [11], it was pointed out that the mean delay of the UWB channel differs significantly depending on the band of transmission. Accordingly they have proposed a timing synchronization algorithm, which they called as multi band timing synchronization (MBTS) algorithm, which essentially proposes to estimate the true start point of FFT window depending on the band of transmission. Note that, this variance of mean delay is due to the manifestation of the multipath channel in multi-band scenario while the channel length remains same.

Hence it may happen for a band, the FFT start point might get estimated say at the sample number 16, rather than 0 or closed to 0. In that case if we use a fixed 'ZP_LEN' of 32 samples for overlap-add operation, then we are essentially picking up samples from the next OFDM symbol which leads

to ISI. Figure 5 shows the offset sensitivity of BER performance of MB-OFDM system. Here offset = 0 implies the true start point of FFT window if there is no noise and there exists a non-zero multipath component at the first sample location. Note that, even if there is no non-zero multipath component at 0th location, still a start point of FFT window at that location will always perform optimally in no noise condition, because equalizer can take care as no multipath component to equalizer will appear as non-causal component. Note that, the curves show that MB-OFDM system is quite sensitive to the ISI incursions from the next OFDM symbol.

IV. A PROPOSED ADAPTIVE OVERLAP-ADD TECHNIQUE

In this section we propose a technique to reduce the ISI incursions from the subsequent OFDM symbol due to the use of fixed 'ZP_LEN' during overlap-add process. At the same time we try to make the method robust with respect to the estimation error of the true start point of the FFT window in the smeared received signal. In general the timing synchronizer block provides the estimated offsets over different bands as signed numbers because the estimation point can shift in left as well as right depending on the situation. If any of the estimated offsets becomes negative, we first make all of them positive using the following algorithm (Alg#1) and provide necessary delay in data path in order to make the receiver a causal system.

Alg#1:

Say, OB_i denotes the signed offset of band i , where $i \in 1, 2, \text{ or } 3$. Let UOB_i denotes the unsigned offset of band i after making the system causal.

If ($OB_1 < 0$ or $OB_2 < 0$ or $OB_3 < 0$) Then

{
For $i = 1$ to 3, % 'i' is the band number

$$UOB_i = OB_i + \max(\text{abs}(\text{all negative } OB_j));$$

Where $j \in 1, 2, 3$.

}

Else,

$$UOB_i = OB_i;$$

We notice that it is expected that $(OB_i \sim OB_j) \leq 32$, i, j belonging to band number, as the channel length is 32 samples. This also guarantees that the range of UOB_i is 0 to 32.

The variation in i UOB is solely due to channel manifestation and the channel length remains same as 32 samples. So to avoid ISI incursion from the next OFDM

symbol we use band-dependent variable ZP length ('ZP_LEN_Bi') during overlap-add operation over multiple bands as per the following algorithm (Alg#2).

Alg#2:

For $i = 1$ to 3, % band number

$$ZP_LEN_B_i = 32 - \{UOB_i - \text{Min}(UOB_1, UOB_2, UOB_3)\};$$

End for loop;

Note that in Alg#2, apart from making the scheme robust to the estimation error of the true start point of the FFT window, we have also made sure that the chances of the equalizer of seeing non-causal multipath components minimal.

The above algorithm (Alg#2) is valid for single band or dual band transmission as well. For single band transmission, the process ceased to be band dependent adaptive and becomes fixed 'ZP_LEN' as 32 samples. So, as per Alg#2, a band-dependent 'ZP_LEN' number of samples after the FFT window is picket up and added to the front portion as shown in Figure 4

V. SIMULATION RESULTS

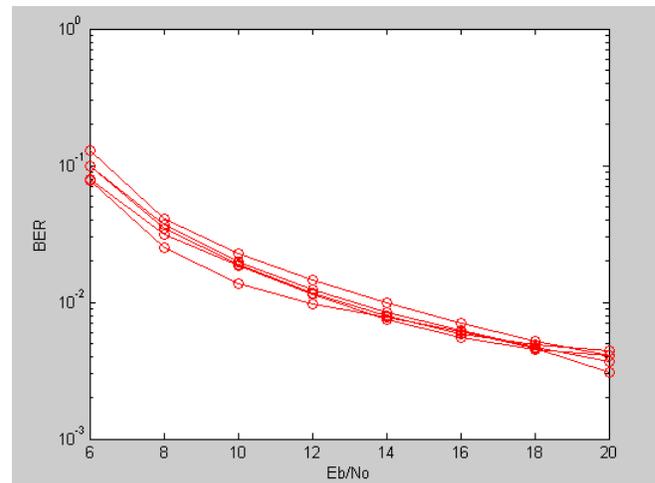

Figure. 5. Offset sensitivity of BER for all channel models at 10 dB Eb/N0 with fixed (32 samples) 'ZP_LEN'

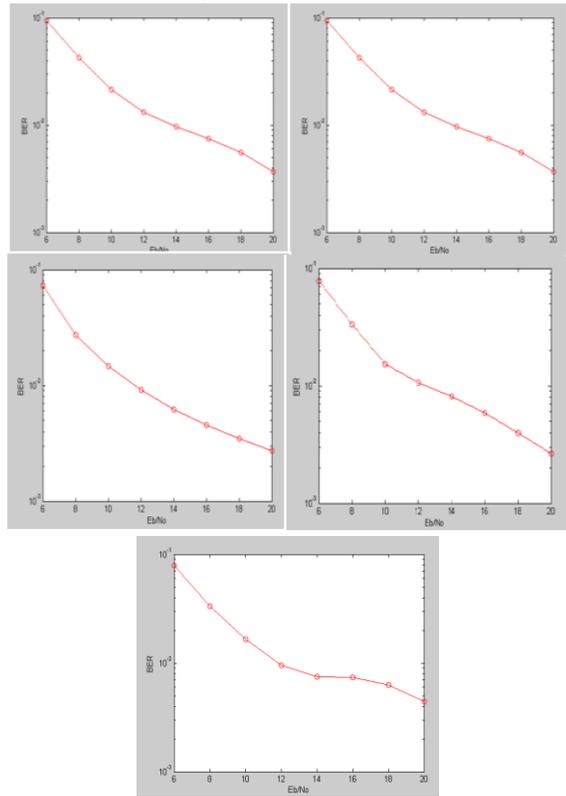

Fig. 6. BER vs Eb/No (in dB) simulation for all channel models in uncoded MB-OFDM system. Data1: using variable ZP length. Data2: Using fixed ZP length of 32.

Figure 6 shows the BER curves for un coded MB-OFDM based UWB system with and without band wise variable ZP length for overlap and add operation. For large delay-spread channels in UWB systems the mean excess delay is more compared to small delay-spread channels. This implies for large delay spread channel, the estimation of FFT window will be more away from the true FFT window resulting in more ISI incursions from next OFDM symbol. Hence the proposed technique is more promising for large delay-spread channels. The curves show a significant amount of performance improvement (for CM4 around 1 dB of Eb/No savings at 10⁻² BER for un coded system) is achieved for large delay-spread channels.

VI. CONCLUSION

In this paper as well as in some prior arts that adaptive overlap-add technique is beneficiary for OFDM based receivers in terms of BER performance. In some related literature [9], it had been proposed to adapt 'ZP_LEN' for overlap-add operation depending on the true channel length in order to avoid picking up pure noise samples during the OLA process. This method is more fruitful to channels having small delay-spread (e.g. CM1) and hence a small estimation error in FFT window will eventually reduce the benefit significantly. Moreover in [9], two independent process runs. One is estimation of the channel delay spread and the other is estimation of FFT window. Both of them are used in adaptive OLA process and hence may make things worse instead of improving if they are not aligned properly.

In an alternative, in this paper, we have proposed a band dependent adaptive OLA technique which tries to minimize ISI incursion from subsequent OFDM symbols. This method is not so sensitive on the estimation of true start point of FFT window, in a sense that a small estimation error will not be able to take away the benefits of the technique. Moreover in this method all the signal processing is dependent on one independent process i.e. estimation of the FFT window and hence the question of dependency of two independent process does not arise at all. The method is more promising for large delay spread channels and provides a significant Eb/No improvement in the detection process. A natural choice of future work would be to mix the above two independent ideas (i.e. one in [9], and the one proposed in this paper) and study its impact on overall system performance.

ABSTRACT: Economic Load Dispatch (ELD) is an important optimization task in power system operation for allocating generation among the committed units such that the constraints imposed are satisfied and the operating cost is minimized. This paper presents an application of Particle swarm optimization (PSO) technique to solve non-linear, non-convex ELD problem for the determination of the global or near global optimum dispatch solution. To illustrate the effectiveness of the proposed approach, a test system consisting of 40-thermal generating units, with incorporation of load balance constraints, operating limits, valve point loadings, is considered and tested. The comparison of numerical results demonstrate the performance and applicability of the proposed method.

Keywords: Economic Load Dispatch(ELD), non-convex problem, valve point loading effect, particle swarm optimization

I. INTRODUCTION

In the traditional ELD problem, the cost function for each generator has been approximately represented by a single quadratic function and is solved using mathematical programming based on the optimization techniques such as lambda-iteration method, gradient-based method, etc. Most of power system optimization problems including economic load dispatch (ELD) have complex and nonlinear characteristics with heavy equality and inequality constraints. The fuel cost functions of generating units can be modeled in a more practical fashion by including the valve-point effects. Thus, the practical ELD problem is represented as a non-smooth optimization problem with equality and inequality constraints, which cannot be solved by the traditional mathematical methods. Many recent works have been around Artificial Intelligence (AI) methods, on par with the development of AI optimization theories, such as Artificial Neural Networks (ANN), Simulated Annealing (SA), Genetic Algorithms (GA), Differential Evolution (DE), Evolutionary Programming (EP), and hybrid methods [3-5]. ELD algorithms for thermal unit system involving combined cycle units presented in [6]. Online solving of economic dispatch problem using neural network approach and comparing it with classical methods were presented in [7]. The evolutionary Algorithms (EAs) are different from the conventional optimization methods, and they do not need to differentiate cost function and constraints. Theoretically, like SA, EAs converge to the global optimum solution. EAs, including Evolutionary Programming (EP), Evolutionary Strategy (ES), and GA are AI methods of optimization based on the mechanics of natural selection, such as mutation, recombination, reproduction, crossover, selection, etc [8]. Many researchers exerted lot of work to improve many optimization and intelligent techniques to solve ELD problems such as GA [11], Hopfield solution [19] and SA [10,22]. N Amjadi, H Nasiri-rad [21] presented a more realistic model for the ED problem considering more practical constraints and non-linear characteristics than previous works in the area. K P Wong, Y W Wong [22] developed and presented the implementation of basic and incremental GA algorithms for determination of the global or near global optimum solution for the economic dispatch problem. A Y saber et al [23] proposed higher order cost function for (a) better curve fitting of running cost (b) less approximation (c) more practical results. There constraint management is incorporated and extra concentration is needed for the higher order cost function of single or multiple fuel units. S Y Lim et al [24] proposed a novel approach to solve the non-smooth ELD Problem with valve point effect by introducing constriction factor concept in the algorithm.

In this paper, an algorithm based on Particle Swarm Optimization technique is proposed as methodology for solving convex and non-convex Economical Load Dispatch problem. In this proposed approach the ELD problem is solved by considering the smooth and non-smooth cost co-efficients, representing the effects of valve point loading, and unit constraints. The results obtained through the approach are analyzed and compared with those existed methods represented in literature.

The proposed algorithm has been implemented in MATLAB 7.0 version on Pentium IV, 2.4 GHZ Personnel Computer with 1 GB RAM.

II. PROBLEM FORMULATION

The Primary concern of an ELD problem is the minimization of its objective function. The total cost generated that meets the demand and satisfies all other constraints associated is selected as the objective function. In general, the ELD problem can be formulated mathematically as a constrained optimization problem with an objective function of the form

$$\text{Minimize } C = \sum_{i=1}^n C_i(P_{Gi}) \quad \dots(1)$$

Where

$C_i (P_{Gi})$ is the fuel cost function of the i^{th} unit,
 P_{Gi} is the power generated by the i^{th} unit,
 n is the total number of generating units,
 C is the total generation cost subject to power balance constraints.

This objective function is modeled in two ways as i) Classical Smooth Fuel Cost Function and ii) Non- Smooth Fuel Cost Function.

2.1 Classical Smooth Fuel Cost Functions

Generally, the fuel cost of a thermal generation unit is considered as a second order polynomial function (neglecting valve-point effects) and this is called classical and smooth fuel cost function. It is represented as

$$C_i (P_{Gi}) = a_i + b_i P_{Gi} + c_i P_{Gi}^2 \quad \dots(2)$$

Where a_i , b_i , and c_i are the fuel-cost coefficients of the i^{th} unit.

2.2 Non – Smooth Fuel Cost Functions

In present scenario, the input-output characteristics of modern generating units are inherently highly non-linear due to valve point loadings, ramp rate limits etc., further they may have multiple local minimum points in the cost functions. For such combinatorial optimization problems, the conventional methods are failing to obtain the global optimal solutions while considering non-Linear characteristics of the units for the solution techniques as they have no restrictions on the shape of the fuel cost curves.

The generating units with multi-valve steam turbines exhibit a greater variation in the fuel cost functions. Since the valve point results in the ripples, a cost function contains higher order nonlinearity. Therefore the cost function should be modified to consider the valve point effects. This valve point effect leads to non-smooth, non-convex input-output characteristics as shown in fig.1

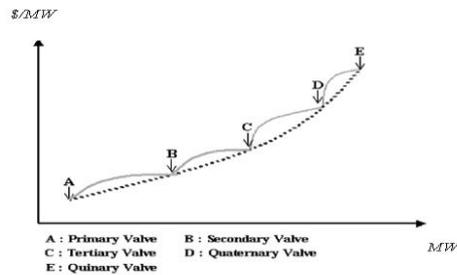

Fig. 1 Input-output characteristics of steam turbine generators with Valve- Point Effects

Typically, the valve point results in, as each steam valve starts to open, the ripples like in to take account for the valve – point effects, sinusoidal functions are added to the quadratic cost functions as:

$$C_i (P_{Gi}) = a_i + b_i P_{Gi} + c_i P_{Gi}^2 + \left| e_i \times \sin \left(f_i \times \left(P_{Gi_{min}} - P_{Gi} \right) \right) \right| \quad \dots(3)$$

Where e_i and f_i are the fuel cost-coefficients of the i^{th} unit reflecting valve-point loading effects.

These classical and non-classical models either with smooth or non smoothed fuel cost functions are subjected to the following equality and inequality constraints.

2.3 Equality Constraints

These constraints are also known as power balance constraints. The total power generated must supply the total load demand and the transmission losses, and expressed as

$$\sum_{i=1}^n P_{Gi} = P_D + P_{TL} \quad \dots (4)$$

Where P_D is the total system load demand and

P_{TL} is the total transmission line losses.

According to Kron’s formula, the total transmission line losses can be calculated by the following expression

$$P_{TL} = \sum_{i=1}^n \sum_{j=1}^n P_{Gi}^T B_{ij} P_{Gj} + \sum_{i=1}^n P_{Gi} B_{oi} + B_{oo} \quad \dots(5)$$

Where B_{ij} , B_{oi} and B_{oo} are the transmission line loss coefficients

P_{Gi}^T is the vector transpose of all generating plants net MW.

B_{ij} is the square matrix of same dimension as P_{Gi}

B_{oi} is a vector of same length as P_{Gi} and

B_{oo} is a constant

2.4 Inequality Constraint

Each generator is constrained between its minimum and maximum generation limits, and represented as inequality constraints as.

$$P_{Gi, min} \leq P_{Gi} \leq P_{Gi, max} \quad \text{for } i = 1, 2, \dots, n \quad \dots(6)$$

Where $P_{Gi, min}$ and $P_{Gi, max}$ are the minimum and maximum power outputs of the i^{th} generating unit.

III. PARTICLE SWARM OPTIMIZATION

Particle swarm optimization is one of the most recent developments in the category of combinatorial metaheuristic optimizations. This method has been developed under the scope of artificial life where PSO is inspired by the natural phenomenon of fish schooling or bird flocking. PSO is basically based on the fact that in quest of reaching the optimum solution in a multi-dimensional space, a population of particles is created whose present coordinate determines the cost function to be minimized. After each iteration the new velocity and hence the new position of each particle is updated on the basis of a summated influence of each particle's present velocity, distance of the particle from its own best performance, achieve so far during the search process and the distance of the particle from the leading particle, i.e. the particle which at present is globally the best particle producing till now the best performance i.e. minimum of the cost function achieved so far. Let x and v denote a particle position and its corresponding velocity in a search space, respectively. Therefore, the i^{th} particle is represented as $x_i = (x_{i1}, x_{i2}, \dots, x_{id})$ in the 'd' dimensional space. The best previous positions of the i^{th} particles recorded and represented as $pbest_i = (pbest_{i1}, pbest_{i2}, \dots, pbest_{id})$. The index of the best particle among all the particles in the group is represented by the $gbest_d$. The rate of the velocity for i^{th} particle is represented as $v_i = (v_{i1}, v_{i2}, \dots, v_{id})$. The modified velocity and position of each particle can be calculated using the current velocity and the distance from $pbest_{id}$ to $gbest_d$ as shown in the following formulae:

$$v_{id}^{k+1} = w v_{id}^k + c_1 \text{rand}() (pbest_{id} - x_{id}^k) + c_2 \text{rand}() (gbest_d - x_{id}^k) \quad \dots (7)$$

$$x_{id}^{k+1} = x_{id}^k + v_{id}^{k+1} \quad \text{for } i=1, 2, \dots, N_p, d=1, 2, \dots, N_g \quad \dots(8)$$

where, N_p is the number of particles in a group, N_g the number of members in a particle, k the pointer of iterations, w the inertia weight factor, c_1, c_2 the acceleration constants, $\text{rand}()$ the uniform random value in the range $[0,1]$, v_i^k the velocity of a particle 'i' at iteration k , $v_d^{\min} \leq v_{id}^k \leq v_d^{\max}$ and x_i^k is the current position of a particle 'i' at iteration k . In the above procedures, the parameter v^{\max} determined the resolution, with which regions are to be searched between the present position and the target position. If v^{\max} is too high, articles might fly past good solutions. If v^{\max} is too small, particles may not explore sufficiently beyond local solutions. The constants c_1 and c_2 represent the weighting of the stochastic acceleration terms that pull each particle toward the $pbest$ and $gbest$ positions. Low values allow particle to roam far from the target regions before being tugged back. On the other hand, high values result in abrupt movement toward or past, target regions. Hence, the acceleration constants c_1 and c_2 were often set to be 2.0 according to past experiences. Suitable selection of inertia weight 'w' provides a balance between global and local explorations, thus requiring less iteration on average to find a sufficiently optimal solution. As originally developed, 'w' often decreases linearly from about 0.3 to 0.2 during a run. In general, the inertia weight w is set according to the following equation:

$$w = w_{\max} - \frac{w_{\max} - w_{\min}}{\text{iter}_{\max}} \times \text{iter} \quad \dots(9)$$

Where,

w_{\max} : Initial value of inertia weight,

w_{\min} : Final value of inertia weight,

Iter_{\max} : Maximum iteration number,

Iter : Current iteration number.

IV. PROPOSED PSO FOR ELD PROBLEMS

In this section, a new approach is designed to implement the PSO algorithm in solving the ELD problems. Especially, it is suggested how to deal with the equality and inequality constraints of the ELD problems in the process of modifying each individual's search point in the PSO algorithm. The dynamic process of the PSO algorithm can be summarized as follows:

Step i : Initialization of a group at random

Step ii : Velocity and position update

Step iii : Update of $Pbest$ and $Gbest$

Step iv : Go to step ii until satisfying stopping criteria.

In the subsequent sections, the detailed implementation strategies of the proposed PSO are described.

i) Initialization: In the initialization process, a set of individuals is created at random. The structure of an individual for ELD problem is composed of a set of elements (i.e., generation outputs). Therefore, individual i 's position at iteration 0 can be represented as the vector $X_i^0 = (P_{i1}, \dots, P_{in})$ where n is the number of generators in the ELD problem. The velocity of individual i (i.e., $V_i^0 = (V_{i1}, \dots, V_{in})$) corresponds to the generation update quantity covering all generators. The elements of position and velocity have the same dimension, i.e., MW in this case. Note that it is very important to create a group of individuals satisfying the equality constraint eqn.(4) and inequality constraint eqn.(6). That is, summation of all elements of

individual 'i' (i.e., $\sum_{j=1}^n P_{ij}$) should be equal to the total system demand P_D and the created element j of individual 'i' at random (i.e., P_{ij}) should be located within its boundary. Although the element j of individual 'i', created at random satisfying the inequality constraint by mapping $[0,1]$ into $[P_{min}, P_{max}]$, it is necessary to develop a new strategy to handle the equality constraint. To do this, the following procedure is suggested for any individual in a group:

Step 1: Set $j = 1$.

Step 2: Select an element (i.e., generator) of an individual at random.

Step 3: Create the value of the element (i.e., generation output) at random satisfying its inequality constraint.

Step 4: If $j = n-1$ then go to Step 5; otherwise $j = j+1$ and go to Step 2.

Step 5: The value of the last element of an individual is determined by subtracting $\sum_{j=1}^{n-1} P_{ij}$ from the total system demand P_D . If the value is in the range of its operating region then go to Step 6; otherwise go to Step 1.

Step 6: Stop the initialization process.

After creating the initial position of each individual, the velocity of each individual is also created at random. The following strategy is used in creating the initial velocity:

$$(P_{ij,min} - \varepsilon) - P_{ij}^0 \leq v_{ij} \leq (P_{ij,max} + \varepsilon) - P_{ij}^0 \quad \dots (10)$$

Where ε is a small positive real number. The velocity element j of individual 'i' is generated at random within the boundary. The developed initialization scheme always guarantees to produce individuals satisfying the constraints as well as not to deviate from the concept of the PSO algorithm. The initial P_{best_i} of individual 'i' is set as the initial position of individual 'i' and the initial G_{best} is determined as the position of an individual with minimum pay off of eqn (1).

ii) Velocity Update: To modify the position of each individual, it is necessary to calculate the velocity of each individual in the next stage, which is obtained from eqn(2). In this velocity updating process, the values of parameters such as ω , c_1 , and c_2 should be determined in advance. The weighting function is defined as eqn (9).

iii) Position Modification Considering Constraints: The position of each individual is modified by eqn(3) based on its updated velocity. The resulting position of an individual is not always guaranteed to satisfy the inequality constraints due to over/under velocity. If any element of an individual violates its inequality constraint due to over/under speed then the position of the individual is fixed to its maximum/minimum operating point. Fig.2 illustrates how the position of element j of individual 'i' is adjusted to its maximum when over-velocity situation occurs. The similar strategy is used for individual's position adjustment to its minimum point.

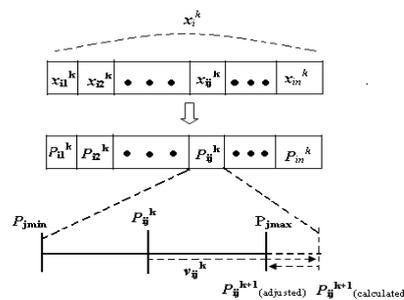

Fig. 2 Adjustment strategy for an individual's position within boundary.

Although the aforementioned method always produces the position of each individual satisfying the inequality constraints given in eqn (6), the problem of equality constraint still remains to be resolved. Therefore, it is necessary to

develop a new strategy such that the summation of all elements in an Individual (i.e., $\sum_{j=1}^n P_{ij}$) is equal to the total system

demand. To resolve the equality constraint problem without intervening the dynamic process inherent in the PSO algorithm, the following heuristic procedures are proposed:

Step 1: Set $j = 1$. Let present iteration be k .

Step 2: Select an element (i.e., generator) of individual i at random and store in an index array $A(n)$.

Step 3: Modify the value of element j (i.e., output of generator j) using eqns.(2) and (3), and the position adjustment strategy to satisfy its inequality constraint as follows:

$$\begin{aligned} P_{ij}^{k+1} &= P_{ij}^k + v_{ij}^{k+1} && \text{if } P_{ij,min} \leq P_{ij}^k + v_{ij}^{k+1} \leq P_{ij,max} \\ &= P_{ij,min} && \text{if } P_{ij}^k + v_{ij}^{k+1} < P_{ij,min} \\ &= P_{ij,max} && \text{if } P_{ij}^k + v_{ij}^{k+1} > P_{ij,max} \end{aligned} \quad \dots (12)$$

Step 4: If $j = n-1$ then go to Step 5, otherwise $j = j+1$ and go to Step 2.

Step 5: The value of the last element of individual i is determined by subtracting $\sum_{j=1}^{n-1} P_{Gij}$ from P_D . If the value is not within its boundary then adjust the value using eqn.(12) and go to *Step 6*, otherwise go to *Step 8*.

Step 6: Set $l = 1$

Step 7: Readjust the value of element l in the index array $A(n)$ to the value satisfying equality condition i.e., $P_D - \sum_{\substack{J=1 \\ J \neq l}}^n P_{ij}$. If the value is within its boundary then go to *Step 8*; otherwise, change the value of element- l using eqn(12). Set $l = l+1$, and go to *Step 7*. If $l = n+1$, go to *Step 6*.

Step 8: Stop the modification procedure

iv) Update of P_{best} and G_{best} : The P_{best} of each individual at iteration $k+1$ is updated as follows:

$$\begin{aligned} P_{best_i}^{k+1} &= X_i^{k+1} && \text{if } TC_i^{k+1} < TC_i^k \\ P_{best_i}^{k+1} &= P_{best_i}^k && \text{if } TC_i^{k+1} > TC_i^k \end{aligned} \quad \dots(9)$$

Where, TC_i is the objective function evaluated at the position of individual ' i '. Also, G_{best} at iteration $k+1$ is set as the best evaluated position among $P_{best_i}^{k+1}$.

v) Stopping criteria: The proposed method is terminated if the iteration approaches to the predefined maximum iteration.

IV. RESULTS AND ANALYSIS

The performance of the proposed PSO algorithm is verified on a test system consisting of 40-units which has been adopted from [15] with modifications to incorporate the effects of valve point loadings. The proposed method is illustrated with two following cases:

- Case -1: Without Valve point effects and
- Case -2: With Valve point effects

At each test system, 50 trials were performed using the proposed method to observe the solution quality, convergence characteristic, and execution time. The PSO parameters used in solving the problem are given in Table-1.

Table 1. PSO parameters and their setting values

PSO Parameters	Setting values
Population size	20
Number of generations	200
Initial weight function, w_{max}	0.9
Final weight function, w_{min}	0.4
Limit of change in velocity of each number in an individual, V_{pd}^{max}	$0.5 P_d^{max}$
Limit of change in velocity of each number in an individual, V_{pd}^{min}	$-0.5 P_d^{min}$
Acceleration constants c_1 and c_2	2

The optimal scheduling and fuel cost comparisons for case-1 & case-2 are given in Table 2. The minimum fuel cost obtained by proposed PSO method for case-1 is 119364.55 \$/hr and by GA is 119683.12 \$/hr. The minimum fuel cost obtained by proposed PSO method for case-2 is 119558.61\$/hr. For case-2, The cost obtained by GA and EP are 119732.25 \$/hr and 123488.29 \$/hr respectively. The convergence characteristics of proposed technique for case-1 and case-2 are shown in fig.3. The results obtained by proposed technique are compared with existing methods and found satisfactorily in terms of execution time and net saving. For case-1, the execution time for proposed PSO technique is 0.98 sec and for existing GA method is 12.52 sec. The net saving in cost by the proposed technique is 318.57 \$/hr when compared to GA. For case-2, the execution time for proposed technique is 1.03 sec and for existing EP method the execution time is 1955.20 sec. The net saving in cost by the proposed technique is 173.64 \$/hr when compared to GA and 3929.68 \$/hr when compared to EP. It is also observed that, the PSO is a very robust and efficient algorithm in terms of control parameters such as the number of particles in a group and condition of initial group generated at random. Although the required number of iterations reacting the global solution is different when the number of particles or the random initial group is changed, the PSO guarantees the convergence to the global solution for the examples taken. It is also observed that the solutions provided by the proposed PSO always satisfy the equality and inequality constraints for all the cases.

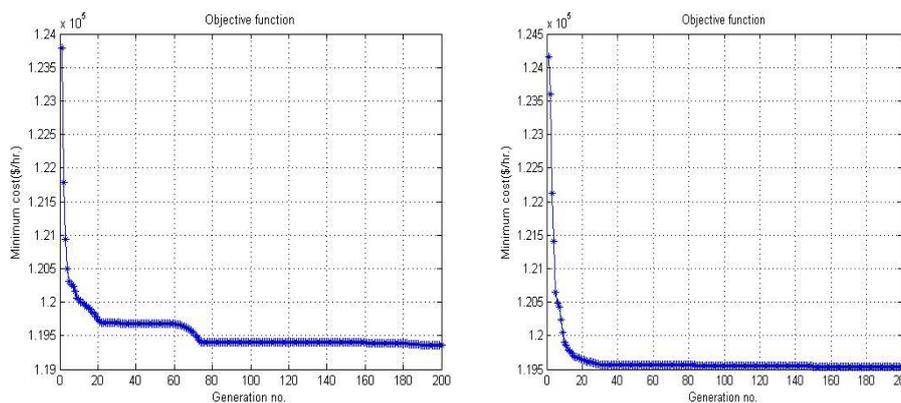

Fig 3 Convergence Characteristics of PSO Algorithm for Case-1 and Case-2 of 40-unit system

V. CONCLUSIONS

In this paper the PSO method is successfully employed to solve the Economic Load Dispatch (ELD) problem with generator constraints and valve point loading effects. The PSO Algorithm has been demonstrated to have superior features, including high quality solutions, stable convergence characteristics and good computation efficiency. The non-linear characteristics of the generator such as valve point loading effects and non-smooth cost functions are considered for practical generator operations in the proposed method. The results show that the proposed method was indeed capable of obtaining higher quality solution efficiently in non-linear, non-convex ELD Problems within a reasonable computation time and iteration numbers when compared to the existing methods given in literature.

About The Authors

***G. Sreenivasan** received his graduation in 1996, Masters in 2001 from JNTUniversity college of Engineering, Anantapur and pursuing Ph.D at JNTUniversity, Kakinada. Presently he is working as Associate Professor in the department of Electrical and Electronics Engineering, Intell Engineering College, Anantapur since 2001. His area of interest is applications of GA and PSO to Power System Operation and Control. He has published research papers in 6 international and 3 national journals and has publications in national and international conferences. He has participated several workshops conducted by various engineering colleges at south India. He authored the text book, "Power System Operation and Control" under the publication of Pearson Education, New Delhi. He is the life member of ISTE and IE.

** **Dr. CH. SaiBabu** received his graduation from Andhra university, Masters from REC, Warangal and Ph.D from JNTU, Hyderabad. He is the Professor in the Department of Electrical and Electronics Engineering and Director of Admissions at JNT University, Kakinada. ABSTRACT: Multi site damage is one of the important aspects to be studied to ensure the safety of the aircraft structure. The rivet hole locations are one of the stress concentration regions. The current study includes a panel which represents the fuselage splice joint. The fuselage splice joint is a location where it experiences the uniform stress field at many rivet locations in a row. This study has relevance in the structural integrity evaluation of aging transport aircraft due to multisite damage. Fatigue cracks will emanate from the rivet holes simultaneously as they experience identical stresses due to internal pressure. In service, the cracks in the fuselage will grow due to internal pressurization load cycling. The objective is to investigate the first failure mechanism out of two competing mechanisms of failure; Failure due to fracture or Failure due to plastic collapse at the net section between two advancing crack tips.

Key words: Fuselage of an aircraft, Fatigue, Net section, Stress intensity factor, finite element analysis

I. INTRODUCTION

The primary objective of the aircraft structure is to carry the required flight loads with as little weight as possible. Today's airplanes use the most advanced lightweight materials and the most advanced structural design and analysis tools to produce the most efficient structures possible.

An ideal aircraft structure would be designed so that every part fails at exactly the same limit load and fatigues at exactly the same number of cycles and these failure conditions are selected, so that they just cannot happen under normal operating conditions. The ideal structure also would have no margin above these conditions because that just means extra weight.

The airframe consists of the fuselage, which is the main component of the airplane. The simultaneous presence of cracks in the same structural element is usually referred to as multi-site fatigue damage. Aging aircraft may develop multiple site fatigue damage that can reduce the structural integrity of fuselage structures.

The recent concept of damage tolerance supposes an aircraft structure to be redundant so that a catastrophic failure should not occur after fatigue failure of a structural element. As a consequence the concept also admits the existence of cracks in the aircraft structure. The probability of crack existence is particularly enhanced in ageing aircraft. In these structures multiple-site damage [1] [2] (MSD) is also more likely to occur. Some examples are frequently referenced, such as the Aloha accident of the Boeing 737, the C5A wing and JAL accident.

The MSD [3] [8] problem is generally associated with a large number of small neighboring cracks located in one line. As a more or less uniform stress field is required for MSD, the cracks mostly originate at the edges of several adjacent and collinear fastener holes in longitudinal skin splices [4] of a pressurized fuselage structure. They occur at the same time, grow and can suddenly coalesce to form a single critical crack, which can lead to a catastrophic failure of the structure. The critical size of the individual cracks can be relatively small, even less than the length easily detected during visual in-service inspections. With MSD the fatigue crack growth and fracture characteristics are significantly different from the characteristics of the isolated cracks. The fatigue lifetime becomes shorter than that of a single-site crack having the same length.

The existence of small cracks emanating from adjacent rivet holes in a fuselage [5] lap splice joint is of major concern. Small collinear cracks greatly reduce the residual strength of a panel with a lead crack.

Thus there is a need to conduct detailed fracture analysis of the crack link up phenomenon in butt-splice joints and Z-stiffener with rivet-loaded fasteners.

Multiple Site fatigue Damage (MSD) – as in the Aloha Airlines Boeing 737 – where fatigue cracks occur at many locations in the same structural element, such that fatigue cracks may coalesce to form one large crack. Failure of specimen [1] due to MSD is shown in the fig. 1

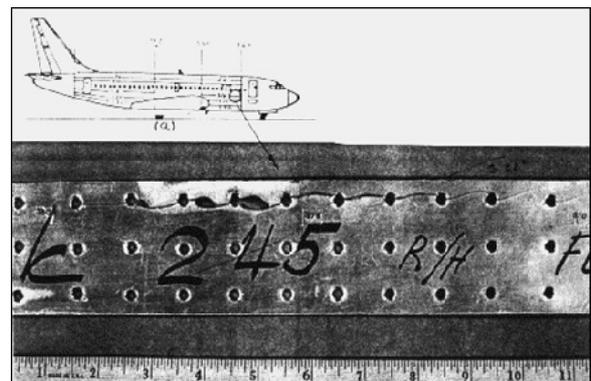

Figure 1: Multi-site damage (MSD) at a B-737 fuselage lap joint [1].

II. MATERIAL USED

Material used for the analysis of fuselage splice joint is Aluminum 2024 –T3 and its composition and properties are given in Table 1 and Table 2.

Table 1: Material compositions

COMPONENT	WEIGHT PERCENTAGE
Aluminum	90.7-94.7
Chromium	Max 0.1
Copper	3.8-4.9
Ferrous	Max 0.5
Magnesium	1.2-1.8
Manganese	0.3-0.9
Titanium	Max 0.15
Zinc	Max 0.25
Other, Total	Max 0.15

Table 2: Material Properties in Al 2024-T3

Properties	Material Aluminum 2024-T3
Density	27.27 N/mm ³
Ultimate Tensile Strength	483 N/mm ²
Tensile Yield Strength	362 N/mm ²
Modulus of Elasticity	72000 N/mm ²
Poisson's Ratio	0.33
Fracture Toughness	98.90 MPa√m

III. GEOMETRICAL CONFIGURATION

The first step is to understand the complex loading conditions in a fuselage structure. The pressurization of the fuselage causes the structure to expand outward like simple balloon. This expansion creates the hoop stress in the circumferential and an axial stress in the longitudinal direction. Due to this complexity in structure, loading conditions and test set-up simplification to simpler test specimen is required.

With full pressurization, the skin and underlying structure will move outward. It is not too difficult to see that a frame or stiffener will not move the same distance as the skin would due to higher local stiffness, thus creating differences in outward movements and higher hoop stresses in the skin between the frames.

Setting up a test as large as a full-scale aircraft structure requires an enormous amount of time and money. Reducing full scale-test to a more simple, easier to understand test specimen such as barrel or fuselage panel including stiffeners and frames reduces the size of the test. Elimination of the stiffeners, frames and curvature reduces the structure to flat sheet longitudinal splice and circumferential butt joints.

The global analysis of the structure is carried out to find the stress distribution. Riveted connection is the common feature in the built up airframe structure. The fatigue crack will initiate from the locations of the maximum tensile stress. The rivet hole locations are one of the stress concentration regions. Therefore rivet hole locations are the most probable location for the fatigue crack initiation.

The fuselage splice joint with Z-Stiffener is the location where it experiences the uniform stress field at many rivet locations in a row. Therefore fine meshing is done at the splice joint with Z-stiffener location to achieve the exactness of the stress and the riveting is being done by 1D element for global model of the fuselage.

Local panel is the sectional cut out of the fuselage to do stress analysis by validating local panel with hoop stress obtained from local panel is equal to the hoop stress obtained from the global model, so by this way we can reduce the time consumed for analysis without compromise on the result variation.

Local panel with rivet holes are next step after the local panel with 1D rivet element, for our problem rivet holes should be there for crack initiation and crack propagation. Here also the hoop stress is validated with global model by applying same uniformly distributed tension load for local panel with rivet holes. So at the rivet holes in the direction of load transfer, the multiple points of semicircle are constrained to transfer the load to obtain the uniform load distribution on the semicircle of the rivet holes in direction of load, which is obtained in practical rivets on the rivet holes. So, it confirms that except at rivet holes, the remaining part of the panel is having the same hoop stress as obtained for global model of the fuselage.

IV. STRESS ANALYSIS

The global analysis of the structure is carried out to find the stress distribution. The fatigue crack will initiate from the locations of the maximum tensile stress. The rivet hole locations are one of the stress concentration regions. Therefore rivet hole locations are the most probable location for the fatigue crack initiation.

4.1. LOAD CALCULATIONS AND GLOBAL MODEL DIMENSIONS FOR THE FUSELAGE

- Length of the fuselage(L) = 2500 mm
- Radius of the fuselage(R) = 1600 mm
- Width of the splice plate(b) = 70 mm
- Length of the splice plate(L) = 2500 mm
- Thickness of the fuselage skin(T) = 1.8 mm
- Thickness of the splice plate(t) = 2 mm
- Diameter of the Rivet Hole(d) = 4.8 mm
- Internal pressurization(P_r) = 0.06695 N/mm²

Both the ends of fuselage are constrained for rotation and translation and internal pressurization is applied.

Hoop stress = (P_r × D) / (2 × T) ----- (1)

Hoop stress (σ_h) = (0.06695 × 3200) / (2 × 1.8)

Hoop stress (σ_h) = 59.51 N/mm²

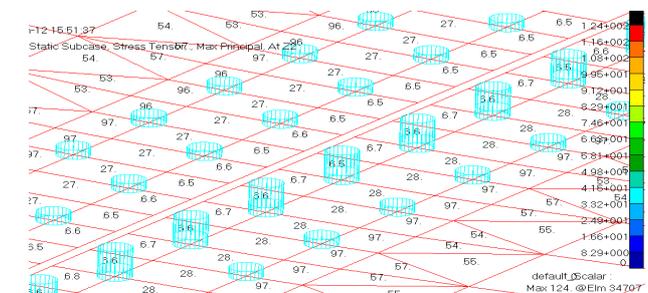

Figure 2: stresses are maximum at rivet holes in global model of the fuselage for 1D rivet element

It can be observed from the Figure 2 that the stress is distributed uniformly and the maximum stress is experienced in the riveted splice joint region for global model for 1D rivet element.

4.2. STRESS ANALYSIS OF THE LOCAL PANEL

A local analysis was done which represents the fuselage splice joint panel. Loading and boundary conditions for the local analysis of the panel are

Length of the panel =1200mm
 Width of the panel =500mm

The total tension load [9] acts on the fuselage structure from the global analysis is found as 53559.47 N. This total load is converted into uniformly distributed load (UDL) and applied at the top side of the panel. Uniformly distributed load of 107.12 N/mm was applied at top end of the plate and other end is fixed. A two dimensional linear static stress analysis is carried out using finite element analysis software tool. Mesh independent stress magnitudes are obtained through iterative mesh refinement process. Aluminum 2024-T3 is well-known aluminum alloy is used for the panel analysis.

It can be observed that the same Hoop stress value is experienced in both global and local analysis by applying same boundary conditions. Even the rivet loading are similar in both the cases. This is the indication to proceed further.

Large structures are usually assemblies of smaller parts are joined together by the variety of production techniques. There are two important joining methods namely; adhesive bonding and mechanically fastening. Mechanically fastened joints are an interesting subject to investigate. The present investigation focuses on solid rivets installed in aluminum plate. The expansion of solid rivet in the rivet hole is important with respect to the fatigue properties of joints. In reality rivet holes will be present. So the stress analysis of panel with rivet holes was carried out with the same applied boundary conditions by adapting multipoint constraint (MPC) at rivet holes as shown in Figure 3.

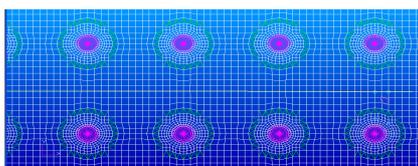

Figure 3: Meshed panel with riveted loading with MPC

V. CRACK ANALYSIS AT THE RIVETED HOLE LOCATION

CALCULATION OF SIF FOR 20 mm PITCH RIVET HOLE

Thus the periodic increase of crack lengths has applied for the panel. By applying same boundary conditions as the stress analysis has been carried out. Near the crack tip the stress intensity factor values are calculated for all the elemental crack length of 20mm pitch rivet hole.

Around the riveted hole section fine meshing has been done with quad4 a 2D elements will results the accurate stress values.

Stress Intensity Factor (SIF), $K = \sigma_R \sqrt{\pi a}$

Where, σ_R = Remote stress in N/mm² and 2a = Crack length in mm

By using FEA and Modified Virtual Crack Closure Integral (MVCCI) [6-7] method:

$$K = \sqrt{G \times E}$$

Where, G = strain energy release rate and E = Young's modulus of elasticity in N/mm²

$$G = \frac{(\Delta v \times f)}{2 \Delta a \times t}$$

Where, Δa =Element edge length at the crack tip in mm, Δv =Crack opening displacement in mm, f = Force at the crack tip in N and t =Skin thickness in mm

Considering the following analysis for 3rd iteration of 7.5mm crack length of 20 mm pitch rivet hole, where the SIF (k) for mode I can be calculated as

$$K = \sqrt{G \times E}$$

$$K = \sqrt{(0.015 \times 438 \times 72000) / (2 \times 0.45 \times 1.8)}$$

$$K = 540.37 \text{ MPa}\sqrt{\text{mm}}$$

$$K = 17.1 \text{ MPa}\sqrt{\text{m}}$$

MVCCI procedure is used for calculating the stress intensity factor. Similarly for all crack lengths and for different pitch holes, the stress intensity factor values has been calculated and compare those values with the fracture toughness of the material, where the fracture toughness of the material is 98.90 MPa√m. once the stress intensity factor value reaches the fracture toughness of the material then it leads to failure through fracture. This is one mode of failure. The other mode of failure is the structure with stress concentration may fails by net section yielding due to local yield at the crack tip. The average stress value between the two advancing crack tips will be compared with the yield strength of the material, where the yield strength of the material is 362 N/mm².

VI. STUDY OF NET SECTION FAILURE

The net section is the region or cross sectional area available between two rivet holes to carry whatever the load the component has to transfer. Due to rivet holes the stress concentration will be more around the rivet holes and also fatigue load will be acting for fuselage skin due to pressure variation, which tends to initiate the crack at the rivet hole edges perpendicular to the direction of the load acting.

Since the pressure variation occurs inside the fuselage according to altitude at which aircraft flies, there will be an uniform load acting on the component due to pressure variation, which in turn causes the growth of cracks in all the rivet holes simultaneously called as MSD.

So, as and when crack grows simultaneously in all the rivet holes, the net section available between the two crack tips will be reducing to carry the required load and at certain crack length if the stress intensity factor of the crack reaches the fracture toughness value of the component, then the component will fail due to fracture leading to bigger crack. But the failure may also occur due to plastic collapse [9] as the crack grows, at the tip of the crack the stress concentration will be more and before propagation there

will be local yield around the crack tip, when the plastic deformation at the two advancing crack tips towards each other coalesce, then the catastrophic failure occurs due to plastic deformation leading to bigger crack.

VII. CRACK TIP PLASTICITY

Under linear elastic fracture mechanics assumptions, the stress at the crack tip is theoretically infinite. Clearly, all materials have a finite strength, thus there will always be a small plastified zone around the crack tip.

If this zone is small compared to the crack size, then our linear elastic assumptions are correct, if not, LEFM is not applicable (thus it would be incorrect to use a *K* or *G* criterion) and a nonlinear model must be used. This damaged zone is referred to as a plastic zone for metals.

The appearance of the plastic zone at the tip does not allow its material to bear high stresses predicted by the elastic analysis. Also the material is soft in front of the crack tip and therefore the effective crack length is longer than the actual.

In fact, owing to the presence of the plastic zone, the stiffness of the component decreases. Consequently, the crack is equivalent to a length that is longer than actual length. The size of the plastic zone in front of the crack tip determines the effective crack length.

Therefore, considerable efforts have been made by many investigators such as Irwin plastic zone approach and Dugdale plastic zone approach to determine the plastic zone size and effective crack length.

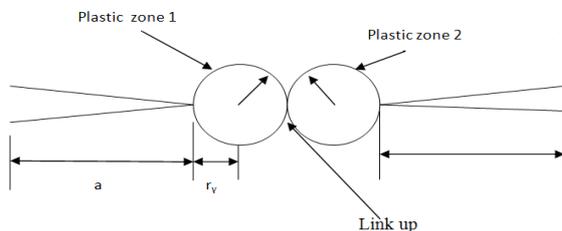

Figure 4: plastic zone around the crack tip

The net section plastic collapse is applied considering the crack sizes. As at each crack tips, the effective crack length is more than the actual crack, there will be plastic zone around the crack tip as shown in Figure 4. As these plastic zone approach each other as crack grows and at certain crack length these two crack length will link up to form the plastic collapse [10] and becomes a bigger crack. The Net section yielding stresses for the presence of multiple cracks are calculated based on the asymptotic formula for stresses near a crack tip, based upon the Irwin and Dugdale formulas [12-14].

Irwin formula

$$r_y = \left(\frac{1}{2 \times 3.14}\right) \times (K/\sigma_y)^2 \text{ ----- (2)}$$

Dugdale Formula

$$r_y = \left(\frac{3.14}{8}\right) \times (K/\sigma_y)^2 \text{ ----- (3)}$$

where, σ_y is the yield stress and r_y is the plastic zone radius.

7.1. CALCULATION OF NET SECTION YEILDING

The local panel taken for the net section failure calculation will have the same dimensions as given for the SIF calculation with same loads and boundary condition. For the different crack lengths the stress intensity factor was calculated, also for the same crack length, net section yielding will be calculated between two advancing crack tips by taking an average value of the elemental stresses obtained between the two crack tips and it is compared with the Irwin formula for validating the average elemental length for plastic zone and its stresses.

Since, the elemental stress at the crack tip will be higher and gradually decreases as moved away from the crack tip and it attains least value at centre in-between the crack tips. The average values of all the elemental stresses are then compared with the yield strength of the material Al 2024-T3 is 362 N/mm².

7.2. NET SECTION YIELDING FOR THE 20 MM PITCH RIVET HOLE

The net section yielding for the 20 mm pitch rivet hole is calculated by taking average of elemental stresses between two crack tips for each iteration in increasing order of crack lengths.

For the crack length of 12 mm, the average of elemental stress is $\sigma_{avg} = 312 \text{ N/mm}^2$

therefore, $\sigma_{avg} \leq \sigma_y$

From Irwin plastic zone formula, we have

$$K_I = 425.351183 \text{ MPa}\sqrt{\text{mm}}$$

$$\sigma_y = 362 \text{ N/mm}^2$$

From equation (1), one can obtain

$$r_y = (1/(2 \times 3.14)) \times (425.351183/362)^2$$

$$r_y = 0.219845 \text{ mm}$$

Since, problem requires only the length of the plastic zone. So, one can add actual crack length and plastic zone length Therefore,

$$a_{effective} = a + 2r_y$$

$$a_{effective} = 2.85 + (2 \times 0.219845) = 3.28969 \text{ mm}$$

but, actual crack length,

$$a = 2.85 \text{ mm}$$

therefore,

$$a_{effective} \geq a$$

The above values indicate that the plastic zone is increasing as crack grows, which is an indication of the plastic deformation.

Similarly, effective plastic length and net section yielding for other crack lengths for different pitch rivet hole distances such as 25mm and 30mm are tabulated below in the Table 3, Table 4 and Table 5.

Table 3: Net section average stress and effective crack length for plastic collapse for 20 mm pitch rivet hole

VIII. RESULTS AND DISCUSSIONS

8.1. RESULTS AND DISCUSSIONS OF SKIN FOR 20MM PITCH RIVET HOLE

The stress intensity factor value is calculated for periodic increase of crack length. For each crack length, the stress intensity factor value is compared with the fracture

toughness of the material. Table 3 shows the results of stress intensity factor values for periodic increase of crack lengths. The graph in the Figure 5 shows the crack analysis result which is obtained for crack length versus stress intensity factor value. The distance between two rivet hole edges are 15.2mm, from the result, it is found that at the half crack length of 6.5 mm the stress intensity

factor value does not reaches the fracture toughness value of the material, where the material does not leads to failure through fracture. In figure 5. the graphical view is shown clearly.

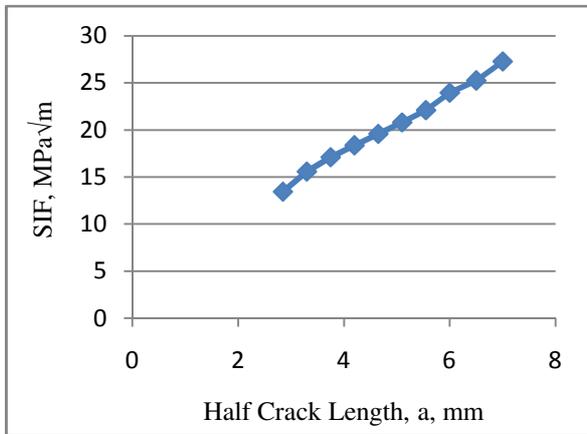

Figure 5: SIF graph for 20mm pitch rivet hole

Similarly the net section yielding calculations are done by means of taking the average stress value between the two advancing crack tips and it is compared with the yield strength of the material. Table 3 shows the results of net section yielding for periodic increase of crack lengths. From the result, it is found that at the crack length of 14 mm the has material crossed the yield strength value of material, where it leads to material yielding failure. The following Figure 6 shows the graph of net section yielding result which is plotted for crack length versus average yield stress of the material for different crack lengths.

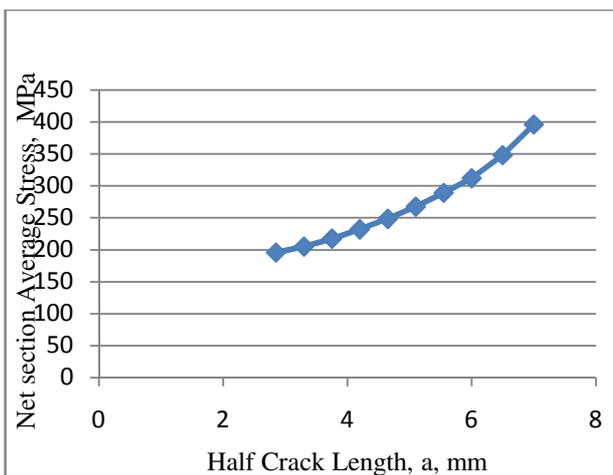

Figure 6: Net section yielding graph for 20mm pitch rivet hole

So from the analysis it is came to know that the structure with stress concentration will fail by net section yielding. Similarly, the results for 25 mm and 30 mm pitch rivet hole, the graphical representation values are given in the Figure 7, Figure 8, Figure 9 and Figure 10.

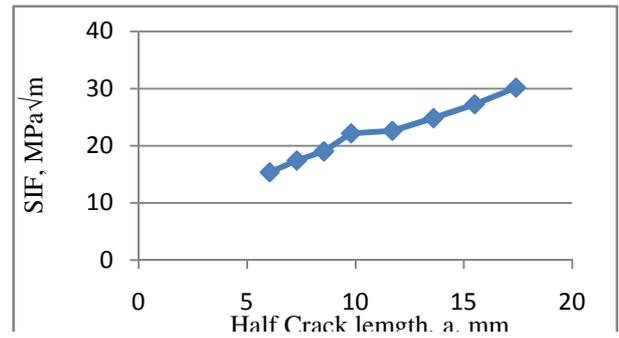

Figure 7: SIF graph for 25mm pitch rivet hole

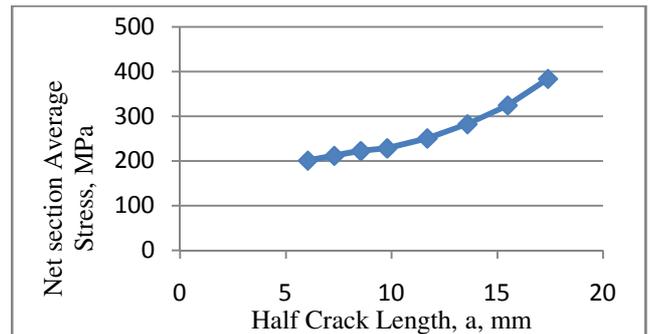

Figure 8: Net section yielding graph for 25mm pitch rivet hole

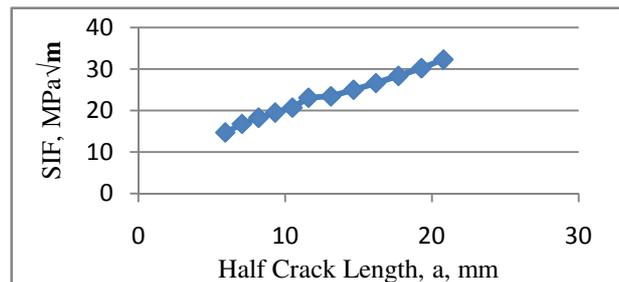

Figure 9: SIF graph for 30mm pitch rivet hole

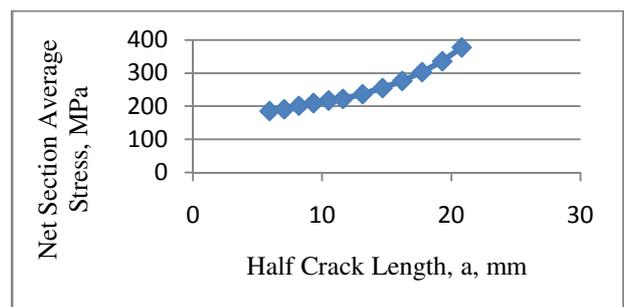

Figure 10: Net section yielding graph for 30mm pitch

IX. DISCUSSIONS

The results of the Net section failure have been discussed in the previous section; from that one can understand that, if the component has a crack, it does not mean that it should fail by fracture. From results of current study, one can understand that the component will fail by plastic collapse even if it has crack.

Also, one can observe that if the distance between rivet holes are increasing net section failure will also occur for bigger cracks. Due to fatigue loading, the net section

yielding is more susceptible to failure than the fracture failure. So, one should not concentrate only on fracture during design and inspection of a component at what crack length the component will fail, one should concentrate also on plastic deformation which occurs due to fracture.

X. CONCLUSIONS

The static stress analysis of the fuselage of a transport aircraft has been performed in the presented work. This study has relevance in the structural integrity evaluation of aging transport aircraft due to multisite damage. Here the MSD analysis was carried out for the aged aircraft.

In the present work only the fuselage with splice through butt joint has been analyzed. Fatigue loads due to internal pressurization acting on the fuselage, stress concentration will be high at rivet holes locations of the fuselage joint, which causes the initiation of cracks on all rivet hole edges due to uniform stress acting on the fuselage due to internal pressurization.

Usually the fuselage of the aircraft structure is subjected to different kinds of loads that include aerodynamic loads, landing loads, taxing loads, pressurization and reaction loads. The present study deals only with MSD, so the loads considered are only internal pressurization.

Taking all the above points into consideration modeling and finite element analysis of fuselage and its local segment was carried out and from that work, some of the information's are concluded as follows

- The Fuselage model was created using a 3D modeling software tool according to the dimensions and the 3D modeled component was imported to analysis tool for pre-processing. The fuselage component was meshed with 2D elements such as quad 4 and Tria 3 elements and loads and boundary conditions were applied.
- The material used was Al 2024-T3, which is widely used in aircraft industry for its good fatigue strength and corrosion resistance.
- Stress analysis of the global model of the fuselage has been carried out to observe the hoop stress on skin is equal to the analytical value of the hoop stress 59.5 N/mm^2 .

Abstract: Wind energy is a viable option to complement other types of pollution-free generation. In the early development of wind energy, the majority of wind turbines were operated at constant speed. Recently, the number of variable-speed wind turbines installed in wind farms has increased and more wind turbine manufacturers are making variable-speed wind turbines.

A wind turbine model for control purposes needs to be based on linear mathematical models. The modeling of the wind turbine is based on certain aerodynamic phenomena (lift and drag) caused by the interaction of the rotor blade of the wind turbine and wind. The modeling of the wind turbine for control purposes involves the modeling of the relevant dynamics that affect the production of power and the stability of the wind turbine. This involves the rotor, the tower, the drive train, generator and the pitch actuator. The resulting non-linear model is then linearised at different working points. The linear model will be used for a rotor speed control algorithm.

This paper analysis the modelling of variable speed wind turbines with active pitch control and active stall control.

I. Introduction

Wind is a form of solar energy. Winds are caused by the uneven heating of the atmosphere by the sun, the irregularities of the earth's surface, and rotation of the earth. Wind flow patterns are modified by the earth's terrain, bodies of water, and vegetative cover. This wind flow, or motion energy, when "harvested" by modern wind turbines, can be used to generate electricity. The terms "wind energy" or "wind power" describe the process by which the wind is used to generate mechanical power or electricity. Wind turbines convert the kinetic energy in the wind into mechanical power. This mechanical power can be used for specific tasks or a generator can convert this mechanical power into electricity.

To successfully convert the kinetic energy of wind into electrical energy, the wind turbine is equipped with a control system that ties the operation of all the subsystems of the wind turbine together. A wind turbine is always designed for specific rated conditions. By rated conditions here we mean rated wind speed, rated rotor speed and rated power. A wind turbine is designed to generate rated power which is the maximum power that the generator is designed to deliver (for example a wind 750i wind turbine is designed to generate a maximum of 750 KW). The speed of the rotor

when the rated power is generated is known as rated rotor speed and the corresponding velocity of the wind is known as rated wind speed. But wind is stochastic (random or probabilistic but with some direction) in nature. Hence it is not always possible to obtain rated conditions for a wind turbine. Hence it is necessary to control the wind turbine in order to increase energy production and realize a long lifetime.

When the velocity of the wind is below the rated wind speed then it is known as below rated wind speed, and when the velocity is more than rated then it is known as above rated windspeed. All wind turbines are designed with some sort of power control. There are different ways to control aerodynamic forces on the turbine rotor and thus to limit the power in very high winds in order to avoid damage to the wind turbine.

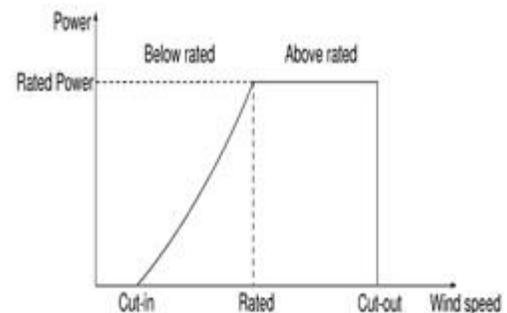

Figure 1 Power Generation as a function of Wind Speed

It is clear from figure 4 that there are two regimes of control, below rated and above rated and the two regimes have different control objectives. Two major systems are used to control wind turbine as follows:

1. For below rated (Generator Torque Control), This control system uses power electronic controller to maximize energy capture by adjusting rotor speed to follow wind speed variations.

Control Law:

$$Q = \frac{Prated}{(\omega_{gen} \cdot \eta_{gen})} \quad 1.1$$

2. For above rated (Blade Pitch Control) vary rotor speed and pitch angle to regulate load and maintain power production at rated value. Blade Pitch Control changes the orientation of blades to change the aerodynamic forces.

It should be noted that wind is a stochastic input. Hence the overall wind speed measured can be defined as a sum of mean wind speed and turbulence. The rotor speed is

always proportional to the mean wind speed. Hence for control purposes the rotor speed is taken as input and wind is considered as a disturbance (at above rated conditions).

II. Active stall control

Active stall control is the combination of stall and pitch control. It has the same regulated properties as in the pitch regulated turbines but has the stall properties of blade. The blades are designed same way as in stall control, but the entire blade can be turned to 90° to adjust its pitch. Thus blade tip brakes are not required as in passive stall control. The idea is to pitch the blade gradually with negative pitch angle in order to increase the performance of blades over a wide range of wind speeds especially with low wind speed. It is found that only small changes of pitch angle are required to maintain the power output at rated, so pitch rates do not need to be as large as in active pitch control. Moreover, full aerodynamic braking requires pitch angles of only about -20° , so the travel of the pitch mechanism is very much reduced compared with positive pitch control. Active Stall control system compares the electric power output of the generator with its reference value which is defined in accordance with the incoming wind and sets the blade angle to minimize the error.

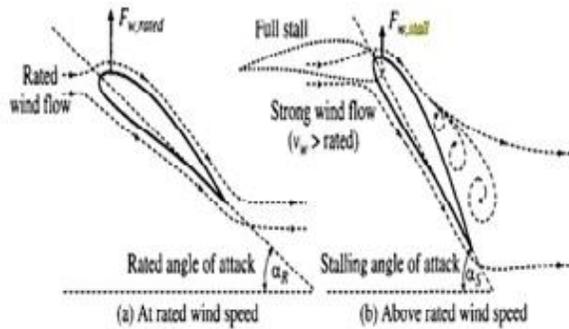

Figure 2 Active Stall Control at rated and above rated speed

The stall phenomenon can be induced not only by higher wind speed but also by increasing the angle of attack. Thus active stall turbine has adjustable blades with a pitch control mechanism. When the wind speed exceeds the rated the blades are controlled to turn more into the wind, leading to reduction of capture power. The captured power thus be maintained at the rated by adjust the blade angle of attack.

One of the advantages of active stall is that one can control the power output more accurately than with passive stall, so as to avoid overshooting the rated power of the machine at the beginning of a gust of wind. Another advantage is that the machine can be run almost exactly at rated power at all high wind speeds.

2.2 Active pitch control

Power limitation in high winds is typically achieved by using pitch angle control. This action, also called active-pitch control (or **pitch-to-feather**), corresponds to changing the pitch value such that the leading edge of the blade is moved into the wind (increase of β), thus inducing blade feathering

effect. The range of blade pitch angles required for power control in this case is large, about 35° from the pitch reference. Therefore, for limiting power excursions, the pitching system has to act rapidly, with fast pitch change rates, i.e., $5^\circ/s$. Therefore, one could expect large gains within the power control loop. The power control structure employed is the same as for the active-stall control machines. Figure 3 shows the effect of pitch control on power flow in wind turbine generation.

1. Pitch Control At Standstill

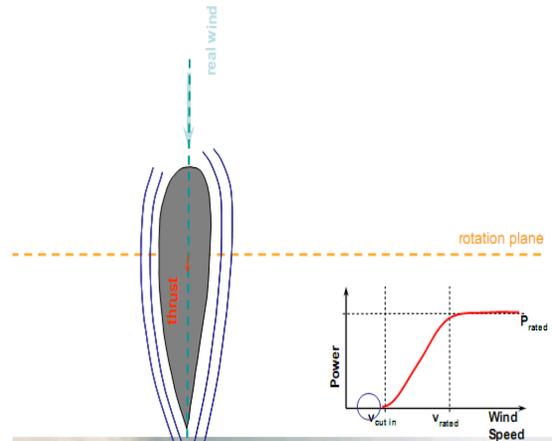

Figure 3 (a) Pitch Control At Standstill

2. Pitch Control At Start of operation

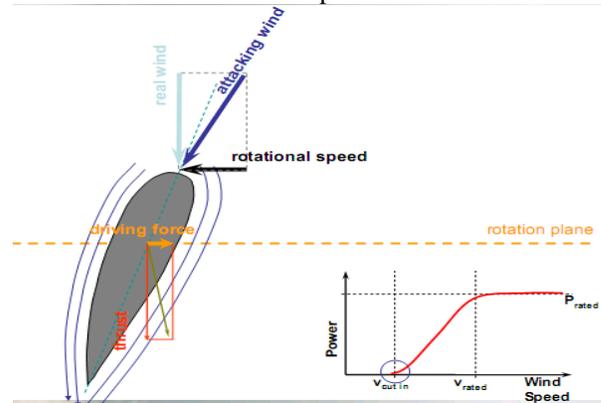

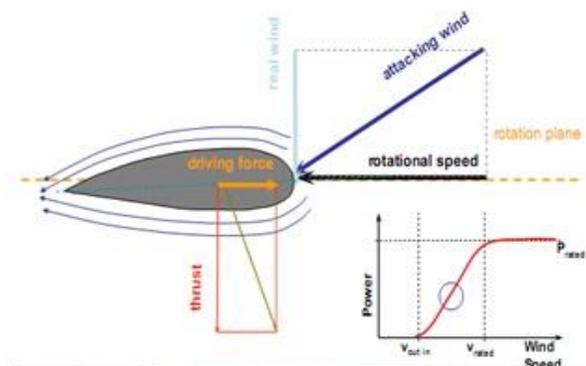

Figure 3 (b) Pitch Control At Start of operation

3. Pitch Control At Power Generation

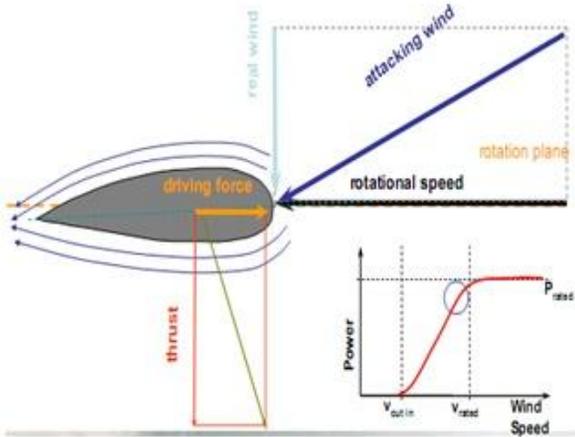

Figure 3(c) Pitch Control At Generation of power

4. Pitch Control At Power Limitation

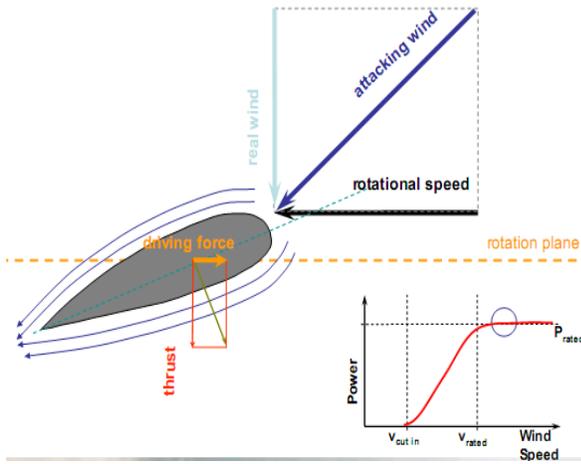

Figure 3(c) Pitch Control At Power Limitation

With pitch control, the power captured, $P_{captured}$, from the wind power P_{wind} can be controlled by a pitch actuator. The acceleration and deceleration is the result of the

3.1 Rotor Modelling of Variable Speed Turbine

The fundamental dynamics of this variable-speed wind turbine are captured with the following simple mathematical model

$$J_T \dot{\omega}_T = Q_A - Q_E \quad 2.1$$

- J_T = Moment of Inertia of Turbine Rotor
 - ω_T = Angular Shaft Speed
 - Q_A = Aerodynamic Torque
 - Q_E = Mechanical Torque necessary to turn on the generator.
- Aerodynamic torque is represented by

$$Q_A = \frac{\rho}{2} A_{wt} R C_p(\lambda, \beta) v_w^2 \quad 2.2$$

- ρ = Air density (kg/m^3)
- C_p = Performance coefficient
- λ = Tip speed ratio vt/vw
- β = Pitch angle (in degrees);
- A_{wt} = Swept area (m^2)

R = Rotor Radius

The following well-known algebraic equation gives the relation between wind speed and mechanical power extracted from the wind (Heier, 1998; Patel, 2000):

$$P_{wt} = \frac{\rho}{2} A_{wt} C_p(\lambda, \beta) v_w^3 \quad 2.3$$

P_{wt} = Power extracted from the wind in watts

The following general equation to describe the rotor of variable-speed wind turbines

$$C_p(\lambda, \beta) = C_1 \left(\frac{C_2}{\lambda_i} - C_3 \beta - C_4 \beta^{c_5} - C_6 \right) \exp\left(\frac{-C_7}{\lambda_i}\right), \text{ where}$$

$$\left[\left(\frac{1}{\lambda + C_8 \beta} \right) - \left(\frac{C_9}{\beta^3 + 1} \right) \right]^{-1} \quad 2.4$$

The structure of this equation originates from Heier (1998). However, the values of the constants c_1 to c_9 have been changed slightly in order to match the manufacturer data.

Table 1 includes both the original parameters and the parameters used here.

Power Co efficients	C_1	C_2	C_3	C_4	C_5
Heier	0.5	116	0.4	0	-
Variable Speed Wind Turbine	0.73	151	0.58	0.002	2.14
Power Co efficients	C_6	C_7	C_8	C_9	C_6
Heier	5	21	0.08	0.035	5
Variable Speed Wind Turbine	13.2	18.4	-0.02	-	13.2

Table 1 Approximation of power curves

High-frequency wind speed variations are very local and therefore even out over the rotor surface, particularly when wind turbines become larger. To approximate this effect, a low-pass filter is included in the rotor model.

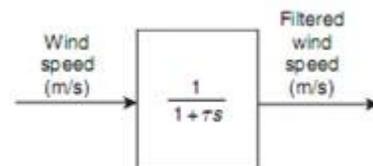

Figure 4: Low pass filter to even out high frequency wind speed

3.1 Unified Power control structure for active pitch and active stall control

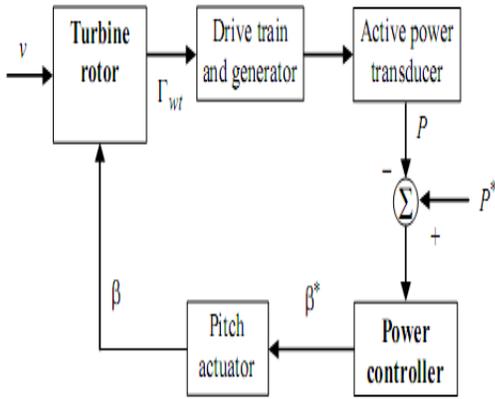

Figure 4 Power Control structure

Power limitation in high winds is typically achieved by using pitch angle control. This action, also called active-pitch control (or pitch-to-feather), corresponds to changing the pitch value such that the leading edge of the blade is moved into the wind (increase of β), thus inducing blade feathering effect. The range of blade pitch angles required for power control in this case is large, about 35° from the pitch reference. Therefore, for limiting power excursions, the pitching system has to act rapidly, with fast pitch change rates, i.e., $5^\circ/s$. Therefore, one could expect large gains within the power control loop. The power control structure employed is the same as for the active-stall control machines.

Active-stall control (also called negative-pitch control) reduces the aerodynamic power by diminishing the blade pitch angle, β , in order to increase the incidence angle. The blades are pitched towards stall, in the contrary direction to the pitch-control case, by turning the leading edge downwind. Only small changes of pitch angle are required to maintain the power output at its rated value, as the range of incidence angles required for power control is much smaller in this case than in the case of pitch control. Compared to the pitch-to-feather technique, the travel of the pitch mechanism is very much reduced; significantly greater thrust loads are encountered, but the thrust is much more constant, inducing smaller mechanical loads. The employed power control structure is briefed in Figure 4

3.2 Pitch Servo

In variable-pitch wind turbines, the blade angle is controlled by a pitch servo. The main control system produces a blade reference angle and the pitch servo is the actuator, which actually turns the turbine blades to the ordered angle. The pitch servo is subject to constructional limitations, such as angular limits β_{min} and β_{max} . That means that the blades can only be turned within certain physical limits. For active-stall-controlled wind turbines, the permissible range will be between -90° and 0° (or even a few degrees to the positive side), whereas for active pitch-controlled wind turbines the permissible range will lie between 0° and 90° (or even a few degrees to the negative side). The control system may impose

other, normally narrower, limits on the reference angle, though. Likewise, there are limitations on the pitch speed, $d\beta/dt$. The pitch speed limit is likely to be higher for pitch-controlled wind turbines than for active-stall-controlled wind turbines, which have a higher angular sensitivity. The pitch speed limit may differ significantly for a positive $d\beta/dt_{pos, max}$ and negative $(d\beta/dt_{neg, max})$ turning of the blade. The pitch speed is normally less than 5° per second, although the pitch speed may exceed 10° per second during emergencies.

The dynamic behaviour of the pitch actuator operating in its linear region is described by the differential equation

$$\dot{\beta} = \left(\frac{1}{\tau} \beta - \frac{1}{\tau} \beta_d \right) \quad 3.1$$

β_d = Desired Pitch Angle

β = actual Pitch angle.

in laplace domain as follows

$$\dot{\beta}(s) = H_{pt}(s) \cdot \dot{\beta}^*(s) \quad 3.2$$

$$H_{pt}(s) = \frac{e^{-(T_d^{ptv} + T_d^{ptx})s}}{\left(\frac{1}{(\omega_o^{pt})^2 s^2 + \frac{2\beta_{pt}}{\omega_o^{pt}} s + 1} \right)} \dot{\beta}^*(s) \quad 3.3$$

T_d^{ptv} = The conditional delay time to overcome Coulomb friction

$T_d^{ptx}, \omega_o^{pt}, \beta_{pt}$ equivalent system parameters

which represent the overall pitch actuation delay during normal operation: pitch delay time, pitch system eigen frequency, damping rate.

There are two modes of control while controlling the wind turbine.

- Below rated wind speed control
- Above rated wind speed control

3.2.1 Below rated wind speed control

Pitch and torque control are used at below rated conditions to generate as much power as possible. To ensure as much as possible energy yield, during partial load the electric torque set point is set such that the tip speed ratio, λ , is maintained at its optimal value, λ_{opt} . with the optima tip speed ratio, $\lambda_{opt}, \lambda_{opt} = \lambda \parallel C_p = C_{p, max}$ 3.2

The rotor speed is adjusted proportional to the wind speed by electric torque control, in such a way that the aerodynamic power extracted by the rotor (efficiency) is maximal.

Simulation Control structure for below rated Speed

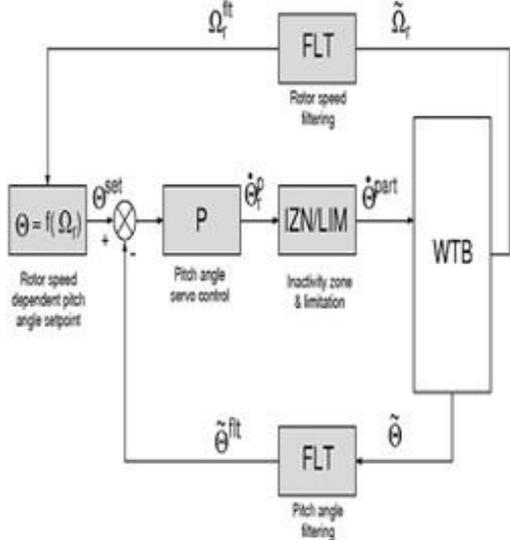

Figure 5 Below Rated Wind Speed Control

3.2.1 Above rated wind speed control

Design of an algorithm to control rotor speed above rated wind speed as follows pitching the rotor blades simultaneously in feathering direction. The ‘constant power’ control of the generator and the rotor inertia (fly wheel) will then establish good power quality. For this reason aerodynamic torque variations will result in rotor speed variations. The amount of rotor speed variation above its rated value, to maintain rated power, is restricted both by the maximum speed of the generator and perhaps by the tower eigen frequency to avoid tower resonance.

Simulation Control structure for above rated Speed

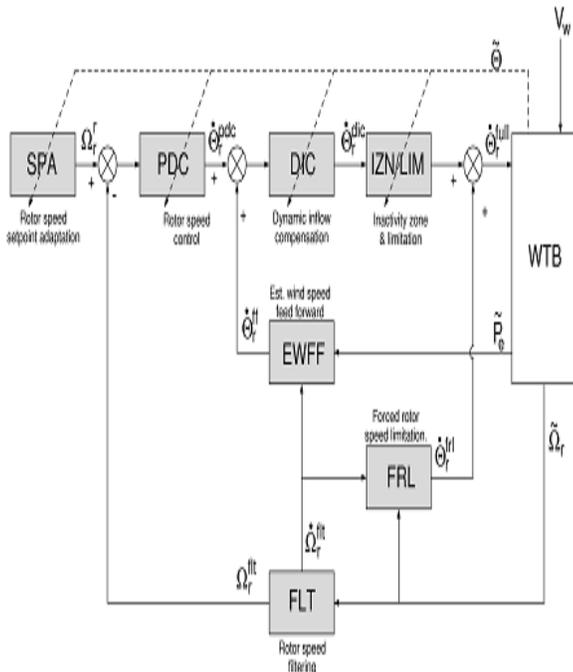

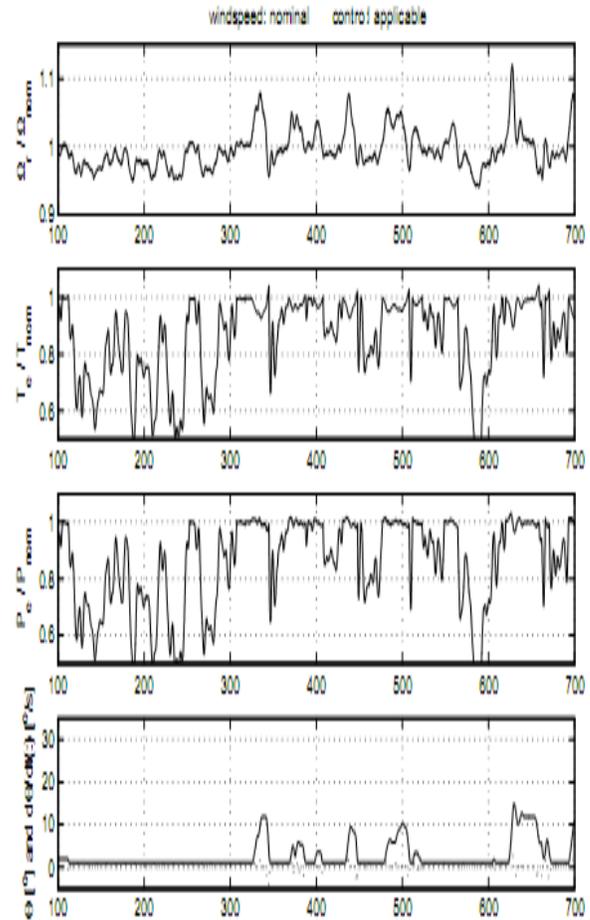

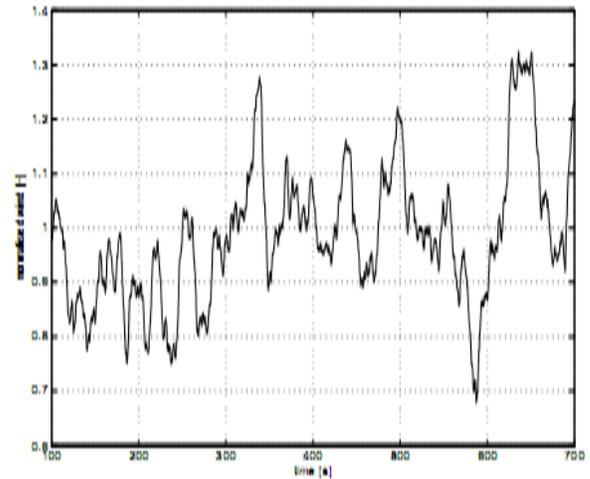

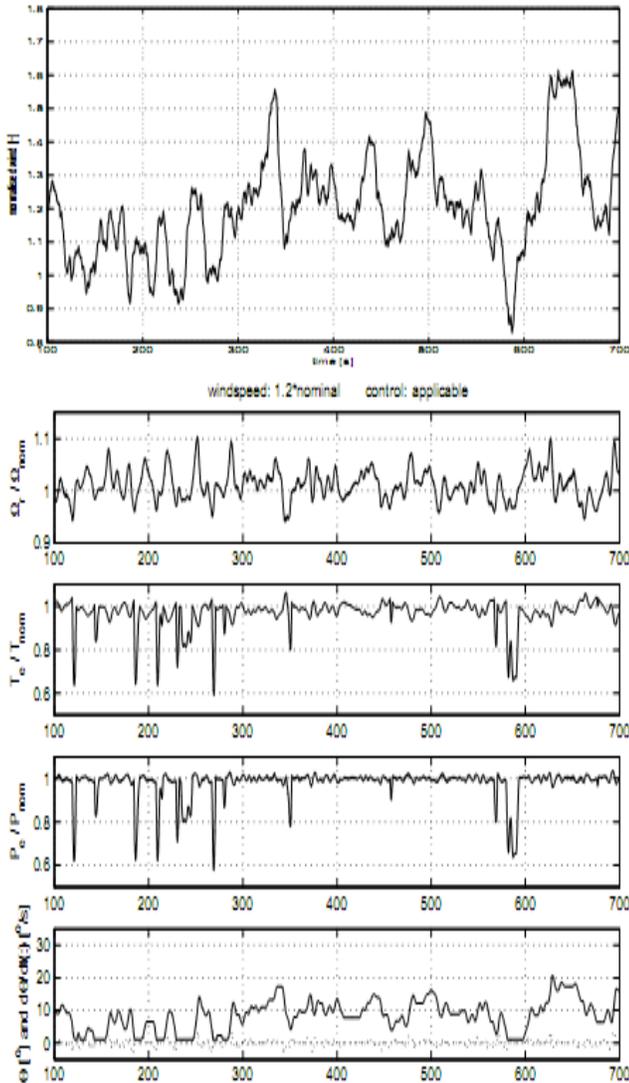

Figure 6 Above Rated Wind Speed Control

Simulation Results

4.1 Below rated wind speed control

4.1 Above rated wind speed control

IV. Conclusion

This paper deals the mathematical modelling of a unified power control of active stall and active pitch controlled variable speed turbine. Active stall control employs below rated operation to extract maximum power from wind .and at rated and above rated wind speed active pitch control method used to avoid damage of turbine.Basic controller structure is simulated. Design of sophisticated unified controller is on further study.Lots of reasearch needed to design such type of controller.Fuzzy logic controller can be employed .It is on further study.

ABSTRACT: The potential for solar energy as a sustainable source of energy is well understood. With the ever increasing use of solar power the necessity of a model is accentuated. The aim of this work is to study the variation of PV module main characteristic parameters as a function of shading, with a special attention to the relationship between output power lowering due to shading.

Keywords: pvc, mppt, solarex

I. INTRODUCTION

India is endowed with vast solar energy potential. About 5,000 trillion kWh per year energy is incident over India's land area with most parts receiving 4-7 kWh per sq. m per day. [1] From an energy security perspective, solar is the most secure of all sources, since it is abundantly available. The objective of the National Solar Mission is to establish India as a global leader in solar energy, by creating the policy conditions for its diffusion across the country as quickly as possible. To create an enabling policy framework for the deployment of 20,000 MW of solar power by 2022.[1]

II. SOLAR INSOLATION IN INDIA

With about 300 clear sunny days in a year, India's theoretical solar power reception, just on its land area, is about 5 PWh.[1] The daily average solar energy incident over India varies from 4 to 7 kWh/m² with about 2,300–3,200 sunshine hours per year[1]. This is far more than current total energy consumption. For example, even assuming 10% conversion efficiency for PV modules, it will still be thousand times greater than the likely electricity demand in India by the year 2015[1]

III. PHOTOVOLTAIC MODULES

Solar cells consist of a p-n junction fabricated in a thin wafer or layer of semiconductor.[2] In the dark, the I-V output characteristic of a solar cell has an exponential characteristic similar to that of a diode.[2] .PV module represents the fundamental power conversion unit of a PV generator system. The output characteristics of PV module depends on the solar insolation, the temperature and output voltage of PV module.[2] Since PV module has nonlinear characteristics, it is necessary to model it for the design and simulation of maximum power point tracking (MPPT) for PV system applications.

IV. PHOTOVOLTAIC SOLAR CELL MODELS IN REVERSE BIAS

In order to describe the electrical behavior of a solar cell, in light and darkness, the one diode model and the two diodes model, derived from physical characteristics of solar cells, are commonly used.[2] When investigations on hot spot

phenomena and mismatch in photovoltaic cells association have become interesting, these models have been reviewed to deal with the reverse characteristics, when solar cells are working in reverse bias. One of the first approaches modifies the one diode model with the assumption that the avalanche multiplication affects mainly the direct current. The mathematical model of the solar cell taking into account the effect of breakdown voltage is given by the equation.

$$I = \left(I_{ph} - I_0 \cdot \left(\exp\left(\frac{V}{mV_t}\right) - 1 \right) \right) M(V) - \frac{V}{R_p} \quad (1)$$

Where the multiplication factor M(V) denotes the effect of the avalanche effect.[5,6] The expression of M(V) is:

$$M(V) = \frac{1}{(1 - (|V|/V_b)^n)} \quad (2)$$

where V_b is the breakdown voltage in reverse bias and n is the Miller constant. Figure 1 shows the electrical equivalent circuit including the effect of M(V) modelled by a controlled current source. Bishop[7] proposed an equation where the avalanche effect is expressed as a non-linear multiplication factor that affects the shunt resistance current term. The proposed model is given by Equation (3) and the corresponding equivalent circuit is shown in Figure 2.

$$I = I_{ph} - I_0 \left[\exp\left(\frac{V + R_s I}{mV_t}\right) - 1 \right] - \left(\frac{V + R_s \cdot I}{R_p} \right) \left[1 + a \left(1 - \frac{V + R_s I}{V_b} \right)^{-n} \right] \quad (3)$$

where V_b is the breakdown voltage, a and n are constants. The additional term, E(V), is added to the leakage current into the shunt resistance term modeled as a controlled current source:

$$E(V) = 1 + a \left(1 - \frac{V + IR_s}{V_{br}} \right)^{-n} \quad (4)$$

V. SIMULINK BASED MODEL FOR PV MODULE

The mathematical PV models used in computer simulation have been built for over the past four decades [6]-[8]. Almost all well-developed PV models describe the output characteristics mainly affected by the solar insolation, cell temperature, and load voltage. Most of the above models do not take into account the effects of shading on the PV characteristics.

We have chosen the Matlab/Simulink[12] environment to study the effects of shadowing in PV module performance because Matlab is today a universal tool for mathematical

applications and has been used before in PV systems' simulation and solar cell parameters' extraction with success.[13,14]

The I-V characteristic simulation, in Matlab/ Simulink environment, of a photovoltaic module under different shadow rates was carried out using Bishop's model described in the previous section. The Solarex MSX60 PV [Table 1]module under study is formed by 36 serially connected solar cells and one of the solar cells is assumed to be shaded with variable rate of shadow: α ($0 \leq \alpha \leq 1$) We consider that a full shadow corresponds to $\alpha = 0$ whereas $\alpha = 1$ indicates no shadow present on the solar cell. The PV module output voltage is the sum of voltages generated across the individual cells, illuminated and shaded:

$$V = \sum_{i=1}^{35} V_{ill_cell} + V_{sh_cell} \quad (5)$$

where V is the total PV module voltage, and V_{ill_cell} and V_{sh_cell} are the voltages across the illuminated cells and the shaded one, respectively. The current through all the cells is the same:

$$I = I_{ill_cell} = I_{sh_cell} \quad (6)$$

where I is the current through the PV module, I_{ill_cell} and I_{sh_cell} are the currents through the illuminated cells and the shaded one, respectively. The following expression, obtained from Equation (3) for the simulation of the I-V characteristic of the PV module has been used:[3]

$$V = \frac{R_p}{E(V)} \left[I_{ph} - I_o \left(\exp \left(\frac{V + R_s I}{m V_t} \right) - 1 \right) \right] - I \left(\frac{R_p + E(V) R_s}{R_p} \right) \quad (7)$$

The same equation is governing the shaded cell with the assumption that the photogenerated current is proportional to the rate of shadow denoted by α . Thus the expression of the photogenerated current at the shaded cell is given by[7]

$$I_{ph} = I_{sco} \cdot \frac{\alpha \cdot \Phi}{\Phi_N} \quad (8)$$

where Φ_N and Φ are the standard and incident irradiance, respectively.

The output power of the whole PV module is always less than the sum of the values of the individual power cells due to dispersion of the parameters. These losses are accentuated in the case of partial or full shadow of one or several cells serially connected to form the PV module. We have tried to report the amount of power lowering due to shadow effect. The power loss is given by the following expression

$$\text{Power loss (\%)} = \frac{P_{max_unsh} - P_{max_sh}}{P_{max_unsh}} \times 100 \quad (9)$$

where P_{max_unsh} and P_{max_sh} , are respectively the maximum powers corresponding to the unshaded cells of the PV module and the shaded one. A single solar cell totally shaded does not cause a significant maximum power loss; it is less than 10% at lower irradiation. Therefore, the

power losses increase with increase of irradiation and shadow rate.

VI. CONCLUSION

An attempt has been made to model a photo voltaic cell under the influence of shadow. The proposed model is found be showing appreciable results in comparison with the data being supplied by the manufacturer It can also be applied to study the reverse characteristics of shadowed solar cells forming part of the PV module. The reduction in the output power of a PV module due to shadowing has been evaluated taking into account the influence of irradiance level and the shadow rate over a cell of the PV module.

Efficient High Speed Power Current Comparators in 180 nm

Sushil Kumar

School of Information and Communication Technology, Gautam Buddha University
Greater Noida, UP, INDIA

ABSTRACT: This research paper proposes a new kind of CMOS based current comparator circuit technique for high speed power applications. The proposed circuitry has been simulated properly in 180 nm CMOS process technology using Cadence Spectre simulator. The current comparator circuit has impressed with current pulses ranging from milli amperes to nano amperes. Also, its speed and power consumption has been successfully simulated and measured. While comparing with the earlier reported circuits, the proposed circuit attains very high speed of operation and acceptable power consumption. The power consumption of the proposed current comparator is very much lower than the other earlier proposed circuits for micron range input currents.

Keywords: CMOS, Current Comparator, Cadence Spectre, Current Pulse, Speed and Power.

I INTRODUCTION

Current mode operations have been considered as an alternative in analog circuit designs as CMOS VLSI devices are scaled down in size. Comparators are used in data converters and other front end signal processing applications. Voltage comparator encounters several difficulties including operational frequency, input offset voltage and power consumption. Current comparison has been done by impressing the current pulse signal at the input of the comparator and finding whether it is positive or negative. The output voltage generated by the comparator is used properly to indicate the result of operation. Circuit uses source follower input stage and a CMOS inverter as a positive feedback. First current comparator which is widely accepted even now a days was proposed by [1]. The circuit operation is limited by the requirement of minimum input current 10 μ A is a must to perform the comparison. The comparator provides distorted output signal below this value. An input current range up to 0.5 μ A had been demonstrated in offset free

current comparator [2]. This comparator has some shortcomings which are, it requires more number of MOS components and more power consumption. Afterwards, Soowon Kim and Byungmoo Min had come up with a new idea of current comparator [3]. It is having the requirement of an extra current reference generator. The speed of the operation of the circuit is very less when compared to present proposed circuit. The authors had come up with a current amplifier cum comparator in the year 2000, had the response time of 50 nS for 5 μ A input current, which indicated delayed response very much while being compared to the response time of the recent designs.

Altogether, a new current comparator had been proposed by [4] which had one CMOS complementary amplifier, two resistive load amplifiers and two CMOS inverters. Although, the circuit given above resolved the

power and speed issue of [1], it consumed more power and took more response time than recently published approaches. The designs in [5], [6], [7] had come up with high speed circuits, but whenever compared to the proposed one those consumed significantly more power and slow in response. The author of the paper [3] had come up with a new approach in the year 2010 of a low input impedance current comparator using pulse width modulation. The circuit in the paper [3] had pre occupied with more number of MOS and capacitors than any of the designs. In this paper, the results obtained by the proposed design are being compared with the earlier proposed design in published papers [5] and [7].

Proposed and conventional current circuit are analyzed and simulated in section 2.2 and 2.3. All the results are discussed and compared in section 2.4.

II CURRENT COMPARATOR ANALYSIS

2.1 Current Comparator

The figure 1 shown below, shows the schematic diagram of a conventional positive feedback current comparator circuit in [5]. The positive feedback operates at output nodes of the inverters M2/M5 and M3/M4 respectively. Transistors M0 and M6 are closed and transistors M1 and M7 are open in the pre decision state. The inverter M5/M2 begins to switch as the voltage on the comparator node is affected by input current. As soon as this slews to either rail, the transistors M0 or M6 are switched open and then with a delay of about 10 ns the transistors M1 or M7 respectively are switched closed. Now, the comparator node can significantly speed the decision process, particularly at the low current inputs as this latched feedback dumps enough charge on the comparator. The one of the main drawbacks of this system is that the input node slews from rail to rail and this can slow the comparator operations.

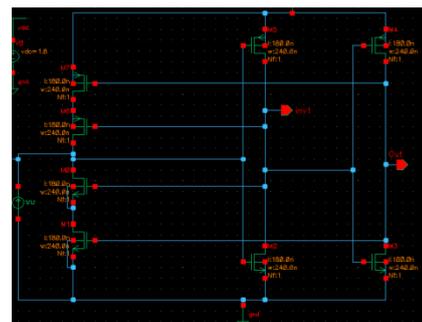

Fig.1. Conventional Current Comparator [5]

DC and Transient analyses had been performed using the Cadence Spectre simulator with 180 nm CMOS technology. The transient response of the current comparator (Min & Kim, 1998) is shown in figure 2, when

the input current pulse is normally kept at 10 μA . In this fashion, the current comparator (Min & Kim, 1998) is subjected to input current pulse range from 10 μA and 400 μA and transient analysis had been performed for the same. Basically, the current comparator performs the comparison till 10 μA and below this range output voltage starts getting distorted. Importantly, the transient analysis could be used to confirm the operating range of the comparator.

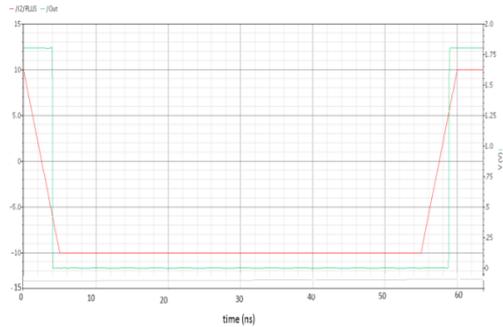

Fig.2. Transient Response of Conventional Current Comparator at 10 Ma

Thus, DC analysis was performed to calculate the average power consumption of the given comparator [5]. Figure 3 Shows the power plot of the current comparator at 10 μA .

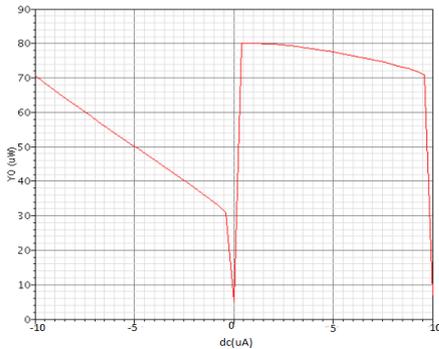

Fig.3. Current Comparator Power Plot

2.2 Current Comparator [7]

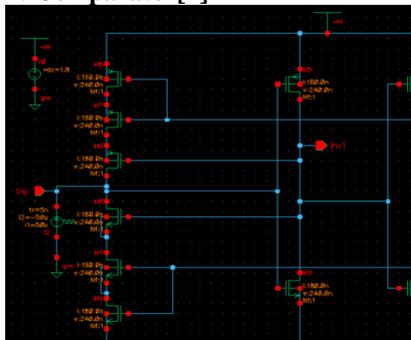

Fig.4. Conventional Current Comparator [7]

Above shown figure 4 is the current comparator circuit published in [7]. The author [7] had added two more additional MOS transistors M8 and M9, when compared to the earlier implemented circuit [5]. These MOS transistors speed up the decision process in the circuit. Transistors M0 and M6 are closed and transistors M7, M8 and M1, M9 are open in the pre decision state. The speed of operation of the comparator [7] is well increased when compared.

The figure 5 given below shows the transient response of the current comparator [7] whenever the input current pulse is at 10 μA . The transient response analysis had been performed and the current comparator [7] is subjected to input current pulse ranges from 1 mA to 400 nA. The comparison operation is well performed by the current comparator till 10 μA and below this range output gets starting distorted. The calculated 50% propagation delay of the circuit is 1.493 ns.

To compute the total power consumed by the comparator [7], DC analysis had been performed. The power consumption of the comparator [7] whenever the input current is at 10 μA , is shown in figure 6. The computed average power consumed by this comparator is comes out to be 32.6 μW at 10 μA .

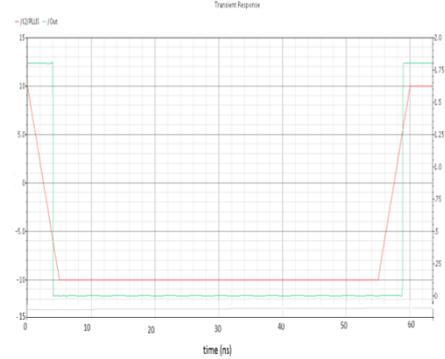

Fig.5. Transient Response of Current Comparator [7] at 10 μA

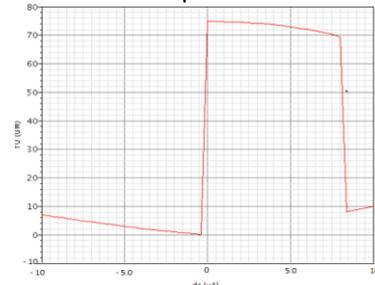

Fig.6. Current Comparator Power Plot [7] at 10 μA

2.3 Proposed Current Comparator Analysis

The given below figure 7 shows the schematic diagram of the proposed current comparator. The circuit contains parts such as power supply, standard current mirror, CMOS inverter, Wilson current mirror and input current pulse generator. To reduce the total power consumed in the circuit, Wilson current mirror was used. The current comparator used the high output impedance of the Wilson current mirror to amplify the small difference in the input currents to large variations in output voltage.

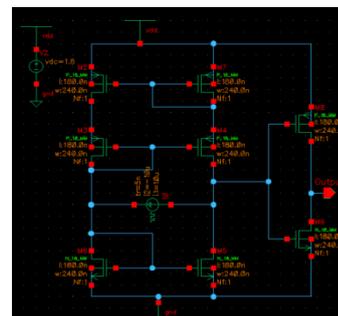

Fig.7. The Proposed Current Comparator

The Transient response of the proposed current comparator for variation of input current pulse from $-10 \mu\text{A}$ to $10 \mu\text{A}$ is shown in given below figure 8. The characteristics curves were plotted and the input current pulse had been varied from 1 mA to 400 nA during the Transient analysis. The current comparator had done a successful comparison till 400 nA and below this value the output gets starting distorted. The proposed circuit design goes working till the range of 400 nA unlike the earlier published papers [5], [7] works till the range of $10 \mu\text{A}$. Thus, the input range is increased when compared to [5] and [7]. The proposed circuit has achieved 50% propagation delay of 550 ps.

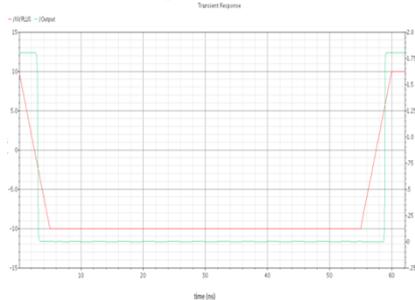

Fig.8. Transient Response of the Proposed Current Comparator at $10 \mu\text{A}$

The total power consumption by the proposed comparator had been performed by the DC analysis. The power consumption by the comparator when the input current is at $10 \mu\text{A}$ is shown in figure 9. The average power consumption by the proposed comparator is $8.7 \mu\text{W}$ at $10 \mu\text{A}$.

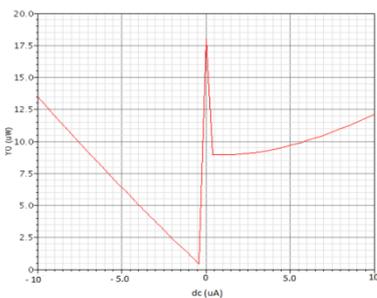

Fig.9. Power Plot of the Proposed Current Comparator at $10 \mu\text{A}$

2.4 Current Comparators Comparison

The simulation characteristics and parameters of the conventional and proposed current comparator are compared and observations are explained in great detail. It is observed from table I that when compared with the current comparators [5] and [7], the proposed new current comparator operates at very high speed. The proposed current comparator operates well up to the input current of 400 nA, although the comparators [5] and [7] functions only up to $10 \mu\text{A}$.

It is also observed from table II that from $10 \mu\text{A}$ onwards the power consumption of the new proposed current comparator is very low when compared to the power consumed by the either of the current comparators [5] and [7]. The proposed comparator consumes a little extra power than [5] and [7] but, the power consumption has been

improved a lot when the circuit is subjected with the input current below $100 \mu\text{A}$. The proposed current comparator consumes very less power than [7] from $100 \mu\text{A}$ onwards.

Table I. Comparison among the Current Comparators – 50% Propagation Delay (ps)

Input Current	Proposed Current Comparator	Current Comparator [6]	Current Comparator [8]
1 mA	110	219	229
100 mA	248	561	577
$10 \mu\text{A}$	550	1964	1493
$1 \mu\text{A}$	1564	Not Worked	Not Worked
400 nA	2408	Not Worked	Not Worked

Table II. Comparison among the Current Comparators – 50% Power Dissipation (W)

Input Current	Proposed Current Comparator	Current Comparator [6]	Current Comparator [8]
1 mA	1.35 m	0.763 m	1.15 m
100 mA	80μ	52.7μ	81.4μ
$10 \mu\text{A}$	8.8μ	61.4μ	32.6μ
$1 \mu\text{A}$	5.27μ	Not Worked	Not Worked
400 nA	21.4μ	Not Worked	Not Worked

The figure 10 given below shows the delay time versus input current graph. The graph vividly states that the proposed current comparator attains better performance than its counter parts [5] and [7].

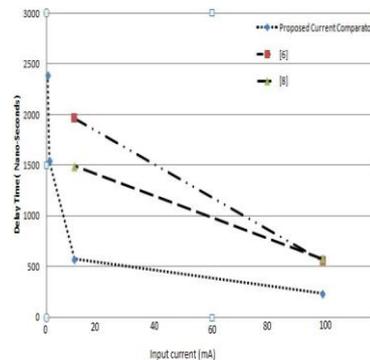

Fig.10. Delay Time versus Input Current

The figure 11 shows the power dissipation versus input current graph. The proposed circuit dissipates little extra power for large current inputs say 1 mA. From $100 \mu\text{A}$ onwards the proposed comparator dissipates lower power than the earlier published paper [7] and from $61 \mu\text{A}$ onwards it dissipates lower power than both [5] and [7]. The circuit power dissipation is far better than its counterparts as shown in table II below $100 \mu\text{A}$.

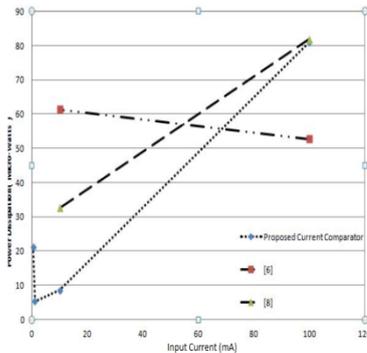

Fig.11.Power Dissipation versus Input Current

III. CONCLUSION

The goal of this paper was to present a simple idea of designing a new CMOS based current comparator topology for high speed applications such as digital switching circuits and data converters. The proposed comparator operates at very high speed in figure 10 and 11, when compared with the performance of the existing current comparators [5] and [7]. Also, the proposed new current comparator consumes very low power from 10 μ A onwards when compared to the comparators in [5] and [7].

Transcoding Method for Regions of Interest

Soon-kak Kwon

Department of Computer Software Engineering, Dongeui University, Korea

Abstract : When a bitstream of the higher bitrate is converted to the lower bitrate through the transcoding process, the ROI (Regions of Interest) can be considered. We classify the ROI as the groups of macro-blocks with non-zero motion vectors. For simple implementation, the motion vectors are not additionally estimated, but extracted from the coded bitstream of the higher bitrate before transcoding. Then, a proposed method assigns a specific quantization step-size differentially according to the ROI within a video. The picture quality can be increased by applying the quantization step-size as a small value relatively for the ROI compared with the non-ROI. We can find the result that the proposed method gives the improved picture quality by assigning the quantization step-size differentially.

Keywords - ROI, Transcoding, Picture Quality

I. INTRODUCTION

For both the homogeneous and heterogeneous transcodings, the bitrate reduction may be needed when the original higher bitrate cannot be accepted. The bitrate reduction algorithm converts from high bitrate bitstream to lower rate bitstream. Although there are several methods for bitrate reductions [1-6], the re-quantization method is well used because of the simple implementation and a less processing time.

All of transcoding methods deal with proper allocation of bitrate or quantization step-size in order to satisfy good picture quality or high PSNR (Peak Signal to Noise Ratio) on the constraint of the limited bitrate after transcoding. However, it is insufficient to meet the need of picture quality for ROI (Regions of Interest) within video sequence.

The several methods [7-12] have been researched for ROI coding, such as a classification of the foreground and background, a detection of the human face, a determination based on user attention model. However it did not include the bitstream transcoding schemes.

We propose a new transcoding method that makes better video quality relatively in ROI. ROI is classified to the moving regions. For searching moving regions, we use the coded information within the bitstream before transcoding. If the coded information before transcoding is used to find ROI, then the extra complexity is not needed. First, the non-zero motion vectors of each macro-blocks are grouped to separate the zero motion vectors. Then the groups with large numbers of non-zero motion vectors are set to ROI, the groups with small numbers of non-zero motion vectors are set to the non-ROI.

The organization of this paper is as follows. Section II provides the conventional relationship of bitrate and quantization step-size for transcoding. In Section III, the proposed transcoding method is described for improving the

subjective picture quality by properly allocating the quantization parameters dependently on the ROI. Section IV shows the simulation results of the proposed method about quantization parameter compared with the conventional one. In Section V, we summarize the main results.

II. RELATIONSHIP OF BITRATE AND QUANTIZATION STEP-SIZE FOR TRANSCODING

The previous researches [13,14] showed the relationship between bitrate and quantization step-size for transcoding, a linear relative formula as a logarithmic function between bitrate (R) and quantization step-size ($Qstep$),

$$\log Qstep = b + a \cdot \log R \quad (1)$$

where, b and a are dependent on the video characteristics. Also a transcoding algorithm has been presented which updates the model parameters given for the previous picture or slice using an approximated relationship between bitrate and quantization step-size according to the coded picture-type. That is, if a target bitrate in bits per second, BR_t (bps) is given in the case of already an encoded bitrate BR_1 (bps) in bits per second, then target quantization step-size $Qstep_t$ is obtained from following equation.

$$Qstep_t = Qstep_1 \cdot \left(\frac{BR_t}{BR_1} \right)^a \quad (2)$$

where, the value of a is approximated by the previous coded results.

Also our previous research[12] has proposed the transcoding method to control the picture quality depended on the subjectively ROI. The subjectively ROI determined using motion vectors were classified by following four different cases in the aspect of subjective importance.

- (1) Central focus video: The focus is on the central regions rather than the whole frame in the case where object movement is primarily in the central regions of a picture. The background may either be fixed or moving uniformly through camera panning. This can be considered a default type if a frame is not classified into the other three types because humans tend to concentrate their viewpoint on the central region of a video.
- (2) Peripheral focus video: The region of interest is focused on the contour in the case where the scene is being zoomed-out. The representative motion vector values of the top and bottom regions have non-zero values while those of the central regions are approximately zero.
- (3) Upper focus video: The region of interest is in the upper regions in the case where object movement is located in the upper regions of a picture. The representative motion vector values in the upper regions of a frame have non-zero values with zero values in the lower regions.

- (4) Lower focus video: The region of interest is in the lower regions in the case where object movement is located in the lower regions of a picture. The representative motion vector values at in the lower of a picture have non-zero values with zero values in the upper regions.

After the above classification of picture for the subjectively interest regions, the value of quantization step-size was differently assigned according to the location of slice of picture.

III. PROPOSED TRANSCODING METHOD FOR ROI

We propose a new transcoding method that makes better video quality relatively in ROI. ROI is classified as the groups of macro-blocks with non-zero motion vectors. For getting the motion vectors, we use the coded information within the bitstream before transcoding. First, the non-zero motion vectors of each macro-blocks are grouped to separate the zero motion vectors. Then the groups with large numbers of non-zero motion vectors are set to ROI, the groups with small numbers of non-zero motion vectors are set to the non-ROI.

Step1) Grouping the non-zero motion vectors of macro-blocks for the bitstream before transcoding

Step2) Eliminating the group with small numbers of non-zero motion vectors. The small number of macro-blocks are not important to give the subjective picture quality. Therefore, in this paper, the group having less than 15 macro-blocks is eliminated from the group of non-zero motion vectors.

Step 3) Classifying the ROI. ROI is the non eliminated groups and the others the non ROI. The groups of large number of non-zero motion vectors is only considered to ROI.

Step 4) Reassigning the quantization step-size. For the ROI, the quantization step-size is assigned to lower value than the target quantization step-size of Eq. (2), but for the non-ROI, the higher quantization step-size is assigned.

$$Qstep = Qstep_t - \alpha, \text{ for ROI} \quad (3)$$

$$Qstep = Qstep_t + \alpha, \text{ for Non-ROI} \quad (4)$$

where, $Qstep$ is final assigned quantization step-size, and α is a constant. α can affect to the difference in the quantization step-size between the maximum and the minimum values. A large value of α makes the large difference of picture quality between ROI and non-ROI.

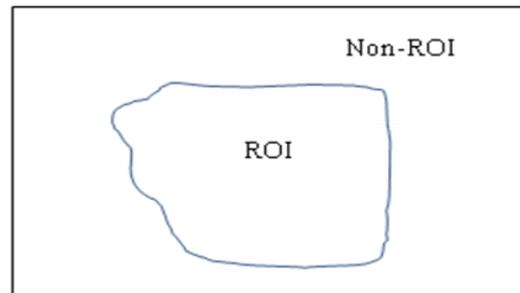

Fig 3. Classified ROI and Non-ROI

IV. SIMULATION RESULTS

The JM [15-18] that is a standard coding software tool of the H.264 was used to the simulation where Foreman video with horizontal and vertical resolutions of 352 and 228 pixels was selected.

The B-picture is not included due to the use of the H.264 baseline profile, and 15 pictures are configured as one GOP in which the video applies 60 pictures. The number of slices is the same as for each picture and that are determined by 18 along the vertical direction.

The quantization step-size was differentially applied for each macro-blocks by using the value of determined in Eq. (3,4). Also, the coding was performed as an objective bitrate for the original video based on four different α of Eq. (3,4), such as 2, 4, 6, and 8, from the classification of the difference between the maximum and the minimum values of the quantization step-size.

1) Measurement of the objective PSNR

This paper investigated the PSNR (peak signal to noise ratio) that is an objective picture quality criterion. The conventional method applied a bitstream coded with of 1.5Mbps, is transcoded to the bitrate of 0.8Mbps. Then, the quantization step-size was differentially assigned with the unit of macro-blocks using the proposed method for the Foreman video, according to the criterion of subjectively ROI.

Table 1 shows the average value of the PSNR for 60 pictures after transcoding in the Foreman video and maximum difference of quantization parameters within picture is set to 2, 4, 6 and 8. It can be seen that the values of the PSNR decreased according to the differential application of the quantization step-size among macro-blocks compared to the method that applies the same quantization step-size values for all macro-blocks within same slice. In the case of $\alpha = 6$, the PSNR was decreased about 0.07dB, and it was decreased about 0.28dB for the $\alpha = 8$.

Table 1. Average PSNR for the bitstream coded with of 1.5Mbps, is transcoded to the bitrate of 0.8Mbps.

Conventional method [dB]	Proposed method, α [dB]			
	2	4	6	8
37.83	37.81	37.76	37.70	37.55

2) Measurement of subjectively picture quality

For measuring of the subjective picture quality, we used DSCQS (Double Stimulus Continuous Quality Scale) [19]. According this method, the assessors are positioned at a distance from the monitor equal to three times the diagonal length of the monitor used to display the videos. They then observe two videos in sequence on the monitor; one is an original video and the other is a video either using the conventional method or the proposed method. The presentation order of the original and processed videos was random.

The presentation of the test material:

- 1 Video A (Original or Processed) 12s,
- 2 Gray 3s,
- 3 Video B (Processed or Original) 12s,
- 4 Gray 3s

Assessors evaluated the picture quality of both videos using an ITU-R quality scale (Excellent=5, Good=4, Fair=3, Poor=2, Bad=1) [12,20].

The final subjectively picture quality assessment score was calculated from the mean over all assessors;

$$U = \frac{1}{N} \sum_{i=1}^N u_i \quad (5)$$

where u_i is score which is determined by each assessor, and N is number of assessors.

The measurement of the subjectively picture quality was performed by distributing reconstructed videos to 10 assessors without notification of the methods and the ROI. We got the same average score of the subjectively picture quality obtained from 10 evaluators as shown in Table 2.

Table 2. Results of the subjectively picture quality for the bitstream coded with of 1.5Mbps, is transcoded to the bitrate of 0.8Mbps .

Conventional method	Proposed method, α			
	2	4	6	8
3.0	3.1	3.2	3.4	3.3

In the results, because the Foreman video showed no movements in the background and some movements at the central region, it represented good picture quality in the aspect of a subject manner based on the assigning of the quantization step-size with ROI of the central moving regions. The desirable difference between the maximum and the minimum values of the quantization step-size between ROI and non-ROI was 6. If the difference between the maximum and the minimum values showed more than 8, then the subjectively picture quality was getting worse.

Although the objective PSNR value that is the average value of the entire picture slightly was decreased for the differential assign of the quantization step-size within the video sequence according to ROI, the subjective picture

quality that has a focus on interest points within the video sequence was increased. It means that the measurement of objective picture quality only will not fully satisfy the visual picture quality of human being. In addition, it is possible to present an improvement effect in picture quality by applying the results of the evaluation of subjective picture quality to the objective picture quality while there is no change in bitrates.

Fig .4 illustrates the reconstructed picture of Foreman video for the bitstream coded with of 1.5Mbps, is transcoded to the bitrate of 0.8Mbps with conventional method and the proposed methods of different α . When $\alpha =6$, the subjective picture quality of Foreman video looked better relatively. When $\alpha =8$, although the subjectively picture quality of ROI was getting best, the subjective picture quality of non-ROI was getting the coarsest picture quality level.

(b) Reconstructed frame of proposed method, $\alpha =4$

(c) Reconstructed frame of proposed method, $\alpha =6$

(d) Reconstructed frame of proposed method, $\alpha =8$

Fig. 4 Comparison of the four reconstructed frames of Foreman video

V. CONCLUSION

This paper classified ROI and non-ROI within the video according to motion vectors. The moving regions of non-zero motion vectors is set to focus region, then quantization step-size (parameter) is assigned to the focus regions differentially compared to the non focus regions. Proposed method obtained an improvement effect in subjective picture quality compared to the conventional method through the intensive application of the quantization step-size.

Although this study focused on the H.264 video coding, it can be directly used to other video coding standards including the HEVC[21]. In addition, it can be expected that this research will be extensively applied with other various bitstream transcoding techniques.
